Examples

f <- function (x,a) (x-a)^2
xmin <- optimize(f, c(0, 1), tol = 0.0001, a = 1/3)
xmin

## See where the function is evaluated:
optimize(function(x) x^2*(print(x)-1), l=0, u=10)

## "wrong" solution with unlucky interval and piecewise constant f():
f <- function(x) ifelse(x > -1, ifelse(x < 4, exp(-1/abs(x - 1)), 10), 10)
fp <- function(x) { print(x); f(x) }
plot(f, -2, 5, ylim = 0:1, col = 2)
optimize(fp, c(-4, 20))# doesn't see the minimum
optimize(fp, c(-7, 20))# ok

order.dendrogram

Ordering or Labels of the Leaves in a Dendrogram

Description

Theses functions return the order (index) or the "label" attribute for the leaves in a dendrogram.
These indices can then be used to access the appropriate components of any additional data.

Usage

order.dendrogram(x)

## S3 method for class 'dendrogram':
labels(object, ...)

Arguments

x, object a dendrogram (see as.dendrogram).

... additional arguments

Details

The indices or labels for the leaves in left to right order are retrieved.
Value

A vector with length equal to the number of leaves in the dendrogram is returned. From \( r \leftarrow \text{order.dendrogram()} \), each element is the index into the original data (from which the dendrogram was computed).

Author(s)

R. Gentleman (\text{order.dendrogram} and Martin Maechler (\text{labels.dendrogram}).

See Also

\text{reorder}, \text{dendrogram}.

Examples

```r
set.seed(123)
x <- rnorm(10)
hc <- hclust(dist(x))
hc$order
dd <- as.dendrogram(hc)
order.dendrogram(dd) # same:
stopifnot(hc$order == order.dendrogram(dd))

d2 <- as.dendrogram(hclust(dist(USArrests)))
labels(d2) # in this case the same as
stopifnot(labels(d2) == rownames(USArrests)[order.dendrogram(d2)])
```

---

\section*{p.adjust}

\textit{Adjust P-values for Multiple Comparisons}

Description

Given a set of p-values, returns p-values adjusted using one of several methods.

Usage

\[
p.\text{adjust}(p, \text{method} = \text{p.\text{adjust.methods}}, \ n = \text{length}(p))
\]

\text{p.\text{adjust.methods}}

\# c("holm", "hochberg", "hommel", "bonferroni", "BH", "BY",
\#   "fdr", "none")

Arguments

\begin{itemize}
\item \text{p} vector of p-values (possibly with NAs).
\item \text{method} correction method
\item \text{n} number of comparisons, must be at least \text{length}(p); only set this (to non-default) when you know what you are doing!
\end{itemize}
**Details**

The adjustment methods include the Bonferroni correction ("bonferroni") in which the p-values are multiplied by the number of comparisons. Less conservative corrections are also included by Holm (1979) ("holm"), Hochberg (1988) ("hochberg"), Hommel (1988) ("hommel"), Benjamini & Hochberg (1995) ("BH"), and Benjamini & Yekutieli (2001) ("BY"), respectively. A pass-through option ("none") is also included. The set of methods are contained in the `p.adjust.methods` vector for the benefit of methods that need to have the method as an option and pass it on to `p.adjust`.

The first four methods are designed to give strong control of the family wise error rate. There seems no reason to use the unmodified Bonferroni correction because it is dominated by Holm’s method, which is also valid under arbitrary assumptions.

Hochberg’s and Hommel’s methods are valid when the hypothesis tests are independent or when they are non-negatively associated (Sarkar, 1998; Sarkar and Chang, 1997). Hommel’s method is more powerful than Hochberg’s, but the difference is usually small and the Hochberg p-values are faster to compute.

The "BH" and "BY" method of Benjamini, Hochberg, and Yekutieli control the false discovery rate, the expected proportion of false discoveries amongst the rejected hypotheses. The false discovery rate is a less stringent condition than the family wise error rate, so these methods are more powerful than the others.

Note that you can set `n` larger than `length(p)` which means the unobserved p-values are assumed to be greater than all the observed p for "bonferroni" and "holm" methods and equal to 1 for the other methods.

**Value**

A vector of corrected p-values (same length as `p`).

**References**

pairwise.prop.test

See Also

pairwise.* functions such as pairwise.t.test.

Examples

set.seed(123)
x <- rnorm(50, m=c(rep(0,25),rep(3,25)))
p <- 2*pnorm( sort(-abs(x)))

round(p, 3)
round(p.adjust(p), 3)
round(p.adjust(p,"BH"), 3)

## or all of them at once (dropping the "fdr" alias):
p.adj <- sapply(p.adjust.M, function(meth) p.adjust(p, meth))
round(p.adj, 3)

## or a bit nicer:
noquote(apply(p.adj, 2, format.pval, digits = 3))

## and a graphic:
matplot(p, p.adj, ylab="p.adjust(p, meth)", type = "l", asp=1, lty=1:6,
main = "P-value adjustments")
legend(.7,.6, p.adjust.M, col=1:6, lty=1:6)

## Can work with NA's:
pN <- p; iN <- c(46,47); pN[iN] <- NA
pN.a <- sapply(p.adjust.M, function(meth) p.adjust(pN, meth))

## The smallest 20 P-values all affected by the NA's :
round((pN.a / p.adj)[1:20, ], 4)

pairwise.prop.test  Pairwise comparisons for proportions

Description

Calculate pairwise comparisons between pairs of proportions with correction for multiple testing

Usage

pairwise.prop.test(x, n, p.adjust.method = p.adjust.methods, ...)

Arguments

x  Vector of counts of successes or a matrix with 2 columns giving the counts of
    successes and failures, respectively.

n  Vector of counts of trials; ignored if x is a matrix.

p.adjust.method
    Method for adjusting p values (see p.adjust)

...  Additional arguments to pass to prop.test
pairwise.t.test

Value
Object of class "pairwise.htest"

See Also
prop.test, p.adjust

Examples
smokers <- c(83, 90, 129, 70)
patients <- c(86, 93, 136, 82)
pairwise.prop.test(smokers, patients)

attach(airquality)
Month <- factor(Month, labels = month.abb[5:9])
pairwise.t.test(Ozone, Month)
pairwise.t.test(Ozone, Month, p.adj = "bonf")
pairwise.t.test(Ozone, Month, pool.sd = FALSE)
detach()
pairwise.table  

**Tabulate p values for pairwise comparisons**

**Description**

Creates table of p values for pairwise comparisons with corrections for multiple testing.

**Usage**

```r
pairwise.table(compare.levels, level.names, p.adjust.method)
```

**Arguments**

- `compare.levels`  
  Function to compute (raw) p value given indices i and j
- `level.names`  
  Names of the group levels
- `p.adjust.method`  
  Method for multiple testing adjustment

**Details**

Functions that do multiple group comparisons create separate `compare.levels` functions (assumed to be symmetrical in i and j) and passes them to this function.

**Value**

Table of p values in lower triangular form.

**See Also**

- `pairwise.t.test`, et al.

pairwise.wilcoxon.test  

**Pairwise Wilcoxon rank sum tests**

**Description**

Calculate pairwise comparisons between group levels with corrections for multiple testing.

**Usage**

```r
pairwise.wilcoxon.test(x, g, p.adjust.method = p.adjust.methods, ...)
```

**Arguments**

- `x`  
  Response vector
- `g`  
  Grouping vector or factor
- `p.adjust.method`  
  Method for adjusting p values (see `p.adjust`)
- `...`  
  Additional arguments to pass to `wilcoxon.test`.  

```
Value

Object of class "pairwise.htest"

See Also

wilcox.test, p.adjust

Examples

attach(airquality)
Month <- factor(Month, labels = month.abb[5:9])
## These give warnings because of ties:
pairwise.wilcox.test(Ozone, Month)
pairwise.wilcox.test(Ozone, Month, p.adj = "bonf")
detach()

plot.acf

Plot Autocovariance and Autocorrelation Functions

Description

Plot method for objects of class "acf".

Usage

## S3 method for class 'acf':
plot(x, ci = 0.95, type = "h", xlab = "Lag", ylab = NULL,
     ylim = NULL, main = NULL,
     ci.col = "blue", ci.type = c("white", "ma"),
     max.mfrow = 6, ask = Npgs > 1 && dev.interactive(),
     mar = if(nser > 2) c(3,2,2,0.8) else par("mar"),
     oma = if(nser > 2) c(1,1.2,1,1) else par("oma"),
     mgp = if(nser > 2) c(1.5,0.6,0) else par("mgp"),
     xpd = par("xpd"), cex.main = if(nser > 2) 1 else par("cex.main"),
     verbose =getOption("verbose"),
     ...)

Arguments

x an object of class "acf".

coverage probability for confidence interval. Plotting of the confidence interval is suppressed if ci is zero or negative.

type the type of plot to be drawn, default to histogram like vertical lines.

xlab the x label of the plot.

ylab the y label of the plot.

numeric of length 2 giving the y limits for the plot.

main overall title for the plot.

colour to plot the confidence interval lines.
ci.type: should the confidence limits assume a white noise input or for lag \( k \) an MA\((k-1)\) input?

max.mfrow: positive integer; for multivariate \( x \) indicating how many rows and columns of plots should be put on one page, using `par(mfrow = c(m,m))`.

ask: logical; if TRUE, the user is asked before a new page is started.

mar, oma, mgp, xpd, cex.main: graphics parameters as in `par(*)`, by default adjusted to use smaller than default margins for multivariate \( x \) only.

verbose: logical. Should R report extra information on progress?

...: graphics parameters to be passed to the plotting routines.

Note

The confidence interval plotted in `plot.acf` is based on an uncorrelated series and should be treated with appropriate caution. Using `ci.type = "ma"` may be less potentially misleading.

See Also

`acf` which calls `plot.acf` by default.

Examples

```r
z4 <- ts(matrix(rnorm(400), 100, 4), start=c(1961, 1), frequency=12)
z7 <- ts(matrix(rnorm(700), 100, 7), start=c(1961, 1), frequency=12)
acf(z4)
acf(z7, max.mfrow = 7)# squeeze on 1 page
acf(z7) # multi-page
```

---

**plot.density**

*Plot Method for Kernel Density Estimation*

Description

The `plot` method for density objects.

Usage

```r
## S3 method for class 'density':
plot(x, main = NULL, xlab = NULL, ylab = "Density", type = "l",
    zero.line = TRUE, ...)
```

Arguments

- `x`: a “density” object.
- `main`, `xlab`, `ylab`, `type`: plotting parameters with useful defaults.
- `...`: further plotting parameters.
- `zero.line`: logical; if TRUE, add a base line at \( y = 0 \)
Value
None.

References

See Also
density.

plot.HoltWinters  Plot function for HoltWinters objects

Description
Produces a chart of the original time series along with the fitted values. Optionally, predicted values
(and their confidence bounds) can also be plotted.

Usage
## S3 method for class 'HoltWinters':
plot(x, predicted.values = NA, intervals = TRUE,
     separator = TRUE, col = 1, col.predicted = 2,
     col.intervals = 4, col.separator = 1, lty = 1,
     lty.predicted = 1, lty.intervals = 1, lty.separator = 3,
     ylab = "Observed / Fitted", main = "Holt-Winters filtering",
     ylim = NULL, ...)

plot.isoreg  

Plot Method for isoreg Objects

Description

The plot and lines method for R objects of class isoreg.

Usage

## S3 method for class 'isoreg':
plot(x, plot.type = c("single", "row.wise", "col.wise"),
    main = paste("Isotonic regression", deparse(x$call)),
    main2 = "Cumulative Data and Convex Minorant",
    xlab = "x0", ylab = "x$y",
    par.fit = list(col = "red", cex = 1.5, pch = 13, lwd = 1.5),
    mar = if (both) 0.1 + c(3.5, 2.5, 1, 1) else par("mar"),
    mgp = if (both) c(1.6, 0.7, 0) else par("mgp"),
    grid = length(x$x) < 12, ...)

## S3 method for class 'isoreg':
lines(x, col = "red", lwd = 1.5,
     do.points = FALSE, cex = 1.5, pch = 13, ...)

Arguments

x  an isoreg object.

plot.type  character indicating which type of plot is desired. The first (default) only draws the data and the fit, where the others add a plot of the cumulative data and fit.

main  main title of plot, see title.

main2  title for second (cumulative) plot.

xlab, ylab  x- and y- axis annotation.

par.fit  a list of arguments (for points and lines) for drawing the fit.

mar, mgp  graphical parameters, see par, mainly for the case of two plots.
plot.lm

grid
logical indicating if grid lines should be drawn. If true, \texttt{grid()} is used for the first plot, where as vertical lines are drawn at “touching” points for the cumulative plot.

do.points for \texttt{lines()}: logical indicating if the step points should be drawn as well (and as they are drawn in \texttt{plot()}).

col, lwd, cex, pch
graphical arguments for \texttt{lines()}, where \texttt{cex} and \texttt{pch} are only used when \texttt{do.points} is \texttt{TRUE}.

... further arguments passed to and from methods.

See Also

\texttt{isoreg} for computation of \texttt{isoreg} objects.

Examples

\begin{verbatim}
example(isoreg)  # for the examples there

plot(y3, main = "simple plot(.) + lines(<isoreg>)")
lines(ir3)

## 'same' plot as above, "proving" that only ranks of 'x' are important
plot(isoreg(2^(1:9), c(1,0,4,3,5,4,2,0)), plot.t = "row", log = "x")

plot(ir3, plot.type = "row", ylab = "y3")
plot(isoreg(y3 - 4), plot.t="r", ylab = "y3 - 4")
plot(ir4, plot.type = "ro", ylab = "y4", xlab = "x = 1:n")

## experiment a bit with these (C-c C-j):
plot(isoreg(sample(9), y3), plot.type="row")
plot(isoreg(sample(9), y3), plot.type="col.wise")

plot(ir <- isoreg(sample(10), sample(10, replace = TRUE)), plot.t = "r")
\end{verbatim}

---

plot.lm

\textit{Plot Diagnostics for an \texttt{lm} Object}

Description

Six plots (selectable by \texttt{which}) are currently available: a plot of residuals against fitted values, a Scale-Location plot of $\sqrt{|\text{residuals}|}$ against fitted values, a Normal Q-Q plot, a plot of Cook’s distances versus row labels, a plot of residuals against leverages, and a plot of Cook’s distances against leverage/(1-leverage). By default, the first three and 5 are provided.

Usage

\begin{verbatim}
## S3 method for class 'lm':
plot(x, which = c(1:3,5),
    caption = c("Residuals vs Fitted", "Normal Q-Q", 
    "Scale-Location", "Cook’s distance", 
    "Residuals vs Leverage", "Cook's distance vs Leverage"),
    panel = if(add.smooth) panel.smooth else points,
\end{verbatim}
sub.caption = NULL, main = "",
ask = prod(par("mfcol")) < length(which) & dev.interactive(),
...
id.n = 3, labels.id = names(residuals(x)), cex.id = 0.75,
qqline = TRUE, cook.levels = c(0.5, 1.0),
add.smooth = getOption("add.smooth"), label.pos = c(4,2))

Arguments

x        lm object, typically result of lm or glm.
which    if a subset of the plots is required, specify a subset of the numbers 1:6.
caption  captions to appear above the plots
panel    panel function. The useful alternative to points, panel.smooth can be
         chosen by add.smooth = TRUE.
sub.caption common title—above figures if there are multiple; used as sub (s.title)
         otherwise. If NULL, as by default, a possible shortened version of
deparse(x$call) is used.
main     title to each plot—in addition to the above caption.
ask      logical; if TRUE, the user is asked before each plot, see par(ask=.)
...
other parameters to be passed through to plotting functions.
id.n     number of points to be labelled in each plot, starting with the most extreme.
labels.id vector of labels, from which the labels for extreme points will be chosen. NULL
         uses observation numbers.
cex.id    magnification of point labels.
qqline    logical indicating if a qqline() should be added to the normal Q-Q plot.
cook.levels levels of Cook’s distance at which to draw contours.
add.smooth logical indicating if a smoother should be added to most plots; see also panel
         above.
label.pos positioning of labels, for the left half and right half of the graph respectively, for
         plots 1-3.

Details

sub.caption—by default the function call—is shown as a subtitle (under the x-axis title) on
each plot when plots are on separate pages, or as a subtitle in the outer margin (if any) when there
are multiple plots per page.

The “Scale-Location” plot, also called “Spread-Location” or “S-L” plot, takes the square root of the
absolute residuals in order to diminish skewness ($\sqrt{|E|}$ is much less skewed than $|E|$ for Gaussian
zero-mean $E$).

The ‘S-L’, the Q-Q, and the Residual-Leverage plot, use standardized residuals which have identical
variance (under the hypothesis). They are given as $R_i/(s \times \sqrt{1-h_{ii}})$ where $h_{ii}$ are the diagonal
entries of the hat matrix, influence()$hat, see also hat.

The Residual-Leverage plot shows contours of equal Cook’s distance, for values of cook.levels
(by default 0.5 and 1) and omits cases with leverage one. If the leverages are constant (as is typically
the case in a balanced aov situation) the plot uses factor level combinations instead of the leverages
for the x-axis. (The factor levels are ordered by mean fitted value.)

In the Cook’s distance vs leverage/(1-leverage) plot, contours of standardized residuals that are
equal in magnitude are lines through the origin. The contour lines are labelled with the magnitudes.

Examples

```r
## Analysis of the life-cycle savings data
## given in Belsley, Kuh and Welsch.
plot(lm.SR <- lm(sr ~ pop15 + pop75 + dpi + ddpi, data = LifeCycleSavings))

## 4 plots on 1 page; allow room for printing model formula in outer margin:
par(mfrow = c(2, 2), oma = c(0, 0, 2, 0))
plot(lm.SR)
plot(lm.SR, id.n = NULL) # no id's
plot(lm.SR, id.n = 5, labels.id = NULL)# 5 id numbers

## Was default in R <= 2.1.x: Cook's distances instead of Residual-Leverage plot
plot(lm.SR, which = 1:4)

## Fit a smooth curve, where applicable:
plot(lm.SR, panel = panel.smooth)
## Gives a smoother curve
plot(lm.SR, panel = function(x,y) panel.smooth(x, y, span = 1))

par(mfrow=c(2,1))# same oma as above
plot(lm.SR, which = 1:2, sub.caption = "Saving Rates, n=50, p=5")
```

Description

Plot ridge functions for projection pursuit regression fit.
Usage

```
## S3 method for class 'ppr':
plot(x, ask, type = "o", ...)
```

Arguments

- `x`: A fit of class "ppr" as produced by a call to `ppr`.
- `ask`: the graphics parameter `ask`: see `par` for details. If set to `TRUE` will ask between the plot of each cross-section.
- `type`: the type of line to draw
- `...`: further graphical parameters

Value

None

Side Effects

A series of plots are drawn on the current graphical device, one for each term in the fit.

See Also

`ppr`, `par`

Examples

```
with(rock, {
  area1 <- area/10000; peri1 <- peri/10000
  par(mfrow=c(3,2)) # maybe: , pty="s"
  rock.ppr <- ppr(log(perm) ~ area1 + peri1 + shape,
                   data = rock, nterms = 2, max.terms = 5)
  plot(rock.ppr, main="ppr(log(perm)~ ., nterms=2, max.terms=5)"
  plot(update(rock.ppr, bass=5), main = "update(..., bass = 5)"
  plot(update(rock.ppr, sm.method="gcv", gcvpen=2),,
        main = "update(..., sm.method="gcv", gcvpen=2)"
})
```

---

**plot.profile.nls**

Plot a profile.nls Object

Description

Displays a series of plots of the profile t function and interpolated confidence intervals for the parameters in a nonlinear regression model that has been fit with `nls` and profiled with `profile.nls`.

Usage

```
## S3 method for class 'profile.nls':
plot(x, levels, conf= c(99, 95, 90, 80, 50)/100,
     nseg = 50, absVal =TRUE, ...)
```
**plot.spec**

### Arguments

- **x**: an object of class "profile.nls"
- **levels**: levels, on the scale of the absolute value of a t statistic, at which to interpolate intervals. Usually `conf` is used instead of giving `levels` explicitly.
- **conf**: a numeric vector of confidence levels for profile-based confidence intervals on the parameters. Defaults to `c(0.99, 0.95, 0.90, 0.80, 0.50)`.
- **nseg**: an integer value giving the number of segments to use in the spline interpolation of the profile t curves. Defaults to 50.
- **absVal**: a logical value indicating whether or not the plots should be on the scale of the absolute value of the profile t. Defaults to `TRUE`.
- **...**: other arguments to the `plot` function can be passed here.

### Author(s)

Douglas M. Bates and Saikat DebRoy

### References

### Examples

```r
# obtain the fitted object
fm1 <- nls(demand ~ SSasympOrig( Time, A, lrc ), data = BOD)
# get the profile for the fitted model
pr1 <- profile( fm1 )
opar <- par(mfrow = c(2,2), oma = c(1.1, 0, 1.1, 0), las = 1)
plot(pr1, conf = c(95, 90, 80, 50)/100)
plot(pr1, conf = c(95, 90, 80, 50)/100, absVal = FALSE)
mtext("Confidence intervals based on the profile sum of squares",
side = 3, outer = TRUE)
mtext("BOD data - confidence levels of 50%, 80%, 90% and 95%",
side = 1, outer = TRUE)
par(opar)
```

---

**plot.spec**

*Plotting Spectral Densities*

### Description

Plotting method for objects of class "spec". For multivariate time series it plots the marginal spectra of the series or pairs plots of the coherency and phase of the cross-spectra.
Usage

## S3 method for class 'spec':
plot(x, add = FALSE, ci = 0.95, log = c("yes", "dB", "no"),
     xlab = "frequency", ylab = NULL, type = "l",
     ci.col = "blue", ci.lty = 3,
     main = NULL, sub = NULL,
     plot.type = c("marginal", "coherency", "phase"),
     ...)

plot.spec.phase(x, ci = 0.95,
     xlab = "frequency", ylab = "phase",
     ylim = c(-pi, pi), type = "l",
     main = NULL, ci.col = "blue", ci.lty = 3, ...)

plot.spec.coherency(x, ci = 0.95,
     xlab = "frequency",
     ylab = "squared coherency",
     ylim = c(0, 1), type = "l",
     main = NULL, ci.col = "blue", ci.lty = 3, ...)

Arguments

x
an object of class "spec".

add
logical. If TRUE, add to already existing plot. Only valid for plot.type = "marginal".

ci
coverage probability for confidence interval. Plotting of the confidence bar/limits is omitted unless ci is strictly positive.

log
If "dB", plot on log10 (decibel) scale (as S-PLUS), otherwise use conventional log scale or linear scale. Logical values are also accepted. The default is "yes" unless options(ts.S.compat = TRUE) has been set, when it is "dB". Only valid for plot.type = "marginal".

xlab
the x label of the plot.

ylab
the y label of the plot. If missing a suitable label will be constructed.

type
the type of plot to be drawn, defaults to lines.

ci.col
colour for plotting confidence bar or confidence intervals for coherency and phase.

ci.lty
line type for confidence intervals for coherency and phase.

main
overall title for the plot. If missing, a suitable title is constructed.

sub
a sub title for the plot. Only used for plot.type = "marginal". If missing, a description of the smoothing is used.

plot.type
For multivariate time series, the type of plot required. Only the first character is needed.

ylim, ...
Graphical parameters.

See Also

spectrum
plot.stepfun

Plot Step Functions

Description

Method of the generic plot for stepfun objects and utility for plotting piecewise constant functions.

Usage

## S3 method for class 'stepfun':
plot(x, xval, xlim, ylim,
 xlab = "x", ylab = "f(x)", main = NULL,
 add = FALSE, verticals = TRUE, do.points = TRUE,
 pch = par("pch"),
 col.points = par("col"), cex.points = par("cex"),
 col.hor = par("col"), col.vert = par("col"),
 lty = par("lty"), lwd = par("lwd"), ...)    

## S3 method for class 'stepfun':
lines(x, ...)

Arguments

x an R object inheriting from "stepfun".
xval numeric vector of abscissa values at which to evaluate x. Defaults to
 knots(x) restricted to xlim.
xlim, ylim numeric(2) each; range of x or y values to use. Both have sensible defaults.
xlab, ylab labels of x and y axis.
main main title.
add logical; if TRUE only add to an existing plot.
verticals logical; if TRUE, draw vertical lines at steps.
do.points logical; if true, also draw points at the (xlim restricted) knot locations.
pch character; point character if do.points.
col.points character or integer code; color of points if do.points.
cex.points numeric; character expansion factor if do.points.
col.hor color of horizontal lines.
col.vert color of vertical lines.
lty, lwd line type and thickness for all lines.
... further arguments of plot(.), or if (add) segments(.).      

Value

A list with two components

t abscissa (x) values, including the two outermost ones.
y y values ‘in between’ the t[].
Author(s)

See Also

ecdf for empirical distribution functions as special step functions, approxfun and splinefun.

Examples

y0 <- c(1,2,4,3)
sfun0 <- stepfun(1:3, y0, f = 0)
sfun.2 <- stepfun(1:3, y0, f = .2)
sfun1 <- stepfun(1:3, y0, right = TRUE)

 tt <- seq(0,3, by=0.1)
op <- par(mfrow=c(2,2))
plot(sfun0); plot(sfun0, xval=tt, add=TRUE, col.h="bisque")
plot(sfun.2);plot(sfun.2,xval=tt, add=TRUE, col.h="orange")
plot(sfun1);lines(sfun1, xval=tt, col.h="coral")
### This is revealing :
plot(sfun0, verticals= FALSE,
     main = "stepfun(x, y0, f=f) for f = 0, .2, 1")
for(i in 1:3)
  lines(list(sfun0,sfun.2,stepfun(1:3,y0,f = 1))[[i]], col.h=i, col.v=i)
legend(2.5, 1.9, paste("f =", c(0,0.2,1)), col=1:3, lty=1, y.inter=1)
par(op)

# Extend and/or restrict 'viewport':
plot(sfun0, xlim = c(0,5), ylim = c(0, 3.5),
     main = "plot(stepfun( *), xlim= . , ylim = .")
###-- this works too (automatic call to ecdf(.)):
plot.stepfun(rt(50, df=3), col.vert = "gray20")

plot.ts

Plotting Time-Series Objects

Description

Plotting method for objects inheriting from class "ts".

Usage

## S3 method for class 'ts':
plot(x, y = NULL, plot.type = c("multiple", "single"),
 xy.labels, xy.lines, panel = lines, nc, yax.flip = FALSE,
 mar.multi = c(0, 5.1, 0, if(yax.flip) 5.1 else 2.1),
 oma.multi = c(6, 0, 5, 0), axes = TRUE, ...)

## S3 method for class 'ts':
lines(x, ...)
**Arguments**

- **x, y**  
  time series objects, usually inheriting from class "ts".

- **plot.type**  
  for multivariate time series, should the series be plotted separately (with a common time axis) or on a single plot?

- **xy.labels**  
  logical, indicating if text () labels should be used for an x-y plot, or character, supplying a vector of labels to be used. The default is to label for up to 150 points, and not for more.

- **xy.lines**  
  logical, indicating if lines should be drawn for an x-y plot. Defaults to the value of xy.labels if that is logical, otherwise to TRUE.

- **panel**  
  a function(x, col, bg, pch, type, ...) which gives the action to be carried out in each panel of the display for plot.type="multiple". The default is lines.

- **nc**  
  the number of columns to use when type="multiple". Defaults to 1 for up to 4 series, otherwise to 2.

- **yax.flip**  
  logical indicating if the y-axis (ticks and numbering) should flip from side 2 (left) to 4 (right) from series to series when type="multiple".

- **mar.multi, oma.multi**  
  the (default) par settings for plot.type="multiple". Modify with care!

- **axes**  
  logical indicating if x- and y- axes should be drawn.

- **...**  
  additional graphical arguments, see plot, plot.default and par.

**Details**

If y is missing, this function creates a time series plot, for multivariate series of one of two kinds depending on plot.type.

If y is present, both x and y must be univariate, and a "scatter" plot y ~ x will be drawn, enhanced by using text if xy.labels is TRUE or character, and lines if xy.lines is TRUE.

**See Also**

- ts for basic time series construction and access functionality.

**Examples**

```r
## Multivariate
z <- ts(matrix(rt(200 * 8, df = 3), 200, 8), start=c(1961, 1), frequency=12)
plot(z, yax.flip = TRUE)
plot(z, axes= FALSE, ann= FALSE, frame.plot= TRUE,
     mar.muti= c(0,0,0,0), oma.muti= c(1,1,5,1))
title("plot(ts(..), axes=FALSE, ann=FALSE, frame.plot=TRUE, mar..., oma...)

z <- window(z[,1:3], end = c(1969,12))
plot(z, type = "b")  # multiple
plot(z, plot.type="single", lty=1:3, col=4:2)

## A phase plot:
plot(nhtemp, c(nhtemp[-1], NA), cex = .8, col="blue",
     main = "Lag plot of New Haven temperatures")
## a clearer way to do this would be
## Not run:
plot(nhtemp, lag(nhtemp, 1), cex = .8, col="blue",
     main = "Phase plot of New Haven temperatures")
```
The Poisson Distribution

Density, distribution function, quantile function and random generation for the Poisson distribution with parameter \( \lambda \).

**Usage**

- \( \text{dpois}(x, \lambda, \text{log} = \text{FALSE}) \)
- \( \text{ppois}(q, \lambda, \text{lower.tail} = \text{TRUE}, \text{log.p} = \text{FALSE}) \)
- \( \text{qpois}(p, \lambda, \text{lower.tail} = \text{TRUE}, \text{log.p} = \text{FALSE}) \)
- \( \text{rpois}(n, \lambda) \)

**Arguments**

- \( x \) vector of (non-negative integer) quantiles.
- \( q \) vector of quantiles.
- \( p \) vector of probabilities.
- \( n \) number of random values to return.
- \( \lambda \) vector of (non-negative) means.
- \( \text{log, log.p} \) logical; if TRUE, probabilities \( p \) are given as \( \log(p) \).
- \( \text{lower.tail} \) logical; if TRUE (default), probabilities are \( P[X \leq x] \), otherwise, \( P[X > x] \).

**Details**

The Poisson distribution has density

\[
    p(x) = \frac{\lambda^x e^{-\lambda}}{x!}
\]

for \( x = 0, 1, 2, \ldots \). The mean and variance are \( E(X) = Var(X) = \lambda \).

If an element of \( x \) is not integer, the result of \( \text{dpois} \) is zero, with a warning. \( p(x) \) is computed using Loader’s algorithm, see the reference in \texttt{dbinom}.

The quantile is left continuous: \( \text{qgeom}(q, \text{prob}) \) is the largest integer \( x \) such that \( P(X \leq x) < q \).

Setting \( \text{lower.tail} = \text{FALSE} \) allows to get much more precise results when the default, \( \text{lower.tail} = \text{TRUE} \) would return 1, see the example below.
Value

dpois gives the (log) density, ppois gives the (log) distribution function, qpois gives the quantile function, and rpois generates random deviates.
Invalid lambda will result in return value NaN, with a warning.

Source

dpois uses C code contributed by Catherine Loader (see dbinom).
ppois uses pgamma.
qpois uses the Cornish–Fisher Expansion to include a skewness correction to a normal approximation, followed by a search.
rpois uses

See Also
dbinom for the binomial and dnbinom for the negative binomial distribution.

Examples

```
-log(dpois(0:7, lambda=1) * gamma(1+ 0:7)) # == 1
Ni <- rpois(50, lam= 4); table(factor(Ni, 0:max(Ni)))

1 - ppois(10*(15:25), lambda=100) # becomes 0 (cancellation)
ppois(10*(15:25), lambda=100, lower=FALSE) # no cancellation
```

```
par(mfrow = c(2, 1))
x <- seq(-0.01, 5, 0.01)
plot(x, ppois(x, 1), type="s", ylab="F(x)", main="Poisson(1) CDF")
plot(x, pbisn(x, 100, 0.01), type="s", ylab="F(x)",
     main="Binomial(100, 0.01) CDF")
```

poly

**Compute Orthogonal Polynomials**

Description

Returns or evaluates orthogonal polynomials of degree 1 to degree over the specified set of points x. These are all orthogonal to the constant polynomial of degree 0. Alternatively, evaluate raw polynomials.

Usage

```
poly(x, ..., degree = 1, coefs = NULL, raw = FALSE)
polym(..., degree = 1, raw = FALSE)
```

```
## S3 method for class 'poly':
predict(object, newdata, ...)
```
Arguments

\texttt{x, newdata} a numeric vector at which to evaluate the polynomial. \texttt{x} can also be a matrix. Missing values are not allowed in \texttt{x}.

\texttt{degree} the degree of the polynomial

\texttt{coefs} for prediction, coefficients from a previous fit.

\texttt{raw} if true, use raw and not orthogonal polynomials.

\texttt{object} an object inheriting from class \texttt{"poly"}, normally the result of a call to \texttt{poly} with a single vector argument.

\ldots \texttt{poly, polym: further vectors. predict.poly: arguments to be passed to or from other methods.}

Details

Although formally \texttt{degree} should be named (as it follows \ldots), an unnamed second argument of length 1 will be interpreted as the degree.

The orthogonal polynomial is summarized by the coefficients, which can be used to evaluate it via the three-term recursion given in Kennedy & Gentle (1980, pp. 343–4), and used in the “predict” part of the code.

Value

For \texttt{poly} with a single vector argument:

A matrix with rows corresponding to points in \texttt{x} and columns corresponding to the degree, with attributes \texttt{"degree"} specifying the degrees of the columns and (unless \texttt{raw = TRUE}) \texttt{"coefs"} which contains the centering and normalization constants used in constructing the orthogonal polynomials. The matrix has given class \texttt{c("poly", "matrix")}.

Other cases of \texttt{poly} and \texttt{polym}, and \texttt{predict.poly}: a matrix.

Note

This routine is intended for statistical purposes such as \texttt{contr.poly}: it does not attempt to orthogonalize to machine accuracy.

References

See Also

\texttt{contr.poly.}

\texttt{cars} for an example of polynomial regression.

Examples

\begin{verbatim}
(z <- poly(1:10, 3))
predict(z, seq(2, 4, 0.5))
poly(seq(4, 6, 0.5), 3, coefs = attr(z, "coefs"))

polym(1:4, c(1, 4:6), degree=3) # or just poly()
poly(cbind(1:4, c(1, 4:6)), degree=3)
\end{verbatim}
Create a Power Link Object

Description

Creates a link object based on the link function $\eta = \mu^\lambda$.

Usage

```r
power(lambda = 1)
```

Arguments

- `lambda`: a real number.

Details

If `lambda` is non-positive, it is taken as zero, and the log link is obtained. The default `lambda = 1` gives the identity link.

Value

A list with components `linkfun`, `linkinv`, `mu.eta`, and `valideta`. See `make.link` for information on their meaning.

References

See Also

- `make.link`, `family`

To raise a number to a power, see `Arithmetic`.

To calculate the power of a test, see various functions in the `stats` package, e.g., `power.t.test`.

Examples

```r
power()
quasi(link=power(1/3))[c("linkfun", "linkinv")]
```
power.anova.test  
*Power calculations for balanced one-way analysis of variance tests*

**Description**

Compute power of test or determine parameters to obtain target power.

**Usage**

`power.anova.test(groups = NULL, n = NULL, between.var = NULL, within.var = NULL, sig.level = 0.05, power = NULL)`

**Arguments**

- `groups`  
  Number of groups
- `n`  
  Number of observations (per group)
- `between.var`  
  Between group variance
- `within.var`  
  Within group variance
- `sig.level`  
  Significance level (Type I error probability)
- `power`  
  Power of test (1 minus Type II error probability)

**Details**

Exactly one of the parameters `groups`, `n`, `between.var`, `power`, `within.var`, and `sig.level` must be passed as `NULL`, and that parameter is determined from the others. Notice that `sig.level` has non-NULL default so `NULL` must be explicitly passed if you want it computed.

**Value**

Object of class "power.htest", a list of the arguments (including the computed one) augmented with method and note elements.

**Note**

`uniroot` is used to solve power equation for unknowns, so you may see errors from it, notably about inability to bracket the root when invalid arguments are given.

**Author(s)**

Claus Ekstrøm

**See Also**

`anova, lm, uniroot`
Examples

```r
power.anova.test(groups=4, n=5, between.var=1, within.var=3)
# Power = 0.3535594

power.anova.test(groups=4, between.var=1, within.var=3, power=.80)
# n = 11.92613

## Assume we have prior knowledge of the group means:
groupmeans <- c(120, 130, 140, 150)
power.anova.test(groups = length(groupmeans),
                 between.var=var(groupmeans),
                 within.var=500, power=.90) # n = 15.18834
```

Description

Compute power of test, or determine parameters to obtain target power.

Usage

```r
power.prop.test(n = NULL, p1 = NULL, p2 = NULL, sig.level = 0.05,
                 power = NULL,
                 alternative = c("two.sided", "one.sided"),
                 strict = FALSE)
```

Arguments

- `n`: Number of observations (per group)
- `p1`: Probability in one group
- `p2`: Probability in other group
- `sig.level`: Significance level (Type I error probability)
- `power`: Power of test (1 minus Type II error probability)
- `alternative`: One- or two-sided test
- `strict`: Use strict interpretation in two-sided case

Details

Exactly one of the parameters `n, p1, p2, power, and sig.level` must be passed as `NULL`, and that parameter is determined from the others. Notice that `sig.level` has a non-NULL default so `NULL` must be explicitly passed if you want it computed.

If `strict = TRUE` is used, the power will include the probability of rejection in the opposite direction of the true effect, in the two-sided case. Without this the power will be half the significance level if the true difference is zero.
power.t.test

Value
Object of class "power.htest", a list of the arguments (including the computed one) augmented with method and note elements.

Note
uniroot is used to solve power equation for unknowns, so you may see errors from it, notably about inability to bracket the root when invalid arguments are given. If one of them is computed \( p_1 < p_2 \) will hold, although this is not enforced when both are specified.

Author(s)
Peter Dalgaard. Based on previous work by Claus Ekstrøm

prop.test, uniroot

Examples
power.prop.test(n = 50, p1 = .50, p2 = .75)
power.prop.test(p1 = .50, p2 = .75, power = .90)
power.prop.test(n = 50, p1 = .5, power = .90)

power.t.test  Power calculations for one and two sample t tests

Description
Compute power of test, or determine parameters to obtain target power.

Usage
power.t.test(n = NULL, delta = NULL, sd = 1, sig.level = 0.05, power = NULL,
type = c("two.sample", "one.sample", "paired"),
alternative = c("two.sided", "one.sided"),
strict = FALSE)

Arguments

n Number of observations (per group)
delta True difference in means
sd Standard deviation
sig.level Significance level (Type I error probability)
power Power of test (1 minus Type II error probability)
type Type of t test
alternative One- or two-sided test
strict Use strict interpretation in two-sided case
Details

Exactly one of the parameters `n`, `delta`, `power`, `sd`, and `sig.level` must be passed as NULL, and that parameter is determined from the others. Notice that the last two have non-NULL defaults so NULL must be explicitly passed if you want to compute them.

If `strict = TRUE` is used, the power will include the probability of rejection in the opposite direction of the true effect, in the two-sided case. Without this the power will be half the significance level if the true difference is zero.

Value

Object of class "power.htest", a list of the arguments (including the computed one) augmented with `method` and `note` elements.

Note

`uniroot` is used to solve power equation for unknowns, so you may see errors from it, notably about inability to bracket the root when invalid arguments are given.

Author(s)

Peter Dalgaard. Based on previous work by Claus Ekstrøm

See Also

`t.test`, `uniroot`

Examples

```r
power.t.test(n = 20, delta = 1)
power.t.test(power = .90, delta = 1)
power.t.test(power = .90, delta = 1, alt = "one.sided")
```
Details

The general regression equation which incorporates a constant and a linear trend is used and the corrected t-statistic for a first order autoregressive coefficient equals one is computed. To estimate \( \sigma^2 \) the Newey-West estimator is used. If `lshort` is TRUE, then the truncation lag parameter is set to \( \text{trunc}(4*(n/100)^{0.25}) \), otherwise \( \text{trunc}(12*(n/100)^{0.25}) \) is used. The \( p \)-values are interpolated from Table 4.2, page 103 of Banerjee et al. (1993).

Missing values are not handled.

Value

A list with class "htest" containing the following components:

- `statistic`: the value of the test statistic.
- `parameter`: the truncation lag parameter.
- `p.value`: the \( p \)-value of the test.
- `method`: a character string indicating what type of test was performed.
- `data.name`: a character string giving the name of the data.

Author(s)

A. Trapletti

References

Examples

```r
x <- rnorm(1000)
PP.test(x)
y <- cumsum(x) # has unit root
PP.test(y)
```

ppoints

Ordinates for Probability Plotting

Description

Generates the sequence of "probability" points \( (1:m - a) / (m + (1-a)-a) \) where \( m \) is either \( n \), if `length(n)==1`, or `length(n)`.

Usage

```r
ppoints(n, a = ifelse(n <= 10, 3/8, 1/2))
```
Arguments

- `n`: either the number of points generated or a vector of observations.
- `a`: the offset fraction to be used; typically in \((0, 1)\).

Details

If \(0 < a < 1\), the resulting values are within \((0, 1)\) (excluding boundaries). In any case, the resulting sequence is symmetric in \([0, 1]\), i.e., \(p + \text{rev}(p) = 1\).

`ppoints()` is used in `qqplot` and `qqnorm` to generate the set of probabilities at which to evaluate the inverse distribution.

The choice of `a` follows the documentation of the function of the same name in Becker *et al* (1988), and appears to have been motivated by results from Blom (1958) on approximations to expect normal order statistics (see also `quantile`).

References

See Also

`qqplot`, `qqnorm`.

Examples

```r
ppoints(4) # the same as ppoints(1:4)
p points(10)
p points(10, a=1/2)
```

---

**ppr**

*Projection Pursuit Regression*

Description

Fit a projection pursuit regression model.

Usage

```r
ppr(x, ...)
```

## S3 method for class ‘formula’:
`ppr(formula, data, weights, subset, na.action, contrasts = NULL, ..., model = FALSE)`

## Default S3 method:
`ppr(x, y, weights = rep(1,n),
   ww = rep(1,q), nterms, max.terms = nterms, optlevel = 2,
   sm.method = c("supsmu", "spline", "gcvspline"),
   bass = 0, span = 0, df = 5, gcvpen = 1, ...)`
Arguments

formula a formula specifying one or more numeric response variables and the explanatory variables.

x numeric matrix of explanatory variables. Rows represent observations, and columns represent variables. Missing values are not accepted.

y numeric matrix of response variables. Rows represent observations, and columns represent variables. Missing values are not accepted.

nterms number of terms to include in the final model.

data a data frame (or similar: see model.frame) from which variables specified in formula are preferentially to be taken.

weights a vector of weights \( w_i \) for each case.

ww a vector of weights for each response, so the fit criterion is the sum over case \( i \) and responses \( j \) of \( w_i \) \( \times w_j \) \( (y_{ij} - \text{fit}_{ij})^2 \) divided by the sum of \( w_i \).

subset an index vector specifying the cases to be used in the training sample. (NOTE: If given, this argument must be named.)

na.action a function to specify the action to be taken if NAs are found. The default action is given by getOption("na.action"). (NOTE: If given, this argument must be named.)

contrasts the contrasts to be used when any factor explanatory variables are coded.

max.terms maximum number of terms to choose from when building the model.

optlevel integer from 0 to 3 which determines the thoroughness of an optimization routine in the SMART program. See the Details section.

sm.method the method used for smoothing the ridge functions. The default is to use Friedman’s super smoother supsmu. The alternatives are to use the smoothing spline code underlying smooth.spline, either with a specified (equivalent) degrees of freedom for each ridge functions, or to allow the smoothness to be chosen by GCV.

bass super smoother bass tone control used with automatic span selection (see supsmu); the range of values is 0 to 10, with larger values resulting in increased smoothing.

span super smoother span control (see supsmu). The default, 0, results in automatic span selection by local cross validation. span can also take a value in \([0, 1]\).

df if sm.method is "spline" specifies the smoothness of each ridge term via the requested equivalent degrees of freedom.

gcv.pen if sm.method is "gcvswpline" this is the penalty used in the GCV selection for each degree of freedom used.

... arguments to be passed to or from other methods.

model logical. If true, the model frame is returned.

Details

The basic method is given by Friedman (1984), and is essentially the same code used by S-PLUS’s ppr. This code is extremely sensitive to the compiler used.

The algorithm first adds up to max.terms ridge terms one at a time; it will use less if it is unable to find a term to add that makes sufficient difference. It then removes the least “important” term at each step until nterms terms are left.
The levels of optimization (argument \texttt{optlevel}) differ in how thoroughly the models are refitted during this process. At level 0 the existing ridge terms are not refitted. At level 1 the projection directions are not refitted, but the ridge functions and the regression coefficients are. Levels 2 and 3 refit all the terms and are equivalent for one response; level 3 is more careful to re-balance the contributions from each regressor at each step and so is a little less likely to converge to a saddle point of the sum of squares criterion.

**Value**

A list with the following components, many of which are for use by the method functions.

- \texttt{call}: the matched call
- \texttt{p}: the number of explanatory variables (after any coding)
- \texttt{q}: the number of response variables
- \texttt{mu}: the argument \texttt{n terms}
- \texttt{ml}: the argument \texttt{max.terms}
- \texttt{gof}: the overall residual (weighted) sum of squares for the selected model
- \texttt{gofn}: the overall residual (weighted) sum of squares against the number of terms, up to \texttt{max.terms}. Will be invalid (and zero) for less than \texttt{n terms}.
- \texttt{df}: the argument \texttt{df}
- \texttt{edf}: if \texttt{sm.method} is \texttt{"spline"} or \texttt{"gcv spline"} the equivalent number of degrees of freedom for each ridge term used.
- \texttt{xnames}: the names of the explanatory variables
- \texttt{ynames}: the names of the response variables
- \texttt{alpha}: a matrix of the projection directions, with a column for each ridge term
- \texttt{beta}: a matrix of the coefficients applied for each response to the ridge terms: the rows are the responses and the columns the ridge terms
- \texttt{yb}: the weighted means of each response
- \texttt{ys}: the overall scale factor used: internally the responses are divided by \texttt{ys} to have unit total weighted sum of squares.
- \texttt{fitted.values}: the fitted values, as a matrix if \texttt{q} > 1.
- \texttt{residuals}: the residuals, as a matrix if \texttt{q} > 1.
- \texttt{smod}: internal work array, which includes the ridge functions evaluated at the training set points.
- \texttt{model}: (only if \texttt{model=TRUE}) the model frame.

prcomp

**Principal Components Analysis**

Description

Performs a principal components analysis on the given data matrix and returns the results as an object of class prcomp.

Usage

```
prcomp(x, ...)  
```

### S3 method for class 'formula':
```
prcomp(formula, data = NULL, subset, na.action, ...)
```

### Default S3 method:
prcomp(x, retx = TRUE, center = TRUE, scale. = FALSE, tol = NULL, ...)

## S3 method for class 'prcomp':
predict(object, newdata, ...)

**Arguments**

- **formula**: a formula with no response variable, referring only to numeric variables.
- **data**: an optional data frame (or similar: see `model.frame`) containing the variables in the formula `formula`. By default the variables are taken from `environment(formula)`. 
- **subset**: an optional vector used to select rows (observations) of the data matrix `x`.
- **na.action**: a function which indicates what should happen when the data contain NAs. The default is set by the `na.action` setting of `options`, and is `na.fail` if that is unset. The “factory-fresh” default is `na.omit`.
- **...**: arguments passed to or from other methods. If `x` is a formula one might specify `scale.` or `tol`.
- **x**: a numeric or complex matrix (or data frame) which provides the data for the principal components analysis.
- **retx**: a logical value indicating whether the rotated variables should be returned.
- **center**: a logical value indicating whether the variables should be shifted to be zero centered. Alternately, a vector of length equal the number of columns of `x` can be supplied. The value is passed to `scale`.
- **scale.**: a logical value indicating whether the variables should be scaled to have unit variance before the analysis takes place. The default is `FALSE` for consistency with S, but in general scaling is advisable. Alternatively, a vector of length equal the number of columns of `x` can be supplied. The value is passed to `scale`.
- **tol**: a value indicating the magnitude below which components should be omitted. (Components are omitted if their standard deviations are less than or equal to `tol` times the standard deviation of the first component.) With the default null setting, no components are omitted. Other settings for `tol` could be `tol = 0` or `tol = sqrt(.Machine$double.eps)`, which would omit essentially constant components.
- **object**: Object of class inheriting from "prcomp"
- **newdata**: An optional data frame or matrix in which to look for variables with which to predict. If omitted, the scores are used. If the original fit used a formula or a data frame or a matrix with column names, `newdata` must contain columns with the same names. Otherwise it must contain the same number of columns, to be used in the same order.

**Details**

The calculation is done by a singular value decomposition of the (centered and possibly scaled) data matrix, not by using `eigen` on the covariance matrix. This is generally the preferred method for numerical accuracy. The `print` method for these objects prints the results in a nice format and the `plot` method produces a scree plot.

Note that `scale = TRUE` cannot be used if there are zero or constant (for `center = TRUE`) variables.
prcomp returns a list with class "prcomp" containing the following components:

- **sdev**: the standard deviations of the principal components (i.e., the square roots of the eigenvalues of the covariance/correlation matrix, though the calculation is actually done with the singular values of the data matrix).
- **rotation**: the matrix of variable loadings (i.e., a matrix whose columns contain the eigenvectors). The function princomp returns this in the element loadings.
- **x**: if retx is true the value of the rotated data (the centred (and scaled if requested) data multiplied by the rotation matrix) is returned. Hence, cov(x) is the diagonal matrix diag(sdev^2). For the formula method, napredict is applied to handle the treatment of values omitted by the na.action.
- **center, scale**: the centering and scaling used, or FALSE.

**Note**

The signs of the columns of the rotation matrix are arbitrary, and so may differ between different programs for PCA, and even between different builds of R.

**Examples**

```r
## the variances of the variables in the
## USArrests data vary by orders of magnitude, so scaling is appropriate
prcomp(USArrests)  # inappropriate
prcomp(USArrests, scale = TRUE)
prcomp(~ Murder + Assault + Rape, data = USArrests, scale = TRUE)
plot(prcomp(USArrests))
summary(prcomp(USArrests, scale = TRUE))
biplot(prcomp(USArrests, scale = TRUE))
```

**predict**

**Model Predictions**

**Description**

**predict** is a generic function for predictions from the results of various model fitting functions. The function invokes particular methods which depend on the class of the first argument.
predict

Usage

predict (object, ...)

Arguments

object  a model object for which prediction is desired.
...
... additional arguments affecting the predictions produced.

Details

Most prediction methods which similar to fitting linear models have an argument `newdata` specifying the first place to look for explanatory variables to be used for prediction. Some considerable attempts are made to match up the columns in `newdata` to those used for fitting, for example that they are of comparable types and that any factors have the same level set in the same order (or can be transformed to be so).

Time series prediction methods in package `stats` have an argument `n.ahead` specifying how many time steps ahead to predict.

Many methods have a logical argument `se.fit` saying if standard errors are to returned.

Value

The form of the value returned by `predict` depends on the class of its argument. See the documentation of the particular methods for details of what is produced by that method.

Examples

```r
## All the "predict" methods found
## NB most of the methods in the standard packages are hidden.
for(fn in methods("predict"))
  try(
    f <- eval(substitute(getAnywhere(fn)$objs[[1]], list(fn = fn)))
    cat(fn, "\n", deparse(args(f)), "\n"), silent = TRUE)
```
**predict.Arima**  
*Forecast from ARIMA fits*

**Description**
Forecast from models fitted by `arima`.

**Usage**
```r
## S3 method for class 'Arima':
predict(object, n.ahead = 1, newxreg = NULL,
        se.fit = TRUE, ...)
```

**Arguments**
- `object`: The result of an `arima` fit.
- `n.ahead`: The number of steps ahead for which prediction is required.
- `newxreg`: New values of `xreg` to be used for prediction. Must have at least `n.ahead` rows.
- `se.fit`: Logical: should standard errors of prediction be returned?
- `...`: arguments passed to or from other methods.

**Details**
Finite-history prediction is used, via `KalmanForecast`. This is only statistically efficient if the MA part of the fit is invertible, so `predict.Arima` will give a warning for non-invertible MA models.

The standard errors of prediction exclude the uncertainty in the estimation of the ARMA model and the regression coefficients. According to Harvey (1993, pp. 58–9) the effect is small.

**Value**
A time series of predictions, or if `se.fit = TRUE`, a list with components `pred`, the predictions, and `se`, the estimated standard errors. Both components are time series.

**References**

**See Also**
- `arima`
Examples

```r
predict(arima(lh, order = c(3,0,0)), n.ahead = 12)
```

```r
(fit <- arima(USAccDeaths, order = c(0,1,1),
             seasonal = list(order=c(0,1,1))))
predict(fit, n.ahead = 6)
```

**predict.glm**

*Predict Method for GLM Fits*

**Description**

Obtains predictions and optionally estimates standard errors of those predictions from a fitted generalized linear model object.

**Usage**

```r
## S3 method for class 'glm':
predict(object, newdata = NULL,
type = c("link", "response", "terms"),
se.fit = FALSE, dispersion = NULL, terms = NULL,
na.action = na.pass, ...)
```

**Arguments**

- **object**: a fitted object of class inheriting from "glm".
- **newdata**: optionally, a data frame in which to look for variables with which to predict. If omitted, the fitted linear predictors are used.
- **type**: the type of prediction required. The default is on the scale of the linear predictors; the alternative "response" is on the scale of the response variable. Thus for a default binomial model the default predictions are of log-odds (probabilities on logit scale) and type = "response" gives the predicted probabilities. The "terms" option returns a matrix giving the fitted values of each term in the model formula on the linear predictor scale.
  The value of this argument can be abbreviated.
- **se.fit**: logical switch indicating if standard errors are required.
- **dispersion**: the dispersion of the GLM fit to be assumed in computing the standard errors. If omitted, that returned by summary applied to the object is used.
- **terms**: with type="terms" by default all terms are returned. A character vector specifies which terms are to be returned
- **na.action**: function determining what should be done with missing values in newdata. The default is to predict NA.
- **...**: further arguments passed to or from other methods.

**Details**

If newdata is omitted the predictions are based on the data used for the fit. In that case how cases with missing values in the original fit is determined by the na.action argument of that fit. If na.action = na.omit omitted cases will not appear in the residuals, whereas if na.action = na.exclude they will appear (in predictions and standard errors), with residual value NA. See also napredict.
predict.HoltWinters

Value

If se = FALSE, a vector or matrix of predictions. If se = TRUE, a list with components

<table>
<thead>
<tr>
<th>Component</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>fit</td>
<td>Predictions</td>
</tr>
<tr>
<td>se.fit</td>
<td>Estimated standard errors</td>
</tr>
<tr>
<td>residual.scale</td>
<td>A scalar giving the square root of the dispersion used in computing the standard errors.</td>
</tr>
</tbody>
</table>

Note

Variables are first looked for in newdata and then searched for in the usual way (which will include the environment of the formula used in the fit). A warning will be given if the variables found are not of the same length as those in newdata if it was supplied.

ldose <- rep(0:5, 2)
umdead <- c(1, 4, 9, 13, 18, 20, 0, 2, 6, 10, 12, 16)
sex <- factor(rep(c("M", "F"), c(6, 6)))
SF <- cbind(numdead, numalive=20-numdead)
budworm.lg <- glm(SF ~ sex*ldose, family=binomial)
summary(budworm.lg)

plot(c(1,32), c(0,1), type = "n", xlab = "dose", ylab = "prob", log = "x")
text(2^ldose, numdead/20, as.character(sex))
ld <- seq(0, 5, 0.1)
lines(2^ld, predict(budworm.lg, data.frame(ldose=ld, sex=factor(rep("M", length(ld)), levels=levels(sex))), type = "response"))
lines(2^ld, predict(budworm.lg, data.frame(ldose=ld, sex=factor(rep("F", length(ld)), levels=levels(sex))), type = "response"))
```

predict.HoltWinters

**prediction function for fitted Holt-Winters models**

Description

Computes predictions and prediction intervals for models fitted by the Holt-Winters method.

Usage

```r
## S3 method for class 'HoltWinters':
predict(object, n.ahead=1, prediction.interval = FALSE, level = 0.95, ...)
```
predict.lm

Arguments

object An object of class HoltWinters.
n.ahead Number of future periods to predict.
prediction.interval logical. If TRUE, the lower and upper bounds of the corresponding prediction intervals are computed.
level Confidence level for the prediction interval.
... arguments passed to or from other methods.

Value

A time series of the predicted values. If prediction intervals are requested, a multiple time series is returned with columns fit, lwr and upr for the predicted values and the lower and upper bounds respectively.

predict.lm  Predict method for Linear Model Fits

Description

Predicted values based on linear model object.

Usage

## S3 method for class 'lm':
predict(object, newdata, se.fit = FALSE, scale = NULL, df = Inf,
 interval = c("none", "confidence", "prediction"),
 level = 0.95, type = c("response", "terms"),
 terms = NULL, na.action = na.pass, pred.var = res.var/weights,
 weights = 1, ...)
**predict.lm**

Arguments

- **object**: Object of class inheriting from "lm"
- **newdata**: An optional data frame in which to look for variables with which to predict. If omitted, the fitted values are used.
- **se.fit**: A switch indicating if standard errors are required.
- **scale**: Scale parameter for std.err. calculation
- **df**: Degrees of freedom for scale
- **interval**: Type of interval calculation.
- **level**: Tolerance/confidence level
- **type**: Type of prediction (response or model term).
- **terms**: If type="terms", which terms (default is all terms)
- **na.action**: function determining what should be done with missing values in newdata. The default is to predict NA.
- **pred.var**: the variance(s) for future observations to be assumed for prediction intervals. See Details.
- **weights**: variance weights for prediction. This can be a numeric vector or a one-sided model formula. In the latter case, it is interpreted as an expression evaluated in newdata
- **...**: further arguments passed to or from other methods.

Details

predict.lm produces predicted values, obtained by evaluating the regression function in the frame newdata (which defaults to model.frame(object). If the logical se.fit is TRUE, standard errors of the predictions are calculated. If the numeric argument scale is set (with optional df), it is used as the residual standard deviation in the computation of the standard errors, otherwise this is extracted from the model fit. Setting intervals specifies computation of confidence or prediction (tolerance) intervals at the specified level, sometimes referred to as narrow vs. wide intervals.

If the fit is rank-deficient, some of the columns of the design matrix will have been dropped. Prediction from such a fit only makes sense if newdata is contained in the same subspace as the original data. That cannot be checked accurately, so a warning is issued.

If newdata is omitted the predictions are based on the data used for the fit. In that case how cases with missing values in the original fit is determined by the na.action argument of that fit. If na.action = na.omit omitted cases will not appear in the residuals, whereas if na.action = na.exclude they will appear (in predictions, standard errors or interval limits), with residual value NA. See also napredict.

The prediction intervals are for a single observation at each case in newdata (or by default, the data used for the fit) with error variance(s) pred.var. This can be a multiple of res.var, the estimated value of $\sigma^2$: the default is to assume that future observations have the same error variance as those used for fitting. If weights is supplied, the inverse of this is used as a scale factor. For a weighted fit, if the prediction is for the original data frame, weights defaults to the weights used for the model fit, with a warning since it might not be the intended result. If the fit was weighted and newdata is given, the default is to assume constant prediction variance, with a warning.
predict.lm

Value

predict.lm produces a vector of predictions or a matrix of predictions and bounds with column names fit, lwr, and upr if interval is set. If se.fit is TRUE, a list with the following components is returned:

- **fit**: vector or matrix as above
- **se.fit**: standard error of predicted means
- **residual.scale**: residual standard deviations
- **df**: degrees of freedom for residual

Note

Variables are first looked for in newdata and then searched for in the usual way (which will include the environment of the formula used in the fit). A warning will be given if the variables found are not of the same length as those in newdata if it was supplied.

Offsets specified by offset in the fit by lm will not be included in predictions, whereas those specified by an offset term in the formula will be.

Notice that prediction variances and prediction intervals always refer to future observations, possibly corresponding to the same predictors as used for the fit. The variance of the residuals will be smaller.

Strictly speaking, the formula used for prediction limits assumes that the degrees of freedom for the fit are the same as those for the residual variance. This may not be the case if res.var is not obtained from the fit.

The model fitting function lm, predict, SafePrediction

Examples

```r
## Predictions
x <- rnorm(15)
y <- x + rnorm(15)
predict(lm(y ~ x))
new <- data.frame(x = seq(-3, 3, 0.5))
predict(lm(y ~ x), new, se.fit = TRUE)
pred.w.plim <- predict(lm(y ~ x), new, interval="prediction")
pred.w.clim <- predict(lm(y ~ x), new, interval="confidence")
matplot(new$x,cbind(pred.w.clim, pred.w.plim[,1:2]), lty=c(1,1,2,2,3,3), type="l", ylab="predicted y")

## Prediction intervals, special cases
## The first three of these throw warnings
w <- 1 + x^2
fit <- lm(y ~ x)
wfit <- lm(y ~ x, weights = w)
predict(fit, interval = "prediction")
predict(wfit, interval = "prediction")
predict(wfit, new, interval = "prediction")
predict(wfit, new, interval = "prediction", weights = (new$x)^2)
predict(wfit, new, interval = "prediction", weights = ~x^2)
```
predict.loess  

**Predict Loess Curve or Surface**

**Description**

Predictions from a loess fit, optionally with standard errors.

**Usage**

```r
## S3 method for class 'loess':
predict(object, newdata = NULL, se = FALSE, ...)
```

**Arguments**

- `object` an object fitted by loess.
- `newdata` an optional data frame in which to look for variables with which to predict. If missing, the original data points are used.
- `se` should standard errors be computed?
- `...` arguments passed to or from other methods.

**Details**

The standard errors calculation is slower than prediction.

When the fit was made using `surface="interpolate"` (the default), `predict.loess` will not extrapolate – so points outside an axis-aligned hypercube enclosing the original data will have missing (NA) predictions and standard errors.

**Value**

If `se = FALSE`, a vector giving the prediction for each row of `newdata` (or the original data). If `se = TRUE`, a list containing components:

- `fit` the predicted values.
- `se` an estimated standard error for each predicted value.
- `residual.scale` the estimated scale of the residuals used in computing the standard errors.
- `df` an estimate of the effective degrees of freedom used in estimating the residual scale, intended for use with t-based confidence intervals.

If `newdata` was the result of a call to `expand.grid`, the predictions (and s.e.’s if requested) will be an array of the appropriate dimensions.

**Note**

Variables are first looked for in `newdata` and then searched for in the usual way (which will include the environment of the formula used in the fit). A warning will be given if the variables found are not of the same length as those in `newdata` if it was supplied.

**Author(s)**

B.D. Ripley, based on the cloess package of Cleveland, Grosse and Shyu.
predict.nls

Predicting from Nonlinear Least Squares Fits

Description

predict.nls produces predicted values, obtained by evaluating the regression function in the frame newdata. If the logical se.fit is TRUE, standard errors of the predictions are calculated. If the numeric argument scale is set (with optional df), it is used as the residual standard deviation in the computation of the standard errors, otherwise this is extracted from the model fit. Setting intervals specifies computation of confidence or prediction (tolerance) intervals at the specified level.

At present se.fit and interval are ignored.

Usage

## S3 method for class 'nls':
predict(object, newdata, se.fit = FALSE, scale = NULL, df = Inf, interval = c("none", "confidence", "prediction"), level = 0.95, ...)

Arguments

object An object that inherits from class nls.
newdata A named list or data frame in which to look for variables with which to predict. If newdata is missing the fitted values at the original data points are returned.
se.fit A logical value indicating if the standard errors of the predictions should be calculated. Defaults to FALSE. At present this argument is ignored.
scale A numeric scalar. If it is set (with optional df), it is used as the residual standard deviation in the computation of the standard errors, otherwise this information is extracted from the model fit. At present this argument is ignored.
df A positive numeric scalar giving the number of degrees of freedom for the scale estimate. At present this argument is ignored.
interval A character string indicating if prediction intervals or a confidence interval on the mean responses are to be calculated. At present this argument is ignored.
level A numeric scalar between 0 and 1 giving the confidence level for the intervals (if any) to be calculated. At present this argument is ignored.
... Additional optional arguments. At present no optional arguments are used.
predict.nls produces a vector of predictions. When implemented, interval will produce a matrix of predictions and bounds with column names fit, lwr, and upr. When implemented, if se.fit is TRUE, a list with the following components will be returned:

- **fit**: vector or matrix as above
- **se.fit**: standard error of predictions
- **residual.scale**: residual standard deviations
- **df**: degrees of freedom for residual

**Note**

Variables are first looked for in newdata and then searched for in the usual way (which will include the environment of the formula used in the fit). A warning will be given if the variables found are not of the same length as those in newdata if it was supplied.

**See Also**

## Form data plot and smooth line for the predictions
opar <- par(las = 1)
plot(demand ~ Time, data = BOD, col = 4,
     main = "BOD data and fitted first-order curve",
     xlim = c(0, 7), ylim = c(0, 20) )
tt <- seq(0, 8, length = 101)
lines(tt, predict(fm, list(Time = tt)))
par(opar)
```
predict.smooth.spline

Arguments

object
a fit from smooth.spline.

x
the new values of x.

deriv
integer; the order of the derivative required.

Value

A list with components

x
The input x.

y
The fitted values or derivatives at x.

}
detach(); par(op)
**preplot**  
*Pre-computations for a Plotting Object*

**Description**

Compute an object to be used for plots relating to the given model object.

**Usage**

```r
preplot(object, ...)
```

**Arguments**

- `object`: a fitted model object.
- `...`: additional arguments for specific methods.

**Details**

Only the generic function is currently provided in base R, but some add-on packages have methods. Principally here for S compatibility.

**Value**

An object set up to make a plot that describes `object`.

---

**princomp**  
*Principal Components Analysis*

**Description**

`princomp` performs a principal components analysis on the given numeric data matrix and returns the results as an object of class `princomp`.

**Usage**

```r
princomp(x, ...)
```

### S3 method for class 'formula':
```r
princomp(formula, data = NULL, subset, na.action, ...)
```

### Default S3 method:
```r
princomp(x, cor = FALSE, scores = TRUE, covmat = NULL, subset = rep(TRUE, nrow(as.matrix(x))), ...)
```

### S3 method for class 'princomp':
```r
predict(object, newdata, ...)
```
Arguments

- **formula**: a formula with no response variable, referring only to numeric variables.
- **data**: an optional data frame (or similar: see `model.frame`) containing the variables in the formula `formula`. By default the variables are taken from `environment(formula)`.
- **subset**: an optional vector used to select rows (observations) of the data matrix \( x \).
- **na.action**: a function which indicates what should happen when the data contain NAs. The default is set by the `na.action` setting of `options`, and is `na.fail` if that is unset. The “factory-fresh” default is `na.omit`.
- **x**: a numeric matrix or data frame which provides the data for the principal components analysis.
- **cor**: a logical value indicating whether the calculation should use the correlation matrix or the covariance matrix. (The correlation matrix can only be used if there are no constant variables.)
- **scores**: a logical value indicating whether the score on each principal component should be calculated.
- **covmat**: a covariance matrix, or a covariance list as returned by `cov.wt` (and `cov.mve` or `cov.mcd` from package `MASS`). If supplied, this is used rather than the covariance matrix of \( x \).
- **...**: arguments passed to or from other methods. If \( x \) is a formula one might specify `cor` or `scores`.
- **object**: Object of class inheriting from "princomp"
- **newdata**: An optional data frame or matrix in which to look for variables with which to predict. If omitted, the scores are used. If the original fit used a formula or a data frame or a matrix with column names, `newdata` must contain columns with the same names. Otherwise it must contain the same number of columns, to be used in the same order.

Details

`princomp` is a generic function with "formula" and "default" methods.

The calculation is done using `eigen` on the correlation or covariance matrix, as determined by `cor`. This is done for compatibility with the S-PLUS result. A preferred method of calculation is to use `svd` on \( x \), as is done in `prcomp`.

Note that the default calculation uses divisor \( N \) for the covariance matrix.

The `print` method for these objects prints the results in a nice format and the `plot` method produces a scree plot (`screeplot`). There is also a `biplot` method.

If \( x \) is a formula then the standard NA-handling is applied to the scores (if requested): see `napredict`.

`princomp` only handles so-called R-mode PCA, that is feature extraction of variables. If a data matrix is supplied (possibly via a formula) it is required that there are at least as many units as variables. For Q-mode PCA use `prcomp`.

Value

`princomp` returns a list with class "princomp" containing the following components:

- **sdev**: the standard deviations of the principal components.
The matrix of variable loadings (i.e., a matrix whose columns contain the eigenvectors). This is of class "loadings": see `loadings` for its print method.

center
the means that were subtracted.

scale
the scalings applied to each variable.

n.obs
the number of observations.

scores
if `scores = TRUE`, the scores of the supplied data on the principal components. These are non-null only if `x` was supplied, and if `covmat` was also supplied if it was a covariance list. For the formula method, `napredict` is applied to handle the treatment of values omitted by the `na.action`.

call
the matched call.

na.action
If relevant.

Note
The signs of the columns of the loadings and scores are arbitrary, and so may differ between different programs for PCA, and even between different builds of R.

```
print.power.htest  Print method for power calculation object

Description

Print object of class "power.htest" in nice layout.

Usage

## S3 method for class 'power.htest':
print(x, ...)

Arguments

x  Object of class "power.htest".
... further arguments to be passed to or from methods.

Details

A power.htest object is just a named list of numbers and character strings, supplemented with method and note elements. The method is displayed as a title, the note as a footnote, and the remaining elements are given in an aligned 'name = value' format.

Value

none

Author(s)

Peter Dalgaard

print.ts  Printing Time-Series Objects

Description

Print method for time series objects.

Usage

## S3 method for class 'ts':
print(x, calendar, ...)

print.ts
Arguments

- **x**: a time series object.
- **calendar**: enable/disable the display of information about month names, quarter names or year when printing. The default is `TRUE` for a frequency of 4 or 12, `FALSE` otherwise.
- **...**: additional arguments to `print`.

Details

This is the `print` methods for objects inheriting from class "ts".

See Also

- `print.ts`.

Examples

```r
print(ts(1:10, freq = 7, start = c(12, 2)), calendar = TRUE)
```

---

printCoefmat  
*Print Coefficient Matrices*

Description

Utility function to be used in “higher level” `print` methods, such as `print.summary.lm`, `print.summary.glm` and `print.anova`. The goal is to provide a flexible interface with smart defaults such that often, only `x` needs to be specified.

Usage

```r
printCoefmat(x, digits=max(3, getOption("digits") - 2),
             signif.stars = getOption("show.signif.stars"),
             signif.legend = signif.stars,
             dig.tst = max(1, min(5, digits - 1)),
             cs.ind = 1:k, tst.ind = k + 1, zap.ind = integer(0),
             P.values = NULL,
             has.Pvalue = nc >= 4 &&
                           substr(colnames(x)[nc],1,3) == "Pr(",
             eps.Pvalue = .Machine$double.eps,
             na.print = "NA", ...)
```

Arguments

- **x**: a numeric matrix like object, to be printed.
- **digits**: minimum number of significant digits to be used for most numbers.
- **signif.stars**: logical; if `TRUE`, P-values are additionally encoded visually as “significance stars” in order to help scanning of long coefficient tables. It defaults to the `show.signif.stars` slot of `options`.
### printCoefmat

- **signif.legend**: logical; if TRUE, a legend for the “significance stars” is printed provided signif.stars=TRUE.
- **dig.tst**: minimum number of significant digits for the test statistics, see tst.ind.
- **cs.ind**: indices (integer) of column numbers which are (like) coefficients and standard errors to be formatted together.
- **tst.ind**: indices (integer) of column numbers for test statistics.
- **zap.ind**: indices (integer) of column numbers which should be formatted by zapsmall, i.e., by “zapping” values close to 0.
- **P.values**: logical or NULL; if TRUE, the last column of x is formatted by format.pval as P values. If P.values = NULL, the default, it is set to TRUE only if options("show.coef.Pvalue") is TRUE and x has at least 4 columns and the last column name of x starts with "Pr(".
- **has.Pvalue**: logical; if TRUE, the last column of x contains P values; in that case, it is printed if and only if P.values (above) is true.
- **eps.Pvalue**: number...
- **na.print**: a character string to code NA values in printed output.
- **...**: further arguments for print.

### Value

Invisibly returns its argument, x.

### Author(s)

Martin Maechler

### See Also

print.summary.lm, format.pval, format.

### Examples

```r
cmat <- cbind(rnorm(3, 10), sqrt(rchisq(3, 12)))
cmat <- cbind(cmat[,1]/cmat[,2])
cmat <- cbind(cmat, 2*pnorm(-cmat[,3]))
colnames(cmat) <- c("Estimate", "Std.Err", "Z value", "Pr(>z)")
printCoefmat(cmat[,1:3])
printCoefmat(cmat)
options(show.coef.Pvalues = FALSE)
printCoefmat(cmat, digits=2)
printCoefmat(cmat, digits=2, P.values = TRUE)
options(show.coef.Pvalues = TRUE)# revert
```
profile

Generic Function for Profiling Models

Description
Investigates behavior of objective function near the solution represented by fitted.
See documentation on method functions for further details.

Usage
profile(fitted, ...)

Arguments
fitted the original fitted model object.
... additional parameters. See documentation on individual methods.

Value
A list with an element for each parameter being profiled. See the individual methods for further details.

See Also
profile.nls, profile.glm in package MASS, ...
For profiling code, see Rprof.

profile.nls
Method for Profiling nls Objects

Description
Investigates the profilelog-likelihood function for a fitted model of class "nls".

Usage
## S3 method for class 'nls':
profile(fitted, which = 1:npar, maxpts = 100, alphamax = 0.01,
delta.t = cutoff/5, ...)

Arguments
fitted the original fitted model object.
which the original model parameters which should be profiled. This can be a numeric
or character vector. By default, all non-linear parameters are profiled.
maxpts maximum number of points to be used for profiling each parameter.
alphamax maximum significance level allowed for the profile t-statistics.
delta.t suggested change on the scale of the profile t-statistics. Default value chosen to
allow profiling at about 10 parameter values.
... further arguments passed to or from other methods.
**Details**

The profile t-statistics is defined as the square root of change in sum-of-squares divided by residual standard error with an appropriate sign.

**Value**

A list with an element for each parameter being profiled. The elements are data-frames with two variables:

- `par.vals` a matrix of parameter values for each fitted model.
- `tau` the profile t-statistics.

**Author(s)**

Of the original version, Douglas M. Bates and Saikat DebRoy

**References**

**See Also**

`nls`, `profile`, `plot.profile.nls`

**Examples**

```r
# obtain the fitted object
fm1 <- nls(demand ~ SSasympOrig( Time, A, lrc ), data = BOD)
# get the profile for the fitted model
pr1 <- profile( fm1 )
# profiled values for the two parameters
pr1$A
pr1$lrc
```

---

**proj**

*Projections of Models*

**Description**

`proj` returns a matrix or list of matrices giving the projections of the data onto the terms of a linear model. It is most frequently used for `aov` models.

**Usage**

```r
proj(object, ...)
```

## S3 method for class 'aov':

`proj(object, onedf = FALSE, unweighted.scale = FALSE, ...)`

## S3 method for class 'aovlist':

`proj(object, onedf = FALSE, unweighted.scale = FALSE, ...)`
## Default S3 method:
proj(object, onedf = TRUE, ...)

## S3 method for class 'lm':
proj(object, onedf = FALSE, unweighted.scale = FALSE, ...)

### Arguments

- **object**: An object of class "lm" or a class inheriting from it, or an object with a similar structure including in particular components `qr` and `effects`.
- **onedf**: A logical flag. If `TRUE`, a projection is returned for all the columns of the model matrix. If `FALSE`, the single-column projections are collapsed by terms of the model (as represented in the analysis of variance table).
- **unweighted.scale**: If the fit producing `object` used weights, this determines if the projections correspond to weighted or unweighted observations.
- **...**: Swallow and ignore any other arguments.

### Details

A projection is given for each stratum of the object, so for `aov` models with an `Error` term the result is a list of projections.

### Value

A projection matrix or (for multi-stratum objects) a list of projection matrices.

Each projection is a matrix with a row for each observation and either a column for each term (onedf = FALSE) or for each coefficient (onedf = TRUE). Projection matrices from the default method have orthogonal columns representing the projection of the response onto the column space of the Q matrix from the QR decomposition. The fitted values are the sum of the projections, and the sum of squares for each column is the reduction in sum of squares from fitting that column (after those to the left of it).

The methods for `lm` and `aov` models add a column to the projection matrix giving the residuals (the projection of the data onto the orthogonal complement of the model space).

Strictly, when onedf = FALSE the result is not a projection, but the columns represent sums of projections onto the columns of the model matrix corresponding to that term. In this case the matrix does not depend on the coding used.

### Author(s)

The design was inspired by the S function of the same name described in Chambers *et al.* (1992).

```r
N <- c(0,1,0,1,1,0,0,0,1,0,1,0,1,0,1,0,1,0,1,0,1,0,1,0)
P <- c(1,1,0,0,1,0,1,1,0,0,0,1,0,1,0,1,0,1,0,1,0,1,0)
K <- c(1,0,0,1,1,0,0,0,1,1,0,0,1,1,0,0,1,1,0,1,0,1,0,1)
yield <- c(49.5,62.8,46.8,57.0,59.8,58.5,55.5,56.0,62.8,55.8,69.5,
          55.0, 62.0,48.8,45.5,44.2,52.0,51.5,49.8,48.8,57.2,59.0,53.2,56.0)
npk <- data.frame(block=gl(6,4), N=factor(N), P=factor(P),
                   K=factor(K), yield=yield)
npk.aov <- aov(yield ~ block + N*P*K, npk)
proj(npk.aov)
## as a test, not particularly sensible
options(contrasts=c("contr.helmert", "contr.treatment"))
npk.aovE <- aov(yield ~ N*P*K + Error(block), npk)
proj(npk.aovE)
```  

### prop.test

#### Test of Equal or Given Proportions

prop.test can be used for testing the null that the proportions (probabilities of success) in several groups are the same, or that they equal certain given values.

#### Usage

```r
prop.test(x, n, p = NULL,
          alternative = c("two.sided", "less", "greater"),
          conf.level = 0.95, correct = TRUE)
```

#### Arguments

- **x**: a vector of counts of successes or a matrix with 2 columns giving the counts of successes and failures, respectively.
- **n**: a vector of counts of trials; ignored if x is a matrix.
- **p**: a vector of probabilities of success. The length of p must be the same as the number of groups specified by x, and its elements must be greater than 0 and less than 1.
- **alternative**: a character string specifying the alternative hypothesis, must be one of "two.sided" (default), "greater" or "less". You can specify just the initial letter. Only used for testing the null that a single proportion equals a given value, or that two proportions are equal; ignored otherwise.
- **conf.level**: confidence level of the returned confidence interval. Must be a single number between 0 and 1. Only used when testing the null that a single proportion equals a given value, or that two proportions are equal; ignored otherwise.
- **correct**: a logical indicating whether Yates’ continuity correction should be applied.
Details

Only groups with finite numbers of successes and failures are used. Counts of successes and failures must be nonnegative and hence not greater than the corresponding numbers of trials which must be positive. All finite counts should be integers.

If \( p \) is \( \text{NULL} \) and there is more than one group, the null tested is that the proportions in each group are the same. If there are two groups, the alternatives are that the probability of success in the first group is less than, not equal to, or greater than the probability of success in the second group, as specified by \( \text{alternative} \). A confidence interval for the difference of proportions with confidence level as specified by \( \text{conf.level} \) and clipped to \([-1,1]\) is returned. Continuity correction is used only if it does not exceed the difference of the sample proportions in absolute value. Otherwise, if there are more than 2 groups, the alternative is always "\text{two.sided}"; the returned confidence interval is \( \text{NULL} \), and continuity correction is never used.

If there is only one group, then the null tested is that the underlying probability of success is \( p \), or \(.5\) if \( p \) is not given. The alternative is that the probability of success if less than, not equal to, or greater than \( p \) or 0.5, respectively, as specified by \( \text{alternative} \). A confidence interval for the underlying proportion with confidence level as specified by \( \text{conf.level} \) and clipped to \([0,1]\) is returned. Continuity correction is used only if it does not exceed the difference between sample and null proportions in absolute value. The confidence interval is computed by inverting the score test. Finally, if \( p \) is given and there are more than 2 groups, the null tested is that the underlying probabilities of success are those given by \( p \). The alternative is always "\text{two.sided}"; the returned confidence interval is \( \text{NULL} \), and continuity correction is never used.

Value

A list with class "\text{htest}" containing the following components:

- \( \text{statistic} \) the value of Pearson’s chi-squared test statistic.
- \( \text{parameter} \) the degrees of freedom of the approximate chi-squared distribution of the test statistic.
- \( \text{p.value} \) the p-value of the test.
- \( \text{estimate} \) a vector with the sample proportions \( x/n \).
- \( \text{conf.int} \) a confidence interval for the true proportion if there is one group, or for the difference in proportions if there are 2 groups and \( p \) is not given, or \( \text{NULL} \) otherwise. In the cases where it is not \( \text{NULL} \), the returned confidence interval has an asymptotic confidence level as specified by \( \text{conf.level} \), and is appropriate to the specified alternative hypothesis.
- \( \text{null.value} \) the value of \( p \) if specified by the null, or \( \text{NULL} \) otherwise.
- \( \text{alternative} \) a character string describing the alternative.
- \( \text{method} \) a character string indicating the method used, and whether Yates’ continuity correction was applied.
- \( \text{data.name} \) a character string giving the names of the data.

`binom.test` for an exact test of a binomial hypothesis.

Examples

```r
heads <- rbinom(1, size=100, pr = .5)
prop.test(heads, 100)  # continuity correction TRUE by default
prop.test(heads, 100, correct = FALSE)

## Data from Fleiss (1981), p. 139.
## H0: The null hypothesis is that the four populations from which
##    the patients were drawn have the same true proportion of smokers.
## A: The alternative is that this proportion is different in at
##    least one of the populations.
smokers <- c(83, 90, 129, 70)
patients <- c(86, 93, 136, 82)
prop.test(smokers, patients)
```

`prop.trend.test`  
Test for trend in proportions

Description

Performs chi-squared test for trend in proportions, i.e., a test asymptotically optimal for local alternatives where the log odds vary in proportion with `score`. By default, `score` is chosen as the group numbers.

Usage

```r
prop.trend.test(x, n, score = 1:length(x))
```

Arguments

- `x` Number of events
- `n` Number of trials
- `score` Group score

Value

An object of class "htest" with title, test statistic, p-value, etc.

Note

This really should get integrated with `prop.test`

Author(s)

Peter Dalgaard

smokers <- c(83, 90, 129, 70)
patients <- c(86, 93, 136, 82)
prop.test(smokers, patients)
prop.trend.test(smokers, patients)
prop.trend.test(smokers, patients, c(0, 0, 0, 1))
```

---

### Description

`qqnorm` is a generic function the default method of which produces a normal QQ plot of the values in `y`. `qqline` adds a line to a normal quantile-quantile plot which passes through the first and third quartiles. `qqplot` produces a QQ plot of two datasets.

Graphical parameters may be given as arguments to `qqnorm`, `qqplot` and `qqline`.

### Usage

```r
qqnorm(y, ...)
## Default S3 method:
qqnorm(y, ylim, main = "Normal Q-Q Plot",
xlab = "Theoretical Quantiles", ylab = "Sample Quantiles",
plot.it = TRUE, datax = FALSE, ...)

qqline(y, datax = FALSE, ...)

qqplot(x, y, plot.it = TRUE, xlab = deparse(substitute(x)),
ylab = deparse(substitute(y)), ...)
```

### Arguments

- `x`: The first sample for `qqplot`.
- `y`: The second or only data sample.
- `xlab`, `ylab`, `main`: plot labels. The `xlab` and `ylab` refer to the y and x axes respectively if `datax = TRUE`.
- `plot.it`: logical. Should the result be plotted?
- `datax`: logical. Should data values be on the x-axis?
- `ylim`, `...`: graphical parameters.

### Value

For `qqnorm` and `qqplot`, a list with components

- `x`: The x coordinates of the points that were/would be plotted.
- `y`: The original y vector, i.e., the corresponding y coordinates including `NAs`. 
quade.test

References

See Also

`ppoints`, used by `qqnorm` to generate approximations to expected order statistics for a normal distribution.

Examples

```r
y <- rt(200, df = 5)
qqnorm(y); qline(y, col = 2)
qqplot(y, rt(300, df = 5))

qqnorm(precip, ylab = "Precipitation [in/yr] for 70 US cities")
```

Description

Performs a Quade test with unreplicated blocked data.

Usage

```r
quade.test(y, ...)
```

### Default S3 method:

```r
quade.test(y, groups, blocks, ...)
```

### S3 method for class 'formula':

```r
quade.test(formula, data, subset, na.action, ...)
```

Arguments

- `y` 
  - either a numeric vector of data values, or a data matrix.
- `groups` 
  - a vector giving the group for the corresponding elements of `y` if this is a vector; ignored if `y` is a matrix. If not a factor object, it is coerced to one.
- `blocks` 
  - a vector giving the block for the corresponding elements of `y` if this is a vector; ignored if `y` is a matrix. If not a factor object, it is coerced to one.
- `formula` 
  - a formula of the form `a ~ b | c`, where `a`, `b` and `c` give the data values and corresponding groups and blocks, respectively.
- `data` 
  - an optional matrix or data frame (or similar: see `model.frame`) containing the variables in the formula `formula`. By default the variables are taken from `environment(formula)`.
- `subset` 
  - an optional vector specifying a subset of observations to be used.
- `na.action` 
  - a function which indicates what should happen when the data contain NAs. Defaults to `getOption("na.action")`.
- `...` 
  - further arguments to be passed to or from methods.
Details

quade.test can be used for analyzing unreplicated complete block designs (i.e., there is exactly one observation in \( y \) for each combination of levels of \( \text{groups} \) and \( \text{blocks} \)) where the normality assumption may be violated.

The null hypothesis is that apart from an effect of \( \text{blocks} \), the location parameter of \( y \) is the same in each of the \( \text{groups} \).

If \( y \) is a matrix, \( \text{groups} \) and \( \text{blocks} \) are obtained from the column and row indices, respectively. NA’s are not allowed in \( \text{groups} \) or \( \text{blocks} \); if \( y \) contains NA’s, corresponding blocks are removed.

Value

A list with class "htest" containing the following components:

- statistic: the value of Quade’s F statistic.
- parameter: a vector with the numerator and denominator degrees of freedom of the approximate F distribution of the test statistic.
- p.value: the p-value of the test.
- method: the character string "Quade test".
- data.name: a character string giving the names of the data.

      1, 3, 1, 0, 2,
      16, 12, 22, 22, 35,
      5, 4, 3, 5, 4,
      10, 9, 7, 13, 10,
      19, 18, 28, 37, 58,
      10, 7, 6, 8, 7),
nr = 7, byrow = TRUE,
dimnames =
list(Store = as.character(1:7),
     Brand = LETTERS[1:5]))
y
quade.test(y)
```
quantile

Sample Quantiles

Description

The generic function quantile produces sample quantiles corresponding to the given probabilities. The smallest observation corresponds to a probability of 0 and the largest to a probability of 1.

Usage

quantile(x, ...)

# Default S3 method:
quantile(x, probs = seq(0, 1, 0.25), na.rm = FALSE,
    names = TRUE, type = 7, ...)

Arguments

x numeric vectors whose sample quantiles are wanted. Missing values are ignored.
probs numeric vector of probabilities with values in [0, 1].
na.rm logical; if true, any NA and NaN’s are removed from x before the quantiles are computed.
names logical; if true, the result has a names attribute. Set to FALSE for speedup with many probs.
type an integer between 1 and 9 selecting one of the nine quantile algorithms detailed below to be used.
... further arguments passed to or from other methods.

Details

A vector of length length(probs) is returned; if names = TRUE, it has a names attribute. NA and NaN values in probs are propagated to the result.

Types

quantile returns estimates of underlying distribution quantiles based on one or two order statistics from the supplied elements in x at probabilities in probs. One of the nine quantile algorithms discussed in Hyndman and Fan (1996), selected by type, is employed.

Sample quantiles of type i are defined by

\[ Q_i(p) = (1 - \gamma)x_j + \gamma x_{j+1} \]

where 1 ≤ i ≤ 9, \( \frac{j-m}{n} \leq p < \frac{j-m+1}{n} \), \( x_j \) is the jth order statistic, \( n \) is the sample size, and \( m \) is a constant determined by the sample quantile type. Here \( \gamma \) depends on the fractional part of \( g = np + m - j \).

For the continuous sample quantile types (4 through 9), the sample quantiles can be obtained by linear interpolation between the kth order statistic and \( p(k) \):

\[ p(k) = \frac{k - \alpha}{n - \alpha - \beta + 1} \]
where \( \alpha \) and \( \beta \) are constants determined by the type. Further, \( m = \alpha + p(1 - \alpha - \beta) \), and \( \gamma = g \).

**Discontinuous sample quantile types 1, 2, and 3**

Type 1 Inverse of empirical distribution function.

Type 2 Similar to type 1 but with averaging at discontinuities.

Type 3 SAS definition: nearest even order statistic.

**Continuous sample quantile types 4 through 9**

Type 4 \( p(k) = \frac{k}{n} \). That is, linear interpolation of the empirical cdf.

Type 5 \( p(k) = \frac{k - 0.5}{n} \). That is a piecewise linear function where the knots are the values midway through the steps of the empirical cdf. This is popular amongst hydrologists.

Type 6 \( p(k) = \frac{k}{n+1} \). Thus \( p(k) = \mathbb{E}[F(x_k)] \). This is used by Minitab and by SPSS.

Type 7 \( p(k) = \frac{k - 1}{n - 1} \). In this case, \( p(k) = \text{mode}[F(x_k)] \). This is used by S.

Type 8 \( p(k) = \frac{k - \frac{1}{3}}{n + \frac{1}{3}} \). Then \( p(k) \approx \text{median}[F(x_k)] \). The resulting quantile estimates are approximately median-unbiased regardless of the distribution of \( x \).

Type 9 \( p(k) = \frac{k - \frac{1}{8}}{n + \frac{1}{4}} \). The resulting quantile estimates are approximately unbiased for the expected order statistics if \( x \) is normally distributed.

Hyndman and Fan (1996) recommend type 8. The default method is type 7, as used by S and by \( \mathbb{R} < 2.0.0 \).

**Examples**

```r
quantile(x <- rnorm(1001)) # Extremes & Quartiles by default
quantile(x, probs=c(.1,.5,1,2,5,10,50, NA)/100)

### Compare different types
p <- c(0.1,0.5,1,2,5,10,50)/100
res <- matrix(as.numeric(NA), 9, 7)
for(type in 1:9) res[type, ] <- y <- quantile(x, p, type=type)
dimnames(res) <- list(1:9, names(y))
round(res, 3)
```
Description

Generate random 2-way tables with given marginals using Patefield’s algorithm.

Usage

```
r2dtable(n, r, c)
```

Arguments

- `n` a non-negative numeric giving the number of tables to be drawn.
- `r` a non-negative vector of length at least 2 giving the row totals, to be coerced to integer. Must sum to the same as `c`.
- `c` a non-negative vector of length at least 2 giving the column totals, to be coerced to integer.

Value

A list of length `n` containing the generated tables as its components.

Examples

```r
## Fisher's Tea Drinker data.
TeaTasting <-
matrix(c(3, 1, 1, 3),
    nr = 2,
    dimnames = list(Guess = c("Milk", "Tea"),
                    Truth = c("Milk", "Tea"))
## Simulate permutation test for independence based on the maximum Pearson residuals (rather than their sum).
rowTotals <- rowSums(TeaTasting)
colTotals <- colSums(TeaTasting)
nOfCases <- sum(rowTotals)
expected <- outer(rowTotals, colTotals, "+") / nOfCases
maxSqResid <- function(x) max((x - expected) ^ 2 / expected)
simMaxSqResid <- sapply(r2dtable(1000, rowTotals, colTotals), maxSqResid)
sum(simMaxSqResid >= maxSqResid(TeaTasting)) / 1000
## Fisher's exact test gives p = 0.4857 ...
```
Manipulate Flat Contingency Tables

**Description**

Read, write and coerce “flat” contingency tables.

**Usage**

```r
read.ftable(file, sep = "", quote = "\n", row.var.names, col.vars, skip = 0)
write.ftable(x, file = "", quote = TRUE, append = FALSE, digits = getOption("digits"))
```

```r
## S3 method for class 'ftable':
format(x, quote = TRUE, digits = getOption("digits"), ...)
```

**Arguments**

- `file` either a character string naming a file or a connection which the data are to be read from or written to. "" indicates input from the console for reading and output to the console for writing.
- `sep` the field separator string. Values on each line of the file are separated by this string.
- `quote` a character string giving the set of quoting characters for `read.ftable`; to disable quoting altogether, use `quote=""`. For `write.table`, a logical indicating whether strings in the data will be surrounded by double quotes.
- `row.var.names` a character vector with the names of the row variables, in case these cannot be determined automatically.
- `col.vars` a list giving the names and levels of the column variables, in case these cannot be determined automatically.
- `skip` the number of lines of the data file to skip before beginning to read data.
- `x` an object of class "ftable".
- `append` logical. If TRUE and `file` is the name of a file (and not a connection or "|cmd"), the output from `write.ftable` is appended to the file. If FALSE, the contents of `file` will be overwritten.
- `digits` an integer giving the number of significant digits to use for (the cell entries of) `x`.
- `...` further arguments to be passed to or from methods.

**Details**

`read.ftable` reads in a flat-like contingency table from a file. If the file contains the written representation of a flat table (more precisely, a header with all information on names and levels of column variables, followed by a line with the names of the row variables), no further arguments are needed. Similarly, flat tables with only one column variable the name of which is the only entry in the first line are handled automatically. Other variants can be dealt with by skipping all header
information using `skip`, and providing the names of the row variables and the names and levels of the column variable using `row.var.names` and `col.vars`, respectively. See the examples below.

Note that flat tables are characterized by their “ragged” display of row (and maybe also column) labels. If the full grid of levels of the row variables is given, one should instead use `read.table` to read in the data, and create the contingency table from this using `xtabs`.

`write.ftable` writes a flat table to a file, which is useful for generating “pretty” ASCII representations of contingency tables.

**References**

**See Also**

`ftable` for more information on flat contingency tables.

**Examples**

```r
## Agresti (1990), page 157, Table 5.8.
## Not in ftable standard format, but o.k.
file <- tempfile()
cat(" Intercourse
" Race Gender Yes No
" White Male 43 134
" Female 26 149
" Black Male 29 23
" Female 22 36
", file = file)
file.show(file)
ft <- read.ftable(file)
ft
unlink(file)

## Agresti (1990), page 297, Table 8.16.
## Almost o.k., but misses the name of the row variable.
file <- tempfile()
cat(" Tonsil Size"
" Noncarriers 497 560 269
" Carriers 19 29 24
", file = file)
file.show(file)
ft <- read.ftable(file, skip = 2,
row.var.names = "Status",
col.vars = list("Tonsil Size" =
c("Not Enl.", "Enl.", "Greatly Enl.")))
ft
unlink(file)

ft22 <- ftable(Titanic, row.vars = 2:1, col.vars = 4:3)
write.ftable(ft22, quote = FALSE)
```
rect.hclust  

**Draw Rectangles Around Hierarchical Clusters**

**Description**

Draws rectangles around the branches of a dendrogram highlighting the corresponding clusters. First the dendrogram is cut at a certain level, then a rectangle is drawn around selected branches.

**Usage**

rect.hclust(tree, k = NULL, which = NULL, x = NULL, h = NULL, border = 2, cluster = NULL)

**Arguments**

- tree: an object of the type produced by hclust.
- k, h: Scalar. Cut the dendrogram such that either exactly k clusters are produced or by cutting at height h.
- which, x: A vector selecting the clusters around which a rectangle should be drawn. which selects clusters by number (from left to right in the tree), x selects clusters containing the respective horizontal coordinates. Default is which = 1:k.
- border: Vector with border colors for the rectangles.
- cluster: Optional vector with cluster memberships as returned by cutree(hclust.obj, k = k), can be specified for efficiency if already computed.

**Value**

(Invisibly) returns a list where each element contains a vector of data points contained in the respective cluster.

**See Also**

hclust, identify.hclust.

**Examples**

```r
hca <- hclust(dist(USArrests))
plot(hca)
rect.hclust(hca, k=3, border="red")
x <- rect.hclust(hca, h=50, which=c(2,7), border=3:4)
x
```
**relevel**  
*Reorder Levels of Factor*

**Description**

The levels of a factor are re-ordered so that the level specified by `ref` is first and the others are moved down. This is useful for `contr.treatment` contrasts which take the first level as the reference.

**Usage**

```
relevel(x, ref, ...)
```

**Arguments**

- `x`: An unordered factor.
- `ref`: The reference level.
- `...`: Additional arguments for future methods.

**Value**

A factor of the same length as `x`.

**See Also**

`factor`, `contr.treatment`, `levels`, `reorder`.

**Examples**

```r
warpbreaks$tension <- relevel(warpbreaks$tension, ref="M")
summary(lm(breaks ~ wool + tension, data=warpbreaks))
```

---

**reorder.dendrogram**  
*Reorder a Dendrogram*

**Description**

A method for the generic function `reorder`.

There are many different orderings of a dendrogram that are consistent with the structure imposed.

This function takes a dendrogram and a vector of values and reorders the dendrogram in the order of the supplied vector, maintaining the constraints on the dendrogram.

**Usage**

```r
## S3 method for class 'dendrogram':
reorder(x, wts, agglo.FUN = sum, ...)
```
Arguments

x          the (dendrogram) object to be reordered
wts        numeric weights (arbitrary values) for reordering.
agglo.FUN  a function for weights agglomeration, see below.
...        additional arguments

Details

Using the weights wts, the leaves of the dendrogram are reordered so as to be in an order as consistent as possible with the weights. At each node, the branches are ordered in increasing weights where the weight of a branch is defined as \(f(w_j)\) where \(f\) is \texttt{agglo.FUN} and \(w_j\) is the weight of the \(j\)-th sub branch.

Value

A dendrogram where each node has a further attribute \texttt{value} with its corresponding weight.

Author(s)

R. Gentleman and M. Maechler

See Also

\texttt{reorder}, \texttt{rev.dendrogram} which simply reverses the nodes' order; \texttt{heatmap}, \texttt{cophenetic}.

Examples

```r
set.seed(123)
x <- rnorm(10)
hc <- hclust(dist(x))
dd <- as.dendrogram(hc)
dd.reorder <- reorder(dd, 10:1)
plot(dd, main = "random dendrogram `dd'")

op <- par(mfcol = 1:2)
plot(dd.reorder, main = "reorder(dd, 10:1)")
plot(reorder(dd,10:1, agglo.FUN= mean),
     main = "reorder(dd, 10:1, mean)")
par(op)
```

---

\texttt{reorder.factor} \hspace{1cm} \textit{Reorder Levels of a Factor}

Description

\texttt{reorder} is a generic function. Its \texttt{"factor"} method reorders the levels of a factor depending on values of a second variable, usually numeric.
**replications**

Usage

```r
reorder(x, ...)
```

```r
## S3 method for class 'factor':
reorder(x, X, FUN = mean, ..., 
    order = is.ordered(x))
```

**Arguments**

- `x`: a factor (possibly ordered) whose levels will be reordered.
- `X`: a vector of the same length as `x`, whose subset of values for each unique level of `x` determines the eventual order of that level.
- `FUN`: a function whose first argument is a vector and returns a scalar, to be applied to each subset of `X` determined by the levels of `x`.
- `...`: optional: extra arguments supplied to `FUN`
- `order`: logical, whether return value will be an ordered factor rather than a factor.

**Value**

A factor or an ordered factor (depending on the value of `order`), with the order of the levels determined by `FUN` applied to `X` grouped by `x`. The levels are ordered such that the values returned by `FUN` are in increasing order.

Additionally, the values of `FUN` applied to the subsets of `X` (in the original order of the levels of `x`) is returned as the "scores" attribute.

**Author(s)**

Deepayan Sarkar (deepayan@stat.wisc.edu)

**See Also**

`reorder.dendrogram`, `levels`, `relevel`.

**Examples**

```r
bymedian <- with(InsectSprays, reorder(spray, count, median))
boxplot(count ~ bymedian, data = InsectSprays, 
    xlab = "Type of spray", ylab = "Insect count", 
    main = "InsectSprays data", varwidth = TRUE, 
    col = "lightgray")
```

**replications**

<table>
<thead>
<tr>
<th>Description</th>
<th>Number of Replications of Terms</th>
</tr>
</thead>
<tbody>
<tr>
<td>Returns a vector or a list of the number of replicates for each term in the formula.</td>
<td></td>
</tr>
</tbody>
</table>

**Usage**

```r
replications(formula, data=NULL, na.action)
```
Arguments

- **formula**: a formula or a terms object or a data frame.
- **data**: a data frame used to find the objects in **formula**.
- **na.action**: function for handling missing values. Defaults to a **na.action** attribute of **data**, then a setting of the option **na.action**, or **na.fail** if that is not set.

Details

If **formula** is a data frame and **data** is missing, **formula** is used for **data** with the formula ~ ..

Value

A vector or list with one entry for each term in the formula giving the number(s) of replications for each level. If all levels are balanced (have the same number of replications) the result is a vector, otherwise it is a list with a component for each terms, as a vector, matrix or array as required.

A test for balance is `!is.list(replications(formula, data))`.

Author(s)

The design was inspired by the S function of the same name described in Chambers *et al.* (1992).

Examples

```r
N <- c(0,1,0,1,1,0,0,0,1,1,0,1,0,1,0,0,1,1,0,1,0,0,1,1,0,0,1,1,0,0)
P <- c(1,1,0,0,0,1,0,1,1,0,0,1,1,0,0,0,1,1,0,0,1,1,0,0,1,1,0,0)
K <- c(1,0,0,1,0,1,1,0,0,1,0,1,0,1,0,0,1,1,0,0,1,1,0,0,1,1,0,0)
yield <- c(49.5,62.8,46.8,57.0,59.8,58.5,55.5,56.0,62.8,55.8,69.5, 55.0, 62.0,48.8,45.5,44.2,52.0,51.5,49.8,48.8,57.2,59.0,53.2,56.0)

npk <- data.frame(block=gl(6,4), N=factor(N), P=factor(P),
                   K=factor(K), yield=yield)
replications(~ . - yield, npk)
```
**reshape**  
*Reshape Grouped Data*

**Description**

This function reshapes a data frame between ‘wide’ format with repeated measurements in separate columns of the same record and ‘long’ format with the repeated measurements in separate records.

**Usage**

```r
reshape(data, varying = NULL, v.names = NULL, timevar = "time",
idvar = "id", ids = 1:NROW(data),
times = seq(length = length(varying[[1]])),
drop = NULL, direction, new.row.names = NULL,
split = list(regexp="\."), include=FALSE))
```

**Arguments**

- **data**: a data frame
- **varying**: names of sets of variables in the wide format that correspond to single variables in long format (‘time-varying’). A list of vectors (or optionally a matrix for `direction="wide"`). See below for more details and options.
- **v.names**: names of variables in the long format that correspond to multiple variables in the wide format.
- **timevar**: the variable in long format that differentiates multiple records from the same group or individual.
- **idvar**: Names of one or more variables in long format that identify multiple records from the same group/individual. These variables may also be present in wide format.
- **ids**: the values to use for a newly created `idvar` variable in long format.
- **times**: the values to use for a newly created `timevar` variable in long format.
- **drop**: a vector of names of variables to drop before reshaping
- **direction**: character string, either "wide" to reshape to wide format, or "long" to re-shape to long format.
- **new.row.names**: logical; if TRUE and `direction="wide"`, create new row names in long format from the values of the id and time variables.
- **split**: information for guessing the `varying`, `v.names`, and `times` arguments. See below for details.

**Details**

The arguments to this function are described in terms of longitudinal data, as that is the application motivating the functions. A ‘wide’ longitudinal dataset will have one record for each individual with some time-constant variables that occupy single columns and some time-varying variables that occupy a column for each time point. In ‘long’ format there will be multiple records for each individual, with some variables being constant across these records and others varying across the records. A ‘long’ format dataset also needs a ‘time’ variable identifying which time point each record comes from and an ‘id’ variable showing which records refer to the same person.
If the data frame resulted from a previous \texttt{reshape} then the operation can be reversed simply by \texttt{reshape(a)}. The direction argument is optional and the other arguments are stored as attributes on the data frame.

If \texttt{direction="long"} and no \texttt{varying} or \texttt{v.names} arguments are supplied it is assumed that all variables except \texttt{idvar} and \texttt{timevar} are time-varying. They are all expanded into multiple variables in wide format.

If \texttt{direction="wide"} the varying argument can be a vector of column names or column numbers (converted to column names). The function will attempt to guess the \texttt{v.names} and times from these names. The default is variable names like x.1, x.2, where \texttt{split=list(regexp="\."), include=FALSE} specifies to split at the dot and drop it from the name. To have alphabetic followed by numeric times use \texttt{split=list(regexp="[A-Za-z][0-9]"), include=TRUE). This splits between the alphabetic and numeric parts of the name and does not drop the regular expression.

\textbf{Value}

The reshaped data frame with added attributes to simplify reshaping back to the original form.

\textbf{See Also}

\texttt{stack, aperm}

\textbf{Examples}

```
summary(Indometh)
wide <- reshape(Indometh, v.names="conc", idvar="Subject",
               timevar="time", direction="wide")
wide
reshape(wide, direction="long")
reshape(wide, idvar="Subject", varying=list(names(wide)[2:12]),
       v.names="conc", direction="long")
## times need not be numeric
df <- data.frame(id=rep(1:4,rep(2,4)),
                 visit=I(rep(c("Before","After"),4)),
                 x=rnorm(4), y=runif(4))
df
reshape(df, timevar="visit", idvar="id", direction="wide")
## warns that y is really varying
reshape(df, timevar="visit", idvar="id", direction="wide", v.names="x")
## unbalanced 'long' data leads to NA fill in 'wide' form
df2 <- df[1:7,]
df2
reshape(df2, timevar="visit", idvar="id", direction="wide")
## Alternative regular expressions for guessing names
df3 <- data.frame(id=1:4, age=c(40,50,60,50), dose1=c(1,2,1,2),
                 dose2=c(2,1,2,1), dose4=c(3,3,3,3))
reshape(df3, direction="long", varying=3:5,
        split=list(regexp="[a-z][0-9]"), include=TRUE))
## an example that isn't longitudinal data
state.x77 <- as.data.frame(state.x77)
```
long <- reshape(state.x77, idvar="state", ids=row.names(state.x77),
    times=names(state.x77), timevar="Characteristic",
    varying=list(names(state.x77)), direction="long")

reshape(long, direction="wide")

reshape(long, direction="wide", new.row.names=unique(long$state))

## multiple id variables
df3 <- data.frame(school=rep(1:3,each=4), class=rep(9:10,6),
    time=rep(c(1,1,2,2),3),
    score=rnorm(12))
wide <- reshape(df3, idvar=c("school","class"), direction="wide")
wide
## transform back
reshape(wide)

---

### residuals

**Extract Model Residuals**

**Description**

residuals is a generic function which extracts model residuals from objects returned by modeling functions.

The abbreviated form resid is an alias for residuals. It is intended to encourage users to access object components through an accessor function rather than by directly referencing an object slot.

All object classes which are returned by model fitting functions should provide a residuals method. (Note that the method is for 'residuals' and not 'resid'.)

Methods can make use of naresid methods to compensate for the omission of missing values. The default, nls and smooth.spline methods do.

**Usage**

residuals(object, ...)
resid(object, ...)

**Arguments**

- **object**
  - an object for which the extraction of model residuals is meaningful.
- **...**
  - other arguments.

**Value**

Residuals extracted from the object object.

**References**

runmed

Running Medians – Robust Scatter Plot Smoothing

Description

Compute running medians of odd span. This is the “most robust” scatter plot smoothing possible. For efficiency (and historical reason), you can use one of two different algorithms giving identical results.

Usage

runmed(x, k, endrule = c("median", "keep", "constant"), algorithm = NULL, print.level = 0)

Arguments

x numeric vector, the “dependent” variable to be smoothed.

k integer width of median window; must be odd. Turlach had a default of \( k \leftarrow 1 + 2 \times \min((n-1)/2, \text{ceiling}(0.1 \times n)) \). Use \( k = 3 \) for “minimal” robust smoothing eliminating isolated outliers.

drule character string indicating how the values at the beginning and the end (of the data) should be treated.

"keep" keeps the first and last \( k/2 \) values at both ends, where \( k/2 \) is the half-bandwidth \( k/2 = k \%/% 2 \), i.e., \( y[j] = x[j] \) for \( j \in \{1, \ldots, k/2; n-k/2+1, \ldots, n\} \);

"constant" copies \( \text{median}(y[1:k/2]) \) to the first values and analogously for the last ones making the smoothed ends constant;

"median" the default, smooths the ends by using symmetrical medians of subsequently smaller bandwidth, but for the very first and last value where Tukey’s robust end-point rule is applied, see smoothEnds.

algorithm character string (partially matching "Turlach" or "Stuetzle") or the default NULL, specifying which algorithm should be applied. The default choice depends on \( n = \text{length}(x) \) and \( k \) where "Turlach" will be used for larger problems.

print.level integer, indicating verboseness of algorithm; should rarely be changed by average users.

Details

Apart from the end values, the result \( y = \text{runmed}(x, k) \) simply has \( y[j] = \text{median}(x[(j-k2):(j+k2)]) \) (\( k = 2 \times k2 + 1 \)), computed very efficiently.

The two algorithms are internally entirely different:

See Also

coefficients, fitted.values.glm, lm.
influence.measures for standardized (rstandard) and studentized (rstudent) residuals.
"Turlach" is the Härdle-Steiger algorithm (see Ref.) as implemented by Berwin Turlach. A tree algorithm is used, ensuring performance $O(n \log k)$ where $n \leftarrow \text{length}(x)$ which is asymptotically optimal.

"Stuetzle" is the (older) Stuetzle-Friedman implementation which makes use of median updating when one observation enters and one leaves the smoothing window. While this performs as $O(n \times k)$ which is slower asymptotically, it is considerably faster for small $k$ or $n$.

Value

vector of smoothed values of the same length as $x$ with an attribute $k$ containing (the 'oddified') $k$.

Author(s)

Martin Maechler (maechler@stat.math.ethz.ch), based on Fortran code from Werner Stuetzle and S-plus and C code from Berwin Turlach.

References

See Also

smoothEnds which implements Tukey’s end point rule and is called by default from runmed(*, endrule = "median"). smooth uses running medians of 3 for its compound smoothers.

Examples

lines(runmed(y, ?), lwd=2, col = "blue")
lines(runmed(y,11), lwd=2, col = "red")

## Lowess is not robust
y <- ys ; y[21] <- 6666 ; x <- seq(y)
col <- c("black", "brown","blue")
plot(y, col=col[1])
lines(lowess(x,y, f = .3), col = col[2])
lines(runmed(y, 7), lwd=2, col = col[3])
legend(length(y),max(y), c("data", "lowess(y, f = 0.3)", "runmed(y, 7)"),
   xjust = 1, col = col, lty = c(0, 1,1), pch = c(1,NA,NA))

scatter.smooth  Scatter Plot with Smooth Curve Fitted by Loess

Description
Plot and add a smooth curve computed by loess to a scatter plot.

Usage
scatter.smooth(x, y = NULL, span = 2/3, degree = 1,
   family = c("symmetric", "gaussian"),
   xlab = NULL, ylab = NULL,
   ylim = range(y, prediction$y, na.rm = TRUE),
   evaluation = 50, ...)

loess.smooth(x, y, span = 2/3, degree = 1,
   family = c("symmetric", "gaussian"), evaluation = 50, ...)

Arguments
x, y         the x and y arguments provide the x and y coordinates for the plot. Any reasonable way of defining the coordinates is acceptable. See the function xy.coords for details.
span         smoothness parameter for loess.
dergree       degree of local polynomial used.
family       if "gaussian" fitting is by least-squares, and if family="symmetric" a re-descending M estimator is used.
xlab         label for x axis.
ylab         label for y axis.
ylim         the y limits of the plot.
evaluation   number of points at which to evaluate the smooth curve.
...           graphical parameters.

Details
loess.smooth is an auxiliary function which evaluates the loess smooth at evaluation equally spaced points covering the range of x.

Value
For scatter.smooth, none.
For loess.smooth, a list with two components, x (the grid of evaluation points) and y (the smoothed values at the grid points).
screeplot

loess

Examples

attach(cars)
scatter.smooth(speed, dist)
detach()

## The variances of the variables in the
## USArrests data vary by orders of magnitude, so scaling is appropriate
(pc.cr <- princomp(USArrests, cor = TRUE))  # inappropriate
screeplot(pc.cr)

fit <- princomp(covmat=Harman74.cor)
screeplot(fit)
screeplot(fit, npcs=24, type="lines")

Description

screeplot.default plots the variances against the number of the principal component. This is also the plot method for classes "princomp" and "prcomp".

Usage

## Default S3 method:
screeplot(x, npcs = min(10, length(x$sdev)),
type = c("barplot", "lines"),
main = deparse(substitute(x)), ...)

Arguments

x an object containing a sdev component, such as that returned by princomp() and prcomp().
npcs the number of components to be plotted.
type the type of plot.
main, ... graphics parameters.

References

See Also

princomp and prcomp.

Examples

## The variances of the variables in the
## USArrests data vary by orders of magnitude, so scaling is appropriate
(pc.cr <- princomp(USArrests, cor = TRUE))  # inappropriate
screeplot(pc.cr)

fit <- princomp(covmat=Harman74.cor)
screeplot(fit)
screeplot(fit, npcs=24, type="lines")
sd                      Standard Deviation

Description

This function computes the standard deviation of the values in x. If na.rm is TRUE then missing values are removed before computation proceeds. If x is a matrix or a data frame, a vector of the standard deviation of the columns is returned.

Usage

sd(x, na.rm = FALSE)

Arguments

x          a numeric vector, matrix or data frame.
na.rm      logical. Should missing values be removed?

See Also

var for its square, and mad, the most robust alternative.

Examples

sd(1:2) ^ 2

se.contrast        Standard Errors for Contrasts in Model Terms

Description

Returns the standard errors for one or more contrasts in an aov object.

Usage

se.contrast(object, ...)
## S3 method for class 'aov':
se.contrast(object, contrast.obj,
            coef = contr.helmert(ncol(contrast))[, 1],
            data = NULL, ...)

Arguments

object      A suitable fit, usually from aov.
contrast.obj The contrasts for which standard errors are requested. This can be specified via a list or via a matrix. A single contrast can be specified by a list of logical vectors giving the cells to be contrasted. Multiple contrasts should be specified by a matrix, each column of which is a numerical contrast vector (summing to zero).
se.contrast

coef used when contrast.obj is a list; it should be a vector of the same length as the list with zero sum. The default value is the first Helmert contrast, which contrasts the first and second cell means specified by the list.

data The data frame used to evaluate contrast.obj.

Details

Contrasts are usually used to test if certain means are significantly different; it can be easier to use se.contrast than compute them directly from the coefficients.

In multistratum models, the contrasts can appear in more than one stratum, in which case the standard errors are computed in the lowest stratum and adjusted for efficiencies and comparisons between strata. (See the comments in the note in the help for aov about using orthogonal contrasts.) Such standard errors are often conservative.

Suitable matrices for use with coef can be found by calling contrasts and indexing the columns by a factor.

Value

A vector giving the standard errors for each contrast.

See Also

contrasts, model.tables

## End(Not run)

selfStart

Construct Self-starting Nonlinear Models

Description

Construct self-starting nonlinear models.

Usage

selfStart(model, initial, parameters, template)

Arguments

model a function object defining a nonlinear model or a nonlinear formula object of the form ~expression.
initial a function object, taking three arguments: mCall, data, and LHS, representing, respectively, a matched call to the function model, a data frame in which to interpret the variables in mCall, and the expression from the left-hand side of the model formula in the call to nls. This function should return initial values for the parameters in model.
parameters a character vector specifying the terms on the right hand side of model for which initial estimates should be calculated. Passed as the namevec argument to the deriv function.
template

an optional prototype for the calling sequence of the returned object, passed as the function.arg argument to the deriv function. By default, a template is generated with the covariates in model coming first and the parameters in model coming last in the calling sequence.

Details

This function is generic; methods functions can be written to handle specific classes of objects.

Value

a function object of class "selfStart", for the formula method obtained by applying deriv to the right hand side of the model formula. An initial attribute (defined by the initial argument) is added to the function to calculate starting estimates for the parameters in the model automatically.

Author(s)

Jose Pinheiro and Douglas Bates

Examples

## self-starting logistic model

SSlogis <- selfStart(~ Asym/(1 + exp((xmid - x)/scal)),
                   function(mCall, data, LHS)
                   {
                     xy <- sortedXyData(mCall["x"], LHS, data)
                     if(nrow(xy) < 4)
                       stop("Too few distinct x values to fit a logistic")
                     z <- xy["y"]
                     if (min(z) <= 0) { z <- z + 0.05 * max(z) } # avoid zeroes
                     z <- z/(1.05 * max(z)) # scale to within unit height
                     xy["z"] <- log(z/(1 - z)) # logit transformation
                     aux <- coef(lm(x ~ z, xy))
                     parameters(xy) <- list(xmid = aux[1], scal = aux[2])
                     pars <- as.vector(coef(nls(y ~ 1/(1 + exp((xmid - x)/scal)),
                                              data = xy, algorithm = "plinear")))
                     value <- c(pars[3], pars[1], pars[2])
                     names(value) <- mCall[c("Asym", "xmid", "scal")]
                     value
                   }, c("Asym", "xmid", "scal"))

# 'first.order.log.model' is a function object defining a first order compartment model
# 'first.order.log.initial' is a function object which calculates initial values for the parameters in 'first.order.log.model'

## Not run:
SSfol <- selfStart(first.order.log.model, first.order.log.initial)
## End(Not run)

---

**setNames**  
*Set the Names in an Object*

### Description

This is a convenience function that sets the names on an object and returns the object. It is most useful at the end of a function definition where one is creating the object to be returned and would prefer not to store it under a name just so the names can be assigned.

### Usage

```r
setNames(object, nm)
```

### Arguments

- `object`: an object for which a `names` attribute will be meaningful
- `nm`: a character vector of names to assign to the object

### Value

An object of the same sort as `object` with the new names assigned.

### Author(s)

Douglas M. Bates and Saikat DebRoy

### See Also

- `clearNames`

### Examples

```r
data <- 1:3
c("foo", "bar", "baz")
# this is just a short form of
tmp <- 1:3	names(tmp) <- c("foo", "bar", "baz")
tmp
```
shapiro.test  Shapiro-Wilk Normality Test

Description

Performs the Shapiro-Wilk test of normality.

Usage

shapiro.test(x)

Arguments

x

a numeric vector of data values, the number of which must be between 3 and 5000. Missing values are allowed.

Value

A list with class "htest" containing the following components:

statistic the value of the Shapiro-Wilk statistic.
p.value the p-value for the test.
method the character string "Shapiro-Wilk normality test".
data.name a character string giving the name(s) of the data.

References

See Also

qqnorm for producing a normal quantile-quantile plot.

Examples

shapiro.test(rnorm(100, mean = 5, sd = 3))
shapiro.test(runif(100, min = 2, max = 4))
Description

Density, distribution function, quantile function and random generation for the distribution of the Wilcoxon Signed Rank statistic obtained from a sample with size \( n \).

Usage

designrank(x, n, log = FALSE)
psignrank(q, n, lower.tail = TRUE, log.p = FALSE)
qsignrank(p, n, lower.tail = TRUE, log.p = FALSE)
rsignrank(nn, n)

Arguments

x, q  vector of quantiles.
p  vector of probabilities.
nn  number of observations. If length(nn) > 1, the length is taken to be the number required.
n  number(s) of observations in the sample(s). A positive integer, or a vector of such integers.
log, log.p  logical; if TRUE, probabilities \( p \) are given as \( \log(p) \).
lower.tail  logical; if TRUE (default), probabilities are \( P[X \leq x] \), otherwise, \( P[X > x] \).

Details

This distribution is obtained as follows. Let \( x \) be a sample of size \( n \) from a continuous distribution symmetric about the origin. Then the Wilcoxon signed rank statistic is the sum of the ranks of the absolute values \( x[i] \) for which \( x[i] \) is positive. This statistic takes values between 0 and \( n(n + 1)/2 \), and its mean and variance are \( n(n + 1)/4 \) and \( n(n + 1)(2n + 1)/24 \), respectively. If either of the first two arguments is a vector, the recycling rule is used to do the calculations for all combinations of the two up to the length of the longer vector.

Value

designrank gives the density, psignrank gives the distribution function, qsignrank gives the quantile function, and rsignrank generates random deviates.

Author(s)

Kurt Hornik

See Also

wilcox.test to calculate the statistic from data, find \( p \) values and so on.
dwilcox etc, for the distribution of two-sample Wilcoxon rank sum statistic.
Examples

```r
par(mfrow=c(2,2))
for(n in c(4:5,10,40)) {
  x <- seq(0, n*(n+1)/2, length=501)
  plot(x, dsignrank(x,n=n), type='l', main=paste("dsignrank(x,n="",n,"")"))
}
```

Simulate Responses

Description

Simulate one or more response vectors from the theoretical distribution corresponding to a fitted model object.

Usage

```r
simulate(object, nsim, seed, ...)
```

Arguments

- `object`: an object representing a fitted model.
- `nsim`: number of response vectors to simulate. Defaults to 1.
- `seed`: an object specifying if and how the random number generator should be initialized ("seeded"). For the "lm" method, either NULL or an integer that will be used in a call to `set.seed` before simulating the response vectors. If set, the value is saved as the "seed" attribute of the returned value. The default, NULL will not change the random generator state, and return `.Random.seed` as "seed" attribute, see below.
- `...`: additional optional arguments.

Details

This is a generic function with a method for `lm` objects. Consult the individual modeling functions for details on how to use this function.

Value

Typically, a list of length `nsim` of simulated response vectors. When appropriate the result can be a data frame (which is a special type of list).

For the "lm" method, the result is a data frame with an attribute "seed" containing the `seed` argument and `as.list(RNGkind())` if `seed` was not `NULL`, or the value of `.Random.seed` before the simulation was started when `seed` was `NULL` as by default.

See Also

`fitted.values` and `residuals` for related methods; `glm`, `lm` for model fitting.
smooth

Tukey’s (Running Median) Smoothing

Description

Tukey’s smoothers, 3RS3R, 3RSS, 3R, etc.

Usage

smooth(x, kind = c("3RS3R", "3RSS", "3RSR", "3R", "3", "S"),
    twiceit = FALSE, endrule = "Tukey", do.ends = FALSE)

Arguments

x

a vector or time series

kind

a character string indicating the kind of smoother required; defaults to "3RS3R".

twiceit

logical, indicating if the result should be “twiced”. Twicing a smoother \( S(y) \)
means \( S(y) + S(y - S(y)) \), i.e., adding smoothed residuals to the smoothed
values. This decreases bias (increasing variance).

drule

a character string indicating the rule for smoothing at the boundary. Either
"Tukey" (default) or "copy".

do.ends

logical, indicating if the 3-splitting of ties should also happen at the boundaries
(“ends”). This is only used for kind = "S".
Details

3 is Tukey’s short notation for running medians of length 3, 3R stands for Repeated 3 until convergence, and S for Splitting of horizontal stretches of length 2 or 3.

Hence, 3RS3R is a concatenation of 3R, S and 3R, 3RSS similarly, whereas 3RSR means first 3R and then (S and 3) Repeated until convergence – which can be bad.

Value

An object of class "tukeysmooth" (which has print and summary methods) and is a vector or time series containing the smoothed values with additional attributes.

Note

S and S-PLUS use a different (somewhat better) Tukey smoother in smooth(*). Note that there are other smoothing methods which provide rather better results. These were designed for hand calculations and may be used mainly for didactical purposes.

Since R version 1.2, smooth does really implement Tukey’s end-point rule correctly (see argument endrule).

kind = "3RSR" has been the default till R-1.1, but it can have very bad properties, see the examples.

Note that repeated application of smooth(*) does smooth more, for the "3RS*" kinds.

References

See Also

lowess; loess, supsmu and smooth.spline.

Examples

```r
## see also demo(smooth) !
x1 <- c(4, 1, 3, 6, 6, 4, 1, 6, 2, 4, 2) # very artificial
(x3R <- smooth(x1, "3R")) # 2 iterations of "3"
smooth(x3R, kind = "S")

sm.3RS <- function(x, ...) 
  smooth(smooth(x, "3R", ...), "S", ...)

y <- c(1,1, 19:1)
plot(y, main = "misbehaviour of \"3RSR\"", col.main = 3)
lines(sm.3RS(y))
lines(smooth(y))
lines(smooth(y, "3RSR"), col = 3, lwd = 2) # the horror

x <- c(8:10, 0, 0, 9,9)
plot(x, main = "breakdown of 3R and S and hence 3RSS")
matlines(cbind(smooth(x,"3R"),smooth(x,"S"), smooth(x,"3RSS"),smooth(x)))
presidents[is.na(presidents)] <- 0 # silly
```
smooth.spline

**Fit a Smoothing Spline**

**Description**

Fits a cubic smoothing spline to the supplied data.

**Usage**

```r
smooth.spline(x, y = NULL, w = NULL, df, spar = NULL,
               cv = FALSE, all.knots = FALSE, nknots = NULL,
               keep.data = TRUE, df.offset = 0, penalty = 1,
               control.spar = list())
```

**Arguments**

- `x` a vector giving the values of the predictor variable, or a list or a two-column matrix specifying `x` and `y`.
- `y` responses. If `y` is missing, the responses are assumed to be specified by `x`.
- `w` optional vector of weights of the same length as `x`; defaults to all 1.
- `df` the desired equivalent number of degrees of freedom (trace of the smoother matrix).
- `spar` smoothing parameter, typically (but not necessarily) in (0, 1]. The coefficient $\lambda$ of the integral of the squared second derivative in the fit (penalized log likelihood) criterion is a monotone function of `spar`, see the details below.
- `cv` ordinary (TRUE) or “generalized” cross-validation (GCV) when FALSE.
- `all.knots` if TRUE, all distinct points in `x` are used as knots. If FALSE (default), a subset of `x[ ]` is used, specifically `x[j]` where the `nknots` indices are evenly spaced in `1:n`, see also the next argument `nknots`.
- `nknots` integer giving the number of knots to use when `all.knots`=FALSE. Per default, this is less than `n`, the number of unique `x` values for `n > 49`.
- `keep.data` logical specifying if the input data should be kept in the result. If TRUE (as per default), fitted values and residuals are available from the result.
- `df.offset` allows the degrees of freedom to be increased by `df.offset` in the GCV criterion.
- `penalty` the coefficient of the penalty for degrees of freedom in the GCV criterion.
control.spar  optional list with named components controlling the root finding when the
smoothing parameter spar is computed, i.e., missing or NULL, see below.

Note that this is partly experimental and may change with general spar com-
putation improvements!

low: lower bound for spar; defaults to -1.5 (used to implicitly default to 0 in
R versions earlier than 1.4).
high: upper bound for spar; defaults to +1.5.
tol: the absolute precision (tolerance) used; defaults to 1e-4 (formerly 1e-3).
eps: the relative precision used; defaults to 2e-8 (formerly 0.00244).
trace: logical indicating if iterations should be traced.
maxit: integer giving the maximal number of iterations; defaults to 500.

Note that spar is only searched for in the interval \([low, high]\).

Details

The \(x\) vector should contain at least four distinct values. Distinct here means “distinct after rounding
to 6 significant digits”, i.e., \(x\) will be transformed to
\(\text{unique(sort(signif}(x, 6)))\), and \(y\) and \(w\) are pooled accordingly.

The computational \(\lambda\) used (as a function of \(s = \text{spar}\)) is
\(\lambda = r \times 256^{3s-1}\) where
\(r = \text{tr}(X'WX) / \text{tr}(\Sigma)\). \(\Sigma\) is the matrix given by
\(\Sigma_{ij} = \int B_j''(t)B_i''(t)dt\). \(X\) is given by \(X_{ij} = B_j(x_i)\),
\(W\) is the diagonal matrix of weights (scaled such that its trace is \(n\), the original number of observations)
and \(B_k(.)\) is the \(k\)-th B-spline.

Note that with these definitions, \(f_i = f(x_i)\), and the B-spline basis representation
\(f = Xc\) (i.e., \(c\) is the vector of spline coefficients), the penalized log likelihood is
\(L = (y - f)'W(y - f) + \lambda c'\Sigma c\), and hence \(c\) is the solution of the (ridge regression)
\((X'WX + \lambda \Sigma)c = X'Wy\).

If spar is missing or NULL, the value of df is used to determine the degree of smoothing. If both are missing,
leave-one-out cross-validation (ordinary or “generalized” as determined by cv) is
used to determine \(\lambda\). Note that from the above relation, spar is
\(s = s_0 + 0.0601 \times \log \lambda\), which is intentionally different from the S-plus implementation of smooth.spline (where spar is
proportional to \(\lambda\)). In R’s (\(\log \lambda\)) scale, it makes more sense to vary spar linearly.

Note however that currently the results may become very unreliable for spar values smaller than
about -1 or -2. The same may happen for values larger than 2 or so. Don’t think of setting spar or
the controls low and high outside such a safe range, unless you know what you are doing!

The “generalized” cross-validation method will work correctly when there are duplicated points
in \(x\). However, it is ambiguous what leave-one-out cross-validation means with duplicated points,
and the internal code uses an approximation that involves leaving out groups of duplicated points.
cv=TRUE is best avoided in that case.

Value

An object of class "smooth.spline" with components

- \(x\): the distinct \(x\) values in increasing order, see the Details above.
- \(y\): the fitted values corresponding to \(x\).
- \(w\): the weights used at the unique values of \(x\).
- \(yin\): the \(y\) values used at the unique \(y\) values.
- \(data\): only if keep.data = TRUE: itself a list with components \(x\), \(y\) and \(w\) of
  the same length. These are the original \((x_i, y_i, w_i), i = 1, \ldots, n\), values where
  \(data$x\) may have repeated values and hence be longer than the above \(x\) com-
  ponent; see details.
smooth.spline

lev
leverages, the diagonal values of the smoother matrix.
cv.crit
cross-validation score, “generalized” or true, depending on cv.
pen.crit
penalized criterion
crit
the criterion value minimized in the underlying Fortran routine ‘sslvrg’.
df
equivalent degrees of freedom used. Note that (currently) this value may become quite unprecise when the true df is between 1 and 2.
spar
the value of spar computed or given.
lambda
the value of λ corresponding to spar, see the details above.
iparms
named integer(3) vector where ..$ipars["iter"] gives number of spar computing iterations used.
fit
list for use by predict.smooth.spline, with components
knot: the knot sequence (including the repeated boundary knots).
nk: number of coefficients or number of “proper” knots plus 2.
coef: coefficients for the spline basis used.
min, range: numbers giving the corresponding quantities of x.
call
the matched call.

Note

The default all.knots = FALSE and nknots = NULL entails using only $O(n^{0.2})$ knots instead of n for n > 49. This cuts speed and memory requirements, but not drastically anymore since R version 1.5.1 where it is only $O(n_k) + O(n)$ where n_k is the number of knots. In this case where not all unique x values are used as knots, the result is not a smoothing spline in the strict sense, but very close unless a small smoothing parameter (or large df) is used.

Author(s)

R implementation by B. D. Ripley and Martin Maechler (spar/lambda, etc).

This function is based on code in the GAMFIT Fortran program by T. Hastie and R. Tibshirani (http://lib.stat.cmu.edu/general/), which makes use of spline code by Finbarr O’Sullivan. Its design parallels the smooth.spline function of Chambers & Hastie (1992).

```r
attach(cars)
plot(speed, dist, main = "data(cars) & smoothing splines")
cars.spl <- smooth.spline(speed, dist)
(cars.spl)
## This example has duplicate points, so avoid cv=TRUE
lines(cars.spl, col = "blue")
lines(smooth.spline(speed, dist, df=10), lty=2, col = "red")
legend(5,120,c(paste("default [C.V.] => df =",round(cars.spl$df,1),
  
  
  "s( * , df = 10)"), col = c("blue","red"), lty = 1:2,
  
  bg='bisque')
detach()
## Residual (Tukey Anscombe) plot:
plot(residuals(cars.spl) ~ fitted(cars.spl))
abline(h = 0, col="gray")
## consistency check:
stopifnot(all.equal(cars$dist,
  fitted(cars.spl) + residuals(cars.spl)))
##-- artificial example
y18 <- c(1:3,5,4,7:3,2*(2:5),rep(10,4))
xx <- seq(1,length(y18), len=201)
(s2 <- smooth.spline(y18)) # GCV
(s02 <- smooth.spline(y18, spar = 0.2))
plot(y18, main=deparse(s2$call), col.main=2)
lines(s2, col = "gray"); lines(predict(s2, xx), col = 2)
lines(predict(s02, xx), col = 3); mtext(deparse(s02$call), col = 3)
## The following shows the problematic behavior of 'spar' searching:
(s2 <- smooth.spline(y18, con = list(trace=TRUE,tol=1e-6, low=-1.5)))
(s2m <- smooth.spline(y18, cv = TRUE,
  con = list(trace=TRUE,tol=1e-6, low=-1.5)))
## both above do quite similarly (Df = 8.5 +- 0.2)
```

---

**smoothEnds**

*End Points Smoothing (for Running Medians)*

**Description**

Smooth end points of a vector y using subsequently smaller medians and Tukey’s end point rule at the very end. (of odd span).

**Usage**

```r
smoothEnds(y, k = 3)
```

**Arguments**

- **y**
  - dependent variable to be smoothed (vector).
- **k**
  - width of largest median window; must be odd.
sortedXyData

Create a sortedXyData object

Description

This is a constructor function for the class of sortedXyData objects. These objects are mostly used in the initial function for a self-starting nonlinear regression model, which will be of the selfStart class.

Usage

sortedXyData(x, y, data)
spec.ar

Arguments

x a numeric vector or an expression that will evaluate in data to a numeric vector
y a numeric vector or an expression that will evaluate in data to a numeric vector
data an optional data frame in which to evaluate expressions for x and y, if they are
given as expressions

Value

A sortedXyData object. This is a data frame with exactly two numeric columns, named x and
y. The rows are sorted so the x column is in increasing order. Duplicate x values are eliminated by
averaging the corresponding y values.

Author(s)

Jose Pinheiro and Douglas Bates

Examples

DNase.2 <- DNase[DNase$Run == "2",]
sortedXyData( expression(log(conc)), expression(density), DNase.2)

---

spec.ar

Estimate Spectral Density of a Time Series from AR Fit

Description

Fits an AR model to x (or uses the existing fit) and computes (and by default plots) the spectral
density of the fitted model.

Usage

spec.ar(x, n.freq, order = NULL, plot = TRUE, na.action = na.fail, 
method = "yule-walker", ...)

Arguments

x A univariate (not yet: or multivariate) time series or the result of a fit by ar.
n.freq The number of points at which to plot.
order The order of the AR model to be fitted. If omitted, the order is chosen by AIC.
plot Plot the periodogram?
na.action NA action function.
method method for ar fit.
... Graphical arguments passed to plot.spec.
spec.pgram

Value

An object of class "spec". The result is returned invisibly if plot is true.

Warning

Some authors, for example Thomson (1990), warn strongly that AR spectra can be misleading.

Note

The multivariate case is not yet implemented.

spec.pgram

Estimate Spectral Density of a Time Series by a Smoothed Periodogram

Description

spec.pgram calculates the periodogram using a fast Fourier transform, and optionally smooths the result with a series of modified Daniell smoothers (moving averages giving half weight to the end values).

Usage

spec.pgram(x, spans = NULL, kernel, taper = 0.1, pad = 0, fast = TRUE, demean = FALSE, detrend = TRUE, plot = TRUE, na.action = na.fail, ...)

Arguments

x  univariate or multivariate time series.
spans vector of odd integers giving the widths of modified Daniell smoothers to be used to smooth the periodogram.
kernel alternatively, a kernel smoother of class "tskernel".
taper specifies the proportion of data to taper. A split cosine bell taper is applied to this proportion of the data at the beginning and end of the series.
pad proportion of data to pad. Zeros are added to the end of the series to increase its length by the proportion pad.
fast logical; if TRUE, pad the series to a highly composite length.
demean logical. If TRUE, subtract the mean of the series.
detrend logical. If TRUE, remove a linear trend from the series. This will also remove the mean.
plot plot the periodogram?
na.action NA action function.
... graphical arguments passed to plot.spec.

Details

The raw periodogram is not a consistent estimator of the spectral density, but adjacent values are asymptotically independent. Hence a consistent estimator can be derived by smoothing the raw periodogram, assuming that the spectral density is smooth.

The series will be automatically padded with zeros until the series length is a highly composite number in order to help the Fast Fourier Transform. This is controlled by the fast and not the pad argument.

The periodogram at zero is in theory zero as the mean of the series is removed (but this may be affected by tapering): it is replaced by an interpolation of adjacent values during smoothing, and no value is returned for that frequency.

Value

A list object of class "spec" (see spectrum) with the following additional components:

kernel The kernel argument, or the kernel constructed from spans.
df The distribution of the spectral density estimate can be approximated by a (scaled) chi square distribution with df degrees of freedom.
bandwidth The equivalent bandwidth of the kernel smoother as defined by Bloomfield (1976, page 201).
taper The value of the taper argument.
pad The value of the pad argument.
detrend The value of the detrend argument.
demean The value of the demean argument.

The result is returned invisibly if plot is true.

---

**spec.taper**  
*Taper a Time Series by a Cosine Bell*

**Description**
Apply a cosine-bell taper to a time series.

**Usage**
```r
spec.taper(x, p = 0.1)
```
The spectrum function estimates the spectral density of a time series.

**Usage**

```r
spectrum(x, ..., method = c("pgram", "ar"))
```

**Arguments**

- `x`: A univariate or multivariate time series.
- `method`: String specifying the method used to estimate the spectral density. Allowed methods are "pgram" (the default) and "ar".
- `...`: Further arguments to specific spec methods or `plot.spec`.

**Details**

`spectrum` is a wrapper function which calls the methods `spec.pgram` and `spec.ar`.

The spectrum here is defined with scaling `1/frequency(x)`, following S-PLUS. This makes the spectral density a density over the range \(-\text{frequency}(x)/2, +\text{frequency}(x)/2\), whereas a more common scaling is `2\pi` and range \((-0.5,0.5]\) (e.g., Bloomfield) or 1 and range \((-\pi,\pi]\).

If available, a confidence interval will be plotted by `plot.spec`: this is asymmetric, and the width of the centre mark indicates the equivalent bandwidth.
Value

An object of class "spec", which is a list containing at least the following components:

freq  vector of frequencies at which the spectral density is estimated. (Possibly approximate Fourier frequencies.) The units are the reciprocal of cycles per unit time (and not per observation spacing): see Details below.

spec  Vector (for univariate series) or matrix (for multivariate series) of estimates of the spectral density at frequencies corresponding to freq.

coh  NULL for univariate series. For multivariate time series, a matrix containing the squared coherency between different series. Column \( i + (j - 1) \cdot (j - 2)/2 \) of coh contains the squared coherency between columns \( i \) and \( j \) of \( x \), where \( i < j \).

phase  NULL for univariate series. For multivariate time series a matrix containing the cross-spectrum phase between different series. The format is the same as coh.

series  The name of the time series.

snames  For multivariate input, the names of the component series.

method  The method used to calculate the spectrum.

The result is returned invisibly if plot is true.

Note

The default plot for objects of class "spec" is quite complex, including an error bar and default title, subtitle and axis labels. The defaults can all be overridden by supplying the appropriate graphical parameters.

spectrum(lh, spans=3)
spectrum(lh, spans=c(3,3))
spectrum(lh, spans=c(3,5))
splinefun

Perform cubic spline interpolation of given data points, returning either a list of points obtained by
the interpolation or a function performing the interpolation.

Usage

splinefun(x, y = NULL, method = "fmm", ties = mean)
spline(x, y = NULL, n = 3*length(x), method = "fmm",
      xmin = min(x), xmax = max(x), ties = mean)

Arguments

x, y vectors giving the coordinates of the points to be interpolated. Alternatively a
single plotting structure can be specified: see xy.coords.
method specifies the type of spline to be used. Possible values are "fmm", "natural" and "periodic".
n interpolation takes place at n equally spaced points spanning the interval [xmin, xmax].
xmin left-hand endpoint of the interpolation interval.
xmax right-hand endpoint of the interpolation interval.
ties Handling of tied x values. Either a function with a single vector argument re-
turning a single number result or the string "ordered".

Details

The inputs can contain missing values which are deleted, so at least one complete (x, y) pair is
required. If method = "fmm", the spline used is that of Forsythe, Malcolm and Moler (an exact
cubic is fitted through the four points at each end of the data, and this is used to determine the end
conditions). Natural splines are used when method = "natural", and periodic splines when
method = "periodic".

These interpolation splines can also be used for extrapolation, that is prediction at points outside the
range of x. Extrapolation makes little sense for method = "fmm"; for natural splines it is linear
using the slope of the interpolating curve at the nearest data point.

## spec.ar

spectrum(lh, method="ar")
spectrum(ldeaths, method="ar")
Value

`spline` returns a list containing components `x` and `y` which give the ordinates where interpolation took place and the interpolated values.

`splinefun` returns a function with formal arguments `x` and `deriv`, the latter defaulting to zero. This function can be used to evaluate the interpolating cubic spline (`deriv=0`), or its derivatives (`deriv=1,2,3`) at the points `x`, where the spline function interpolates the data points originally specified. This is often more useful than `spline`.

References

`approx` and `approxfun` for constant and linear interpolation.

Package `splines`, especially `interpSpline` and `periodicSpline` for interpolation splines. That package also generates spline bases that can be used for regression splines.

`splinefun` for smoothing splines.

Examples

```r
op <- par(mfrow = c(2,1), mgp = c(2,.8,0), mar = .1+c(3,3,3,1))
n <- 9
x <- 1:n
y <- rnorm(n)
plot(x, y, main = paste("spline[fun](.) through", n, "points"))
lines(spline(x, y))
lines(spline(x, y, n = 201), col = 2)
y <- (x-6)^2
plot(x, y, main = "spline(.) -- 3 methods")
lines(spline(x, y, n = 201), col = 2)
lines(spline(x, y, n = 201, method = "natural"), col = 3)
lines(spline(x, y, n = 201, method = "periodic"), col = 4)
legend(6,25, c("fmm","natural","periodic"), col=2:4, lty=1)
y <- sin((x-0.5)*pi)
f <- splinefun(x, y)
ls(envir = environment(f))
splinecoef <- get("z", envir = environment(f))
curve(f(x), 1, 10, col = "green", lwd = 1.5)
points(splinecoef, col = "purple", cex = 2)
curve(f(x, deriv=1), 1, 10, col = 2, lwd = 1.5)
curve(f(x, deriv=2), 1, 10, col = 2, lwd = 1.5, n = 401)
curve(f(x, deriv=3), 1, 10, col = 2, lwd = 1.5, n = 401)
par(op)
```

### An example with ties (non-unique x values):
```
set.seed(1); x <- round(rnorm(30), 1); y <- sin(pi * x) + rnorm(30)/10
plot(x,y, main="spline(x,y) when x has ties")
lines(spline(x,y, n= 201), col = 2)
```
SSasymp

## visualizes the non-unique ones:
```
tx <- table(x); mx <- as.numeric(names(tx[tx > 1]))
ry <- matrix(unlist(tapply(y, match(x, mx), range, simplify = FALSE)),
              ncol = 2, byrow = TRUE)
segments(mx, ry[, 1], mx, ry[, 2], col = "blue", lwd = 2)
```

SSasymp

Asymptotic Regression Model

Description

This selfStart model evaluates the asymptotic regression function and its gradient. It has an initial attribute that will evaluate initial estimates of the parameters Asym, R0, and lrc for a given set of data.

Usage

```
SSasymp(input, Asym, R0, lrc)
```

Arguments

- **input**: a numeric vector of values at which to evaluate the model.
- **Asym**: a numeric parameter representing the horizontal asymptote on the right side (very large values of input).
- **R0**: a numeric parameter representing the response when input is zero.
- **lrc**: a numeric parameter representing the natural logarithm of the rate constant.

Value

a numeric vector of the same length as input. It is the value of the expression Asym + (R0 - Asym) * \(\exp(-\exp(lrc) \times \text{input})\). If all of the arguments Asym, R0, and lrc are names of objects, the gradient matrix with respect to these names is attached as an attribute named gradient.

Asym <- 100
resp0 <- -8.5
lrc <- -3.2
SSasymp( Lob.329$age, Asym, resp0, lrc ) # response and gradient
getInitial(height ~ SSasymp( age, Asym, resp0, lrc), data = Lob.329)
## Initial values are in fact the converged values
```
SSasympOff <- nls(height ~ SSasymp(age, Asym, resp0, lrc), data = Lob.329)
sweep(fm1)

Description

This selfStart model evaluates an alternative parametrization of the asymptotic regression function and the gradient with respect to those parameters. It has an initial attribute that creates initial estimates of the parameters Asym, lrc, and c0.

Usage

SSasympOff(input, Asym, lrc, c0)

Arguments

input a numeric vector of values at which to evaluate the model.
Asym a numeric parameter representing the horizontal asymptote on the right side (very large values of input).
lrc a numeric parameter representing the natural logarithm of the rate constant.
c0 a numeric parameter representing the input for which the response is zero.

Value

a numeric vector of the same length as input. It is the value of the expression Asym*(1 - exp(-exp(lrc)*(input - c0))). If all of the arguments Asym, lrc, and c0 are names of objects, the gradient matrix with respect to these names is attached as an attribute named gradient.

**SSasympOrig**

### Asymptotic Regression Model through the Origin

**Description**

This selfStart model evaluates the asymptotic regression function through the origin and its gradient. It has an initial attribute that will evaluate initial estimates of the parameters `Asym` and `lrc` for a given set of data.

**Usage**

```r
SSasympOrig(input, Asym, lrc)
```

**Arguments**

- `input` a numeric vector of values at which to evaluate the model.
- `Asym` a numeric parameter representing the horizontal asymptote.
- `lrc` a numeric parameter representing the natural logarithm of the rate constant.

**Value**

A numeric vector of the same length as `input`. It is the value of the expression `Asym*(1 - exp(-exp(lrc)*input))`. If all of the arguments `Asym` and `lrc` are names of objects, the gradient matrix with respect to these names is attached as an attribute named `gradient`.

SSbiexp  

**Biexponential model**

Description

This `selfStart` model evaluates the biexponential model function and its gradient. It has an `initial` attribute that creates initial estimates of the parameters \(A_1, lrc_1, A_2,\) and \(lrc_2.\)

Usage

\[
SSbiexp(input, A1, lrc1, A2, lrc2)
\]

Arguments

- `input`: a numeric vector of values at which to evaluate the model.
- `A1`: a numeric parameter representing the multiplier of the first exponential.
- `lrc1`: a numeric parameter representing the natural logarithm of the rate constant of the first exponential.
- `A2`: a numeric parameter representing the multiplier of the second exponential.
- `lrc2`: a numeric parameter representing the natural logarithm of the rate constant of the second exponential.

Value

a numeric vector of the same length as `input`. It is the value of the expression \(A_1\exp(-\exp(lrc_1)\times input)+A_2\exp(-\exp(lrc_2)\times input).\) If all of the arguments `A1, lrc1, A2,\) and `lrc2` are names of objects, the gradient matrix with respect to these names is attached as an attribute named `gradient`.

SSD Matrix and Estimated Variance Matrix in Multivariate Models

Description

Functions to compute matrix of residual sums of squares and products, or the estimated variance matrix for multivariate linear models.

Usage

```r
# S3 method for class 'mlm'
SSD(object, ...)

# S3 methods for class 'SSD' and 'mlm'
estVar(object, ...)
```

Arguments

- `object`: object of class "mlm", or "SSD" in the case of `estVar`.
- `...`: Unused

Value

- `SSD()`: returns a list of class "SSD" containing the following components
  - `SSD`: The residual sums of squares and products matrix
  - `df`: Degrees of freedom
  - `call`: Copied from `object`

- `estVar`: returns a matrix with the estimated variances and covariances.

SSfol

First-order Compartment Model

Description

This selfStart model evaluates the first-order compartment function and its gradient. It has an initial attribute that creates initial estimates of the parameters lKe, lKa, and lCl.

Usage

SSfol(Dose, input, lKe, lKa, lCl)

Arguments

Dose a numeric value representing the initial dose.
input a numeric vector at which to evaluate the model.
lKe a numeric parameter representing the natural logarithm of the elimination rate constant.
lKa a numeric parameter representing the natural logarithm of the absorption rate constant.
lCl a numeric parameter representing the natural logarithm of the clearance.

Value

a numeric vector of the same length as input, which is the value of the expression Dose * \exp(lKe+lKa-lCl) * (\exp(-\exp(lKe)*input)-\exp(-\exp(lKa)*input)) / (\exp(lKa)-\exp(lKe)).

If all of the arguments lKe, lKa, and lCl are names of objects, the gradient matrix with respect to these names is attached as an attribute named gradient.

SSfpl  Four-parameter Logistic Model

Description

This selfStart model evaluates the four-parameter logistic function and its gradient. It has an initial attribute that will evaluate initial estimates of the parameters A, B, xmid, and scal for a given set of data.

Usage

SSfpl(input, A, B, xmid, scal)

Arguments

input  a numeric vector of values at which to evaluate the model.
A  a numeric parameter representing the horizontal asymptote on the left side (very small values of input).
B  a numeric parameter representing the horizontal asymptote on the right side (very large values of input).
xmid  a numeric parameter representing the input value at the inflection point of the curve. The value of SSfpl will be midway between A and B at xmid.
scal  a numeric scale parameter on the input axis.

Value

a numeric vector of the same length as input. It is the value of the expression A+(B-A)/(1+exp((xmid-input)/scal)). If all of the arguments A, B, xmid, and scal are names of objects, the gradient matrix with respect to these names is attached as an attribute named gradient.

SSgompertz

Gompertz Growth Model

Description

This selfStart model evaluates the Gompertz growth model and its gradient. It has an initial attribute that creates initial estimates of the parameters Asym, b2, and b3.

Usage

SSgompertz(x, Asym, b2, b3)

Arguments

x a numeric vector of values at which to evaluate the model.
Asym a numeric parameter representing the asymptote.
b2 a numeric parameter related to the value of the function at \( x = 0 \)
b3 a numeric parameter related to the scale the \( x \) axis.

Value

a numeric vector of the same length as input. It is the value of the expression \( \text{Asym} \times \exp\left(-b2 \times b3^x\right) \). If all of the arguments Asym, b2, and b3 are names of objects the gradient matrix with respect to these names is attached as an attribute named gradient.

Logistic Model

Description

This selfStart model evaluates the logistic function and its gradient. It has an initial attribute that creates initial estimates of the parameters Asym, xmid, and scal.

Usage

SSlogis(input, Asym, xmid, scal)

Arguments

input a numeric vector of values at which to evaluate the model.
Asym a numeric parameter representing the asymptote.
xmid a numeric parameter representing the x value at the inflection point of the curve. The value of SSlogis will be Asym/2 at xmid.
scal a numeric scale parameter on the input axis.

Value

a numeric vector of the same length as input. It is the value of the expression
Asym/(1+exp((xmid-input)/scal)). If all of the arguments Asym, xmid, and scal are names of objects the gradient matrix with respect to these names is attached as an attribute named gradient.

SSmicmen

**Michaelis-Menten Model**

Description

This selfStart model evaluates the Michaelis-Menten model and its gradient. It has an initial attribute that will evaluate initial estimates of the parameters \( V_m \) and \( K \).

Usage

SSmicmen(input, Vm, K)

Arguments

- **input**: a numeric vector of values at which to evaluate the model.
- **Vm**: a numeric parameter representing the maximum value of the response.
- **K**: a numeric parameter representing the input value at which half the maximum response is attained. In the field of enzyme kinetics this is called the Michaelis parameter.

Value

a numeric vector of the same length as input. It is the value of the expression \( V_m \times \text{input}/(K+\text{input}) \). If both the arguments \( V_m \) and \( K \) are names of objects, the gradient matrix with respect to these names is attached as an attribute named gradient.

SSweibull  Weibull growth curve model

Description

This selfStart model evaluates the Weibull model for growth curve data and its gradient. It has an initial attribute that will evaluate initial estimates of the parameters Asym, Drop, lrc, and pwr for a given set of data.

Usage

```r
SSweibull(x, Asym, Drop, lrc, pwr)
```

Arguments

- `x`: a numeric vector of values at which to evaluate the model.
- `Asym`: a numeric parameter representing the horizontal asymptote on the right side (very small values of x).
- `Drop`: a numeric parameter representing the change from Asym to the y intercept.
- `lrc`: a numeric parameter representing the natural logarithm of the rate constant.
- `pwr`: a numeric parameter representing the power to which x is raised.

Details

This model is a generalization of the SSasymp model in that it reduces to SSasymp when pwr is unity.

Value

A numeric vector of the same length as x. It is the value of the expression Asym-Drop*exp(-exp(lrc)*x^pwr). If all of the arguments Asym, Drop, lrc, and pwr are names of objects, the gradient matrix with respect to these names is attached as an attribute named gradient.

### start

*Encode the Terminal Times of Time Series*

#### Description

Extract and encode the times the first and last observations were taken. Provided only for compatibility with S version 2.

#### Usage

```r
start(x, ...)  
end(x, ...)  
```

#### Arguments

- `x`  
  a univariate or multivariate time-series, or a vector or matrix.

- `...`  
  extra arguments for future methods.

#### Details

These are generic functions, which will use the `tsp` attribute of `x` if it exists. Their default methods decode the start time from the original time units, so that for a monthly series 1995.5 is represented as `c(1995, 7)`. For a series of frequency `f`, time `n+i/f` is presented as `c(n, i+1)` (even for `i = 0` and `f = 1`).

#### Warning

The representation used by `start` and `end` has no meaning unless the frequency is supplied.

#### See Also

`ts`, `time`, `tsp`. 
**Description**

This is a utility function, used in `lm` and `glm` methods for `anova(..., test != NULL)` and should not be used by the average user.

**Usage**

```r
stat.anova(table, test = c("Chisq", "F", "Cp"), scale, df.scale, n)
```

**Arguments**

- `table`: numeric matrix as results from `anova.glm(..., test=NULL)`.  
- `test`: a character string, matching one of "Chisq", "F" or "Cp".  
- `scale`: a residual mean square or other scale estimate to be used as the denominator in an F test.  
- `df.scale`: degrees of freedom corresponding to `scale`.  
- `n`: number of observations.

**Value**

A matrix which is the original `table`, augmented by a column of test statistics, depending on the `test` argument.

**References**

**See Also**

`anova.lm`, `anova.glm`.

**Examples**

```r
##-- Continued from '?glm':
print(ag <- anova(glm.D93))
stat.anova(ag$table, test = "Cp",
           scale = sum(resid(glm.D93, "pearson")^2)/4, df = 4, n = 9)
```
stats-deprecated  Deprecated Functions in Stats package

Description

These functions are provided for compatibility with older versions of R only, and may be defunct as soon as the next release.

Details

There are currently no deprecated functions in this package.

step

Choose a model by AIC in a Stepwise Algorithm

Description

Select a formula-based model by AIC.

Usage

```
step(object, scope, scale = 0,
     direction = c("both", "backward", "forward"),
     trace = 1, keep = NULL, steps = 1000, k = 2, ...)
```

Arguments

- **object**: an object representing a model of an appropriate class (mainly "lm" and "glm"). This is used as the initial model in the stepwise search.
- **scope**: defines the range of models examined in the stepwise search. This should be either a single formula, or a list containing components `upper` and `lower`, both formulae. See the details for how to specify the formulae and how they are used.
- **scale**: used in the definition of the AIC statistic for selecting the models, currently only for `lm`, `aov` and `glm` models. The default value, 0, indicates the scale should be estimated: see `extractAIC`.
- **direction**: the mode of stepwise search, can be one of "both", "backward", or "forward", with a default of "both". If the scope argument is missing the default for direction is "backward".
- **trace**: if positive, information is printed during the running of `step`. Larger values may give more detailed information.
- **keep**: a filter function whose input is a fitted model object and the associated AIC statistic, and whose output is arbitrary. Typically keep will select a subset of the components of the object and return them. The default is not to keep anything.
**step**

**steps**
the maximum number of steps to be considered. The default is 1000 (essentially as many as required). It is typically used to stop the process early.

**k**
the multiple of the number of degrees of freedom used for the penalty. Only $k = 2$ gives the genuine AIC: $k = \log(n)$ is sometimes referred to as BIC or SBC.

... any additional arguments to `extractAIC`.

**Details**

`step` uses `add1` and `drop1` repeatedly; it will work for any method for which they work, and that is determined by having a valid method for `extractAIC`. When the additive constant can be chosen so that AIC is equal to Mallows' $C_p$, this is done and the tables are labelled appropriately.

The set of models searched is determined by the `scope` argument. The right-hand-side of its lower component is always included in the model, and right-hand-side of the model is included in the upper component. If `scope` is a single formula, it specifies the upper component, and the lower model is empty. If `scope` is missing, the initial model is used as the upper model.

Models specified by `scope` can be templates to update object as used by `update.formula`. So using `. in a scope formula means ‘what is already there’, with .^2 indicating all interactions of existing terms.

There is a potential problem in using `glm` fits with a variable `scale`, as in that case the deviance is not simply related to the maximized log-likelihood. The "glm" method for function `extractAIC` makes the appropriate adjustment for a gaussian family, but may need to be amended for other cases. (The binomial and poisson families have fixed scale by default and do not correspond to a particular maximum-likelihood problem for variable scale.)

**Value**

the stepwise-selected model is returned, with up to two additional components. There is an "anova" component corresponding to the steps taken in the search, as well as a "keep" component if the `keep=` argument was supplied in the call. The "Resid. Dev" column of the analysis of deviance table refers to a constant minus twice the maximized log likelihood: it will be a deviance only in cases where a saturated model is well-defined (thus excluding `lm`, `aov` and `survreg` fits, for example).

**Warning**

The model fitting must apply the models to the same dataset. This may be a problem if there are missing values and R's default of `na.action = na.omit` is used. We suggest you remove the missing values first.

**Note**

This function differs considerably from the function in S, which uses a number of approximations and does not in general compute the correct AIC.

This is a minimal implementation. Use `stepAIC` in package `MASS` for a wider range of object classes.

**Author(s)**

B. D. Ripley: `step` is a slightly simplified version of `stepAIC` in package `MASS` (Venables & Ripley, 2002 and earlier editions).
The idea of a step function follows that described in Hastie & Pregibon (1992); but the implementation in R is more general.

stepfun

Step Function Class

Description

Given the vectors \((x_1, \ldots, x_n)\) and \((y_0, y_1, \ldots, y_n)\) (one value more!), \texttt{stepfun}(x, y, \ldots) returns an interpolating “step” function, say \(f_n\). I.e., \(f_n(t) = c_i\) (constant) for \(t \in (x_i, x_{i+1})\) and at the abscissa values, if (by default) \(\text{right} = \text{FALSE}\), \(f_n(x_i) = y_i\) and for \(\text{right} = \text{TRUE}\), \(f_n(x_i) = y_{i-1}\) for \(i = 1, \ldots, n\).

The value of the constant \(c_i\) above depends on the “continuity” parameter \(f\). For the default, \(\text{right} = \text{FALSE}, f = 0\), \(f_n\) is a “cadlag” function, i.e., continuous at right, limit (“the point”) at left. In general, \(c_i\) is interpolated in between the neighbouring \(y\) values, \(c_i = (1 - f) y_i + f \cdot y_{i+1}\). Therefore, for non-0 values of \(f\), \(f_n\) may no longer be a proper step function, since it can be discontinuous from both sides, unless \(\text{right} = \text{TRUE}, f = 1\) which is right-continuous.

Usage

\texttt{stepfun}(x, y, f = \text{as.numeric(right)}, \text{ties} = "ordered", \text{right} = \text{FALSE})

is.stepfun(x)
knots(Fn, \ldots)
as.stepfun(x, \ldots)

## S3 method for class 'stepfun':
\texttt{print}(x, \text{digits} = \text{getOption("digits") - 2}, \ldots)

## S3 method for class 'stepfun':
\texttt{summary}(object, \ldots)
Arguments

- **x**: numeric vector giving the knots or jump locations of the step function for `stepfun()`. For the other functions, x is as object below.
- **y**: numeric vector one longer than x, giving the heights of the function values between the x values.
- **f**: a number between 0 and 1, indicating how interpolation outside the given x values should happen. See `approxfun`.
- **ties**: Handling of tied x values. Either a function or the string "ordered". See `approxfun`.
- **right**: logical, indicating if the intervals should be closed on the right (and open on the left) or vice versa.
- **Fn, object**: an R object inheriting from "stepfun".
- **digits**: number of significant digits to use, see `print`.
- **...**: potentially further arguments (required by the generic).

Value

A function of class "stepfun", say fn. There are methods available for summarizing ("summary(.)"), representing ("print(.)") and plotting ("plot(.)", see `plot.stepfun") "stepfun" objects.

The environment of fn contains all the information needed:

- "x", "y" the original arguments
- "n" number of knots (x values)
- "f" continuity parameter
- "yleft", "yright" the function values outside the knots
- "method" (always == "constant", from `approxfun(.)").

The knots are also available via `knots(fn)`.

stl

Seasonal Decomposition of Time Series by Loess

Description

Decompose a time series into seasonal, trend and irregular components using loess, acronym STL.

Usage

stl(x, s.window, s.degree = 0,
    t.window = NULL, t.degree = 1,
    l.window = nextodd(period), l.degree = t.degree,
    s.jump = ceiling(s.window/10),
    t.jump = ceiling(t.window/10),
    l.jump = ceiling(l.window/10),
    robust = FALSE,
    inner = if(robust) 1 else 2,
    outer = if(robust) 15 else 0,
    na.action = na.fail)

Arguments

x
    univariate time series to be decomposed. This should be an object of class "ts"
    with a frequency greater than one.
s.window
    either the character string "periodic" or the span (in lags) of the loess window
    for seasonal extraction, which should be odd. This has no default.
s.degree
    degree of locally-fitted polynomial in seasonal extraction. Should be zero or
    one.
t.window
    the span (in lags) of the loess window for trend extraction, which should be
    odd. If NULL, the default, nextodd(ceiling((1.5*period) / (1-
    (1.5/s.window)))), is taken.
t.degree
    degree of locally-fitted polynomial in trend extraction. Should be zero or one.
l.window
    the span (in lags) of the loess window of the low-pass filter used for each
    subseries. Defaults to the smallest odd integer greater than or equal to
    frequency(x) which is recommended since it prevents competition between
    the trend and seasonal components. If not an odd integer its given value is in-
    creased to the next odd one.
l.degree: degree of locally-fitted polynomial for the subseries low-pass filter. Must be 0 or 1.

s.jump, t.jump, l.jump: integers at least one to increase speed of the respective smoother. Linear interpolation happens between every \( \ast \).jump\text{th} value.

robust: logical indicating if robust fitting be used in the \text{loess} procedure.

inner: integer; the number of ‘inner’ (backfitting) iterations; usually very few (2) iterations suffice.

outer: integer; the number of ‘outer’ robustness iterations.

na.action: action on missing values.

Details
The seasonal component is found by \text{loess} smoothing the seasonal sub-series (the series of all January values, ...); if s.window = "periodic" smoothing is effectively replaced by taking the mean. The seasonal values are removed, and the remainder smoothed to find the trend. The overall level is removed from the seasonal component and added to the trend component. This process is iterated a few times. The \text{remainder} component is the residuals from the seasonal plus trend fit.

Several methods for the resulting class "\text{stl}" objects, see \text{plot.stl}.

Value
\text{stl} returns an object of class "\text{stl}" with components

- \text{time.series}: a multiple time series with columns \text{seasonal, trend} and \text{remainder}.
- \text{weights}: the final robust weights (all one if fitting is not done robustly).
- \text{call}: the matched call.
- \text{win}: integer (length 3 vector) with the spans used for the "s", "t", and "l" smoothers.
- \text{deg}: integer (length 3) vector with the polynomial degrees for these smoothers.
- \text{jump}: integer (length 3) vector with the “jumps” (skips) used for these smoothers.
- \text{ni}: number of inner iterations
- \text{no}: number of outer robustness iterations

Note
This is similar to but not identical to the \text{stl} function in S-PLUS. The \text{remainder} component given by S-PLUS is the sum of the \text{trend} and \text{remainder} series from this function.

summary(stmR <- stl(mdeaths, s.w = "per", robust = TRUE))
op <- par(mar = c(0, 4, 0, 3), oma = c(5, 0, 4, 0),
          tck = -0.01, mfrow = c(nplot, 1),
          main = "stl(mdeaths, s.w = "per", robust = FALSE / TRUE )")
plot(stmd, set.pars=NULL, labels = NULL,
     main = "stl(mdeaths, s.w = "per", robust = FALSE / TRUE )")
plot(stmR, set.pars=NULL)
# mark the 'outliers' :
(iO <- which(stmR$weights < 1e-8)) # 10 were considered outliers
sts <- stmR$time.series
points(time(sts)[iO], .8* sts[,"remainder"][iO], pch = 4, col = "red")
par(op)# reset

stlmethods

Methods for STL Objects

Description

Methods for objects of class stl, typically the result of stl. The plot method does a multiple figure plot with some flexibility.

There are also (non-visible) print and summary methods.

Usage

## S3 method for class 'stl':
plot(x, labels = colnames(X),
     set.pars = list(mar = c(0, 6, 0, 6), oma = c(6, 0, 4, 0),
                    tck = -0.01, mfrow = c(nplot, 1)),
     main = NULL, range.bars = TRUE, ..., col.range = "light gray")

Arguments

x stl object.
labels character of length 4 giving the names of the component time-series.
set.pars settings for par(.) when setting up the plot.
main plot main title.
range.bars logical indicating if each plot should have a bar at its right side which are of equal heights in user coordinates.
... further arguments passed to or from other methods.
col.range colour to be used for the range bars, if plotted. Note this appears after ... and so cannot be abbreviated.
**StructTS**

**Fit Structural Time Series**

**See Also**
- `plot.ts` and `stl`, particularly for examples.

**Description**

Fit a structural model for a time series by maximum likelihood.

**Usage**

```r
StructTS(x, type = c("level", "trend", "BSM"), init = NULL,
          fixed = NULL, optim.control = NULL)
```

**Arguments**

- **x**: a univariate numeric time series. Missing values are allowed.
- **type**: the class of structural model. If omitted, a BSM is used for a time series with `frequency(x) > 1`, and a local trend model otherwise.
- **init**: initial values of the variance parameters.
- **fixed**: optional numeric vector of the same length as the total number of parameters. If supplied, only NA entries in `fixed` will be varied. Probably most useful for setting variances to zero.
- **optim.control**: List of control parameters for `optim`. Method "L-BFGS-B" is used.

**Details**

*Structural time series* models are (linear Gaussian) state-space models for (univariate) time series based on a decomposition of the series into a number of components. They are specified by a set of error variances, some of which may be zero.

The simplest model is the *local level* model specified by `type = "level"`. This has an underlying level $\mu_t$ which evolves by

$$
\mu_{t+1} = \mu_t + \xi_t, \quad \xi_t \sim N(0, \sigma_\xi^2)
$$

The observations are

$$
x_t = \mu_t + \epsilon_t, \quad \epsilon_t \sim N(0, \sigma_\epsilon^2)
$$

There are two parameters, $\sigma_\xi^2$ and $\sigma_\epsilon^2$. It is an ARIMA(0,1,1) model, but with restrictions on the parameter set.

The *local linear trend model*, `type = "trend"`, has the same measurement equation, but with a time-varying slope in the dynamics for $\mu_t$, given by

$$
\mu_{t+1} = \mu_t + \nu_t + \xi_t, \quad \xi_t \sim N(0, \sigma_\xi^2)
$$

$$
\nu_{t+1} = \nu_t + \zeta_t, \quad \zeta_t \sim N(0, \sigma_\zeta^2)
$$

with three variance parameters. It is not uncommon to find $\sigma_\zeta^2 = 0$ (which reduces to the local level model) or $\sigma_\zeta^2 = 0$, which ensures a smooth trend. This is a restricted ARIMA(0,2,2) model.
The basic structural model, type = "BSM", is a local trend model with an additional seasonal component. Thus the measurement equation is

\[ x_t = \mu_t + \gamma_t + \epsilon_t, \quad \epsilon_t \sim N(0, \sigma^2_\epsilon) \]

where \( \gamma_t \) is a seasonal component with dynamics

\[ \gamma_{t+1} = -\gamma_t + \cdots + \gamma_{t-s+2} + \omega_t, \quad \omega_t \sim N(0, \sigma^2_\omega) \]

The boundary case \( \sigma^2_\omega = 0 \) corresponds to a deterministic (but arbitrary) seasonal pattern. (This is sometimes known as the 'dummy variable' version of the BSM.)

Value

A list of class "StructTS" with components:

- coef: the estimated variances of the components.
- loglik: the maximized log-likelihood. Note that as all these models are non-stationary this includes a diffuse prior for some observations and hence is not comparable with arima nor different types of structural models.
- data: the time series \( x \).
- residuals: the standardized residuals.
- fitted: a multiple time series with one component for the level, slope and seasonal components, estimated contemporaneously (that is at time \( t \) and not at the end of the series).
- call: the matched call.
- series: the name of the series \( x \).
- code: the convergence code returned by optim.
- model, model0: Lists representing the Kalman Filter used in the fitting. See KalmanLike. model0 is the initial state of the filter, model its final state.
- xtsp: the tsp attributes of \( x \).

Note

Optimization of structural models is a lot harder than many of the references admit. For example, the AirPassengers data are considered in Brockwell & Davis (1996): their solution appears to be a local maximum, but nowhere near as good a fit as that produced by StructTS. It is quite common to find fits with one or more variances zero, and this can include \( \sigma^2_\epsilon \).

References

See Also

KalmanLike, tsSmooth.

Examples

```r
## see also JohnsonJohnson, Nile and AirPassengers

trees <- window(treering, start=0)
(fit <- StructTS(trees, type = "level"))
plot(trees)
lines(fitted(fit), col = "green")
tsdia(fit)

(fit <- StructTS(log10(UKgas), type = "BSM"))
par(mfrow = c(4, 1))
plot(log10(UKgas))
plot(cbind(fitted(fit), resid=resid(fit)), main = "UK gas consumption")

## keep some parameters fixed; trace optimizer:
StructTS(log10(UKgas), type = "BSM", fixed = c(0.1,0.001,NA,NA),
          optim.control = list(trace=TRUE))
```

### Summary

**summary.aov**

Summarize an Analysis of Variance Model

**Description**

Summarize an analysis of variance model.

**Usage**

```r
## S3 method for class 'aov':
summary(object, intercept = FALSE, split,
        expand.split = TRUE, keep.zero.df = TRUE, ...)

## S3 method for class 'aovlist':
summary(object, ...)
```

**Arguments**

- `object`: An object of class "aov" or "aovlist".
- `intercept`: logical: should intercept terms be included?
- `split`: an optional named list, with names corresponding to terms in the model. Each component is itself a list with integer components giving contrasts whose contributions are to be summed.
- `expand.split`: logical: should the split apply also to interactions involving the factor?
- `keep.zero.df`: logical: should terms with no degrees of freedom be included?
- `...`: Arguments to be passed to or from other methods, for `summary.aovlist` including those for `summary.aov`.
An object of class `c("summary.aov", "listof")` or "summary.aovlist" respectively. For a fits with a single stratum the result will be a list of ANOVA tables, one for each response (even if there is only one response): the tables are of class "anova" inheriting from class "data.frame". They have columns "Df", "Sum Sq", "Mean Sq", as well as "F value" and "Pr(>F)" if there are non-zero residual degrees of freedom. There is a row for each term in the model, plus one for "Residuals" if there are any.

For multistratum fits the return value is a list of such summaries, one for each stratum.

Note

The use of `expand.split = TRUE` is little tested: it is always possible to set it to `FALSE` and specify exactly all the splits required.

                            P = list(L = 1, Q = 2)))

# Split only the interaction
summary(CC.aov, split = list("N:P" = list(L.L = 1, Q = 2:4)))

# split on just one var
summary(CC.aov, split = list(P = list(lin = 1, quad = 2)))
summary(CC.aov, split = list(P = list(lin = 1, quad = 2)),
       expand.split=FALSE)
```
summary.glm

Summarizing Generalized Linear Model Fits

Description

These functions are all methods for class glm or summary.glm objects.

Usage

## S3 method for class 'glm':
summary(object, dispersion = NULL, correlation = FALSE,
symbolic.cor = FALSE, ...)

## S3 method for class 'summary.glm':
print(x, digits = max(3, getOption("digits") - 3),
symbolic.cor = x$symbolic.cor,
signif.stars = getOption("show.signif.stars"), ...)

Arguments

object  an object of class "glm", usually, a result of a call to glm.

x  an object of class "summary.glm", usually, a result of a call to summary.glm.

dispersion  the dispersion parameter for the family used. Either a single numerical value or NULL (the default), when it is inferred from object (see Details).

correlation  logical; if TRUE, the correlation matrix of the estimated parameters is returned and printed.

digits  the number of significant digits to use when printing.

symbolic.cor  logical. If TRUE, print the correlations in a symbolic form (see symnum) rather than as numbers.

signif.stars  logical. If TRUE, "significance stars" are printed for each coefficient.

...  further arguments passed to or from other methods.

Details

print.summary.glm tries to be smart about formatting the coefficients, standard errors, etc. and additionally gives \textit{"significance stars"} if signif.stars is TRUE. The coefficients component of the result gives the estimated coefficients and their estimated standard errors, together with their ratio. This third column is labelled \textit{t ratio} if the dispersion is estimated, and \textit{z ratio} if the dispersion is known (or fixed by the family). A fourth column gives the two-tailed p-value corresponding to the t or z ratio based on a Student t or Normal reference distribution. (It is possible that the dispersion is not known and there are no residual degrees of freedom from which to estimate it. In that case the estimate is NaN.)

Aliased coefficients are omitted in the returned object but restored by the \texttt{print} method.

Correlations are printed to two decimal places (or symbolically): to see the actual correlations print summary(object)$correlation directly.

The dispersion of a GLM is not used in the fitting process, but it is needed to find standard errors. If dispersion is not supplied or NULL, the dispersion is taken as 1 for the binomial and
Poisson families, and otherwise estimated by the residual Chisquared statistic (calculated from cases with non-zero weights) divided by the residual degrees of freedom.

`summary` can be used with Gaussian `glm` fits to handle the case of a linear regression with known error variance, something not handled by `summary.lm`.

**Value**

`summary.glm` returns an object of class "summary.glm", a list with components

```r
call the component from object.
family the component from object.
deviance the component from object.
contrasts the component from object.
df.residual the component from object.
null.deviance the component from object.
df.null the component from object.
deviance.resid the deviance residuals: see `residuals.glm`.
coefficients the matrix of coefficients, standard errors, z-values and p-values. Aliased coefficients are omitted.
aliased named logical vector showing if the original coefficients are aliased.
dispersion either the supplied argument or the inferred/estimated dispersion if the latter is NULL.
df a 3-vector of the rank of the model and the number of residual degrees of freedom, plus number of non-aliased coefficients.
cov.unscaled the unscaled (dispersion = 1) estimated covariance matrix of the estimated coefficients.
cov.scaled ditto, scaled by dispersion.
correlation (only if `correlation` is true.) The estimated correlations of the estimated coefficients.
symbolic.cor (only if `correlation` is true.) The value of the argument `symbolic.cor`.
```

**See Also**

`glm`, `summary`.

**Examples**

```r
## --- Continuing the Example from '?glm':

summary(glm.D93)
```
Summary

Summary method for class "lm".

Usage

```r
## S3 method for class 'lm':
summary(object, correlation = FALSE, symbolic.cor = FALSE, ...)
## S3 method for class 'summary.lm':
print(x, digits = max(3, getOption("digits") - 3),
     symbolic.cor = x$symbolic.cor,
     signif.stars = getOption("show.signif.stars"), ...)
```

Arguments

- `object`: an object of class "lm", usually, a result of a call to `lm`.
- `x`: an object of class "summary.lm", usually, a result of a call to `summary.lm`.
- `correlation`: logical; if TRUE, the correlation matrix of the estimated parameters is returned and printed.
- `digits`: the number of significant digits to use when printing.
- `symbolic.cor`: logical. If TRUE, print the correlations in a symbolic form (see `symnum`) rather than as numbers.
- `signif.stars`: logical. If TRUE, "significance stars" are printed for each coefficient.
- `...`: further arguments passed to or from other methods.

Details

`print.summary.lm` tries to be smart about formatting the coefficients, standard errors, etc. and additionally gives "significance stars" if `signif.stars` is TRUE.

Correlations are printed to two decimal places (or symbolically): to see the actual correlations print `summary(object)$correlation` directly.

Value

The function `summary.lm` computes and returns a list of summary statistics of the fitted linear model given in `object`, using the components (list elements) "call" and "terms" from its argument, plus:

- `residuals`: the weighted residuals, the usual residuals rescaled by the square root of the weights specified in the call to `lm`.
- `coefficients`: a $p \times 4$ matrix with columns for the estimated coefficient, its standard error, t-statistic and corresponding (two-sided) p-value. Aliased coefficients are omitted.
- `aliased`: named logical vector showing if the original coefficients are aliased.
sigma  the square root of the estimated variance of the random error

\[ \hat{\sigma}^2 = \frac{1}{n-p} \sum_{i} w_i R_i^2, \]

where \( R_i \) is the \( i \)-th residual, residuals[i].

df  degrees of freedom, a 3-vector \((p, n - p, p^*)\), the last being the number of non-aliased coefficients.

fstatistic  (for models including non-intercept terms) a 3-vector with the value of the F-statistic with its numerator and denominator degrees of freedom.

r.squared  \( R^2 \), the “fraction of variance explained by the model”,

\[ R^2 = 1 - \frac{\sum_i R_i^2}{\sum (y_i - y^*)^2}, \]

where \( y^* \) is the mean of \( y_i \) if there is an intercept and zero otherwise.

adj.r.squared  the above \( R^2 \) statistic “adjusted”, penalizing for higher \( p \).

cov.unscaled  a \( p \times p \) matrix of (unscaled) covariances of the \( \hat{\beta}_j, j = 1, \ldots, p \).

correlation  the correlation matrix corresponding to the above cov.unscaled, if correlation = TRUE is specified.

symbolic.cor  (only if correlation is true.) The value of the argument symbolic.cor.

na.action  from object, if present there.

See Also

The model fitting function lm, summary.

Function coef will extract the matrix of coefficients with standard errors, t-statistics and p-values.

Examples

```r
##-- Continuing the lm(.) example:
coef(lm.D90)# the bare coefficients
sld90 <- summary(lm.D90 <- lm(weight ~ group -1))# omitting intercept
sld90
coef(sld90)# much more
```
Arguments

- **object**: An object of class "manova" or an aov object with multiple responses.
- **test**: The name of the test statistic to be used. Partial matching is used so the name can be abbreviated.
- **intercept**: logical. If TRUE, the intercept term is included in the table.
- **...**: further arguments passed to or from other methods.

Details

The `summary.manova` method uses a multivariate test statistic for the summary table. Wilks’ statistic is most popular in the literature, but the default Pillai–Bartlett statistic is recommended by Hand and Taylor (1987).

The table gives a transformation of the test statistic which has approximately an F distribution. The approximations used follow S-PLUS and SAS (the latter apart from some cases of the Hotelling–Lawley statistic), but many other distributional approximations exist: see Anderson (1984) and Krzanowski and Marriott (1994) for further references. All four approximate F statistics are the same when the term being tested has one degree of freedom, but in other cases that for the Roy statistic is an upper bound.

Value

A list with components

- **SS**: A named list of sums of squares and product matrices.
- **Eigenvalues**: A matrix of eigenvalues.
- **stats**: A matrix of the statistics, approximate F value, degrees of freedom and P value.

References

See Also

- `manova`, `aov`

Examples

```r
## Example on producing plastic film from Krzanowski (1998, p. 381)
tear <- c(6.5, 6.2, 5.8, 6.5, 6.5, 6.9, 7.2, 6.9, 6.1, 6.3, 6.7, 6.6, 7.2, 7.1, 6.8, 7.1, 7.0, 7.2, 7.5, 7.6)
gloss <- c(9.5, 9.9, 9.6, 9.6, 9.2, 9.1, 10.0, 9.9, 9.5, 9.4, 9.1, 9.3, 8.3, 8.4, 8.5, 9.2, 8.8, 9.7, 10.1, 9.2)
opacity <- c(4.4, 6.4, 3.0, 4.1, 8.8, 5.7, 2.0, 3.9, 1.9, 5.7, 2.8, 4.1, 3.8, 1.6, 3.4, 8.4, 5.2, 6.9, 2.7, 1.9)
Y <- cbind(tear, gloss, opacity)
rate <- factor(gl(2,10), labels=c("Low", "High"))
```
additive <- factor(gl(2, 5, len=20), labels=c("Low", "High"))
fit <- manova(Y ~ rate * additive)
summary.aov(fit) # univariate ANOVA tables
summary(fit, test="Wilks") # ANOVA table of Wilks' lambda
summary(fit) # same F statistics as single-df terms

summary.nls

### S3 method for class 'nls':
summary(object, correlation = FALSE, symbolic.cor = FALSE, ...)

### S3 method for class 'summary.nls':
print(x, digits = max(3, getOption("digits") - 3),
    symbolic.cor = x$symbolic.cor,
    signif.stars = getOption("show.signif.stars"), ...)

Arguments

object an object of class "nls".

x an object of class "summary.nls", usually the result of a call to summary.nls.
correlation logical; if TRUE, the correlation matrix of the estimated parameters is returned and printed.
digits the number of significant digits to use when printing.
symbolic.cor logical. If TRUE, print the correlations in a symbolic form (see symnum) rather than as numbers.
signif.stars logical. If TRUE, "significance stars" are printed for each coefficient.
... further arguments passed to or from other methods.

Details

The distribution theory used to find the distribution of the standard errors and of the residual standard error (for t ratios) is based on linearization and is approximate, maybe very approximate.

print.summary.nls tries to be smart about formatting the coefficients, standard errors, etc. and additionally gives "significance stars" if signif.stars is TRUE.

Correlations are printed to two decimal places (or symbolically): to see the actual correlations print summary(object)$correlation directly.
**Value**

The function `summary.nls` computes and returns a list of summary statistics of the fitted model given in `object`, using the component "formula" from its argument, plus:

- **residuals**: the weighted residuals, the usual residuals rescaled by the square root of the weights specified in the call to `nls`.
- **coefficients**: a $p \times 4$ matrix with columns for the estimated coefficient, its standard error, t-statistic and corresponding (two-sided) p-value.
- **sigma**: the square root of the estimated variance of the random error

$$\hat{\sigma}^2 = \frac{1}{n - p} \sum_i R_i^2,$$

where $R_i$ is the $i$-th weighted residual.
- **df**: degrees of freedom, a 2-vector $(p, n - p)$. (Here and elsewhere $n$ omits observations with zero weights.)
- **cov.unscaled**: a $p \times p$ matrix of (unscaled) covariances of the parameter estimates.
- **correlation**: the correlation matrix corresponding to the above `cov.unscaled`, if `correlation = TRUE` is specified and there are a non-zero number of residual degrees of freedom.
- **symbolic.cor**: (only if `correlation` is true.) The value of the argument `symbolic.cor`.

**See Also**

The model fitting function `nls.summary`. Function `coef` will extract the matrix of coefficients with standard errors, t-statistics and p-values.

---

**summary.princomp**: Summary method for Principal Components Analysis

**Description**

The `summary` method for class "princomp".

**Usage**

```r
## S3 method for class 'princomp':
summary(object, loadings = FALSE, cutoff = 0.1, ...)
```

```r
## S3 method for class 'summary.princomp':
print(x, digits = 3, loadings = x$print.loadings, cutoff = x$cutoff, ...)
```

**Arguments**

- **object**: an object of class "princomp", as from `princomp()`.
- **loadings**: logical. Should loadings be included?
- **cutoff**: numeric. Loadings below this cutoff in absolute value are shown as blank in the output.
- **x**: an object of class "summary.princomp".
- **digits**: the number of significant digits to be used in listing loadings.
- **...**: arguments to be passed to or from other methods.
supsmu

Value

object with additional components cutoff and print.loadings.

See Also

princomp

Examples

summary(pc.cr <- princomp(USArrests, cor=TRUE))
print(summary(princomp(USArrests, cor=TRUE),
loadings = TRUE, cutoff = 0.2), digits = 2)

supsmu  Friedman’s SuperSmoother

Description

Smooth the (x, y) values by Friedman’s “super smoother”.

Usage

supsmu(x, y, wt, span = "cv", periodic = FALSE, bass = 0)

Arguments

x x values for smoothing
y y values for smoothing
wt case weights, by default all equal
span the fraction of the observations in the span of the running lines smoother, or "cv" to choose this by leave-one-out cross-validation.
periodic if TRUE, the x values are assumed to be in [0, 1] and of period 1.
bass controls the smoothness of the fitted curve. Values of up to 10 indicate increasing smoothness.

Details

supsmu is a running lines smoother which chooses between three spans for the lines. The running lines smoothers are symmetric, with k/2 data points each side of the predicted point, and values of k as 0.5 * n, 0.2 * n and 0.05 * n, where n is the number of data points. If span is specified, a single smoother with span span * n is used.

The best of the three smoothers is chosen by cross-validation for each prediction. The best spans are then smoothed by a running lines smoother and the final prediction chosen by linear interpolation.

The FORTRAN code says: “For small samples (n < 40) or if there are substantial serial correlations between observations close in x-value, then a pre-specified fixed span smoother (span > 0) should be used. Reasonable span values are 0.2 to 0.4.”

Cases with non-finite values of x, y or wt are dropped, with a warning.
Value

A list with components

\( x \) the input values in increasing order with duplicates removed.

\( y \) the corresponding \( y \) values on the fitted curve.

References

See Also

ppr

Examples

```r
with(cars, {
  plot(speed, dist)
  lines(supsmu(speed, dist))
  lines(supsmu(speed, dist, bass = 7), lty = 2)
})
```

Description

Symbolically encode a given numeric or logical vector or array. Particularly useful for “visualization” of structured matrices, e.g., correlation, sparse, or logical ones.

Usage

```r
symnum(x, cutpoints = c(0.3, 0.6, 0.8, 0.9, 0.95),
         symbols = if(numeric.x) c(" ", ".", ",", "+", "+", "B") else c(".", ",") ,
         legend = length(symbols) >= 3, 
         na = "?", eps = 1e-5, numeric.x = is.numeric(x),
         corr = missing(cutpoints) && numeric.x,
         show.max = if(corr) "1", show.min = NULL,
         abbr.colnames = has.colnames,
         lower.triangular = corr && is.numeric(x) && is.matrix(x),
         diag.lower.tri = corr && !is.null(show.max))
```
Arguments

x numeric or logical vector or array.

cutpoints numeric vector whose values \( \text{cutpoints}[j] = c_j \) (after augmentation, see corr below) are used for intervals.

symbols character vector, one shorter than (the augmented, see corr below) cutpoints. \( \text{symbols}[j] = s_j \) are used as “code” for the (half open) interval \([c_j, c_{j+1})\].

When numeric.x is FALSE, i.e., by default when argument x is logical, the default is c(".", ";") (graphical 0 / 1 s).

legend logical indicating if a "legend" attribute is desired.

na character or logical. How NAs are coded. If na == FALSE, NAs are coded invisibly, including the "legend" attribute below, which otherwise mentions NA coding.

eps absolute precision to be used at left and right boundary.

numeric.x logical indicating if \( x \) should be treated as numbers, otherwise as logical.

corr logical. If TRUE, \( x \) contains correlations. The cutpoints are augmented by 0 and 1 and \( \text{abs}(x) \) is coded.

show.max if TRUE, or of mode character, the maximal cutpoint is coded especially.

show.min if TRUE, or of mode character, the minimal cutpoint is coded especially.

abbr.colnames logical, integer or NULL indicating how column names should be abbreviated (if they are); if NULL (or FALSE and \( x \) has no column names), the column names will all be empty, i.e., ";". otherwise if abbr.colnames is false, they are left unchanged. If TRUE or integer, existing column names will be abbreviated to abbreviate(*, minlength = abbr.colnames).

lower.triangular logical. If TRUE and \( x \) is a matrix, only the lower triangular part of the matrix is coded as non-blank.

diag.lower.tri logical. If lower.triangular and this are TRUE, the diagonal part of the matrix is shown.

Value

An atomic character object of class noquote and the same dimensions as \( x \).

If legend is TRUE (as by default when there are more than two classes), the result has an attribute "legend" containing a legend of the returned character codes, in the form

\[ c_1 s_1 c_2 s_2 \ldots s_n c_{n+1} \]

where \( c_j = \text{cutpoints}[j] \) and \( s_j = \text{symbols}[j] \).

Note

The optional (mostly logical) arguments all try to use smart defaults. Specifying them explicitly may lead to considerably improved output in many cases.

Author(s)

Martin Maechler (maechler@stat.math.ethz.ch)
t.test

Student's t-Test

Description

Performs one and two sample t-tests on vectors of data.

Usage

t.test(x, ...)

## Default S3 method:
t.test(x, y = NULL,
alternative = c("two.sided", "less", "greater"),
mu = 0, paired = FALSE, var.equal = FALSE,
conf.level = 0.95, ...)

## S3 method for class 'formula':
t.test(formula, data, subset, na.action, ...)

Arguments

x  
a (non-empty) numeric vector of data values.
y  
an optional (non-empty) numeric vector of data values.
alternative  
a character string specifying the alternative hypothesis, must be one of "two.sided" (default), "greater" or "less". You can specify just the initial letter.
mu  
a number indicating the true value of the mean (or difference in means if you are performing a two sample test).
paired  
a logical indicating whether you want a paired t-test.
var.equal  
a logical variable indicating whether to treat the two variances as being equal. If TRUE then the pooled variance is used to estimate the variance otherwise the Welch (or Satterthwaite) approximation to the degrees of freedom is used.
conf.level  
confidence level of the interval.
formula  
a formula of the form lhs ~ rhs where lhs is a numeric variable giving the data values and rhs a factor with two levels giving the corresponding groups.
data  
an optional matrix or data frame (or similar: see model.frame) containing the variables in the formula formula. By default the variables are taken from environment(formula).
subset  
an optional vector specifying a subset of observations to be used.
na.action  
a function which indicates what should happen when the data contain NAs. Defaults to getOption("na.action").
...  
further arguments to be passed to or from methods.

Details

The formula interface is only applicable for the 2-sample tests.
alternative = "greater" is the alternative that x has a larger mean than y.

If paired is TRUE then both x and y must be specified and they must be the same length. Missing values are removed (in pairs if paired is TRUE). If var.equal is TRUE then the pooled estimate of the variance is used. By default, if var.equal is FALSE then the variance is estimated separately for both groups and the Welch modification to the degrees of freedom is used.
If the input data are effectively constant (compared to the larger of the two means) an error is generated.

Value

A list with class "htest" containing the following components:

statistic  
the value of the t-statistic.
parameter  
the degrees of freedom for the t-statistic.
p.value  
the p-value for the test.
TDist

conf.int a confidence interval for the mean appropriate to the specified alternative hypothesis.
estimate the estimated mean or difference in means depending on whether it was a one-sample test or a two-sample test.
null.value the specified hypothesized value of the mean or mean difference depending on whether it was a one-sample test or a two-sample test.
alternative a character string describing the alternative hypothesis.
method a character string indicating what type of t-test was performed.
data.name a character string giving the name(s) of the data.

See Also
prop.test

Examples

t.test(1:10, y=c(7:20))  # P = .00001855
t.test(1:10, y=c(7:20, 200))  # P = .1245  -- NOT significant anymore

## Classical example: Student’s sleep data
plot(extra ~ group, data = sleep)

## Traditional interface
with(sleep, t.test(extra[group == 1], extra[group == 2]))

## Formula interface
   t.test(extra ~ group, data = sleep)

TDist  The Student t Distribution

Description
Density, distribution function, quantile function and random generation for the t distribution with
df degrees of freedom (and optional non-centrality parameter ncp).

Usage
dt(x, df, ncp, log = FALSE)
pt(q, df, ncp, lower.tail = TRUE, log.p = FALSE)
qt(p, df, ncp, lower.tail = TRUE, log.p = FALSE)
rt(n, df, ncp)

Arguments
x, q vector of quantiles.
p vector of probabilities.
n number of observations. If length(n) > 1, the length is taken to be the number required.
df degrees of freedom (> 0, maybe non-integer). df = Inf is allowed. For qt only values of at least one are currently supported.
ncp non-centrality parameter \( \delta \); currently except for \( rt() \), only for \( \text{abs}(ncp) \leq 37.62 \). If omitted, use the central t distribution.

log, log.p logical; if TRUE, probabilities p are given as \( \log(p) \).

lower.tail logical; if TRUE (default), probabilities are \( P[X \leq x] \), otherwise, \( P[X > x] \).

Details

The \( t \) distribution with \( \text{df} = \nu \) degrees of freedom has density

\[
f(x) = \frac{\Gamma((\nu + 1)/2)}{\sqrt{\pi \nu} \Gamma(\nu/2)} \left(1 + x^2/\nu\right)^{-(\nu+1)/2}
\]

for all real \( x \). It has mean 0 (for \( \nu > 1 \)) and variance \( \frac{\nu}{\nu-2} \) (for \( \nu > 2 \)).

The general non-central \( t \) with parameters \( (\nu, \delta) = (\text{df}, \ ncp) \) is defined as the distribution of

\[
T_\nu(\delta) := U + \delta \chi_\nu/\sqrt{\nu}
\]

where \( U \) and \( \chi_\nu \) are independent random variables, \( U \sim N(0, 1) \), and \( \chi_\nu^2 \) is chi-squared, see Chisquare.

The most used applications are power calculations for \( t \)-tests:

Let \( T = \frac{\bar{X} - \mu_0}{S/\sqrt{n}} \) where \( \bar{X} \) is the mean and \( S \) the sample standard deviation (sd) of \( X_1, X_2, \ldots, X_n \) which are i.i.d. \( N(\mu, \sigma^2) \). Then \( T \) is distributed as non-centrally \( t \) with \( \text{df} = n - 1 \) degrees of freedom and non-centrality parameter \( ncp = (\mu - \mu_0)\sqrt{n}/\sigma \).

Value

dt gives the density, pt gives the distribution function, qt gives the quantile function, and rt generates random deviates.

Invalid arguments will result in return value NaN, with a warning.

Note

Setting \( ncp = 0 \) is not equivalent to omitting \( ncp \). R uses the non-centrality functionality whenever \( ncp \) is specified which provides continuous behavior at \( ncp = 0 \).

Source

The central \( dt \) is computed via an accurate formula provided by Catherine Loader (see the reference in \( \text{dbinom} \)).

For the non-central case of \( dt \), contributed by Claus Ekstrom based on the relationship (for \( x \neq 0 \)) to the cumulative distribution.

For the central case of \( pt \), a normal approximation in the tails, otherwise via \( \text{pbeta} \).

For the non-central case of \( pt \) based on a C translation of

For central \( qt \), a C translation of

altered to take account of

The non-central case is done by inversion.
termplot

plot(function(x) dt(x, df = 3, ncp = 2), -3, 11, ylim = c(0, 0.32),
main="Non-central t - Density", yaxs="i")

termplot

Plot regression terms

Description

Plots regression terms against their predictors, optionally with standard errors and partial residuals added.

Usage

termplot(model, data=NULL, envir=environment(formula(model)),
partial.resid=FALSE, rug=FALSE,
terms=NULL, se=FALSE, xlabs=NULL, ylabs=NULL, main = NULL,
col.term = 2, lwd.term = 1.5,
col.se = "orange", lty.se = 2, lwd.se = 1,
col.res = "gray", cex = 1, pch = par("pch"),
col.smth = "darkred", lty.smth = 2, span.smth = 2/3,
ask = interactive() && nb.fig < n.tms &&
.Device != "postscript",
use.factor.levels = TRUE, smooth = NULL, ...)

Arguments

model fitted model object
data data frame in which variables in model can be found
envir environment in which variables in model can be found
partial.resid
  logical; should partial residuals be plotted?

rug
  add rug plots (jittered 1-d histograms) to the axes?

terms
  which terms to plot (default NULL means all terms)

se
  plot pointwise standard errors?

xlabs
  vector of labels for the x axes

ylabs
  vector of labels for the y axes

main
  logical, or vector of main titles; if TRUE, the model’s call is taken as main title, NULL or FALSE mean no titles.

col.term, lwd.term
  color and line width for the “term curve”, see lines.

col.se, lty.se, lwd.se
  color, line type and line width for the “twice-standard-error curve” when se = TRUE.

col.res, cex, pch
  color, plotting character expansion and type for partial residuals, when partial.resid = TRUE, see points.

ask
  logical; if TRUE, the user is asked before each plot, see par(ask=.).

use.factor.levels
  Should x-axis ticks use factor levels or numbers for factor terms?

smooth
  NULL or a function with the same arguments as panel.smooth to draw a smooth through the partial residuals for non-factor terms

lty.smth, col.smth, span.smth
  Passed to smooth

...  other graphical parameters

Details

The model object must have a predict method that accepts type=terms, eg glm in the base package, coxph and survreg in the survival package.

For the partial.resid=TRUE option it must have a residuals method that accepts type="partial", which lm and glm do.

The data argument should rarely be needed, but in some cases termplot may be unable to reconstruct the original data frame. Using na.action=na.exclude makes these problems less likely.

Nothing sensible happens for interaction terms.

See Also

For (generalized) linear models, plot.lm and predict.glm.

Examples

had.splines <- "package:splines" %in% search()
if(!had.splines) rs <- require(splines)
x <- 1:100
z <- factor(rep(LETTERS[1:4],25))
y <- rnorm(100,sin(x/10)+as.numeric(z))
model <- glm(y ~ ns(x,6) + z)
terms

Model Terms

Description
The function `terms` is a generic function which can be used to extract terms objects from various kinds of R data objects.

Usage
```r
terms(x, ...)
```

Arguments
- `x` object used to select a method to dispatch.
- `...` further arguments passed to or from other methods.

Details
There are methods for classes "aovlist", and "terms" "formula" (see `terms.formula`): the default method just extracts the terms component of the object (if any).

There are `print` and `labels` methods for class "terms": the latter prints the term labels (see `terms.object`).

Value
An object of class c("terms", "formula") which contains the terms representation of a symbolic model. See `terms.object` for its structure.

References

See Also
`terms.object, terms.formula, lm, glm, formula`
Construct a terms Object from a Formula

Description

This function takes a formula and some optional arguments and constructs a terms object. The terms object can then be used to construct a model.matrix.

Usage

```r
## S3 method for class 'formula':
terms(x, specials = NULL, abb = NULL, data = NULL, neg.out = TRUE,
      keep.order = FALSE, simplify = FALSE, ..., allowDotAsName = FALSE)
```

Arguments

- `x`: a formula.
- `specials`: which functions in the formula should be marked as special in the terms object.
- `abb`: Not implemented in R.
- `data`: a data frame from which the meaning of the special symbol \( . \) can be inferred. It is unused if there is no \( . \) in the formula.
- `neg.out`: Not implemented in R.
- `keep.order`: a logical value indicating whether the terms should keep their positions. If `FALSE` the terms are reordered so that main effects come first, followed by the interactions, all second-order, all third-order and so on. Effects of a given order are kept in the order specified.
- `simplify`: should the formula be expanded and simplified, the pre-1.7.0 behaviour?
- `...`: further arguments passed to or from other methods.
- `allowDotAsName`: normally \( . \) in a formula refers to the remaining variables contained in `data`. Exceptionally, \( . \) can be treated as a name for non-standard uses of formulae.

Details

Not all of the options work in the same way that they do in S and not all are implemented.

Value

A terms.object object is returned. The object itself is the re-ordered (unless `keep.order = TRUE`) formula. In all cases variables within an interaction term in the formula are re-ordered by the ordering of the "variables" attribute, which is the order in which the variables occur in the formula.

See Also

terms, terms.object
Description

An object of class `terms` holds information about a model. Usually the model was specified in terms of a `formula` and that formula was used to determine the terms object.

Value

The object itself is simply the formula supplied to the call of `terms.formula`. The object has a number of attributes and they are used to construct the model frame:

- **factors**: A matrix of variables by terms showing which variables appear in which terms. The entries are 0 if the variable does not occur in the term, 1 if it does occur and should be coded by contrasts, and 2 if it occurs and should be coded via dummy variables for all levels (as when an intercept or lower-order term is missing). If there are no terms other than an intercept and offsets, this is numeric(0).

- **term.labels**: A character vector containing the labels for each of the terms in the model, except for offsets. Non-syntactic names will be quoted by backticks. Note that these are after possible re-ordering (unless argument `keep.order` was false).

- **variables**: A call to `list` of the variables in the model.

- **intercept**: Either 0, indicating no intercept is to be fit, or 1 indicating that an intercept is to be fit.

- **order**: A vector of the same length as `term.labels` indicating the order of interaction for each term.

- **response**: The index of the variable (in variables) of the response (the left hand side of the formula). Zero, if there is no response.

- **offset**: If the model contains `offset` terms there is an `offset` attribute indicating which variable(s) are offsets.

- **specials**: If a `specials` argument was given to `terms.formula` there is a `specials` attribute, a list of vectors (one for each specified special function) giving numeric indices of the arguments of the list returned as the `variables` attribute which contain these special functions.

- **dataClasses**: optional. A named character vector giving the classes (as given by `.MFclass`) of the variables used in a fit.

The object has class `c("terms", "formula")`.

Note

These objects are different from those found in S. In particular there is no `formula` attribute, instead the object is itself a formula. Thus, the mode of a terms object is different as well.

Examples of the `specials` argument can be seen in the `aov` and `coxph` functions.

See Also

`terms`, `formula`. 
Examples

```r
## use of specials (as used for gam() in packages mgcv and gam)
(tf <- terms(y ~ x + x:z + s(x), specials = "s"))
## Note that the "factors" attribute has variables as row names
## and term labels as column labels, both as character vectors.
attr(tf, "specials") # index 's' variable(s)
rownames(attr(tf, "factors"))[attr(tf, "specials")$s]

## we can keep the order by
terms(y ~ x + x:z + s(x), specials = "s", keep.order = TRUE)
```

---

### time

**Sampling Times of Time Series**

**Description**

time creates the vector of times at which a time series was sampled.
cycle gives the positions in the cycle of each observation.
frequency returns the number of samples per unit time and deltat the time interval between observations (see ts).

**Usage**

time(x, ...)

## Default S3 method:
time(x, offset=0, ...)

cycle(x, ...)
frequency(x, ...)
deltat(x, ...)

**Arguments**

- `x` a univariate or multivariate time-series, or a vector or matrix.
- `offset` can be used to indicate when sampling took place in the time unit. 0 (the default) indicates the start of the unit, 0.5 the middle and 1 the end of the interval.
- `...` extra arguments for future methods.

**Details**

These are all generic functions, which will use the tsp attribute of `x` if it exists. time and cycle have methods for class ts that coerce the result to that class.

**References**

toeplitz

cycle(presidents)
# a simple series plot: c() makes the x and y arguments into vectors
plot(c(time(presidents)), c(presidents), type="l")

---
toepilzt  Form Symmetric Toeplitz Matrix

Description
Forms a symmetric Toeplitz matrix given its first row.

Usage
toeplitz(x)

Arguments
x  the first row to form the Toeplitz matrix.

Value
The Toeplitz matrix.

Author(s)
A. Trapletti

Examples
x <- 1:5
toeplitz (x)
The function `ts` is used to create time-series objects.

`as.ts` and `is.ts` coerce an object to a time-series and test whether an object is a time series.

### Usage

```r
ts(data = NA, start = 1, end = numeric(0), frequency = 1,
    deltat = 1, ts.eps = getOption("ts.eps"), class = , names = )

as.ts(x, ...)

is.ts(x)
```

### Arguments

- **data**: a numeric vector or matrix of the observed time-series values. A data frame will be coerced to a numeric matrix via `data.matrix`.
- **start**: the time of the first observation. Either a single number or a vector of two integers, which specify a natural time unit and a (1-based) number of samples into the time unit. See the examples for the use of the second form.
- **end**: the time of the last observation, specified in the same way as `start`.
- **frequency**: the number of observations per unit of time.
- **deltat**: the fraction of the sampling period between successive observations; e.g., 1/12 for monthly data. Only one of `frequency` or `deltat` should be provided.
- **ts.eps**: time series comparison tolerance. Frequencies are considered equal if their absolute difference is less than `ts.eps`.
- **class**: class to be given to the result, or none if NULL or "none". The default is "ts" for a single series, c("mts", "ts") for multiple series.
- **names**: a character vector of names for the series in a multiple series: defaults to the colnames of `data`, or Series 1, Series 2,....
- **x**: an arbitrary R object.
- **...**: arguments passed to methods (unused for the default method).

### Details

The function `ts` is used to create time-series objects. These are vector or matrices with class of "ts" (and additional attributes) which represent data which has been sampled at equispaced points in time. In the matrix case, each column of the matrix `data` is assumed to contain a single (univariate) time series. Time series must have at least one observation, and although they need not be numeric there is very limited support for non-numeric series.

Class "ts" has a number of methods. In particular arithmetic will attempt to align time axes, and subsetting to extract subsets of series can be used (e.g., `EuStockMarkets[, "DAX"]`). However, subsetting the first (or only) dimension will return a matrix or vector, as will matrix subsetting. Subassignment can be used to replace values but not to extend a series (see `window`). There is a method for `t` that transposes the series as a matrix (a one-column matrix if a vector) and hence returns a result that does not inherit from class "ts".
The value of argument `frequency` is used when the series is sampled an integral number of times in each unit time interval. For example, one could use a value of 7 for `frequency` when the data are sampled daily, and the natural time period is a week, or 12 when the data are sampled monthly and the natural time period is a year. Values of 4 and 12 are assumed in (e.g.) `print` methods to imply a quarterly and monthly series respectively.

`as.ts` is generic. Its default method will use the `tsp` attribute of the object if it has one to set the start and end times and frequency.

`is.ts` tests if an object is a time series. It is generic: you can write methods to handle specific classes of objects, see `InternalMethods`.

**References**

**See Also**

`tsp`, `frequency`, `start`, `end`, `time`, `window`; `print.ts`, the print method for time series objects; `plot.ts`, the plot method for time series objects.

**Examples**

```r
ts(1:10, frequency = 4, start = c(1959, 2)) # 2nd Quarter of 1959
print(ts(1:10, freq = 7, start = c(12, 2)), calendar = TRUE) # print.ts(.)
```

```r
## Using July 1954 as start date:
gnp <- ts(cumsum(1 + round(rnorm(100), 2)),
           start = c(1954, 7), frequency = 12)
plot(gnp) # using 'plot.ts' for time-series plot
```

```r
## Multivariate
z <- ts(matrix(rnorm(300), 100, 3), start=c(1961, 1), frequency=12)
class(z)
plot(z)
plot(z, plot.type="single", lty=1:3)
```

```r
## A phase plot:
plot(nhtemp, c(nhtemp[-1], NA), cex = .8, col="blue",
     main = "Lag plot of New Haven temperatures")
## a clearer way to do this would be
## Not run:
plot(nhtemp, lag(nhtemp, 1), cex = .8, col="blue",
     main = "Lag plot of New Haven temperatures")
## End(Not run)
```

---

**ts-methods**

Methods for Time Series Objects

**Description**

Methods for objects of class "ts", typically the result of `ts`. 
Usage

```r
## S3 method for class 'ts':
diff(x, lag = 1, differences = 1, ...)

## S3 method for class 'ts':
aomit(object, ...)
```

Arguments

- `x`: an object of class "ts" containing the values to be differenced.
- `lag`: an integer indicating which lag to use.
- `differences`: an integer indicating the order of the difference.
- `object`: a univariate or multivariate time series.
- `...`: further arguments to be passed to or from methods.

Details

The `na.omit` method omits initial and final segments with missing values in one or more of the series. 'Internal' missing values will lead to failure.

Value

For the `na.omit` method, a time series without missing values. The class of `object` will be preserved.

See Also

diff; na.omit, na.fail, na.contiguous.

---

**ts.plot**  
*Plot Multiple Time Series*

Description

Plot several time series on a common plot. Unlike `plot.ts` the series can have a different time bases, but they should have the same frequency.

Usage

```r
ts.plot(..., gpars = list())
```

Arguments

- `...`: one or more univariate or multivariate time series.
- `gpars`: list of named graphics parameters to be passed to the plotting functions. Those commonly used can be supplied directly in `...`.

Value

None.
ts.union

Description

Bind time series which have a common frequency. ts.union pads with NAs to the total time coverage, ts.intersect restricts to the time covered by all the series.

Usage

\[
\text{ts.intersect}(\ldots, \text{dframe} = \text{FALSE}) \\
\text{ts.union}(\ldots, \text{dframe} = \text{FALSE})
\]

Arguments

\ldots \quad \text{two or more univariate or multivariate time series, or objects which can coerced to time series.}

dframe \quad \text{logical; if TRUE return the result as a data frame.}

Details

As a special case, \ldots can contain vectors or matrices of the same length as the combined time series of the time series present, as well as those of a single row.

Value

A time series object if dframe is FALSE, otherwise a data frame.

See Also

\text{cbind}

Examples

\[
\text{ts.union}(\text{mdeaths, fdeaths}) \\
\text{cbind}(\text{mdeaths, fdeaths}) \quad \# \text{same as the previous line} \\
\text{ts.intersect}(\text{window(mdeaths, 1976), window(fdeaths, 1974, 1978)})
\]

sales1 <- ts.union(\text{BJsales, lead} = \text{BJsales.lead})
\text{ts.intersect}(\text{sales1, lead3} = \text{lag(BJsales.lead, -3)})
tsdiag

Diagnostic Plots for Time-Series Fits

Description

A generic function to plot time-series diagnostics.

Usage

\texttt{tsdiag(object, gof.lag, \ldots)}

Arguments

\begin{itemize}
\item \textit{object} \hspace{1cm} a fitted time-series model
\item \textit{gof.lag} \hspace{1cm} the maximum number of lags for a Portmanteau goodness-of-fit test
\item \textit{\ldots} \hspace{1cm} further arguments to be passed to particular methods
\end{itemize}

Details

This is a generic function. It will generally plot the residuals, often standardized, the autocorrelation function of the residuals, and the p-values of a Portmanteau test for all lags up to \textit{gof.lag}.

The methods for \texttt{arima} and \texttt{StructTS} objects plots residuals scaled by the estimate of their (individual) variance, and use the Ljung–Box version of the portmanteau test.

Value

None. Diagnostics are plotted.

See Also

\texttt{arima, StructTS, Box.test}

Examples

\begin{verbatim}
## Not run: fit <- arima(lh, c(1,0,0))
tsdia(fit)

## see also examples(arima)

(fit <- StructTS(log10(JohnsonJohnson), type="BSM"))
tsdia(fit)
## End(Not run)
\end{verbatim}
tsp

Tsp Attribute of Time-Series-like Objects

Description

tsp returns the tsp attribute (or NULL). It is included for compatibility with S version 2. tsp<- sets the tsp attribute. hasTsp ensures x has a tsp attribute, by adding one if needed.

Usage

tsp(x)
tsp(x) <- value
hasTsp(x)

Arguments

x a vector or matrix or univariate or multivariate time-series.
value a numeric vector of length 3 or NULL.

Details

The tsp attribute was previously described here as c(start(x), end(x), frequency(x)), but this is incorrect. It gives the start time in time units, the end time and the frequency.

Assignments are checked for consistency.

Assigning NULL which removes the tsp attribute and any "ts" (or "mts") class of x.

References

See Also

ts, time, start.

tsSmooth

Use Fixed-Interval Smoothing on Time Series

Description

Performs fixed-interval smoothing on a univariate time series via a state-space model. Fixed-interval smoothing gives the best estimate of the state at each time point based on the whole observed series.

Usage

tsSmooth(object, ...)

Arguments

object a time-series fit. Currently only class "StructTS" is supported
... possible arguments for future methods.

Value

A time series, with as many dimensions as the state space and results at each time point of the original series. (For seasonal models, only the current seasonal component is returned.)

Author(s)

B. D. Ripley

References

Tukey

The Studentized Range Distribution

Description

Functions of the distribution of the studentized range, $R/s$, where $R$ is the range of a standard normal sample and $df \times s^2$ is independently distributed as chi-squared with $df$ degrees of freedom, see pchisq.

Usage

ptukey(q, nmeans, df, nranges = 1, lower.tail = TRUE, log.p = FALSE)
qtukey(p, nmeans, df, nranges = 1, lower.tail = TRUE, log.p = FALSE)

Arguments

q vector of quantiles.
p vector of probabilities.
nmeans sample size for range (same for each group).
df degrees of freedom for $s$ (see below).
nranges number of groups whose maximum range is considered.
log.p logical; if TRUE, probabilities p are given as log(p).
lower.tail logical; if TRUE (default), probabilities are $P[X \leq x]$, otherwise, $P[X > x]$. 
TukeyHSD

Details

If \( n_g = n \text{ranges} \text{ is greater than one, } R \text{ is the maximum of } n_g \text{ groups of } n \text{means observations each.} \)

Value

\text{ptukey} \text{ gives the distribution function and qtukey its inverse, the quantile function.}

Note

A Legendre 16-point formula is used for the integral of \text{ptukey}. The computations are relatively expensive, especially for \text{qtukey} which uses a simple secant method for finding the inverse of \text{ptukey}. \text{qtukey} will be accurate to the 4th decimal place.

References

See Also

\text{pnorm} \text{ and } \text{qnorm} \text{ for the corresponding functions for the normal distribution.}

Examples

\text{if(interactive())}
\begin{verbatim}
  curve(ptukey(x, nm=6, df=5), from=-1, to=8, n=101)
  (ptt <- ptukey(0:10, 2, df=5))
  (qtt <- qtukey(.95, 2, df=2:11))
  ## The precision may be not much more than about 8 digits:
  summary(abs(.95 - ptukey(qtt,2, df = 2:11))
\end{verbatim}

TukeyHSD

\text{Compute Tukey Honest Significant Differences}

Description

Create a set of confidence intervals on the differences between the means of the levels of a factor with the specified family-wise probability of coverage. The intervals are based on the Studentized range statistic, Tukey’s ‘Honest Significant Difference’ method. There is a plot method.

Usage

\text{TukeyHSD(x, which, ordered = FALSE, conf.level = 0.95, ...)}
TukeyHSD

Arguments

- **x**: A fitted model object, usually an `aov` fit.
- **which**: A character vector listing terms in the fitted model for which the intervals should be calculated. Defaults to all the terms.
- **ordered**: A logical value indicating if the levels of the factor should be ordered according to increasing average in the sample before taking differences. If `ordered` is true then the calculated differences in the means will all be positive. The significant differences will be those for which the `lwr` end point is positive.
- **conf.level**: A numeric value between zero and one giving the family-wise confidence level to use.
- **...**: Optional additional arguments. None are used at present.

Details

When comparing the means for the levels of a factor in an analysis of variance, a simple comparison using t-tests will inflate the probability of declaring a significant difference when it is not in fact present. This because the intervals are calculated with a given coverage probability for each interval but the interpretation of the coverage is usually with respect to the entire family of intervals.

John Tukey introduced intervals based on the range of the sample means rather than the individual differences. The intervals returned by this function are based on this Studentized range statistics.

Technically the intervals constructed in this way would only apply to balanced designs where there are the same number of observations made at each level of the factor. This function incorporates an adjustment for sample size that produces sensible intervals for mildly unbalanced designs.

If `which` specifies non-factor terms these will be dropped with a warning: if no terms are left this is an error.

Value

A list with one component for each term requested in `which`. Each component is a matrix with columns `diff` giving the difference in the observed means, `lwr` giving the lower end point of the interval, `upr` giving the upper end point and `p adj` giving the p-value after adjustment for the multiple comparisons.

Author(s)

Douglas Bates

References

- `aov`, `qtukey`, `model.tables`, `simint`

Examples

```r
summary(fml <- aov(breaks ~ wool + tension, data = warpbreaks))
TukeyHSD(fml, "tension", ordered = TRUE)
plot(TukeyHSD(fml, "tension"))
```
Description

These functions provide information about the uniform distribution on the interval from \( \min \) to \( \max \). \texttt{dunif} gives the density, \texttt{punif} gives the distribution function \texttt{qunif} gives the quantile function and \texttt{runif} generates random deviates.

Usage

\begin{verbatim}
dunif(x, min=0, max=1, log = FALSE)
punif(q, min=0, max=1, lower.tail = TRUE, log.p = FALSE)
qunif(p, min=0, max=1, lower.tail = TRUE, log.p = FALSE)
runif(n, min=0, max=1)
\end{verbatim}

Arguments

\begin{itemize}
  \item \textbf{x,q} vector of quantiles.
  \item \textbf{p} vector of probabilities.
  \item \textbf{n} number of observations. If \texttt{length(n)} > 1, the length is taken to be the number required.
  \item \textbf{min,max} lower and upper limits of the distribution. Must be finite.
  \item \textbf{log, log.p} logical; if TRUE, probabilities \( p \) are given as \( \log(p) \).
  \item \textbf{lower.tail} logical; if TRUE (default), probabilities are \( P[X \leq x] \), otherwise, \( P[X > x] \).
\end{itemize}

Details

If \texttt{min} or \texttt{max} are not specified they assume the default values of 0 and 1 respectively.

The uniform distribution has density

\[ f(x) = \frac{1}{max - min} \]

for \( \min \leq x \leq \max \).

For the case of \( u := min == max \), the limit case of \( X \equiv u \) is assumed, although there is no density in that case and \texttt{dunif} will return \texttt{NaN} (the error condition).

\texttt{runif} will not generate either of the extreme values unless \texttt{max} = \texttt{min} or \texttt{max-min} is small compared to \texttt{min}, and in particular not for the default arguments.

References

See Also

\texttt{.Random.seed} about random number generation, \texttt{rnorm}, etc for other distributions.
Examples

```r
u <- runif(20)

## The following relations always hold:
punif(u) == u
dunif(u) == 1

var(runif(10000))#- ~ = 1/12 = .08333
```

Description

The function `uniroot` searches the interval from `lower` to `upper` for a root (i.e., zero) of the function `f` with respect to its first argument.

Usage

```r
uniroot(f, interval, lower = min(interval), upper = max(interval),
tol = .Machine$double.eps^0.25, maxiter = 1000, ...)
```

Arguments

- `f`: the function for which the root is sought.
- `interval`: a vector containing the end-points of the interval to be searched for the root.
- `lower`: the lower end point of the interval to be searched.
- `upper`: the upper end point of the interval to be searched.
- `tol`: the desired accuracy (convergence tolerance).
- `maxiter`: the maximum number of iterations.
- `...`: additional named or unnamed arguments to be passed to `f` (but beware of partial matching to other arguments).

Details

Either `interval` or both `lower` and `upper` must be specified: the upper endpoint must be strictly larger than the lower endpoint. The function values at the endpoints must be of opposite signs (or zero).

The function uses Fortran subroutine "zeroin" (from Netlib) based on algorithms given in the reference below. They assume a continuous function (which then is known to have at least one root in the interval).

Convergence is declared either if `f(x) == 0` or the change in `x` for one step of the algorithm is less than `tol` (plus an allowance for representation error in `x`).

If the algorithm does not converge in `maxiter` steps, a warning is printed and the current approximation is returned.

`f` will be called as `f(x, ...)` for a numeric value of `x`. 
Value

A list with four components: root and f.root give the location of the root and the value of the function evaluated at that point. iter and estim.prec give the number of iterations used and an approximate estimated precision for root. (If the root occurs at one of the endpoints, the estimated precision is NA.)

Source

Based on ’zeroin.c’ in http://www.netlib.org/c/brent.shar.

References

polyroot for all complex roots of a polynomial; optimize, nlm.

Examples

```r
f <- function (x,a) x - a
str(xmin <- uniroot(f, c(0, 1), tol = 0.0001, a = 1/3))
str(unroot(function(x) x*(x^2-1) + .5, low = -2, up = 2, tol = 0.0001),
     dig = 10)
str(unroot(function(x) x*(x^2-1) + .5, low = -2, up = 2, tol = 1e-10 ),
     dig = 10)

## Find the smallest value x for which exp(x) > 0 (numerically):

r <- unroot{function(x) 1e80*exp(x)-1e-300, c(-1000,0), tol = 1e-15}
str(r, digits= 15) ##> around -745, depending on the platform.
exp(r$r)            # = 0, but not for r$r * 0.999...
minexp <- r$r * (1 - 10*.Machine$double.eps)
exp(minexp)         # typically denormalized
```

Description

update will update and (by default) re-fit a model. It does this by extracting the call stored in the object, updating the call and (by default) evaluating that call. Sometimes it is useful to call update with only one argument, for example if the data frame has been corrected.

Usage

```r
update(object, ...)
```

## Default S3 method:
```
update(object, formula., ..., evaluate = TRUE)
```
Arguments

object: An existing fit from a model function such as lm, glm and many others.
formula: Changes to the formula – see update.formula for details.
...: Additional arguments to the call, or arguments with changed values. Use name=NULL to remove the argument name.
evaluate: If true evaluate the new call else return the call.

Value

If evaluate = TRUE the fitted object, otherwise the updated call.

References

See Also

update.formula

Model Updating

Description

update.formula is used to update model formulae. This typically involves adding or dropping terms, but updates can be more general.

Usage

## S3 method for class 'formula':
update(old, new, ...)

**Arguments**

- **old**: a model formula to be updated.
- **new**: a formula giving a template which specifies how to update.
- **...**: further arguments passed to or from other methods.

**Details**

Either or both of `old` and `new` can be objects such as length-one character vectors which can be coerced to a formula via `as.formula`.

The function works by first identifying the left-hand side and right-hand side of the `old` formula. It then examines the `new` formula and substitutes the `lhs` of the `old` formula for any occurrence of `.` on the left of `new`, and substitutes the `rhs` of the `old` formula for any occurrence of `.` on the right of `new`. The result is then simplified via `terms.formula(simplify = TRUE)`.

**Value**

The updated formula is returned. The environment of the result will that of `old`.

**See Also**

- `terms`, `model.matrix`.

**Examples**

```
update(y ~ x, ~ . + x2) #> y ~ x + x2
update(y ~ x, log(.) ~ . ) #> log(y) ~ x
```

---

**var.test**

*F Test to Compare Two Variances*

**Description**

Performs an F test to compare the variances of two samples from normal populations.

**Usage**

```r
var.test(x, ...) # Default S3 method:
var.test(x, y, ratio = 1,
         alternative = c("two.sided", "less", "greater"),
         conf.level = 0.95, ...)
```

```r
# S3 method for class 'formula':
var.test(formula, data, subset, na.action, ...)
```
Arguments

x, y
numeric vectors of data values, or fitted linear model objects (inheriting from class "lm").

ratio
the hypothesized ratio of the population variances of x and y.

alternative
a character string specifying the alternative hypothesis, must be one of "two.sided" (default), "greater" or "less". You can specify just the initial letter.

conf.level
confidence level for the returned confidence interval.

formula
a formula of the form lhs ~ rhs where lhs is a numeric variable giving the data values and rhs a factor with two levels giving the corresponding groups.

data
an optional matrix or data frame (or similar: see model.frame) containing the variables in the formula formula. By default the variables are taken from environment(formula).

subset
an optional vector specifying a subset of observations to be used.

na.action
a function which indicates what should happen when the data contain NAs. Defaults to getOption("na.action").

...
further arguments to be passed to or from methods.

Details

The null hypothesis is that the ratio of the variances of the populations from which x and y were drawn, or in the data to which the linear models x and y were fitted, is equal to ratio.

Value

A list with class "htest" containing the following components:

 statistic the value of the F test statistic.
 parameter the degrees of the freedom of the F distribution of the test statistic.
 p.value the p-value of the test.
 conf.int a confidence interval for the ratio of the population variances.
 estimate the ratio of the sample variances of x and y.
 null.value the ratio of population variances under the null.
 alternative a character string describing the alternative hypothesis.
 method the character string "F test to compare two variances".
 data.name a character string giving the names of the data.

See Also

bartlett.test for testing homogeneity of variances in more than two samples from normal distributions; ansari.test and mood.test for two rank based (nonparametric) two-sample tests for difference in scale.

Examples

x <- rnorm(50, mean = 0, sd = 2)
y <- rnorm(30, mean = 1, sd = 1)
var.test(x, y) # Do x and y have the same variance?
var.test(lm(x ~ 1), lm(y ~ 1)) # The same.
Description

These functions ‘rotate’ loading matrices in factor analysis.

Usage

```
varimax(x, normalize = TRUE, eps = 1e-5)
promax(x, m = 4)
```

Arguments

- `x` A loadings matrix, with `p` rows and `k < p` columns
- `m` The power used the target for `promax`. Values of 2 to 4 are recommended.
- `normalize` logical. Should Kaiser normalization be performed? If so the rows of `x` are re-scaled to unit length before rotation, and scaled back afterwards.
- `eps` The tolerance for stopping: the relative change in the sum of singular values.

Details

These seek a ‘rotation’ of the factors `x %*% T` that aims to clarify the structure of the loadings matrix. The matrix `T` is a rotation (possibly with reflection) for `varimax`, but a general linear transformation for `promax`, with the variance of the factors being preserved.

Value

A list with components

- `loadings` The ‘rotated’ loadings matrix, `x %*% rotmat`, of class "loadings".
- `rotmat` The ‘rotation’ matrix.

References

See Also

`factanal`, `Harman74.cor`
### Examples

```r
## varimax with normalize = TRUE is the default
fa <- factanal(~., 2, data = swiss)
varimax(loadings(fa), normalize = FALSE)
promax(loadings(fa))
```

---

**vcov**

*Calculate Variance-Covariance Matrix for a Fitted Model Object*

**Description**

Returns the variance-covariance matrix of the main parameters of a fitted model object.

**Usage**

```r
vcov(object, ...)
```

**Arguments**

- `object` a fitted model object.
- `...` additional arguments for method functions. For the `glm` method this can be used to pass a dispersion parameter.

**Details**

This is a generic function. Functions with names beginning in `vcov.` will be methods for this function. Classes with methods for this function include: `lm, mlm, glm, nls, lme, gls, coxph` and `survreg` (the last two in package `survival`).

**Value**

A matrix of the estimated covariances between the parameter estimates in the linear or non-linear predictor of the model.

---

**Weibull**

*The Weibull Distribution*

**Description**

Density, distribution function, quantile function and random generation for the Weibull distribution with parameters `shape` and `scale`.

**Usage**

```r
dweibull(x, shape, scale = 1, log = FALSE)
pweibull(q, shape, scale = 1, lower.tail = TRUE, log.p = FALSE)
qweibull(p, shape, scale = 1, lower.tail = TRUE, log.p = FALSE)
rweibull(n, shape, scale = 1)
```
Arguments

- x, q: vector of quantiles.
- p: vector of probabilities.
- n: number of observations. If `length(n) > 1`, the length is taken to be the number required.
- shape, scale: shape and scale parameters, the latter defaulting to 1.
- log, log.p: logical; if TRUE, probabilities p are given as log(p).
- lower.tail: logical; if TRUE (default), probabilities are $P[X \leq x]$, otherwise, $P[X > x]$.

Details

The Weibull distribution with shape parameter $a$ and scale parameter $\sigma$ has density given by

$$f(x) = (a/\sigma)(x/\sigma)^{a-1}\exp(-(x/\sigma)^a)$$

for $x \geq 0$. The cumulative distribution function is $F(x) = 1 - \exp(-(x/\sigma)^a)$ on $x \geq 0$, the mean is $E(X) = \sigma\Gamma(1 + 1/a)$, and the $Var(X) = \sigma^2\left(\Gamma(1 + 2/a) - (\Gamma(1 + 1/a))^2\right)$.

Value

dweibull gives the density, pweibull gives the distribution function, qweibull gives the quantile function, and rweibull generates random deviates.

Invalid arguments will result in return value NaN, with a warning.

Note

The cumulative hazard $H(t) = -\log(1 - F(t))$ is `-pweibull(t, a, b, lower = FALSE, log = TRUE)` which is just $H(t) = (t/b)^a$.

Source

[dpq]weibull are calculated directly from the definitions. rweibull uses inversion.

References

See Also

The Exponential is a special case of the Weibull distribution.

Examples

```r
x <- c(0, rlnorm(50))
all.equal(dweibull(x, shape = 1), dexp(x))
all.equal(pweibull(x, shape = 1, scale = pi), pexp(x, rate = 1/pi))
## Cumulative hazard H():
all.equal(pweibull(x, 2.5, pi, lower=FALSE, log=TRUE), -(x/pi)^2.5, tol = 1e-15)
all.equal(qweibull(x/11, shape = 1, scale = pi), qexp(x/11, rate = 1/pi))
```
weighted.mean

Weighted Arithmetic Mean

Description

Compute a weighted mean of a numeric vector.

Usage

weighted.mean(x, w, na.rm = FALSE)

Arguments

x
a numeric vector containing the values whose mean is to be computed.

w
a vector of weights the same length as x giving the weights to use for each element of x.

na.rm
a logical value indicating whether NA values in x should be stripped before the computation proceeds.

Details

If w is missing then all elements of x are given the same weight.
Missing values in w are not handled.

See Also

mean

Examples

## GPA from Siegel 1994
wt <- c(5, 5, 4, 1)/15
x <- c(3.7,3.3,3.5,2.8)
xm <- weighted.mean(x,wt)

weighted.residuals

Compute Weighted Residuals

Description

Computed weighted residuals from a linear model fit.

Usage

weighted.residuals(obj, drop0 = TRUE)

Arguments

obj
\(\text{R object, typically of class } \text{lm or glm.}\)

drop0
logical. If TRUE, drop all cases with weights == 0.
Details

Weighted residuals are based on the deviance residuals, which for a \texttt{lm} fit are the raw residuals $R_i$ multiplied by $\sqrt{w_i}$, where $w_i$ are the weights as specified in \texttt{lm}'s call.

Dropping cases with weights zero is compatible with \texttt{influence} and related functions.

Value

Numeric vector of length $n'$, where $n'$ is the number of non-0 weights (\texttt{drop0 = TRUE}) or the number of observations, otherwise.

See Also

\texttt{residuals}, \texttt{lm.influence}, etc.

Examples

\begin{verbatim}
example("lm")
all.equal(weighted.residuals(lm.D9),
          residuals(lm.D9))
x <- 1:10
w <- 0:9
y <- rnorm(x)
weighted.residuals(lmxy <- lm(y ~ x, weights = w))
weighted.residuals(lmxy, drop0 = FALSE)
\end{verbatim}

---

\texttt{wilcox.test} \hfill \textit{Wilcoxon Rank Sum and Signed Rank Tests}

Description

Performs one and two sample Wilcoxon tests on vectors of data; the latter is also known as 'Mann-Whitney' test.

Usage

\begin{verbatim}
wilcox.test(x, ...)

## Default S3 method:
wilcox.test(x, y = NULL,
            alternative = c("two.sided", "less", "greater"),
            mu = 0, paired = FALSE, exact = NULL, correct = TRUE,
            conf.int = FALSE, conf.level = 0.95, ...)

## S3 method for class 'formula':
wilcox.test(formula, data, subset, na.action, ...)
\end{verbatim}
Arguments

- **x**: numeric vector of data values. Non-finite (e.g. infinite or missing) values will be omitted.
- **y**: an optional numeric vector of data values.
- **alternative**: a character string specifying the alternative hypothesis, must be one of "two.sided" (default), "greater" or "less". You can specify just the initial letter.
- **mu**: a number specifying an optional parameter used to form the null hypothesis. See Details.
- **paired**: a logical indicating whether you want a paired test.
- **exact**: a logical indicating whether an exact p-value should be computed.
- **correct**: a logical indicating whether to apply continuity correction in the normal approximation for the p-value.
- **conf.int**: a logical indicating whether a confidence interval should be computed.
- **conf.level**: confidence level of the interval.
- **formula**: a formula of the form lhs ~ rhs where lhs is a numeric variable giving the data values and rhs a factor with two levels giving the corresponding groups.
- **data**: an optional matrix or data frame (or similar: see model.frame) containing the variables in the formula formula. By default the variables are taken from environment(formula).
- **subset**: an optional vector specifying a subset of observations to be used.
- **na.action**: a function which indicates what should happen when the data contain NAs. Defaults togetOption("na.action").
- **...**: further arguments to be passed to or from methods.

Details

The formula interface is only applicable for the 2-sample tests.

If only x is given, or if both x and y are given and paired is TRUE, a Wilcoxon signed rank test of the null that the distribution of x (in the one sample case) or of x - y (in the paired two sample case) is symmetric about mu is performed.

Otherwise, if both x and y are given and paired is FALSE, a Wilcoxon rank sum test (equivalent to the Mann-Whitney test: see the Note) is carried out. In this case, the null hypothesis is that the distributions of x and y differ by a location shift of mu and the alternative is that they differ by some other location shift (and the one-sided alternative "greater" is that x is shifted to the right of y).

By default (if exact is not specified), an exact p-value is computed if the samples contain less than 50 finite values and there are no ties. Otherwise, a normal approximation is used.

Optionally (if argument conf.int is true), a nonparametric confidence interval and an estimator for the pseudomedian (one-sample case) or for the difference of the location parameters x - y is computed. (The pseudomedian of a distribution F is the median of the distribution of (u + v)/2, where u and v are independent, each with distribution F. If F is symmetric, then the pseudomedian and median coincide. See Hollander & Wolfe (1973), page 34.) If exact p-values are available, an exact confidence interval is obtained by the algorithm described in Bauer (1972), and the Hodges-Lehmann estimator is employed. Otherwise, the returned confidence interval and point estimate are based on normal approximations.

With small samples it may not be possible to achieve very high confidence interval coverages. If this happens a warning will be given and an interval with lower coverage will be substituted.
Value

A list with class "htest" containing the following components:

- statistic: the value of the test statistic with a name describing it.
- parameter: the parameter(s) for the exact distribution of the test statistic.
- p.value: the \( p \)-value for the test.
- null.value: the location parameter \( \mu \).
- alternative: a character string describing the alternative hypothesis.
- method: the type of test applied.
- data.name: a character string giving the names of the data.
- conf.int: a confidence interval for the location parameter. (Only present if argument conf.int = TRUE.)
- estimate: an estimate of the location parameter. (Only present if argument conf.int = TRUE.)

Warning

This function can use large amounts of memory and stack (and even crash \( R \) if the stack limit is exceeded) if exact = TRUE and one sample is large (several thousands or more).

Note

The literature is not unanimous about the definitions of the Wilcoxon rank sum and Mann-Whitney tests. The two most common definitions correspond to the sum of the ranks of the first sample with the minimum value subtracted or not: \( R \) subtracts and S-PLUS does not, giving a value which is larger by \( m(m+1)/2 \) for a first sample of size \( m \). (It seems Wilcoxon's original paper used the unadjusted sum of the ranks but subsequent tables subtracted the minimum.)

\( R \)'s value can also be computed as the number of all pairs \((x[i], y[j])\) for which \( y[j] \) is not greater than \( x[i] \), the most common definition of the Mann-Whitney test.

References

See Also

- `psignrank`, `pwilcox`.
- `wilcox.exact` in package *exactRankTests* covers much of the same ground, but also produces exact \( p \)-values in the presence of ties.
- `wilcoxon_test` in package *coin* for exact and approximate conditional \( p \)-values for the Wilcoxon tests.
- `kruskal.test` for testing homogeneity in location parameters in the case of two or more samples; `t.test` for an alternative under normality assumptions [or large samples]
Examples

### One-sample test.
### Hollander & Wolfe (1973), 29f.
### Hamilton depression scale factor measurements in 9 patients with
### mixed anxiety and depression, taken at the first (x) and second
### (y) visit after initiation of a therapy (administration of a
### tranquilizer).
```r
x <- c(1.83, 0.50, 1.62, 2.48, 1.68, 1.88, 1.55, 3.06, 1.30)
y <- c(0.878, 0.647, 0.598, 2.05, 1.06, 1.29, 1.06, 3.14, 1.29)
wilcox.test(x, y, paired = TRUE, alternative = "greater")
wilcox.test(y - x, alternative = "less")  # The same.
wilcox.test(y - x, alternative = "less",
            exact = FALSE, correct = FALSE)  # H&W large sample
            # approximation
```

### Two-sample test.
### Hollander & Wolfe (1973), 69f.
### Permeability constants of the human chorioamnion (a placental
### membrane) at term (x) and between 12 to 26 weeks gestational
### age (y). The alternative of interest is greater permeability
### of the human chorioamnion for the term pregnancy.
```r
x <- c(0.80, 0.83, 1.89, 1.04, 1.45, 1.38, 1.91, 1.64, 0.73, 1.46)
y <- c(1.15, 0.88, 0.90, 0.74, 1.21)
wilcox.test(x, y, alternative = "g")  # greater
wilcox.test(x, y, alternative = "greater",
            exact = FALSE, correct = FALSE)  # H&W large sample
            # approximation
wilcox.test(rnorm(10), rnorm(10, 2), conf.int = TRUE)
```

### Formula interface.
```r
boxplot(Ozone ~ Month, data = airquality)
wilcox.test(Ozone ~ Month, data = airquality,
            subset = Month %in% c(5, 8))
```

---

### Wilcoxon Distribution of the Wilcoxon Rank Sum Statistic

**Description**

Density, distribution function, quantile function and random generation for the distribution of the Wilcoxon rank sum statistic obtained from samples with size \( m \) and \( n \), respectively.

**Usage**

```r
dwilcoxon(x, m, n, log = FALSE)
pwilcoxon(q, m, n, lower.tail = TRUE, log.p = FALSE)
qwilcoxon(p, m, n, lower.tail = TRUE, log.p = FALSE)
rwilcoxon(nn, m, n)
```

**Arguments**

- \( x \), \( q \) : vector of quantiles.
p  vector of probabilities.

nn  number of observations. If length(nn) > 1, the length is taken to be the number required.

m, n  numbers of observations in the first and second sample, respectively. Can be vectors of positive integers.

log, log.p  logical; if TRUE, probabilities p are given as log(p).

lower.tail  logical; if TRUE (default), probabilities are $P[X \leq x]$, otherwise, $P[X > x]$.

Details

This distribution is obtained as follows. Let $x$ and $y$ be two random, independent samples of size $m$ and $n$. Then the Wilcoxon rank sum statistic is the number of all pairs $(x[i], y[j])$ for which $y[j]$ is not greater than $x[i]$. This statistic takes values between 0 and $m \times n$, and its mean and variance are $m \times n / 2$ and $m \times n \times (m + n + 1) / 12$, respectively.

If any of the first three arguments are vectors, the recycling rule is used to do the calculations for all combinations of the three up to the length of the longest vector.

Value
dwilcox gives the density, pwilcox gives the distribution function, qwilcox gives the quantile function, and rwilcox generates random deviates.

Warning

These functions can use large amounts of memory and stack (and even crash R if the stack limit is exceeded and stack-checking is not in place) if one sample is large (several thousands or more).

Note

S-PLUS uses a different (but equivalent) definition of the Wilcoxon statistic: see wilcox.test for details.

Author(s)

Kurt Hornik

Source

These are calculated via recursion, based on cwilcox(k, m, n), the number of choices with statistic $k$ from samples of size $m$ and $n$, which is itself calculated recursively and the results cached. Then dwilcox and pwilcox sum appropriate values of cwilcox, and qwilcox is based on inversion.

rwilcox generates a random permutation of ranks and evaluates the statistic.

See Also

wilcox.test to calculate the statistic from data, find p values and so on.
dsignrank etc, for the distribution of the one-sample Wilcoxon signed rank statistic.
Examples

```r
x <- -1:(4*6 + 1)
f <- dwilcox(x, 4, 6)
Fx <- pwilcox(x, 4, 6)
layout(rbind(1,2),width=1,heights=c(3,2))
plot(x, f, type='h', col='violet',
     main = 'Probabilities (density) of Wilcoxon-Statist.(n=6,m=4)')
plot(x, Fx, type='s', col='blue',
     main = 'Distribution of Wilcoxon-Statist.(n=6,m=4)')
abline(h=0:1, col='gray20',lty=2)
layout(1)# set back
N <- 200
hist(U <- rwilcox(N, m=4,n=6), breaks=0:25 - 1/2, border="red", col="pink",
    sub = paste("N =",N))
mtext("N * f(x), f() = true "density\"", side=3, col="blue")
lines(x, N*f, type='h', col='blue', lwd=2)
points(x, N*f, cex=2)
## Better is a Quantile-Quantile Plot
qqplot(U, qw <- qwilcox((1:N - 1/2)/N, m=4,n=6),
       main = paste("Q-Q-Plot of empirical and theoretical quantiles",
                   "Wilcoxon Statistic, (m=4, n=6)\n"))
n <- as.numeric(names(print(tU <- table(U))))
text(n+.2, n+.5, labels=tU, col="red")
```

Description

`window` is a generic function which extracts the subset of the object `x` observed between the times `start` and `end`. If a frequency is specified, the series is then re-sampled at the new frequency.

Usage

```r
window(x, ...)  
## S3 method for class 'ts':
window(x, ...)  
## Default S3 method:  
window(x, start = NULL, end = NULL,  
       frequency = NULL, deltat = NULL, extend = FALSE, ...)
```

```r
window(x, ...) <- value  
## S3 replacement method for class 'ts':  
window(x, start, end, frequency, deltat, ...) <- value
```

Arguments

- `x`  
  a time-series (or other object if not replacing values).
- `start`  
  the start time of the period of interest.
end the end time of the period of interest.
frequency, deltat
the new frequency can be specified by either (or both if they are consistent).
extend logical. If true, the start and end values are allowed to extend the series. If false, attempts to extend the series give a warning and are ignored.
...
value replacement values.

Details

The start and end times can be specified as for \texttt{ts}. If there is no observation at the new start or end, the immediately following (start) or preceding (end) observation time is used.

The replacement function has a method for \texttt{ts} objects, and is allowed to extend the series (with a warning). There is no default method.

Value

The value depends on the method. \texttt{window.default} will return a vector or matrix with an appropriate \texttt{tsp} attribute.

\texttt{window.ts} differs from \texttt{window.default} only in ensuring the result is a \texttt{ts} object.

If \texttt{extend} = \texttt{TRUE} the series will be padded with NAs if needed.

\texttt{time,ts}.

Examples

\begin{verbatim}
window(presidents, 1960, c(1969,4)) # values in the 1960's
window(presidents, deltat=1)   # All Qtr1s
window(presidents, start=c(1945,3), deltat=1) # All Qtr3s
window(presidents, 1944, c(1979,2), extend=TRUE)

pres <- window(presidents, 1945, c(1949,4)) # values in the 1940's
window(pres, 1945.25, 1945.50) <- c(60, 70)
window(pres, 1944, 1944.75) <- 0 # will generate a warning
window(pres, c(1945,4), c(1949,4), freq=1) <- 85:89
pres
\end{verbatim}
Description

Create a contingency table from cross-classifying factors, usually contained in a data frame, using a formula interface.

Usage

xtabs(formula = ~., data = parent.frame(), subset, na.action, exclude = c(NA, NaN), drop.unused.levels = FALSE)

Arguments

formula a formula object with the cross-classifying variables (separated by +) on the right hand side (or an object which can be coerced to a formula). Interactions are not allowed. On the left hand side, one may optionally give a vector or a matrix of counts; in the latter case, the columns are interpreted as corresponding to the levels of a variable. This is useful if the data have already been tabulated, see the examples below.

data an optional matrix or data frame (or similar: see model.frame) containing the variables in the formula formula. By default the variables are taken from environment(formula).

subset an optional vector specifying a subset of observations to be used.

na.action a function which indicates what should happen when the data contain NAs.

exclude a vector of values to be excluded when forming the set of levels of the classifying factors.

drop.unused.levels a logical indicating whether to drop unused levels in the classifying factors. If this is FALSE and there are unused levels, the table will contain zero marginals, and a subsequent chi-squared test for independence of the factors will not work.

Details

There is a summary method for contingency table objects created by table or xtabs, which gives basic information and performs a chi-squared test for independence of factors (note that the function chisq.test currently only handles 2-d tables).

If a left hand side is given in formula, its entries are simply summed over the cells corresponding to the right hand side; this also works if the lhs does not give counts.

Value

A contingency table in array representation of class c("xtabs", "table"), with a "call" attribute storing the matched call.

See Also

table for “traditional” cross-tabulation, and as.data.frame.table which is the inverse operation of xtabs (see the DF example below).
Examples

## 'esoph' has the frequencies of cases and controls for all levels of
## the variables 'agegp', 'alcgp', and 'tobgp'.
xtabs(cbind(ncases, ncontrols) ~ ., data = esoph)
## Output is not really helpful ... flat tables are better:
ftable(xtabs(cbind(ncases, ncontrols) ~ ., data = esoph))
## In particular if we have fewer factors ...
ftable(xtabs(cbind(ncases, ncontrols) ~ agegp, data = esoph))

## This is already a contingency table in array form.
DF <- as.data.frame(UCBAdmissions)
## Now 'DF' is a data frame with a grid of the factors and the counts
## in variable 'Freq'.
DF
## Nice for taking margins ...
xtabs(Freq ~ Gender + Admit, DF)
## And for testing independence ...
summary(xtabs(Freq ~ ., DF))

## Create a nice display for the warp break data.
warpbreaks$replicate <- rep(1:9, len = 54)
ftable(xtabs(breaks ~ wool + tension + replicate, data = warpbreaks))
Chapter 8

The tools package

tools-package  Tools for Package Development

**Description**
Tools for package development, administration and documentation

**Details**
This package contains tools for manipulating R packages and their documentation.
For a complete list of functions, use library(help="tools").

**Author(s)**
Kurt Hornik and Friedrich Leisch
Maintainer: R Core Team (R-core@r-project.org)

---

buildVignettes  List and Build Package Vignettes

**Description**
Run Sweave and texi2dvi on all vignettes of a package.

**Usage**
builtVignettes(package, dir, lib.loc = NULL, quiet = TRUE)
pkgVignettes(package, dir, lib.loc = NULL)
Arguments

package a character string naming an installed package. If given, Sweave files are searched in subdirectory doc.
dir a character string specifying the path to a package's root source directory. This subdirectory inst/doc is searched for Sweave files.
lib.loc a character vector of directory names of R libraries, or NULL. The default value of NULL corresponds to all libraries currently known. The specified library trees are used to to search for package.
quiet logical. Run Sweave and texi2dvi in quiet mode.

Value

buildVignettes is called for its side effect of creating the PDF versions of all vignettes.
pkgVignettes returns an object of class "pkgVignettes".

Description

charset_to_Unicode is a matrix of Unicode points with columns for the common 8-bit encodings.
Adobe_glyphs is a dataframe which gives Adobe glyph names for Unicode points. It has two character columns, "adobe" and "unicode" (a 4-digit hex representation).

Usage

charset_to_Unicode
Adobe_glyphs

Details

charset_to_Unicode is an integer matrix of class c("noquote", "noquote") so prints in hexadecimal. The mappings are those used by libiconv: there are differences in the way quotes and minus/hyphen are mapped between sources (and the postscript encoding files use a different mapping).
Adobe_glyphs include all the Adobe glyph names which correspond to single Unicode characters. It is sorted by Unicode point and within a point alphabetically on the glyph (there can be more than one name for a Unicode point). The data are in the file 'R_HOME/share/encodings/Adobe_glyphlist'.

Source

Examples

```r
## find Adobe names for ISOLatin2 chars.
latin2 <- charset_to_Unicode[, "ISOLatin2"]
aUnicode <- as.numeric(paste("0x", Adobe_glyphs$unicode, sep=""))
keep <- aUnicode %in% latin2
aUnicode <- aUnicode[keep]
aAdobe <- Adobe_glyphs[keep, 1]
## first match
aLatin2 <- aAdobe[match(latin2, aUnicode)]
## all matches
bLatin2 <- lapply(1:256, function(x) aAdobe[aUnicode == latin2[x]])
format(bLatin2, justify="none")
```

checkFF  
Check Foreign Function Calls

Description

Performs checks on calls to compiled code from R code. Currently only whether the interface functions such as `.C` and `.Fortran` are called with a "NativeSymbolInfo" first argument or with argument `PACKAGE` specified, which is highly recommended to avoid name clashes in foreign function calls.

Usage

```r
checkFF(package, dir, file, lib.loc = NULL, verbose = getOption("verbose"))
```

Arguments

- `package`: a character string naming an installed package. If given, the installed R code of the package is checked.
- `dir`: a character string specifying the path to a package’s root source directory. This should contain the subdirectory `R` (for R code). Only used if `package` is not given.
- `file`: the name of a file containing R code to be checked. Used if neither `package` nor `dir` are given.
- `lib.loc`: a character vector of directory names of R libraries, or NULL. The default value of NULL corresponds to all libraries currently known. The specified library trees are used to to search for `package`.
- `verbose`: a logical. If TRUE, additional diagnostics are printed (and the result is returned invisibly).

Details

Note that we can only check if the `name` argument is a symbol or a character string, not what class of object the symbol resolves to at run-time.

If the package has a namespace and if that contains a `useDynLib` directive, calls in top-level functions in the package are not reported as their symbols will be preferentially looked up in the DLL named in the first `useDynLib` directive.
An object of class "checkFF", which currently is a list of the (parsed) foreign function calls with a character first argument and no PACKAGE argument.

There is a print method to display the information contained in such objects.

This function is still experimental. Both name and interface might change in future versions.

checkMD5sums checks the files against a file MD5.

checkMD5sums(pkg, dir)

dir is missing, an installed package of name pkg is searched for.

The private function tools:::.installMD5sums is used to create MD5 files in the Windows build.

checkMD5sums returns a logical, NA if there is no MD5 file to be checked.

See Also

md5sum
checkTnF

Check R Packages or Code for T/F

Description

Checks the specified R package or code file for occurrences of `T` or `F`, and gathers the expression containing these. This is useful as in R `T` and `F` are just variables which are set to the logicals `TRUE` and `FALSE` by default, but are not reserved words and hence can be overwritten by the user. Hence, one should always use `TRUE` and `FALSE` for the logicals.

Usage

```r
checkTnF(package, dir, file, lib.loc = NULL)
```

Arguments

- `package`: a character string naming an installed package. If given, the installed R code and the examples in the documentation files of the package are checked. R code installed as an image file cannot be checked.
- `dir`: a character string specifying the path to a package’s root source directory. This must contain the subdirectory ‘R’ (for R code), and should also contain ‘man’ (for documentation). Only used if `package` is not given. If used, the R code files and the examples in the documentation files are checked.
- `file`: the name of a file containing R code to be checked. Used if neither `package` nor `dir` are given.
- `lib.loc`: a character vector of directory names of R libraries, or `NULL`. The default value of `NULL` corresponds to all libraries currently known. The specified library trees are used to search for `package`.

Value

An object of class "checkTnF" which is a list containing, for each file where occurrences of `T` or `F` were found, a list with the expressions containing these occurrences. The names of the list are the corresponding file names.

There is a `print` method for nicely displaying the information contained in such objects.

Warning

This function is still experimental. Both name and interface might change in future versions.
checkVignettes  Check Package Vignettes

Description

Check all Sweave files of a package by running Sweave and/or Stangle on them. All R source code files found after the tangling step are sourced to check whether all code can be executed without errors.

Usage

checkVignettes(package, dir, lib.loc = NULL, tangle = TRUE, weave = TRUE, workdir = c("tmp", "src", "cur"), keepfiles = FALSE)

Arguments

package a character string naming an installed package. If given, Sweave files are searched in subdirectory doc.
dir a character string specifying the path to a package's root source directory. This subdirectory inst/doc is searched for Sweave files.
lib.loc a character vector of directory names of R libraries, or NULL. The default value of NULL corresponds to all libraries currently known. The specified library trees are used to search for package.
tangle Perform a tangle and source the extracted code?
weave Perform a weave?
workdir Directory used as working directory while checking the vignettes. If "tmp" then a temporary directory is created, this is the default. If "src" then the directory containing the vignettes itself is used, if "cur" then the current working directory of R is used.
keepfiles Delete file in temporary directory? This option is ignored when workdir!="tmp".

Value

An object of class "checkVignettes" which is a list with the error messages found during the tangle and weave steps. There is a print method for nicely displaying the information contained in such objects.

codoc  Check Code/Documentation Consistency

Description

Find inconsistencies between actual and documented "structure" of R objects in a package. codoc compares names and optionally also corresponding positions and default values of the arguments of functions. codocClasses and codocData compare slot names of S4 classes and variable names of data sets, respectively.
Usage

codoc(package, dir, lib.loc = NULL,
      use.values = NULL, verbose = getOption("verbose"))
codocClasses(package, lib.loc = NULL)
codocData(package, lib.loc = NULL)

Arguments

package  a character string naming an installed package.
dir      a character string specifying the path to a package’s root source directory. This
         must contain the subdirectories ‘man’ with R documentation sources (in Rd
         format) and ‘R’ with R code. Only used if package is not given.
lib.loc  a character vector of directory names of R libraries, or NULL. The default value
         of NULL corresponds to all libraries currently known. The specified library trees
         are used to to search for package.
use.values if FALSE, do not use function default values when comparing code and docs.
         Otherwise, compare all default values if TRUE, and only the ones documented
         in the usage otherwise (default).
verbose  a logical. If TRUE, additional diagnostics are printed.

Details

The purpose of codoc is to check whether the documented usage of function objects agrees with
their formal arguments as defined in the R code. This is not always straightforward, in particular
as the usage information for methods to generic functions often employs the name of the generic
rather than the method.

The following algorithm is used. If an installed package is used, it is loaded (unless it is the base
package), after possibly detaching an already loaded version of the package. Otherwise, if the
sources are used, the R code files of the package are collected and sourced in a new environment.
Then, the usage sections of the Rd files are extracted and parsed “as much as possible” to give the
formals documented. For interpreted functions in the code environment, the formals are compared
between code and documentation according to the values of the argument use.values. Synopsis
sections are used if present; their occurrence is reported if verbose is true.

If a package has a name space both exported and unexported objects are checked, as well as regist-
ered S3 methods. (In the unlikely event of differences the order is exported objects in the package,
registered S3 methods and finally objects in the name space and only the first found is checked.)

Currently, the R documentation format has no high-level markup for the basic “structure” of classes
and data sets (similar to the usage sections for function synopses). Variable names for data frames
in documentation objects obtained by suitably editing “shells” created by prompt are recognized
by codocData and used provided that the documentation object is for a single data frame (i.e.,
only has one alias). codocClasses analogously handles slot names for classes in documentation
objects obtained by editing shells created by promptClass.

Help files named pkg_name-defunct.Rd for the appropriate pkg_name are checked more
loosely, as they may have undocumented arguments.

Value

codoc returns an object of class "codoc". Currently, this is a list which, for each Rd object in
the package where an inconsistency was found, contains an element with a list of the mismatches
(which in turn are lists with elements code and docs, giving the corresponding arguments obtained from the function’s code and documented usage).

codocClasses and codocData return objects of class "codocClasses" and "codocData", respectively, with a structure similar to class "codoc".

There are print methods for nicely displaying the information contained in such objects.

**Warning**

Both codocClasses and codocData are still experimental. Names, interfaces and values might change in future versions.

**Note**

The default for use.values has been changed from FALSE to NULL, for R versions 1.9.0 and later.

**See Also**

undoc, QC

delimMatch  

**Delimited Pattern Matching**

**Description**

Match delimited substrings in a character vector, with proper nesting.

**Usage**

delimMatch(x, delim = c("{", "}"), syntax = "Rd")

**Arguments**

- `x` a character vector.
- `delim` a character vector of length 2 giving the start and end delimiters. Future versions might allow for arbitrary regular expressions.
- `syntax` currently, always the string "Rd" indicating Rd syntax (i.e., '%' starts a comment extending till the end of the line, and '\' escapes). Future versions might know about other syntaxes, perhaps via "syntax tables" allowing to flexibly specify comment, escape, and quote characters.

**Value**

An integer vector of the same length as `x` giving the starting position (in characters) of the first match, or −1 if there is none, with attribute "match.length" giving the length (in characters) of the matched text (or −1 for no match).

**See Also**

regexp for “simple” pattern matching.
**Examples**

```r
x <- c("\value{foo}", "function(bar)")
delimMatch(x)
delimMatch(x, c("\", "))
```

---

**encoded_text_to_latex**

*Translate non-ASCII Text to \LaTeX\ Escapes*

**Description**

Translate non-ASCII characters in text to \LaTeX\ escape sequences.

**Usage**

```r
encoded_text_to_latex(x, encoding = c("latin1", "latin2", "latin9", "UTF-8", "utf8"))
```

**Arguments**

- `x`: a character vector.
- `encoding`: the encoding to be assumed. "latin9" officially ISO-8859-15 or Latin-9, but known as latin9 to \LaTeX\’s inputenc package.

**Details**

Non-ASCII characters in `x` are replaced by an appropriate \LaTeX\ escape sequence, or `?` if there is no appropriate sequence.

Even if there is an appropriate sequence, it may not be supported by the font in use. Hyphen is mapped to `-`.

**Value**

A character vector of the same length as `x`.

**See Also**

`iconv`

**Examples**

```r
x <- "fa\xE7ile"
encoded_text_to_latex(x, "latin1")
## Not run:
## create a tex file to show the upper half of 8-bit charsets
x <- rawToChar(as.raw(160:255), multiple=TRUE)
(x <- matrix(x, ncol=16, byrow=TRUE))
xx <- x
xx[] <- encoded_text_to_latex(x, "latin1") # or latin2 or latin9
xx <- apply(xx, 1, paste, collapse="\&")
con <- file("test-encoding.tex", "w")
```
header <- c(
  "\documentclass{article}",
  "\usepackage[T1]{fontenc}",
  "\usepackage{Rd}",
  "\begin{document}",
  "\HeaderA{test}{}{test}",
  "\begin{Details}\relax",
  "\Tabular{cccccccccccccccc}{")
trailer <- c("}, "\end{Details}"", "\end{document}")
writeLines(header, con)
writeLines(paste(xx, "\\", sep=""), con)
writeLines(trailer, con)
close(con)
## and some UTF_8 chars
x <- intToUtf8(as.integer(
  c(160:383,0x0192,0x02C6,0x02C7,0x02CA,0x02D8,
    0x02D9, 0x02DD, 0x200C, 0x2018, 0x2019, 0x201C,
    0x201D, 0x2020, 0x2022, 0x2026, 0x20AC)),
  multiple=TRUE)
x <- matrix(x, ncol=16, byrow=TRUE)
xx[] <- encoded_text_to_latex(x, "UTF-8")
xx[] <- apply(xx, 1, paste, collapse="\\")
con <- file("test-utf8.tex", "w")
writeLines(header, con)
writeLines(paste(xx, "\\", sep=""), con)
writeLines(trailer, con)
close(con)
## End(Not run)

---

### File Utilities

#### Description

Utilities for testing and listing files, and manipulating file paths.

#### Usage

```r
file_path_as_absolute(x)
file_path_sans_ext(x)
list_files_with_exts(dir, exts, all.files = FALSE, full.names = TRUE)
list_files_with_type(dir, type, all.files = FALSE, full.names = TRUE,
  OS_subdirs = .OStype())
```

#### Arguments

- **x** character vector giving file paths.
- **dir** a character string with the path name to a directory.
- **exts** a character vector of possible file extensions.
- **all.files** a logical. If FALSE (default), only visible files are considered; if TRUE, all files are used.
full.names  
a logical indicating whether the full paths of the files found are returned (default), or just the file names.

type  
a character string giving the “type” of the files to be listed, as characterized by their extensions. Currently, possible values are "code" (R code), "data" (data sets), "demo" (demos), "docs" (R documentation), and "vignette" (vignettes).

OS_subdirs  
a character vector with the names of OS-specific subdirectories to possibly include in the listing of R code and documentation files. By default, the value of the environment variable R_OS_TYPE, or if this is empty, the value of .Platform$OS.type, is used.

Details

file_path_as_absolute  
turns a possibly relative file path absolute, performing tilde expansion if necessary. Currently, only a single existing path can be given.

file_path_sans_ext  
returns the file paths without extensions. (Only purely alphanumeric extensions are recognized.)

list_files_with_exts  
returns the paths or names of the files in directory dir with extension matching one of the elements of exts. Note that by default, full paths are returned, and that only visible files are used.

list_files_with_type  
returns the paths of the files in dir of the given “type”, as determined by the extensions recognized by R. When listing R code and documentation files, files in OS-specific subdirectories are included if present according to the value of OS_subdirs. Note that by default, full paths are returned, and that only visible files are used.

See Also

file.path, file.info, list.files

Examples

dir <- file.path(R.home(), "library", "stats")
file_test("-d", dir)
file_test("-nt", file.path(dir, "R"), file.path(dir, "demo"))
list_files_with_exts(file.path(dir, "demo"), "R")
list_files_with_type(file.path(dir, "demo"), "demo") # the same
file_path_sans_ext(list.files(file.path(R.home(), "modules")))

getDepList  
Functions to Retrieve Dependency Information

Description

Given a dependency matrix, will create a DependsList object for that package which will include the dependencies for that matrix, which ones are installed, which unresolved dependencies were found online, which unresolved dependencies were not found online, and any R dependencies.
Usage

getDepList(depMtrx, instPkgs, recursive = TRUE, local = TRUE, reduce = TRUE, lib.loc = NULL)

pkgDepends(pkg, recursive = TRUE, local = TRUE, reduce = TRUE, lib.loc = NULL)

Arguments

depMtrx A dependency matrix as from package.dependencies
pkg The name of the package
instPkgs A matrix specifying all packages installed on the local system, as from installed.packages
recursive Whether or not to include indirect dependencies
local Whether or not to search only locally
reduce Whether or not to collapse all sets of dependencies to a minimal value
lib.loc What libraries to use when looking for installed packages. NULL indicates all library directories in the user's .libPaths().

Details

The function pkgDepends is a convenience function which wraps getDepList and takes as input a package name. It will then query installed.packages and also generate a dependency matrix, calling getDepList with this information and returning the result.

These functions will retrieve information about the dependencies of the matrix, resulting in a DependsList object. This is a list with four elements:

Depends A vector of the dependencies for this package.
Installed A vector of the dependencies which have been satisfied by the currently installed packages.
Found A list representing the dependencies which are not in Installed but were found online. This list has element names which are the URLs for the repositories in which packages were found and the elements themselves are vectors of package names which were found in the respective repositories. If local=TRUE, the Found element will always be empty.

R Any R version dependencies.

If recursive is TRUE, any package that is specified as a dependency will in turn have its dependencies included (and so on), these are known as indirect dependencies. If recursive is FALSE, only the dependencies directly stated by the package will be used.

If local is TRUE, the system will only look at the user's local install and not online to find unresolved dependencies.

If reduce is TRUE, the system will collapse the fields in the DependsList object such that a minimal set of dependencies are specified (for instance if there was ('foo', 'foo (>= 1.0.0)', 'foo (>= 1.3.0)'), it would only return 'foo (>= 1.3.0)').

Value

An object of class DependsList
installFoundDepends

Author(s)
Jeff Gentry

See Also
installFoundDepends

Examples

pkgDepends("tools", local = FALSE)

installFoundDepends

A function to install unresolved dependencies

Description
This function will take the Found element of a pkgDependsList object and attempt to install all of the listed packages from the specified repositories.

Usage

installFoundDepends(depPkgList, ...)

Arguments

depPkgList  A Found element from a pkgDependsList object
...

Arguments to pass on to install.packages

Details
This function takes as input the Found list from a pkgDependsList object. This list will have element names being URLs corresponding to repositories and the elements will be vectors of package names. For each element, install.packages is called for that URL to install all packages listed in the vector.

Author(s)
Jeff Gentry

See Also
pkgDepends, install.packages

Examples

## Set up a temporary directory to install packages to
tmp <- tempfile()
dir.create(tmp)

pDL <- pkgDepends("tools", local=FALSE)
installFoundDepends(pDL$Found, destdir=tmp)
**makeLazyLoading**  
*Lazy Loading of Packages*

**Description**
Tools for Lazy Loading of Packages from a Database.

**Usage**
```
makeLazyLoading(package, lib.loc = NULL, compress = TRUE,
                keep.source = getOption("keep.source.pkgs"))
```

**Arguments**
- **package**  
  package name string
- **lib.loc**  
  library trees, as in `library`
- **keep.source**  
  logical; should sources be kept when saving from source
- **compress**  
  logical; whether to compress entries on the database.

**Details**
A tool to set up packages for lazy loading from a database. For packages other than base you can use `makeLazyLoading(package)` to convert them to use lazy loading.

**Author(s)**
Luke Tierney and Brian Ripley

**Examples**
```
# set up package "splines" for lazy loading -- already done
## Not run:
  tools::.makeLazyLoading("splines")

## End(Not run)
```

---

**md5sum**  
*Compute MD5 Checksums*

**Description**
Compute the 32-byte MD5 checksums of one or more files.

**Usage**
```
md5sum(files)
```

**Arguments**
- **files**  
  character. The paths of file(s) to be check-summed.
Value

A character vector of the same length as files, with names equal to files. The elements will be NA for non-existent or unreadable files, otherwise a 32-character string of hexadecimal digits.

On Windows all files are read in binary mode (as the md5sum utilities there do): on other OSes the files are read in the default way.

See Also

checkMD5sums

Examples

md5sum(dir(R.home(), pattern="^COPY", full.names=TRUE))
QC Checks for R Code and/or Documentation

Description

Functions for performing various quality checks.

Usage

checkDocFiles(package, dir, lib.loc = NULL)
checkDocStyle(package, dir, lib.loc = NULL)
checkReplaceFuns(package, dir, lib.loc = NULL)
checkS3methods(package, dir, lib.loc = NULL)

Arguments

package a character string naming an installed package.
dir a character string specifying the path to a package’s root source directory. This should contain the subdirectories R (for R code) and ‘man’ with R documentation sources (in Rd format). Only used if package is not given.
lib.loc a character vector of directory names of R libraries, or NULL. The default value of NULL corresponds to all libraries currently known. The specified library trees are used to to search for package.

Details

checkDocFiles checks, for all Rd files in a package, whether all arguments shown in the usage sections of the Rd file are documented in its arguments section. It also reports duplicated entries in the arguments section, and “over-documented” arguments which are given in the arguments section but not in the usage. Note that the match is for the usage section and not a possibly existing synopsis section, as the usage is what gets displayed.

checkDocStyle investigates how (S3) methods are shown in the usages of the Rd files in a package. It reports the methods shown by their full name rather than using the Rd \method markup for indicating S3 methods. Earlier versions of R also reported about methods shown along with their generic, which typically caused problems for the documentation of the primary argument in the generic and its methods. With \method now being expanded in a way that class information is preserved, “joint” documentation is no longer necessarily a problem. (The corresponding information is still contained in the object returned by checkDocStyle.)

checkReplaceFuns checks whether replacement functions or S3/S4 replacement methods in the package R code have their final argument named value.

checkS3methods checks whether all S3 methods defined in the package R code have all arguments of the corresponding generic, with positional arguments of the generics in the same positions for the method. As an exception, the first argument of a formula method may be called formula even if this is not the name used by the generic. The rules when \ldots is involved are subtle: see the source code. Functions recognized as S3 generics are those with a call to UseMethod in their body, internal S3 generics (see InternalMethods), and S3 group generics (see Math). Possible dispatch under a different name is not taken into account. The generics are sought first in the given package, then in the base package and (currently) the packages graphics, stats, and utils added in R 1.9.0 by splitting the former base, and, if an installed package is tested, also in the loaded namespaces/packages listed in the package’s ‘DESCRIPTION’ Depends field.
Rdindex

1319

If using an installed package, the checks needing access to all R objects of the package will load
the package (unless it is the base package), after possibly detaching an already loaded version of
the package.
Value
The functions return objects of class the same as the respective function names containing the information about problems detected. There is a print method for nicely displaying the information
contained in such objects.
Warning
These functions are still experimental. Names, interfaces and values might change in future versions.

Rdindex

Generate Index from Rd Files

Description
Print a 2-column index table with “names” and titles from given R documentation files to a given
output file or connection. The titles are nicely formatted between two column positions (typically
25 and 72, respectively).
Usage
Rdindex(RdFiles, outFile = "", type = NULL,
width = 0.9 * getOption("width"), indent = NULL)
Arguments
RdFiles

a character vector specifying the Rd files to be used for creating the index, either
by giving the paths to the files, or the path to a single directory with the sources
of a package.

outFile

a connection, or a character string naming the output file to print to. "" (the
default) indicates output is to the console.

type

a character string giving the documentation type of the Rd files to be included
in the index, or NULL (the default). The type of an Rd file is typically specified
via the \docType tag; if type is "data", Rd files whose only keyword is
datasets are included as well.

width

a positive integer giving the target column for wrapping lines in the output.

indent

a positive integer specifying the indentation of the second column. Must not be
greater than width/2, and defaults to width/3.

Details
If a name is not a valid alias, the first alias (or the empty string if there is none) is used instead.


Rdutils  

Rd Utilities

Description

Utilities for computing on the information in Rd objects.

Usage

\texttt{Rd_db(package, dir, lib.loc = NULL)}
\texttt{Rd_parse(file, text = NULL)}

Arguments

\begin{itemize}
\item \texttt{package} a character string naming an installed package.
\item \texttt{dir} a character string specifying the path to a package’s root source directory. This should contain the subdirectory ‘\texttt{man}’ with \texttt{R} documentation sources (in Rd format). Only used if \texttt{package} is not given.
\item \texttt{lib.loc} a character vector of directory names of \texttt{R} libraries, or \texttt{NULL}. The default value of \texttt{NULL} corresponds to all libraries currently known. The specified library trees are used to to search for \texttt{package}.
\item \texttt{file} a connection, or a character string giving the name of a file or a URL to read documentation in Rd format from.
\item \texttt{text} character vector with documentation in Rd format. Elements are treated as if they were lines of a file.
\end{itemize}

Details

\texttt{Rd_db} builds a simple “data base” of all Rd sources in a package, as a list of character vectors with the lines of the Rd files in the package. This is particularly useful for working on installed packages, where the individual Rd files in the sources are no longer available.

\texttt{Rd_parse} is a simple top-level Rd parser/analyzer. It returns a list with components

\begin{description}
\item[meta] a list containing the Rd metadata (aliases, concepts, keywords, and documentation type);
\item[data] a data frame with the names (\texttt{tags}) and corresponding text (\texttt{vals}) of the top-level sections in the \texttt{R} documentation object;
\item[rest] top-level text not accounted for (currently, silently discarded by Rdconv, and hence usually the indication of a problem).
\end{description}

Note that at least for the time being, only the top-level structure is analyzed.

Warning

These functions are still experimental. Names, interfaces and values might change in future versions.
## Examples

```r
## Build the Rd db for the (installed) base package.
db <- Rd_db("base")
## Run Rd_parse on all entries in the Rd db.
db <- lapply(db, function(txt) Rd_parse(text = txt))
## Extract the metadata.
meta <- lapply(db, "[[", "meta")
## Keyword metadata per Rd file.
keywords <- lapply(meta, "[[", "keywords")
## Tabulate the keyword entries.
kw_table <- sort(table(unlist(keywords)))
## The 5 most frequent ones:
rev(kw_table)[1:5]
## The "most informative" ones:
kw_table[kw_table == 1]
## Concept metadata per Rd file.
concepts <- lapply(meta, "[[", "concepts")
## How many files already have \concept metadata?
sum(sapply(concepts, length) > 0)
## How many concept entries altogether?
length(unlist(concepts))
```

---

### read.00Index

**Read 00Index-style Files**

**Description**

Read item/description information from 00Index-style files. Such files are description lists rendered in tabular form, and currently used for the ‘INDEX’ and ‘demo/00Index’ files of add-on packages.

**Usage**

```r
read.00Index(file)
```

**Arguments**

- `file` the name of a file to read data values from. If the specified file is ",", then input is taken from the keyboard (in this case input can be terminated by a blank line). Alternatively, `file` can be a `connection`, which will be opened if necessary, and if so closed at the end of the function call.

**Value**

a character matrix with 2 columns named "Item" and "Description" which hold the items and descriptions.

**See Also**

`formatDL` for the inverse operation of creating a 00Index-style file from items and their descriptions.
texi2dvi  Compile LaTeX Files

Description

Run latex and bibtex until all cross-references are resolved and create either a dvi or PDF file.

Usage

texi2dvi(file, pdf = FALSE, clean = FALSE, quiet = TRUE, 
texi2dvi = getOption("texi2dvi"))

Arguments

file  character. Name of TeX source file.
pdf  logical. If TRUE, a PDF file is produced instead of the default dvi file (texi2dvi command line option '--pdf').
clean  logical. If TRUE, all auxiliary files are removed (texi2dvi command line option '--clean'). Does not work on some platforms.
quiet  logical. No output unless an error occurs.
texi2dvi  character (or NULL). Script or program used to compile a TeX file to dvi or PDF, respectively. If set to NULL, the 'texi2dvi' script in R's 'bin' directory is used (if it exists), otherwise it is assumed that texi2dvi is in the search path.

Details

Some TeX installations do not have 'texi2dvi.exe'. If 'texify.exe' is present, then it can be used instead: set options(texi2dvi="texify.exe") or to the full path of the program.

Author(s)

Achim Zeileis

tools-deprecated  Deprecated Objects in Package tools

Description

The functions or variables listed here are provided for compatibility with older versions of R only, and may be defunct as soon as of the next release.

Usage

See Also

Deprecated, Defunct
Find Undocumented Objects

Description

Finds the objects in a package which are undocumented, in the sense that they are visible to the user (or data objects or S4 classes provided by the package), but no documentation entry exists.

Usage

undoc(package, dir, lib.loc = NULL)

Arguments

package a character string naming an installed package.
dir a character string specifying the path to a package’s root source directory. This must contain the subdirectory ‘man’ with R documentation sources (in Rd format), and at least one of the ‘R’ or ‘data’ subdirectories with R code or data objects, respectively.
lib.loc a character vector of directory names of R libraries, or NULL. The default value of NULL corresponds to all libraries currently known. The specified library trees are used to search for package.

Details

This function is useful for package maintainers mostly. In principle, all user level R objects should be documented; note however that the precise rules for documenting methods of generic functions are still under discussion.

The base package is special as it contains the primitives and these do not have definitions available at code level. We provide equivalent closures in environments .ArgsEnv and .GenericArgsEnv in the base package that are used for various purposes: undoc("base") checks that that all the primitive that are not language constructs are prototyped in those environments and no others.

Value

An object of class "undoc" which is a list of character vectors containing the names of the undocumented objects split according to documentation type. This representation is still experimental, and might change in future versions.

There is a print method for nicely displaying the information contained in such objects.

See Also

codoc, QC

Examples

undoc("tools") # Undocumented objects in 'tools'
vignetteDepends  Retrieve Dependency Information for a Vignette

Description

Given a vignette name, will create a DependsList object that reports information about the packages the vignette depends on.

Usage

vignetteDepends(vignette, recursive = TRUE, reduce = TRUE,
local = TRUE, lib.loc = NULL)

Arguments

vignette  The path to the vignette source
recursive  Whether or not to include indirect dependencies
reduce    Whether or not to collapse all sets of dependencies to a minimal value
local     Whether or not to search only locally
lib.loc   What libraries to search in locally

Details

If recursive is TRUE, any package that is specified as a dependency will in turn have its dependencies included (and so on), these are known as indirect dependencies. If recursive is FALSE, only the dependencies directly named by the vignette will be used.

If local is TRUE, the system will only look at the user’s local machine and not online to find dependencies.

If reduce is TRUE, the system will collapse the fields in the DependsList to the minimal set of dependencies (for instance if the dependencies were ’foo’, ’foo (>= 1.0.0)’, ’foo (>= 1.3.0)’), the return value would be ’foo (>= 1.3.0)’).

Value

An object of class DependsList

pkgDepends

Examples

gridEx <- system.file("doc", "grid.Snw", package = "grid")
vignetteDepends(gridEx)
### write_PACKAGES

**Generate PACKAGES files**

#### Description

Generate ‘PACKAGES’ and ‘PACKAGES.gz’ files for a repository of source or Mac/Windows binary packages.

#### Usage

```r
write_PACKAGES(dir, fields = NULL,
               type = c("source", "mac.binary", "win.binary"),
               verbose = FALSE, unpacked = FALSE)
```

#### Arguments

- `dir`  
  Character vector describing the location of the repository (directory including source or binary packages) to generate the ‘PACKAGES’ and ‘PACKAGES.gz’ files from and write them to.

- `fields`  
  A character vector giving the fields to be used in the ‘PACKAGES’ and ‘PACKAGES.gz’ files in addition to the default ones, or `NULL` (default). The default corresponds to the fields needed by `available.packages`: “Package”, “Bundle”, “Priority”, “Version”, “Depends”, “Suggests”, “Imports” and “Contains”.

- `type`  
  Type of packages: currently source `.tar.gz` archives, and Mac or Windows binary (`.tgz` or `.zip`, respectively) packages are supported. Defaults to "win.binary" on Windows and to "source" otherwise.

- `verbose`  
  Logical. Should packages be listed as they are processed?

- `unpacked`  
  A logical indicating whether the package contents are available in unpacked form or not (default).

#### Details

- `type = "win.binary"` uses `unz` connections to read all ‘DESCRIPTION’ files contained in the (zipped) binary packages for Windows in the given directory `dir`, and builds ‘PACKAGES’ and ‘PACKAGES.gz’ files from these information.

#### Value

Invisibly returns the number of packages described in the resulting ‘PACKAGES’ and ‘PACKAGES.gz’ files. If 0, no packages were found and no files were written.

#### Note

Processing `.tar.gz` archives to extract the ‘DESCRIPTION’ files is quite slow.

This function can be useful on other OSes to prepare a repository to be accessed by Windows machines, so `type = "win.binary"` should work on all OSes.

#### Author(s)

Uwe Ligges and R-core.
See Also

See `read.dcf` and `write.dcf` for reading ‘DESCRIPTION’ files and writing the ‘PACKAGES’ and ‘PACKAGES.gz’ files.

Examples

```r
## Not run:
write_PACKAGES("c:/myFolder/myRepository")  # on Windows
write_PACKAGES("/pub/RWin/bin/windows/contrib/2.1",
  type="win.binary")  # on Linux
## End(Not run)
```

---

**xgettext**

*Extract Translatable Messages from R Files in a Package*

**Description**

For each file in the ‘R’ directory (including system-specific subdirectories) of a package, extract the unique arguments passed to `stop`, `warning`, `message`, `gettext` and `gettextf`, or to `ngettext`.

**Usage**

```r
xgettext(dir, verbose = FALSE, asCall = TRUE)

xngettext(dir, verbose = FALSE)

xgettext2pot(dir, potFile)
```

**Arguments**

- `dir`  
  the directory of a source package.

- `verbose`  
  logical: should each file be listed as it is processed?

- `asCall`  
  logical: if TRUE each argument is returned whole, otherwise the strings within each argument are extracted.

- `potFile`  
  name of po template file to be produced. Defaults to "R-pkg.pot" where pkg is the basename of dir.

**Details**

Leading and trailing white space (space, tab and linefeed) is removed for calls to `gettext`, `gettextf`, `stop`, `warning`, and `message`, as it is by the internal code that passes strings for translation.

We look to see if these functions were called with `domain = NA` and if so omit the call if `asCall = TRUE`: note that the call might contain a call to `gettext` which would be visible if `asCall = FALSE`.

`xgettext2pot` calls `xgettext` and then `xngettext`, and writes a PO template file for use with the GNU Gettext tools. This ensures that the strings for simple translation are unique in the file (as GNU Gettext requires), but does not do so for `ngettext` calls (and the rules are not stated in the Gettext manual).

If applied to the `base` package, this also looks in the `.R files in ‘R_HOME/share/R’.
Value

For \texttt{xgettext}, a list of objects of class "\texttt{xgettext}" (which has a \texttt{print} method), one per source file that potentially contains translatable strings.

For \texttt{xngettext}, a list of objects of class "\texttt{xngettext}" which are themselves lists of length-2 character strings.

Examples

```r
## Not run:
## in a source-directory build of R:
xgettext(file.path(R.home(), "src", "library", "splines"))
## End(Not run)
```
Chapter 9

The utils package

utils-package  The R Utils Package

Description
R utility functions

Details
This package contains a collection of utility functions.
For a complete list, use library(help="utils").

Author(s)
R Development Core Team and contributors worldwide
Maintainer: R Core Team (R-core@r-project.org)

alarm  Alert the user

Description
Gives an audible or visual signal to the user.

Usage
alarm()

Details
alarm() works by sending a "\a" character to the console. On most platforms this will ring a bell, beep, or give some other signal to the user (unless standard output has been redirected).
apropos

Value

No useful value is returned.

Examples

```r
alarm()
```

---

Find Objects by (Partial) Name

**Description**

`apropos()` returns a character vector giving the names of all objects in the search list matching `what`.

`find()` is a different user interface to the same task.

**Usage**

```r
apropos(what, where = FALSE, ignore.case = TRUE, mode = "any")
find(what, mode = "any", numeric. = FALSE, simple.words = TRUE)
```

**Arguments**

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>what</code></td>
<td>character string with name of an object, or more generally a regular expression to match against.</td>
</tr>
<tr>
<td><code>where</code>, <code>numeric.</code></td>
<td>a logical indicating whether positions in the search list should also be returned</td>
</tr>
<tr>
<td><code>ignore.case</code></td>
<td>logical indicating if the search should be case-insensitive, TRUE by default. Note that in R versions prior to 2.5.0, the default was implicitly <code>ignore.case = FALSE</code>.</td>
</tr>
<tr>
<td><code>mode</code></td>
<td>character; if not &quot;any&quot;, only objects whose mode equals mode are searched.</td>
</tr>
<tr>
<td><code>simple.words</code></td>
<td>logical; if TRUE, the what argument is only searched as whole word.</td>
</tr>
</tbody>
</table>

**Details**

If `mode != "any"` only those objects which are of mode `mode` are considered. If `where` is TRUE, the positions in the search list are returned as the names attribute.

`find` is a different user interface for the same task as `apropos`. However, by default (`simple.words == TRUE`), only full words are searched with `grep(fixed = TRUE)`.

Note that in R versions prior to 2.5.0, `what` was allowed to be non-character, such that `find(cor)` worked as it does in S. This possibility has been dropped in line with the aim of minimizing all use of non-standard evaluation in R.

**Author(s)**

Kurt Hornik and Martin Maechler (May 1997).
See Also

- `glob2rx` to convert wildcard patterns to regular expressions.
- `objects` for listing objects from one place, `help.search` for searching the help system, `search` for the search path.

Examples

```r
## Not run: apropos("lm")
apropos("GLM") # more than a dozen
apropos("GLM", ignore.case = FALSE) # not one
apropos("1q")

cor <- 1:pi
find("cor") #> ".GlobalEnv"  "package:stats"
find("cor", num=TRUE) # numbers with these names
find("cor", num=TRUE, mode="function")# only the second one
rm(cor)

## Not run: apropos(".*", mode="list") # a long list

# need a DOUBLE backslash '\' (in case you don't see it anymore)
apropos("\\[")

## Not run: # everything
length(apropos("."))

# those starting with 'pr'
apropos("^pr")

# the 1-letter things
apropos("^.\$")

# the 1-2-letter things
apropos("^.\?\$")

# the 2-to-4 letter things
apropos("^.\{2,4}\$")

# the 8-and-more letter things
apropos("^.\{8,}\$")
table(nchar(apropos("^.\{8,}\$")))

## End(Not run)
```

Batch Execution of R

Description

Run R non-interactively with input from `infile` and send output (stdout/stderr) to another file.

Usage

```
R CMD BATCH [options] infile [outfile]
```
**Arguments**

infile  
the name of a file with R code to be executed.

options  
a list of R command line options, e.g., for setting the amount of memory available and controlling the load/save process. If infile starts with a '-', use '--' as the final option. The default options are '--restore --save --no-readline'.

outfile  
the name of a file to which to write output. If not given, the name used is that of infile, with a possible '.R' extension stripped, and '.Rout' appended.

**Details**

Use R CMD BATCH --help to be reminded of the usage.

By default, the input commands are printed along with the output. To suppress this behavior, add options(echo = FALSE) at the beginning of infile, or use option '--slave'.

The infile can have end of line marked by LF or CRLF (but not just CR), and files with an incomplete last line (missing end of line (EOL) mark) are processed correctly.

A final expression `proc.time()` will be executed after the input script unless the latter calls q(runLast=FALSE) or is aborted.

Additional options can be set by the environment variable R_BATCH_OPTIONS: these come after '--restore --save --no-readline' and before any options given on the command line.

**Note**

Unlike Splus BATCH, this does not run the R process in the background. In most shells, R CMD BATCH [options] infile [outfile] & will do so.

Report bugs to ⟨r-bugs@r-project.org⟩.

---

**browseEnv**  
**Browse Objects in Environment**

**Description**

The browseEnv function opens a browser with list of objects currently in `sys.frame()` environment.

**Usage**

```r
browseEnv(envir = .GlobalEnv, pattern,
          excludepatt = "^last\.\.warning",
          html = .Platform$OS.type != "mac",
          expanded = TRUE, properties = NULL,
          main = NULL, debugMe = FALSE)
```
**browseEnv**

**Arguments**

- **envir**: an *environment* the objects of which are to be browsed.
- **pattern**: a *regular expression* for object subselection is passed to the internal `ls()` call.
- **excludepatt**: a regular expression for *dropping* objects with matching names.
- **html**: is used on non Macintosh objects to display the workspace on a HTML page in your favorite browser.
- **expanded**: whether to show one level of recursion. It can be useful to switch it to `FALSE` if your workspace is large. This option is ignored if `html` is set to `FALSE`.
- **properties**: a named list of global properties (of the objects chosen) to be showed in the browser; when `NULL` (as per default), user, date, and machine information is used.
- **main**: a title string to be used in the browser; when `NULL` (as per default) a title is constructed.
- **debugMe**: logical switch; if true, some diagnostic output is produced.

**Details**

Very experimental code. Only allows one level of recursion into object structures. The HTML version is not dynamic.

It can be generalized. See sources (`'../library/base/R/databrowser.R`”) for details.

`wsbrowser()` is currently just an internally used function; its argument list will certainly change. Most probably, this should rather work through using the ‘tkWidget’ package (from www.Bioconductor.org).

**See Also**

`str`, `ls`.

**Examples**

```r
if(interactive()) {
  ## create some interesting objects:
ofa <- ordered(4:1)
ex1 <- expression(1+ 0:9)
ex3 <- expression(u,v, 1+ 0:9)
example(factor, echo = FALSE)
example(table, echo = FALSE)
example(ftable, echo = FALSE)
example(lm, echo = FALSE, ask = FALSE)
example(str, echo = FALSE)

  ## and browse them:
browseEnv()

  ## a (simple) function's environment:
  af12 <- approxfun(1:2, 1:2, method = "const")
browseEnv(envir = environment(af12))
}
```
browseURL  

Load URL into a WWW Browser

Description

Load a given URL into a WWW browser.

Usage

browseURL(url, browser = getOption("browser"))

Arguments

url a non-empty character string giving the URL to be loaded.

browser a non-empty character string giving the name of the program to be used as hypertext browser. It should be in the PATH, or a full path specified.

Details

The default browser is set by option "browser", in turn set by the environment variable R_BROWSER which is by default set in file 'R_HOME/etc/renviron' to a choice made manually or automatically when R was configured. (See Startup for where to override that default value.)

If browser supports remote control and R knows how to perform it, the URL is opened in any already running browser or a new one if necessary. This mechanism currently is available for browsers which support the "-remote openURL(...)" interface (which includes Netscape 4.x, 6.2.x (but not 6.0/1), 7.1, Opera 5/6, Mozilla >= 0.9.5 and Mozilla Firefox), Galeon, KDE konqueror (via kfmclient) and the GNOME interface to Mozilla. Netscape 7.0 and Opera 7 behave slightly differently, and you will need to open them first. Note that the type of browser is determined from its name, so this mechanism will only be used if the browser is installed under its canonical name.

Because "-remote" will use any browser displaying on the X server (whatever machine it is running on), the remote control mechanism is only used if DISPLAY points to the local host. This may not allow displaying more than one URL at a time from a remote host.

It is the caller’s responsibility to encode url if necessary (see URLencode). This can be tricky for file URLs, where the format accepted can depend on the browser and OS.

Examples

## Not run:
## for KDE users who want to open files in a new tab
option(browser="kfmclient newTab")
browseURL("http://www.r-project.org")
## End(Not run)
Description

Invokes an editor to write a bug report and optionally mail it to the automated r-bugs repository at ⟨r-bugs@r-project.org⟩. Some standard information on the current version and configuration of R are included automatically.

Usage

```r
bug.report(subject = "",
            ccaddress = Sys.getenv("USER"),
            method = getOption("mailer"),
            address = "r-bugs@r-project.org",
            file = "R.bug.report")
```

Arguments

- `subject`: Subject of the email. Please do not use single quotes (’’) in the subject! File separate bug reports for multiple bugs.
- `ccaddress`: Optional email address for copies (default is current user). Use `ccaddress = FALSE` for no copies.
- `method`: Submission method, one of "mailx", "gnudoit", "none", or "ess".
- `address`: Recipient’s email address.
- `file`: File to use for setting up the email (or storing it when method is "none" or sending mail fails).

Details

Currently direct submission of bug reports works only on Unix systems. If the submission method is "mailx", then the default editor is used to write the bug report. Which editor is used can be controlled using `options`. Type `getOption("editor")` to see what editor is currently defined. Please use the help pages of the respective editor for details of usage. After saving the bug report (in the temporary file opened) and exiting the editor the report is mailed using a Unix command line mail utility such as `mailx`. A copy of the mail is sent to the current user.

If method is "gnudoit", then an emacs mail buffer is opened and used for sending the email.

If method is "none" or NULL (and in every case on Windows systems), then only an editor is opened to help writing the bug report. The report can then be copied to your favorite email program and be sent to the r-bugs list.

If method is "ess" the body of the mail is simply sent to stdout.

Value

Nothing useful.
When is there a bug?

If \( R \) executes an illegal instruction, or dies with an operating system error message that indicates a problem in the program (as opposed to something like “disk full”), then it is certainly a bug.

Taking forever to complete a command can be a bug, but you must make certain that it was really \( R \)’s fault. Some commands simply take a long time. If the input was such that you KNOW it should have been processed quickly, report a bug. If you don’t know whether the command should take a long time, find out by looking in the manual or by asking for assistance.

If a command you are familiar with causes an \( R \) error message in a case where its usual definition ought to be reasonable, it is probably a bug. If a command does the wrong thing, that is a bug. But be sure you know for certain what it ought to have done. If you aren’t familiar with the command, or don’t know for certain how the command is supposed to work, then it might actually be working right. Rather than jumping to conclusions, show the problem to someone who knows for certain.

Finally, a command’s intended definition may not be best for statistical analysis. This is a very important sort of problem, but it is also a matter of judgement. Also, it is easy to come to such a conclusion out of ignorance of some of the existing features. It is probably best not to complain about such a problem until you have checked the documentation in the usual ways, feel confident that you understand it, and know for certain that what you want is not available. The mailing list r-devel@r-project.org is a better place for discussions of this sort than the bug list.

If you are not sure what the command is supposed to do after a careful reading of the manual this indicates a bug in the manual. The manual’s job is to make everything clear. It is just as important to report documentation bugs as program bugs.

If the online argument list of a function disagrees with the manual, one of them must be wrong, so report the bug.

How to report a bug

When you decide that there is a bug, it is important to report it and to report it in a way which is useful. What is most useful is an exact description of what commands you type, from when you start \( R \) until the problem happens. Always include the version of \( R \), machine, and operating system that you are using; type \texttt{version} in \( R \) to print this. To help us keep track of which bugs have been fixed and which are still open please send a separate report for each bug.

The most important principle in reporting a bug is to report FACTS, not hypotheses or categorizations. It is always easier to report the facts, but people seem to prefer to strain to posit explanations and report them instead. If the explanations are based on guesses about how \( R \) is implemented, they will be useless; we will have to try to figure out what the facts must have been to lead to such speculations. Sometimes this is impossible. But in any case, it is unnecessary work for us.

For example, suppose that on a data set which you know to be quite large the command \texttt{data.frame(x, y, z, monday, tuesday)} never returns. Do not report that \texttt{data.frame()} fails for large data sets. Perhaps it fails when a variable name is a day of the week. If this is so then when we got your report we would try out the \texttt{data.frame()} command on a large data set, probably with no day of the week variable name, and not see any problem. There is no way in the world that we could guess that we should try a day of the week variable name.

Or perhaps the command fails because the last command you used was a \texttt{method} that had a bug causing \( R \)’s internal data structures to be corrupted and making the \texttt{data.frame()} command fail from then on. This is why we need to know what other commands you have typed (or read from your startup file).

It is very useful to try and find simple examples that produce apparently the same bug, and somewhat useful to find simple examples that might be expected to produce the bug but actually do not. If you want to debug the problem and find exactly what caused it, that is wonderful. You should still report the facts as well as any explanations or solutions.
Invoking R with the \texttt{--vanilla} option may help in isolating a bug. This ensures that the site profile and saved data files are not read.

A bug report can be generated using the \texttt{bug.report()} function. This automatically includes the version information and sends the bug to the correct address. Alternatively the bug report can be emailed to \texttt{(r-bugs@r-project.org)} or submitted to the Web page at \url{http://bugs.r-project.org}.

Bug reports on \textbf{contributed packages} should be sent to the package maintainer rather than to r-bugs.

\textbf{Author(s)}

This help page is adapted from the Emacs manual and the R FAQ

\textbf{See Also}

R FAQ, also \texttt{sessionInfo()} from which you may add to the bug report.

capture.output \texttt{Send output to a character string or file}

description

Evaluates its arguments with the output being returned as a character string or sent to a file. Related to \texttt{sink} in the same way that \texttt{with} is related to \texttt{attach}.

Usage

capture.output(..., file = NULL, append = FALSE)

Arguments

\begin{verbatim}
... Expressions to be evaluated
file A file name or a connection, or NULL to return the output as a string. If the
connection is not open it will be opened and then closed on exit.
append Append or overwrite the file?
\end{verbatim}

Value

A character string, or NULL if a file argument was supplied.

\textbf{See Also}

\texttt{sink}, \texttt{textConnection}
Examples

```r
require(stats)
glm.out <- capture.output(example(glm))
glm.out[1:5]
capture.output(1+1, 2+2)
capture.output((1+1; 2+2))
```

```r
## Not run:
## on Unix with enscript available
ps <- pipe("enscript -o tempout.ps","w")
capture.output(example(glm), file=ps)
close(ps)
## End(Not run)
```

chooseCRANmirror  Select a CRAN Mirror

Description

Interact with the user to choose a CRAN mirror.

Usage

```r
chooseCRANmirror(graphics = getOption("menu.graphics"))
```

Arguments

- `graphics` Logical. If true and `tcltk` and an X server are available, use a Tk widget, or if under the AQUA interface use a MacOS X widget, otherwise use `menu`.

Details

A list of mirrors is stored in file `R_HOME/doc/CRAN_mirrors.csv`, but first an on-line list of current mirrors is consulted, and the file copy used only if the on-line list is inaccessible.

This function was originally written to support a Windows GUI menu item, but is also called by `contrib.url` if it finds the initial dummy value of `options("repos")`.

Value

None. This function is invoked for its side effect of updating `options("repos")`

See Also

`setRepositories`, `contrib.url`
Description

How to cite R and R packages in publications.

Usage

citation(package = "base", lib.loc = NULL)
## S3 method for class 'citation':
toBibtex(object, ...)
## S3 method for class 'citationList':
toBibtex(object, ...)

Arguments

package a character string with the name of a single package. An error occurs if more
than one package name is given.
lib.loc a character vector with path names of R libraries, or NULL. The default value
of NULL corresponds to all libraries currently known. If the default is used, the
loaded packages are searched before the libraries.
object return object of citation.
... currently not used.

Details

The R core development team and the very active community of package authors have invested a
lot of time and effort in creating R as it is today. Please give credit where credit is due and cite R
and R packages when you use them for data anlysis.

Execute function citation() for information on how to cite the base R system in publications.
If the name of a non-base package is given, the function either returns the information contained
in the CITATION file of the package or auto-generates citation information. In the latter case the
package ‘DESCRIPTION’ file is parsed, the resulting citation object may be arbitrarily bad, but is
quite useful (at least as a starting point) in most cases.

If only one reference is given, the print method shows both a text version and a BibTeX entry for
it, if a package has more than one reference then only the text versions are shown. The BibTeX
versions can be obtained using function toBibtex (see the examples below).

Value

An object of class "citationList".

See Also

citEntry
Examples

```r
## the basic R reference
citation()

## references for a package -- might not have these installed
if(nchar(system.file(package="lattice"))) citation("lattice")
if(nchar(system.file(package="foreign"))) citation("foreign")

## extract the bibtex entry from the return value
x <- citation()
toBibtex(x)
```

---

**citEntry**  

### Writing Package CITATION Files

**Description**

The `CITATION` file of R packages contains an annotated list of references that should be used for citing the packages.

**Usage**

```r
citEntry(entry, textVersion, header = NULL, footer = NULL, ...)
citHeader(...) 
citFooter(...) 
readCitationFile(file)
```

**Arguments**

- `entry` a character string with a BibTeX entry type
- `textVersion` a character string with a text representation of the reference
- `header` a character string with optional header text
- `footer` a character string with optional footer text
- `file` a file name
- `...` see details below

**Details**

The `CITATION` file of an R package should be placed in the `inst` subdirectory of the package source. The file is an R source file and may contain arbitrary R commands including conditionals and computations. The file is `source()`ed by the R parser in a temporary environment and all resulting objects of class "citation" (the return value of `citEntry`) are collected.

Typically the file will contain zero or more calls to `citHeader`, then one or more calls to `citEntry`, and finally zero or more calls to `citFooter`. `citHeader` and `citFooter` are simply wrappers to `paste`, and their `...` argument is passed on to `paste` as is.

**Value**

`citEntry` returns an object of class "citation", `readCitationFile` returns an object of class "citationList".
Entry Types

citEntry creates "citation" objects, which are modeled after BibTeX entries. The entry should be a valid BibTeX entry type, e.g.,

article: An article from a journal or magazine.
inbook: A part of a book, which may be a chapter (or section or whatever) and/or a range of pages.
incollection: A part of a book having its own title.
inproceedings: An article in a conference proceedings.
mastersthesis: A Master's thesis.
misc: Use this type when nothing else fits.
phdthesis: A PhD thesis.
proceedings: The proceedings of a conference.
technote: A report published by a school or other institution, usually numbered within a series.
unpublished: A document having an author and title, but not formally published.

Entry Fields

The ... argument of citEntry can be any number of BibTeX fields, including

address: The address of the publisher or other type of institution.
author: The name(s) of the author(s), either as a character string in the format described in the LaTeX book, or a personList object.
booktitle: Title of a book, part of which is being cited.
chapter: A chapter (or section or whatever) number.
editor: Name(s) of editor(s), same format as author.
institution: The publishing institution of a technical report.
journal: A journal name.
note: Any additional information that can help the reader. The first word should be capitalized.
number: The number of a journal, magazine, technical report, or of a work in a series.
pages: One or more page numbers or range of numbers.
publisher: The publisher's name.
school: The name of the school where a thesis was written.
series: The name of a series or set of books.
title: The work's title.
volume: The volume of a journal or multi-volume book.
year: The year of publication.

Examples

basecit <- system.file("CITATION", package="base")
source(basecit, echo=TRUE)
readCitationFile(basecit)
close.socket  
**Close a Socket**

**Description**

Closes the socket and frees the space in the file descriptor table. The port may not be freed immediately.

**Usage**

```r
close.socket(socket, ...)
```

**Arguments**

- `socket`: A socket object
- `...`: further arguments passed to or from other methods.

**Value**

logical indicating success or failure

**Author(s)**

Thomas Lumley

**See Also**

`make.socket`, `read.socket`

---

combn  
**Generate All Combinations of n Elements, Taken m at a Time**

**Description**

Generate all combinations of the elements of `x` taken `m` at a time. If `x` is a positive integer, returns all combinations of the elements of `seq(x)` taken `m` at a time. If argument `FUN` is not `NULL`, applies a function given by the argument to each point. If `simplify` is `FALSE`, returns a list; otherwise returns an array, typically a matrix. ... are passed unchanged to the `FUN` function, if specified.

**Usage**

```r
combn(x, m, FUN = NULL, simplify = TRUE, ...)
```
Arguments

- \( x \) vector source for combinations, or integer \( n \) for \( x \leftarrow \text{seq}(n) \).
- \( m \) number of elements to choose.
- \( \text{FUN} \) function to be applied to each combination; default NULL means the identity, i.e., to return the combination (vector of length \( m \)).
- \( \text{simplify} \) logical indicating if the result should be simplified to an array (typically a matrix); if FALSE, the function returns a list. Note that when \( \text{simplify} = \text{TRUE} \) as by default, the dimension of the result is simply determined from \( \text{FUN}(<\text{lst combination}>)) \), for efficiency reasons. This will badly fail if \( \text{FUN}(u) \) is not of constant length.
- ... optionally, further arguments to \( \text{FUN} \).

Value

a list or array (in nondegenerate cases), see the simplify argument above.

Author(s)

Scott Chasalow wrote the original in 1994 for S; R package \( \text{combinat} \) and documentation by Vince Carey (stvjc@channing.harvard.edu); small changes by the R core team, notably to return an array in all cases of \( \text{simplify} = \text{TRUE} \), e.g., for \( \text{combn}(5,5) \).

References

See Also

\( \text{choose} \) for fast computation of the number of combinations. \( \text{expand.grid} \) for creating a data frame from all combinations of factors or vectors.

Examples

```r
combn(letters[1:4], 2)
(m <- combn(10, 5, min)) # minimum value in each combination
mm <- combn(15, 6, function(x) matrix(x, 2,3))
stopifnot(round(choose(10,5)) == length(m),
  c(2,3, round(choose(15,6))) == dim(mm))

## Different way of encoding points:
combn(c(1,1,1,1,2,2,2,3,3,4), 3, tabulate, nbins = 4)

## Compute support points and (scaled) probabilities for a
## Multivariate-Hypergeometric(n = 3, N = c(4,3,2,1)) p.f.:
# table.mat(t(combn(c(1,1,1,1,2,2,2,3,3,4), 3, tabulate,nbins=4)))
```
**compareVersion**  
*Compare Two Package Version Numbers*

**Description**

Compare two package version numbers to see which is later.

**Usage**

```r
compareVersion(a, b)
```

**Arguments**

- `a, b`  
  Character strings representing package version numbers.

**Details**

R package version numbers are of the form `x.y-z` for integers `x`, `y` and `z`, with components after `x` optionally missing (in which case the version number is older than those with the components present).

**Value**

- `0` if the numbers are equal, `-1` if `b` is later and `1` if `a` is later (analogous to the C function `strcmp`).

**See Also**

- `package_version`, `library`, `packageStatus`.

**Examples**

```r
compareVersion("1.0", "1.0-1")
cmpareVersion("7.2-0", "7.1-12")
```

---

**COMPILE**  
*Compile Files for Use with R*

**Description**

Compile given source files so that they can subsequently be collected into a shared library using R CMD SHLIB and be loaded into R using `dyn.load()`.

**Usage**

```r
R CMD COMPIL [options] srcfiles
```
count.fields

Arguments

srcfiles A list of the names of source files to be compiled. Currently, C, C++, Objective C, Objective C++ and FORTRAN are supported; the corresponding files should have the extensions `.c`, `.cc` (or `.cpp` or `.C`), `.m`, `.mm` (or `.M`) and `.f`, respectively.

options A list of compile-relevant settings, such as special values for CFLAGS or FFLAGS, or for obtaining information about usage and version of the utility.

Details

Note that Ratfor is not supported. If you have Ratfor source code, you need to convert it to FORTRAN. On many Solaris systems mixing Ratfor and FORTRAN code will work.

Objective C and Objective C++ support is optional and will work only if the corresponding compilers were available at R configure time.

Note

Some binary distributions of R have COMPILE in a separate bundle, e.g. an R-devel RPM.

See Also

SLIB, dyn.load; the section on “Customizing compilation under Unix” in “R Administration and Installation” (see the ‘doc/manual’ subdirectory of the R source tree).

count.fields Count the Number of Fields per Line

Description

count.fields counts the number of fields, as separated by sep, in each of the lines of file read.

Usage

count.fields(file, sep = "", quote = "\"\", skip = 0,
blank.lines.skip = TRUE, comment.char = "#")

Arguments

file a character string naming an ASCII data file, or a connection, which will be opened if necessary, and if so closed at the end of the function call.
sep the field separator character. Values on each line of the file are separated by this character. By default, arbitrary amounts of whitespace can separate fields.
quote the set of quoting characters
skip the number of lines of the data file to skip before beginning to read data.
blank.lines.skip logical: if TRUE blank lines in the input are ignored.
comment.char character: a character vector of length one containing a single character or an empty string.
Details

This used to be used by \texttt{read.table} and can still be useful in discovering problems in reading a file by that function.

For the handling of comments, see \texttt{scan}.

Value

A vector with the numbers of fields found.

See Also

\texttt{read.table}

Examples

\begin{verbatim}
cat("NAME", "1:John", "2:Paul", file = "foo", sep = "\n")
count.fields("foo", sep = ":")
unlink("foo")
\end{verbatim}

---

\textbf{data} \hspace{1cm} \textit{Data Sets}

Description

Loads specified data sets, or list the available data sets.

Usage

\begin{verbatim}
data(..., list = character(0), package = NULL, lib.loc = NULL,
    verbose = getOption("verbose"), envir = .GlobalEnv)
\end{verbatim}

Arguments

\begin{itemize}
\item \texttt{...} \hspace{1cm} a sequence of names or literal character strings.
\item \texttt{list} \hspace{1cm} a character vector.
\item \texttt{package} \hspace{1cm} a character vector giving the package(s) to look in for data sets, or \texttt{NULL}.
\item \texttt{lib.loc} \hspace{1cm} a character vector of directory names of \texttt{R} libraries, or \texttt{NULL}. The default value of \texttt{NULL} corresponds to all libraries currently known.
\item \texttt{verbose} \hspace{1cm} a logical. If \texttt{TRUE}, additional diagnostics are printed.
\item \texttt{envir} \hspace{1cm} the \texttt{environment} where the data should be loaded.
\end{itemize}
Currently, four formats of data files are supported:

1. Files ending `.R` or `.r` are source()ed in, with the R working directory changed temporarily to the directory containing the respective file. (data ensures that the utils package is attached, in case it had been run via utils::data.)
2. Files ending `.RData` or `.rda` are load()ed.
3. Files ending `.tab`, `.txt` or `.TXT` are read using read.table(..., header = TRUE), and hence result in a data frame.
4. Files ending `.csv` or `.CSV` are read using read.table(..., header = TRUE, sep = `";"`), and also result in a data frame.

If more than one matching file name is found, the first on this list is used.

The data sets to be loaded can be specified as a sequence of names or character strings, or as the character vector list, or as both.

For each given data set, the first two types (`.R` or `.r`, and `.RData` or `.rda` files) can create several variables in the load environment, which might all be named differently from the data set. The second two (`.tab`, `.txt`, or `.TXT`, and `.csv` or `.CSV` files) will always result in the creation of a single variable with the same name as the data set.

If no data sets are specified, data lists the available data sets. It looks for a new-style data index in the ‘Meta’ or, if this is not found, an old-style ‘00Index’ file in the ‘data’ directory of each specified package, and uses these files to prepare a listing. If there is a ‘data’ area but no index, available data files for loading are computed and included in the listing, and a warning is given: such packages are incomplete. The information about available data sets is returned in an object of class "packageIQR". The structure of this class is experimental. Where the datasets have a different name from the argument that should be used to retrieve them the index will have an entry like beaver1 (beavers) which tells us that dataset beaver1 can be retrieved by the call data(beaver).

If lib.loc and package are both NULL (the default), the data sets are searched for in all the currently loaded packages then in the ‘data’ directory (if any) of the current working directory.

If lib.loc = NULL but package is specified as a character vector, the specified package(s) are searched for first amongst loaded packages and then in the default library/ies (see .libPaths).

If lib.loc is specified (and not NULL), packages are searched for in the specified library/ies, even if they are already loaded from another library.

To just look in the ‘data’ directory of the current working directory, set package = character(0) (and lib.loc = NULL, the default).

**Value**

A character vector of all data sets specified, or information about all available data sets in an object of class "packageIQR" if none were specified.

**Note**

The data files can be many small files. On some file systems it is desirable to save space, and the files in the ‘data’ directory of an installed package can be zipped up as a zip archive ‘Rdata.zip’.

You will need to provide a single-column file ‘filelist’ of file names in that directory.

One can take advantage of the search order and the fact that a `.R` file will change directory. If raw data are stored in ‘mydata.txt’ then one can set up ‘mydata.R’ to read ‘mydata.txt’ and preprocess it, e.g., using transform. For instance one can convert numeric vectors to factors with
the appropriate labels. Thus, the `.R` file can effectively contain a metadata specification for the plaintext formats.

See Also

`help` for obtaining documentation on data sets, `save` for creating the second (`.rda`) kind of data, typically the most efficient one.

Examples

```r
require(utils)
data() # list all available data sets
try(data(package = "rpart")) # list the data sets in the rpart package
data(USArrests, "VADeaths") # load the data sets 'USArrests' and 'VADeaths'
help(USArrests) # give information on data set 'USArrests'
```

---

**dataentry**

*Spreadsheet Interface for Entering Data*

**Description**

A spreadsheet-like editor for entering or editing data.

**Usage**

```r
data.entry(...) Modes = NULL, Names = NULL
dataentry(data, modes)
d(e(..., Modes = list(), Names = NULL)
```

**Arguments**

... A list of variables: currently these should be numeric or character vectors or list containing such vectors.

Modes The modes to be used for the variables.

Names The names to be used for the variables.

data A list of numeric and/or character vectors.

modes A list of length up to that of data giving the modes of (some of) the variables.

list() is allowed.

**Details**

The data entry editor is only available on some platforms and GUIs. Where available it provides a means to visually edit a matrix or a collection of variables (including a data frame) as described in the “Notes” section.

data.entry has side effects, any changes made in the spreadsheet are reflected in the variables. The functions `de`, `de.ncols`, `de.setup` and `de.restore` are designed to help achieve these side effects. If the user passes in a matrix, `X` say, then the matrix is broken into columns before `dataentry` is called. Then on return the columns are collected and glued back together and the result assigned to the variable `X`. If you don’t want this behaviour use `dataentry` directly.
The primitive function is `dataentry`. It takes a list of vectors of possibly different lengths and modes (the second argument) and opens a spreadsheet with these variables being the columns. The columns of the dataentry window are returned as vectors in a list when the spreadsheet is closed.

`de.ncols` counts the number of columns which are supplied as arguments to `data.entry`. It attempts to count columns in lists, matrices and vectors. `de.setup` sets things up so that on return the columns can be regrouped and reassigned to the correct name. This is handled by `de.restore`.

**Value**

`de` and `dataentry` return the edited value of their arguments. `data.entry` invisibly returns a vector of variable names but its main value is its side effect of assigning new version of those variables in the user’s workspace.

**Resources**

The data entry window responds to X resources of class `R_dataentry`. Resources `foreground`, `background` and `geometry` are utilized.

**Note**

The details of interface to the data grid may differ by platform and GUI. The following description applies to the X11-based implementation under Unix.

You can navigate around the grid using the cursor keys or by clicking with the (left) mouse button on any cell. The active cell is highlighted by thickening the surrounding rectangle. Moving to the right or down will scroll the grid as needed: there is no constraint to the rows or columns currently in use.

There are alternative ways to navigate using the keys. Return and (keypad) Enter and LineFeed all move down. Tab moves right and Shift-Tab move left. Home moves to the top left.

PageDown or Control-F moves down a page, and PageUp or Control-B up by a page. End will show the last used column and the last few rows used (in any column).

Using any other key starts an editing process on the currently selected cell: moving away from that cell enters the edited value whereas Esc cancels the edit and restores the previous value. When the editing process starts the cell is cleared. In numerical columns (the default) only letters making up a valid number (including \texttt{-,eE}) are accepted, and entering an invalid edited value (such as blank) enters \texttt{NA} in that cell. The last entered value can be deleted using the BackSpace or Del(ete) key. Only a limited number of characters (currently 29) can be entered in a cell, and if necessary only the start or end of the string will be displayed, with the omissions indicated by $>$ or $<$. (The start is shown except when editing.)

Entering a value in a cell further down a column than the last used cell extends the variable and fills the gap (if any) by \texttt{NA}s (not shown on screen).

The column names can only be selected by clicking in them. This gives a popup menu to select the column type (currently Real (numeric) or Character) or to change the name. Changing the type converts the current contents of the column (and converting from Character to Real may generate \texttt{NA}s.) If changing the name is selected the header cell becomes editable (and is cleared). As with all cells, the value is entered by moving away from the cell by clicking elsewhere or by any of the keys for moving down (only).

New columns are created by entering values in them (and not by just assigning a new name). The mode of the column is auto-detected from the first value entered: if this is a valid number it gives a numeric column. Unused columns are ignored, so adding data in `var5` to a three-column grid adds one extra variable, not two.
The Copy button copies the currently selected cell: paste copies the last copied value to the current cell, and right-clicking selects a cell and copies in the value. Initially the value is blank, and attempts to paste a blank value will have no effect.

Control-L will refresh the display, recalculating field widths to fit the current entries.

In the default mode the column widths are chosen to fit the contents of each column, with a default of 10 characters for empty columns. you can specify fixed column widths by setting option de.cellwidth to the required fixed width (in characters). (set it to zero to return to variable widths). The displayed width of any field is limited to 600 pixels (and by the window width).

See Also

vi.edit: edit uses dataentry to edit data frames.

Examples

```r
# call data entry with variables x and y
## Not run: data.entry(x,y)
```

---

**debugger**

**Post-Mortem Debugging**

**Description**

Functions to dump the evaluation environments (frames) and to examine dumped frames.

**Usage**

```r
dump.frames(dumpto = "last.dump", to.file = FALSE)
debugger(dump = last.dump)
```

**Arguments**

- `dumpto`: a character string. The name of the object or file to dump to.
- `to.file`: logical. Should the dump be to an R object or to a file?
- `dump`: An R dump object created by `dump.frames`.

**Details**

To use post-mortem debugging, set the option `error` to be a call to `dump.frames`. By default this dumps to an R object "last.dump" in the workspace, but it can be set to dump to a file (a dump of the object produced by a call to `save`). The dumped object contain the call stack, the active environments and the last error message as returned by `geterrmessage`.

When dumping to file, `dumpto` gives the name of the dumped object and the file name has `.rda` appended.

A dump object of class "dump.frames" can be examined by calling `debugger`. This will give the error message and a list of environments from which to select repeatedly. When an environment is selected, it is copied and the browser called from within the copy.

If `dump.frames` is installed as the error handler, execution will continue even in non-interactive sessions. See the examples for how to dump and then quit.
Value

Invisible NULL.

Note

Functions such as `sys.parent` and `environment` applied to closures will not work correctly inside debugger.

If the error occurred when computing the default value of a formal argument the debugger will report "recursive default argument reference" when trying to examine that environment.

Of course post-mortem debugging will not work if R is too damaged to produce and save the dump, for example if it has run out of workspace.

References

See Also

`options` for setting error options; `recover` is an interactive debugger working similarly to debugger but directly after the error occurs.

Examples

```r
## Not run:
options(error=quote(dump.frames("testdump", TRUE)))

f <- function() {
  g <- function() stop("test dump.frames")
  g()
}
f() # will generate a dump on file "testdump.rda"
options(error=NULL)

## possibly in another R session
load("testdump.rda")
debugger(testdump)
Available environments had calls:
1: f()
2: g()
3: stop("test dump.frames")

Enter an environment number, or 0 to exit
Selection: 1
Browsing in the environment with call:
f()
Called from: debugger.look(ind)
Browse[1]> ls()
[1] "g"
Browse[1]> g
function() stop("test dump.frames")
<environment: 759818>
Browse[1]>
Available environments had calls:
1: f()
```
## A possible setting for non-interactive sessions

```r
options(error=quote({
  dump.frames(to.file=TRUE); q()}))
```

```
## End(Not run)
```

---

**demo**  
*Demonstrations of R Functionality*

### Description

demo is a user-friendly interface to running some demonstration R scripts. demo() gives the list of available topics.

### Usage

```r
demo(topic, package = NULL, lib.loc = NULL,  
     character.only = FALSE, verbose = getOption("verbose"))
```

### Arguments

- **topic**  
  the topic which should be demonstrated, given as a name or literal character string, or a character string, depending on whether character.only is FALSE (default) or TRUE. If omitted, the list of available topics is displayed.

- **package**  
  a character vector giving the packages to look into for demos, or NULL. By default, all packages in the search path are used.

- **lib.loc**  
  a character vector of directory names of R libraries, or NULL. The default value of NULL corresponds to all libraries currently known. If the default is used, the loaded packages are searched before the libraries.

- **character.only**  
  logical; if TRUE, use topic as character string.

- **verbose**  
  a logical. If TRUE, additional diagnostics are printed.

### Details

If no topics are given, demo lists the available demos. The corresponding information is returned in an object of class "packageIQR". The structure of this class is experimental. In earlier versions of R, an empty character vector was returned along with listing available demos.

### See Also

- `source` which is called by demo.
Examples

demo() # for attached packages
## All available demos:
demo(package = .packages(all.available = TRUE))

demo(lm.glm, package="stats")
## Not run:
ch <- "scoping"
demo(ch, character = TRUE)
## End(Not run)

download.file

Description

This function can be used to download a file from the Internet.

Usage

download.file(url, destfile, method, quiet = FALSE, mode = "w",
cacheOK = TRUE)

Arguments

url A character string naming the URL of a resource to be downloaded.
destfile A character string with the name where the downloaded file is saved. Tilde-expansion is performed.
method Method to be used for downloading files. Currently download methods "internal", "wget" and "lynx" are available, and there is a value "auto": see Details. The method can also be set through the option "download.file.method": see options().
quiet If TRUE, suppress status messages (if any).
mode character. The mode with which to write the file. Useful values are "w", "wb" (binary), "a" (append) and "ab". Only used for the "internal" method.
cacheOK logical. Is a server-side cached value acceptable? Implemented for the "internal" and "wget" methods.

Details

The function download.file can be used to download a single file as described by url from the internet and store it in destfile. The url must start with a scheme such as "http://", "ftp://" or "file://".

If method = "auto" is chosen (the default), the internal method is chosen for "file://" URLs, and for the others provided capabilities("http/ftp") is true (which it almost always is). Otherwise methods "wget" and "lynx" are tried in turn.
cacheOK = FALSE is useful for "http://" URLs, and will attempt to get a copy directly from the site rather than from an intermediate cache. (Not all platforms support it.) It is used by available.packages.
The remaining details apply to method "internal" only.
Note that https:// connections are not supported.

See url for how "file://" URLs are interpreted, especially on Windows. This function does decode encoded URLs.

The timeout for many parts of the transfer can be set by the option \texttt{timeout} which defaults to 60 seconds.

The level of detail provided during transfer can be set by the \texttt{quiet} argument and the \texttt{internet.info} option. The details depend on the platform and scheme, but setting \texttt{internet.info} to 0 gives all available details, including all server responses. Using 2 (the default) gives only serious messages, and 3 or more suppresses all messages.

A progress bar tracks the transfer. If the file length is known, an equals represents 2% of the transfer completed: otherwise a dot represents 10Kb.

Method "wget" can be used with proxy firewalls which require user/password authentication if proper values are stored in the configuration file for \texttt{wget}.

\subsection*{Value}

An (invisible) integer code, 0 for success and non-zero for failure. For the "wget" and "lynx" methods this is the status code returned by the external program. The "internal" method can return 1, but will in most cases throw an error.

\subsection*{Setting Proxies}

This applies to the internal code only.

Proxies can be specified via environment variables. Setting "no_proxy" stops any proxy being tried. Otherwise the setting of "http_proxy" or "ftp_proxy" (or failing that, the all upper-case version) is consulted and if non-empty used as a proxy site. For FTP transfers, the username and password on the proxy can be specified by "ftp_proxy_user" and "ftp_proxy_password". The form of "http_proxy" should be "http://proxy.dom.com/" or "http://proxy.dom.com:8080/" where the port defaults to 80 and the trailing slash may be omitted. For "ftp_proxy" use the form "ftp://proxy.dom.com:3128/" where the default port is 21. These environment variables must be set before the download code is first used: they cannot be altered later by calling \texttt{Sys.setenv}.

Usernames and passwords can be set for HTTP proxy transfers via environment variable \texttt{http_proxy_user} in the form user:passwd. Alternatively, "http_proxy" can be of the form "http://user:pass@proxy.dom.com:8080/" for compatibility with wget. Only the HTTP/1.0 basic authentication scheme is supported.

\subsection*{Note}

Methods "wget" and "lynx" are for historical compatibility. They will block all other activity on the R process.

For methods "wget" and "lynx" a system call is made to the tool given by \texttt{method}, and the respective program must be installed on your system and be in the search path for executables.

\subsection*{See Also}

\texttt{options} to set the \texttt{timeout} and \texttt{internet.info} options.

\texttt{url} for a finer-grained way to read data from URLs.

\texttt{url.show}, \texttt{available.packages}, \texttt{download.packages} for applications
**Description**

Invoke a text editor on an R object.

**Usage**

```r
## Default S3 method:
edit(name = NULL, file = "", title = NULL,
    editor = getOption("editor"), ...)
```

```r
vi(name = NULL, file = "")
emacs(name = NULL, file = "")
pico(name = NULL, file = "")
xemacs(name = NULL, file = "")
xedit(name = NULL, file = "")
```

**Arguments**

- `name`: a named object that you want to edit. If name is missing then the file specified by `file` is opened for editing.
- `file`: a string naming the file to write the edited version to.
- `title`: a display name for the object being edited.
- `editor`: a string naming the text editor you want to use. On Unix the default is set from the environment variables `EDITOR` or `VISUAL` if either is set, otherwise `vi` is used. On Windows it defaults to `notepad`.
- `...`: further arguments to be passed to or from methods.

**Details**

`edit` invokes the text editor specified by `editor` with the object `name` to be edited. It is a generic function, currently with a default method and one for data frames and matrices.

`data.entry` can be used to edit data, and is used by `edit` to edit matrices and data frames on systems for which `data.entry` is available.

It is important to realize that `edit` does not change the object called `name`. Instead, a copy of name is made and it is that copy which is changed. Should you want the changes to apply to the object `name` you must assign the result of `edit` to `name`. (Try `fix` if you want to make permanent changes to an object.)

In the form `edit(name)`, `edit` deparses `name` into a temporary file and invokes the editor `editor` on this file. Quitting from the editor causes `file` to be parsed and that value returned. Should an error occur in parsing, possibly due to incorrect syntax, no value is returned. Calling `edit()`, with no arguments, will result in the temporary file being reopened for further editing.

Currently only the internal editor in Windows makes use of the `title` option; it displays the given name in the window header.
Note

The functions `vi`, `emacs`, `pico`, `xemacs`, `xedit` rely on the corresponding editor being available and being on the path. This is system-dependent.

See Also

`edit.data.frame`, `data.entry`, `fix`.

Examples

```r
## Not run:
# use xedit on the function mean and assign the changes
mean <- edit(mean, editor = "xedit")

# use vi on mean and write the result to file mean.out
vi(mean, file = "mean.out")
## End(Not run)
```

### Description

Use data editor on data frame or matrix contents.

### Usage

```r
## S3 method for class 'data.frame':
edit(name, factor.mode = c("character", "numeric"),
     edit.row.names = any(row.names(name) != 1:nrow(name)), ...)

## S3 method for class 'matrix':
edit(name, edit.row.names = !is.null(dn[[1]]), ...)
```

### Arguments

- `name`: A data frame or matrix.
- `factor.mode`: How to handle factors (as integers or using character levels) in a data frame.
- `edit.row.names`: logical. Show the row names be displayed as a separate editable column?
- `...`: further arguments passed to or from other methods.

### Details

At present, this only works on simple data frames containing numeric, logical or character vectors and factors. Factors are represented in the spreadsheet as either numeric vectors (which is more suitable for data entry) or character vectors (better for browsing). After editing, vectors are padded with `NA` to have the same length and factor attributes are restored. The set of factor levels can not be changed by editing in numeric mode; invalid levels are changed to `NA` and a warning is issued.

If new factor levels are introduced in character mode, they are added at the end of the list of levels in the order in which they encountered.
It is possible to use the data-editor’s facilities to select the mode of columns to swap between numerical and factor columns in a data frame. Changing any column in a numerical matrix to character will cause the result to be coerced to a character matrix. Changing the mode of logical columns is not supported.

The columns are coerced on input to numeric unless logical, character or factor (which may well not be what you want).

For a data frame, the row names will be taken from the original object if `edit.row.names = FALSE` and the number of rows is unchanged, and from the edited output if `edit.row.names = TRUE` and there are no duplicates. (If the `row.names` column is incomplete, it is extended by entries like `row223`.) In all other cases the row names are replaced by `seq(length=nrows)`.

For a matrix, `colnames` will be added (of the form `col7`) if needed. The `rownames` will be taken from the original object if `edit.row.names = FALSE` and the number of rows is unchanged (otherwise `NULL`), and from the edited output if `edit.row.names = TRUE`. (If the `row.names` column is incomplete, it is extended by entries like `row223`.)

**Value**

The edited data frame.

**Note**

`fix(dataframe)` works for in-place editing by calling this function.

If the data editor is not available, a dump of the object is presented for editing using the default method of `edit`.

At present the data editor is limited to 65535 rows.

**Author(s)**

Peter Dalgaard

**See Also**

data.entry, edit

**Examples**

```r
## Not run:
edit(InsectSprays)
edit(InsectSprays, factor.mode="numeric")
## End(Not run)
```

---

**Description**

Run all the R code from the Examples part of R’s online help topic topic with two possible exceptions, `dontrun` and `dontshow`, see Details below.
Usage

```r
example(topic, package = NULL, lib.loc = NULL,
      local = FALSE, echo = TRUE, verbose = getOption("verbose"),
      setRNG = FALSE, ask = getOption("example.ask"),
      prompt.prefix = abbreviate(topic, 6))
```

Arguments

- **topic**: name or literal character string: the online help topic the examples of which should be run.
- **package**: a character vector giving the package names to look into for example code, or NULL. By default, all packages in the search path are used.
- **lib.loc**: a character vector of directory names of R libraries, or NULL. The default value of NULL corresponds to all libraries currently known. If the default is used, the loaded packages are searched before the libraries.
- **local**: logical: if TRUE evaluate locally, if FALSE evaluate in the workspace.
- **echo**: logical; if TRUE, show the R input when sourcing.
- **verbose**: logical; if TRUE, show even more when running example code.
- **setRNG**: logical or expression: if not FALSE, the random number generator state is saved, then initialized to a specified state, the example is run and the (saved) state is restored. setRNG = TRUE sets the same state as R CMD check does for running a package's examples. This is currently equivalent to setRNG = {RNGkind("default", "default"); set.seed(1)}.
- **ask**: logical (or "default") indicating if par(ask=TRUE) should be called before graphical output happens from the example code. The value "default" (the factory-fresh default) means to ask if echo == TRUE and the graphics device appears to be interactive. This parameter applies both to any currently opened device and to any devices opened by the example code.
- **prompt.prefix**: character; prefixes the prompt to be used if echo = TRUE.

Details

If lib.loc is not specified, the packages are searched for amongst those already loaded, then in the specified libraries. If lib.loc is specified, they are searched for only in the specified libraries, even if they are already loaded from another library.

An attempt is made to load the package before running the examples, but this will not replace a package loaded from another location.

If local=TRUE objects are not created in the workspace and so not available for examination after example completes: on the other hand they cannot clobber objects of the same name in the workspace.

As detailed in the manual Writing R Extensions, the author of the help page can markup parts of the examples for two exception rules

- **dontrun** encloses code that should not be run.
- **dontshow** encloses code that is invisible on help pages, but will be run both by the package checking tools, and the example() function. This was previously testonly, and that form is still accepted.
If the examples file contains non-ASCII characters the encoding used will matter. If in a UTF-8 locale `example` first tries UTF-8 and then Latin-1. (This can be overridden by setting the encoding in the `.Rd` file.)

**Value**

The value of the last evaluated expression.

**Note**

The examples can be many small files. On some file systems it is desirable to save space, and the files in the ‘R-ex’ directory of an installed package can be zipped up as a zip archive ‘Rex.zip’.

demo

**Examples**

eexample(InsectSprays)

```r
## force use of the standard package 'stats':
eexample("smooth", package="stats", lib.loc=.Library)
```

```r
## set RNG *before* example as when R CMD check is run:

r1 <- example(quantile, setRNG = TRUE)
x1 <- rnorm(1)
u <- runif(1)
## identical random numbers
r2 <- example(quantile, setRNG = TRUE)
x2 <- rnorm(1)
stopifnot(identical(r1, r2))
## but x1 and x2 differ since the RNG state from before example()
## differs and is restored!
x1; x2
```

---

**file.edit**

*Edit One or More Files*

**Description**

Edit one or more files in a text editor.

**Usage**

```r
file.edit(..., title = file, editor = getOption("editor"))
```
Arguments

... one or more character vectors containing the names of the files to be edited.
title the title to use in the editor; defaults to the filename.
default the text editor to be used.

Details

The behaviour of this function is very system dependent. Currently files can be opened only one at a time on Unix; on Windows, the internal editor allows multiple files to be opened, but has a limit of 50 simultaneous edit windows.

The title argument is used for the window caption in Windows, and is ignored on other platforms.

See Also

files, file.show, edit, fix,

Examples

## Not run:
# open two R scripts for editing
file.edit("script1.R", "script2.R")
## End(Not run)

Description

Utility for testing files.

Usage

file_test(op, x, y)

Arguments

op a character string specifying the test to be performed. Unary tests (only x is used) are "-f" (existence and not being a directory) and "-d" (existence and directory); binary tests are "-nt" (newer than, using the modification dates) and "-ot".

x, y character vectors giving file paths.

Details

file_test performs shell-style file tests.

Note that file.exists only tests for existence (test -e on some systems) but not for not being a directory.

See Also

file.path, file.info
Examples

```r
dir <- file.path(R.home(), "library", "stats")
file_test("-d", dir)
file_test("-nt", file.path(dir, "R"), file.path(dir, "demo"))
```

**fix**

**Fix an Object**

Description

`fix` invokes `edit` on `x` and then assigns the new (edited) version of `x` in the user’s workspace.

Usage

```r
fix(x, ...)
```

Arguments

- `x` the name of an R object, as a name or a character string.
- `...` arguments to pass to editor: see `edit`.

Details

The name supplied as `x` need not exist as an R object, in which case a function with no arguments and an empty body is supplied for editing.

See Also

`edit.edit.data.frame`

Examples

```r
## Not run:
## Assume 'my.fun' is a user defined function:
fix(my.fun)
## now my.fun is changed
## Also,
fix(my.data.frame) # calls up data editor
fix(my.data.frame, factor.mode="char") # use of ...
## End(Not run)
```

**flush.console**

**Flush Output to A Console**

Description

This does nothing except on console-based versions of R. On the Mac OS X and Windows GUIs, it ensures that the display of output in the console is current, even if output buffering is on.

Usage

```r
flush.console()
```
Format Unordered and Ordered Lists

Description

Format unordered (itemize) and ordered (enumerate) lists.

Usage

\[
\text{formatUL}(x, \text{label} = "\ast", \text{offset} = 0, \\
width = 0.9 \times \text{getOption("width")}) \\
\text{formatOL}(x, \text{type} = "\text{arabic}", \text{offset} = 0, \text{start} = 1, \\
width = 0.9 \times \text{getOption("width")})
\]

Arguments

- **x**: a character vector of list items.
- **label**: a character string used for labelling the items.
- **offset**: a non-negative integer giving the offset (indentation) of the list.
- **width**: a positive integer giving the target column for wrapping lines in the output.
- **type**: a character string specifying the “type” of the labels in the ordered list. If "arabic" (default), arabic numerals are used. For "Alph" or "alph", single upper or lower case letters are employed (in this case, the number of the last item must not exceed 26. Finally, for "Roman" or "roman", the labels are given as upper or lower case roman numerals (with the number of the last item maximally 3899). **type** can be given as a unique abbreviation of the above, or as one of the HTML style tokens "1" (arabic), "A"/"a" (alphabetic), or "I"/"i" (roman), respectively.
- **start**: a positive integer specifying the starting number of the first item in an ordered list.

Value

A character vector with the formatted entries.

See Also

- **formatDL** for formatting description lists.

Examples

```r
## A simpler recipe.
x <- c("Mix dry ingredients thoroughly.", 
      "Pour in wet ingredients.", 
      "Mix for 10 minutes.", 
      "Bake for one hour at 300 degrees.") 
## Format and output as an unordered list.
writeLines(formatUL(x)) 
## Format and output as an ordered list.
writeLines(formatOL(x)) 
## Ordered list using lower case roman numerals.
```
getAnywhere

## Ordered list using upper case letters and some offset.
writeLines(formatOL(x, type = "A", offset = 5))

---

### Description

These functions locate all objects with name matching its argument, whether visible on the search path, registered as an S3 method or in a namespace but not exported. `getAnywhere()` returns the objects and `argsAnywhere()` returns the arguments of any objects that are functions.

### Usage

```r
getAnywhere(x)
argsAnywhere(x)
```

### Arguments

- `x`  
  a character string or name.

### Details

The function looks at all loaded namespaces, whether or not they are associated with a package on the search list.

Where functions are found as an S3 method, an attempt is made to find which namespace registered them. This may not be correct, especially if a namespace is unloaded.

### Value

For `getAnywhere()` an object of class "getAnywhere". This is a list with components:

- `name`  
  the name searched for.
- `objs`  
  a list of objects found
- `where`  
  a character vector explaining where the object(s) were found
- `visible`  
  logical: is the object visible
- `dups`  
  logical: is the object identical to one earlier in the list.

Normally the structure will be hidden by the `print` method. There is a `[]` method to extract one or more of the objects found.

For `argsAnywhere()` one or more argument lists as returned by `args`.

### See Also

- `get`, `getFromNamespace`, `args`

### Examples

```r
getAnywhere("format.dist")
getAnywhere("simpleLoess") # not exported from stats
argsAnywhere(format.dist)
```
**getFromNamespace**

Utility functions for Developing Namespaces

**Description**

Utility functions to access and replace the non-exported functions in a namespace, for use in developing packages with namespaces.

**Usage**

```r
getFromNamespace(x, ns, pos = -1, envir = as.environment(pos))
assignInNamespace(x, value, ns, pos = -1, envir = as.environment(pos))
fixInNamespace(x, ns, pos = -1, envir = as.environment(pos), ...)
```

**Arguments**

- `x` an object name (given as a character string).
- `value` an R object.
- `ns` a namespace, or character string giving the namespace.
- `pos` where to look for the object: see `get`.
- `envir` an alternative way to specify an environment to look in.
- `...` arguments to pass to the editor: see `edit`.

**Details**

The namespace can be specified in several ways. Using, for example, `ns = "stats"` is the most direct, but a loaded package with a namespace can be specified via any of the methods used for `get`: `ns` can also be the environment printed as `<namespace:foo>`.

`getFromNamespace` is similar to (but predates) the `:::` operator, but is more flexible in how the namespace is specified.

`fixInNamespace` invokes `edit` on the object named `x` and assigns the revised object in place of the original object. For compatibility with `fix`, `x` can be unquoted.

**Value**

`getFromNamespace` returns the object found (or gives an error).

`assignInNamespace` and `fixInNamespace` are invoked for their side effect of changing the object in the namespace.

**Note**

`assignInNamespace` and `fixInNamespace` change the copy in the namespace, but not any copies already exported from the namespace, in particular an object of that name in the package (if already attached) and any copies already imported into other namespaces. They are really intended to be used only for objects which are not exported from the namespace. They do attempt to alter a copy registered as an S3 method if one is found.

They can only be used to change the values of objects in the namespace, not to create new objects.
getS3method

Get An S3 Method

Description
Get a method for an S3 generic, possibly from a namespace.

Usage
getS3method(f, class, optional = FALSE)

Arguments
f character: name of the generic.
class character: name of the class.
onoptional logical: should failure to find the generic or a method be allowed?

Details
S3 methods may be hidden in packages with namespaces, and will not then be found by get: this function can retrieve such functions, primarily for debugging purposes.

Value
The function found, or NULL if no function is found and optional = TRUE.

See Also
methods, get

Examples
require(stats)
exists("predict.ppr") # false
g getS3method("predict", "ppr")
Description

Change wildcard aka globbing (or “ls” like) pattern into the corresponding regular expression (regexp).

Usage

glob2rx(pattern, trim.head = FALSE, trim.tail = TRUE)

Arguments

- pattern: character vector
- trim.head: logical specifying if leading "^.*" should be trimmed from the result.
- trim.tail: logical specifying if trailing ".*$" should be trimmed from the result.

Details

This takes a wildcard as used by most shells and returns an equivalent regular expression. "?" is mapped to . (match a single character), "*" to .* (match any string, including an empty one), and the pattern is anchored (it must start at the beginning and end at the end). Optionally, the resulting regexp is simplified.

Value

A character vector of the same length as the input pattern where each “wild card” is translated to the corresponding regular expression.

Author(s)

Martin Maechler, Unix/sed based version, 1991; current: 2004

See Also

regexp about regular expression, sub, etc about substitutions using regexps.

Examples

```r
stopifnot(glob2rx("abc.*") == "^abc\..",
glob2rx("a?b.*") == "^a\..",
glob2rx("a?b.*", trim.tail=FALSE) == "^a\..*$",
glob2rx("*.doc") == "^.*\..doc$",
glob2rx("*.doc", trim.head=TRUE) == "\..doc$",
glob2rx("*.t\*") == "^.*\..t",
glob2rx("*.t??") == "^.*\..t..$"
)```
head

Return the First or Last Part of an Object

Description

Returns the first or last parts of a vector, matrix, table, data frame or function. Since head() and tail() are generic functions, they may also have been extended to other classes.

Usage

head(x, ...)
## Default S3 method:
head(x, n = 6, ...)
## S3 method for class 'data.frame':
head(x, n = 6, ...)
## S3 method for class 'matrix':
head(x, n = 6, ...)
## S3 method for class 'ftable':
head(x, n = 6, ...)
## S3 method for class 'table':
head(x, n = 6, ...)
## S3 method for class 'function':
head(x, n = 6, ...)

tail(x, ...)
## Default S3 method:
tail(x, n = 6, ...)
## S3 method for class 'data.frame':
tail(x, n = 6, ...)
## S3 method for class 'matrix':
tail(x, n = 6, addrownums = TRUE, ...)
## S3 method for class 'ftable':
tail(x, n = 6, addrownums = FALSE, ...)
## S3 method for class 'table':
tail(x, n = 6, addrownums = TRUE, ...)
## S3 method for class 'function':
tail(x, n = 6, ...)

Arguments

x  
an object

n  
a single integer. If positive, size for the resulting object: number of elements for a vector (including lists), rows for a matrix or data frame or lines for a function. If negative, all but the n last/first number of elements of x.

addrownums  
if there are no row names, create them from the row numbers.

...  
arguments to be passed to or from other methods.
Details

For matrices, 2-dim tables and data frames, \texttt{head()} (\texttt{tail()}) returns the first (last) \( n \) rows when \( n > 0 \) or all but the last (first) \( n \) rows when \( n < 0 \). \texttt{head.matrix()} and \texttt{tail.matrix()} are exported. For functions, the lines of the deparsed function are returned as character strings.

If a matrix has no row names, then \texttt{tail()} will add row names of the form "\([n,]\)" to the result, so that it looks similar to the last lines of \( x \) when printed. Setting \texttt{addrownums = FALSE} suppresses this behaviour.

Value

An object (usually) like \( x \) but generally smaller. For \texttt{ftable} objects \( x \), a transformed \texttt{format(x)}.

Author(s)

Patrick Burns, improved and corrected by R-Core. Negative argument added by Vincent Goulet.

Examples

\begin{verbatim}
head(letters)
head(letters, n = -6)
head(freeny.x, n = 10)
head(freeny.y)
tail(letters)
tail(letters, n = -6)
tail(freeny.x)
tail(freeny.y)
tail(library)
head(ftable(Titanic))
\end{verbatim}

help

Documentation

Description

These functions provide access to documentation. Documentation on a topic with name \texttt{name} (typically, an R object or a data set) can be printed with either \texttt{help(name)} or \texttt{?name}.

Usage

\begin{verbatim}
help(topic, offline = FALSE, package = NULL,
     lib.loc = NULL, verbose = getOption("verbose"),
     try.all.packages = getOption("help.try.all.packages"),
     chmhelp = getOption("chmhelp"),
     htmlhelp = getOption("htmlhelp"),
     pager = getOption("pager"))
\end{verbatim}
help

?topic

type?topic

Arguments

topic usually, the name on which documentation is sought. The name may be quoted
or unquoted (but note that if topic is the name of a variable containing a char-
acter string documentation is provided for the name, not for the character string).
The topic argument may also be a function call, to ask for documentation on
a corresponding method. See the section on method documentation.
See Details for what happens if this is omitted.
offline a logical indicating whether documentation should be displayed on-line to the
screen (the default) or hardcopy of it should be produced.
package a name or character vector giving the packages to look into for documentation,
or NULL. By default, all packages in the search path are used.
lib.loc a character vector of directory names of R libraries, or NULL. The default value
of NULL corresponds to all libraries currently known. If the default is used, the
loaded packages are searched before the libraries.
verbose logical; if TRUE, the file name is reported.
try.all.packages logical; see Note.
chmhelp logical (or NULL). Only relevant under Windows. If TRUE the Compiled HTML
version of the help on the topic will be shown in a help viewer. If none is
available, plain text help will be shown.
htmlhelp logical (or NULL). If TRUE (which is the default after help.start has been
called), the HTML version (if available) of the help on the topic will be shown
in the browser specified by options("browser"). See browseURL for
details of the browsers that are supported. Where possible an existing browser
window is re-used.
pager the pager to be used for file.show.
type the special type of documentation to use for this topic; for example, if the type
is class, documentation is provided for the class with name topic. The
function topicName returns the actual name used in this case. See the section
on method documentation for the uses of type to get help on formal methods.

Details

topic is not optional: if it is omitted R will give a hint as to suitable topics if a package is specified,
to available packages if lib.loc only is specified, and help on help itself if nothing is specified.
(In all cases this will be text help.)

In the case of unary and binary operators and control-flow special forms (including if, for and
function), the topic may need to be quoted.

If multiple help files matching topic are found, in interactive use a menu is presented for the user
to choose one: otherwise the first on the search path is used. (The menu will be a graphical menu if
possible if getOption("menu.graphics") is true, the default.)

If offline is TRUE, hardcopy of the documentation is produced by running the LaTeX version
of the help page through latex (note that LaTeX 2e is needed) and dvips. Depending on your
dvips configuration, hardcopy will be sent to the printer or saved in a file. If the programs are
in non-standard locations and hence were not found at compile time, you can either set the options `latexcmd` and `dvipscmd`, or the environment variables `R_LATEXCMD` and `R_DVIPSCMD` appropriately. The appearance of the output can be customized through a file `Rhelp.cfg` somewhere in your LaTeX search path. The appearance of the output can be customized through a file `Rhelp.cfg` somewhere in your LaTeX search path.

If LaTeX versions of help pages were not built at the installation of the package, the `print` method will ask if conversion with `R CMD Rdconv` (which requires Perl) should be attempted.

**S4 Method Documentation**

The authors of formal ('S4') methods can provide documentation on specific methods, as well as overall documentation on the methods of a particular function. The "?" operator allows access to this documentation in three ways.

The expression `methods ? f` will look for the overall documentation methods for the function `f`. Currently, this means the documentation file containing the alias `f-methods`.

There are two different ways to look for documentation on a particular method. The first is to supply the `topic` argument in the form of a function call, omitting the `type` argument. The effect is to look for documentation on the method that would be used if this function call were actually evaluated. See the examples below. If the function is not a generic (no S4 methods are defined for it), the help reverts to documentation on the function name.

The "?" operator can also be called with `type` supplied as "method"; in this case also, the `topic` argument is a function call, but the arguments are now interpreted as specifying the class of the argument, not the actual expression that will appear in a real call to the function. See the examples below.

The first approach will be tedious if the actual call involves complicated expressions, and may be slow if the arguments take a long time to evaluate. The second approach avoids these difficulties, but you do have to know what the classes of the actual arguments will be when they are evaluated.

Both approaches make use of any inherited methods; the signature of the method to be looked up is found by using `selectMethod` (see the documentation for `getMethod`).

**Note**

Unless `lib.loc` is specified explicitly, the loaded packages are searched before those in the specified libraries. This ensures that if a library is loaded from a library not in the known library trees, then the help from the loaded library is used. If `lib.loc` is specified explicitly, the loaded packages are not searched.

If this search fails and argument `try.all.packages` is `TRUE` and neither `packages` nor `lib.loc` is specified, then all the packages in the known library trees are searched for help on `topic` and a list of (any) packages where help may be found is printed (but no help is shown).

**N.B.** searching all packages can be slow.

The help files can be many small files. On some file systems it is desirable to save space, and the text files in the ‘help’ directory of an installed package can be zipped up as a zip archive ‘Rhelp.zip’. Ensure that file ‘AnIndex’ remains un-zipped. Similarly, all the files in the ‘latex’ directory can be zipped to ‘Rhelp.zip’.

**References**

help.search

See Also

help.search() for finding help pages on a “vague” topic; help.start() which opens the HTML version of the R help pages; library() for listing available packages and the user-level objects they contain; data() for listing available data sets; methods().

Examples

define a S4 generic function and some methods
combo <- function(x, y) c(x, y)
setGeneric("combo")
setMethod("combo", c("numeric", "numeric"), function(x, y) x+y)

## assume we have written some documentation for combo, and its methods ....

?combo ## produces the function documentation

methods?combo ## looks for the overall methods documentation

method?combo("numeric", "numeric") ## documentation for the method above

?combo(1:10, rnorm(10)) ## ... the same method, selected according to
## the arguments (one integer, the other numeric)

?combo(1:10, letters) ## documentation for the default method

## End(Not run)
**Description**

Allows for searching the help system for documentation matching a given character string in the (file) name, alias, title, concept or keyword entries (or any combination thereof), using either fuzzy matching or regular expression matching. Names and titles of the matched help entries are displayed nicely formatted.

**Usage**

```
help.search(pattern, fields = c("alias", "concept", "title"),
            apropos, keyword, whatis, ignore.case = TRUE,
            package = NULL, lib.loc = NULL,
            help.db = getOption("help.db"),
            verbose = getOption("verbose"),
            rebuild = FALSE, agrep = NULL)
```

**Arguments**

- `pattern` a character string to be matched in the specified fields. If this is given, the arguments `apropos`, `keyword`, and `whatis` are ignored.
- `fields` a character vector specifying the fields of the help data bases to be searched. The entries must be abbreviations of "name", "title", "alias", "concept", and "keyword", corresponding to the help page’s (file) name, its title, the topics and concepts it provides documentation for, and the keywords it can be classified to.
- `apropos` a character string to be matched in the help page topics and title.
- `keyword` a character string to be matched in the help page ‘keywords’. ‘Keywords’ are really categories: the standard categories are listed in file ‘RHOME/doc/KEYWORDS’ (see also the example) and some package writers have defined their own. If `keyword` is specified, `agrep` defaults to FALSE.
- `whatis` a character string to be matched in the help page topics.
- `ignore.case` a logical. If TRUE, case is ignored during matching; if FALSE, pattern matching is case sensitive.
- `package` a character vector with the names of packages to search through, or NULL in which case all available packages in the library trees specified by `lib.loc` are searched.
- `lib.loc` a character vector describing the location of R library trees to search through, or NULL. The default value of `lib.loc` corresponds to all libraries currently known.
- `help.db` a character string giving the file path to a previously built and saved help data base, or NULL.
- `verbose` logical; if TRUE, the search process is traced.
- `rebuild` a logical indicating whether the help data base should be rebuilt. This will be done automatically if `lib.loc` or the search path is changed, or if `package` is used and a value is not found.
- `agrep` if NULL (the default unless `keyword` is used) and the character string to be matched consists of alphanumeric characters, whitespace or a dash only, approximate (fuzzy) matching via `agrep` is used unless the string has fewer than 5 characters; otherwise, it is taken to contain a regular expression to be matched via `grep`. If FALSE, approximate matching is not used. Otherwise, one can give a numeric or a list specifying the maximal distance for the approximate match, see argument `max.distance` in the documentation for `agrep`.

Details

Upon installation of a package, a pre-built help.search index is serialized as ‘hsearch.rds’ in the ‘Meta’ directory. These files are used to create the database.

The arguments `apropos` and `whatis` play a role similar to the Unix commands with the same names.

If possible, the help database is saved in memory or (if memory limits have been set: see `mem.limits`) to a file in the session temporary directory for use by subsequent calls in the session.

Note that currently the aliases in the matching help files are not displayed.

Value

The results are returned in a list object of class "hsearch", which has a print method for nicely formatting the results of the query. This mechanism is experimental, and may change in future versions of R.

The internal format of the class is undocumented and subject to change.

See Also

`help;help.start` for starting the hypertext (currently HTML) version of R’s online documentation, which offers a similar search mechanism.

`RSiteSearch` to access an on-line search of R resources.

`apropos` uses regexps and has nice examples.

Examples

```
help.search("linear models")  # In case you forgot how to fit linear # models
help.search("non-existent topic")
## Not run:
help.search("print")  # All help pages with topics or title # matching 'print'
help.search(apropos = "print")  # The same
help.search(keyword = "hplot")  # All help pages documenting high-level # plots.
file.show(file.path(R.home(), "doc", "KEYWORDS"))  # show all keywords
## Help pages with documented topics starting with 'try'.
help.search("\btry\", fields = "alias")
## Do not use '^' or '$' when matching aliases or keywords
## (unless all packages were installed using R 1.7 or newer).
## End(Not run)
```

Description

Start the hypertext (currently HTML) version of R’s online documentation.
Usage

```r
call = help.start(gui = "irrelevant", browser = getOption("browser"),
remote = NULL)
```

Arguments

- `gui` just for compatibility with S-PLUS.
- `browser` the name of the program to be used as hypertext browser. It should be in the PATH, or a full path specified.
- `remote` A character giving a valid URL for the `$R_HOME` directory on a remote location.

Details

All the packages in the known library trees are linked to directory `.R` in the per-session temporary directory. The links are re-made each time `help.start` is run, which should be done after packages are installed, updated or removed.

If the browser given by the `browser` argument is different from the default browser as specified by `options("browser")`, the default is changed to the given browser so that it gets used for all future help requests.

Note

There is a Java-based search facility available from the HTML page that `help.start` brings up. Should this not work, please consult the ‘R Installation and Administration’ manual which is linked from that page.

See Also

- `help()` for on- and off-line help in ASCII/Editor or PostScript format.
- `browseURL` for how the help file is displayed.
- `RSiteSearch` to access an on-line search of R resources.

Examples

```r
## Not run:
help.start()
## End(Not run)
```

---

**index.search**

**Search Indices for Help Files**

Description

Used to search the indices for help files, possibly under aliases.

Usage

```r
index.search(topic, path, file="AnIndex", type = "help")
```
Arguments

- **topic**: The keyword to be searched for in the indices.
- **path**: The path(s) to the packages to be searched.
- **file**: The index file to be searched. Normally "AnIndex".
- **type**: The type of file required.

Details

For each package in **path**, examine the file **file** in directory 'type', and look up the matching file stem for **topic**, if any.

Value

A character vector of matching files, as if they are in directory **type** of the corresponding package. In the special cases of **type** = "html", "R-ex" and "latex" the file extensions "html", "R" and "tex" are added.

See Also

- help, example

---

**INSTALL**  
**Install Add-on Packages**

Description

Utility for installing add-on packages.

Usage

```
R CMD INSTALL [options] [-l lib] pkgs
```

Arguments

- **pkgs**: A space-separated list with the path names of the packages to be installed.
- **lib**: the path name of the **R** library tree to install to.
- **options**: a space-separated list of options through which in particular the process for building the help files can be controlled. Options should only be given once. Use `R CMD INSTALL --help` for the current list of options.

Details

This will stop at the first error, so if you want all the **pkgs** to be tried, call this via a shell **for** or **foreach** loop.

If used as `R CMD INSTALL pkgs` without explicitly specifying **lib**, packages are installed into the library tree rooted at the first directory in the library path which would be used by **R** run in the current environment.

To install into the library tree **lib**, use `R CMD INSTALL -l lib pkgs`. This prepends **lib** to **R_LIBS** for duration of the install, so required packages in the installation directory will be found (and used in preference to those in other libraries).
Both `lib` and the elements of `pkgs` may be absolute or relative path names of directories. `pkgs` may also contain names of package/bundle archive files of the form ‘pkg_version.tar.gz’ as obtained from CRAN: these are then extracted in a temporary directory. Finally, binary package/bundle archive files (as created by `R CMD build --binary`) can be supplied.

Some package sources contain a ‘configure’ script that can be passed arguments or variables via the option ‘--configure-args’ and ‘--configure-vars’, respectively, if necessary. The latter is useful in particular if libraries or header files needed for the package are in non-system directories. In this case, one can use the configure variables `LIBS` and `CPPFLAGS` to specify these locations (and set these via ‘--configure-vars’), see section “Configuration variables” in “R Installation and Administration” for more information. (If these are used more than once on the command line, only the last instance is used.) One can bypass the configure mechanism using the option ‘--no-configure’.

If ‘--no-docs’ is given, no help files are built. Options ‘--no-text’, ‘--no-html’, and ‘--no-latex’ suppress creating the text, HTML, and LaTeX versions, respectively. The default is to build help files in all three versions.

If the attempt to install the package fails, leftovers are removed. If the package was already installed, the old version is restored. This happens either if a command encounters an error or if the install is interrupted from the keyboard: after cleaning up the script terminates.

Use `R CMD INSTALL --help` for more usage information.

**Packages using the methods package**

Packages that require the methods package, and that use functions such as `setMethod` or `setClass`, should be installed either (preferably) using lazy-loading or by creating a binary image: use the flags `LazyLoad` and `SaveImage` in the ‘DESCRIPTION’ file to ensure this.

**See Also**

`REMOVE` and `library` for information on using several library trees; `update.packages` for automatic update of packages using the internet (or other R level installation of packages, such as by `install.packages`).

The section on “Add-on packages” in “R Installation and Administration” and the chapter on “Creating R packages” in “Writing R Extensions” (see `RShowDoc` and the ‘doc/manual’ subdirectory of the R source tree).

---

**installed.packages**  
*Find Installed Packages*

**Description**

Find (or retrieve) details of all packages installed in the specified libraries.

**Usage**

```r
installed.packages(lib.loc = NULL, priority = NULL, noCache = FALSE, fields = NULL)
```
Arguments

lib.loc character vector describing the location of R library trees to search through.
priority character vector or NULL (default). If non-null, used to select packages; "high" is equivalent to c("base", "recommended"). To select all packages without an assigned priority use priority = "NA".
noCache Do not use cached information.
fields a character vector giving the fields to extract from each package's DESCRIPTION file in addition to the default ones, or NULL (default).Unavailable fields result in NA values.

Details

installed.packages scans the 'DESCRIPTION' files of each package found along lib.loc and returns a matrix of package names, library paths and version numbers.

Note: this works with package names, not bundle names, and for versioned installs with the name under which the package is installed, in the style mypkg_1.3-7.
The information found is cached (by library) for the R session and specified fields argument, and updated only if the top-level library directory has been altered, for example by installing or removing a package. If the cached information becomes confused, it can be refreshed by running installed.packages(noCache = TRUE).

Value

A matrix with one row per package, row names the package names and column names "Package", "LibPath", "Version", "Priority", "Bundle", "Contains", "Depends", "Suggests", "Imports" and "Built" (the R version the package was built under). Additional columns can be specified using the fields argument.

See Also

update.packages, INSTALL, REMOVE.

Examples

str(ip <- installed.packages(priority = "high"))
ip[, c(1,3:5)]
PLIC <- installed.packages(priority = "high", fields="License")
## what licenses are there:
table(PLIC[,"License"] )

Description

Front-end for creating executable programs.

Usage

R CMD LINK [options] linkcmd
localeToCharset

Select a Suitable Encoding Name from a Locale Name

Description

This functions aims to find a suitable coding for the locale named, by default the current locale, and if it is a UTF-8 locale a suitable single-byte encoding.

Usage

localeToCharset(locale = Sys.getlocale("LC_CTYPE"))

Arguments

locale character string naming a locale.

Details

The operation differs by OS. Locale names are normaly like es_MX.iso88591. If final component indicates an encoding and it is not utf8 we just need to look up the equivalent encoding name. Otherwise, the language (here es) is used to choose a primary or fallback encoding.

In the C locale the answer will be "ASCII".

Value

A character vector naming an encoding and possibly a fallback single-encoding, NA if unknown.

Note

The encoding names are those used by libiconv, and ought also to work with glibc but maybe not with commercial Unixen.
**See Also**

`Sys.getlocale`, `iconv`.

**Examples**

`localeToCharset()`

---

### ls.str

**List Objects and their Structure**

**Description**

`ls.str` and `lsf.str` are “variations” of `ls` applying `str()` to each matched name, see section ‘Value’.

**Usage**

```r
ls.str(pos = 1, pattern, ..., envir = as.environment(pos),
  mode = "any")
lsf.str(pos = 1, ..., envir = as.environment(pos))
```

```
## S3 method for class 'ls_str':
print(x, max.level = 1, give.attr = FALSE, ...)
```

**Arguments**

- `pos` integer indicating search path position.
- `pattern` a regular expression passed to `ls`. Only names matching `pattern` are considered.
- `max.level` maximal level of nesting which is applied for displaying nested structures, e.g., a list containing sub lists. Default 0: Display all nesting levels.
- `give.attr` logical; if TRUE (default), show attributes as sub structures.
- `envir` environment to use, see `ls`.
- `mode` character specifying the `mode` of objects to consider. Passed to `exists` and `get`.
- `x` an object of class "ls_str".
- `...` further arguments to pass. and `lsf.str` passes them to `ls.str` which passes them on to `ls`. The (non-exported) print method `print.ls_str` passes them to `str`.

**Value**

`ls.str` and `lsf.str` return an object of class "ls_str", basically the character vector of matching names (functions only for `lsf.str`), similarly to `ls`, with a `print()` method that calls `str()` on each object.

**Author(s)**

Martin Maechler
Description

Functions to re-create the HTML documentation files to reflect all installed packages.

Usage

make.packages.html(lib.loc = .libPaths())

Arguments

lib.loc character vector. List of libraries to be included.

Details

This sets up the links from packages in libraries to the `.R` subdirectory of the per-session directory (see `tempdir`) and then creates the `packages.html` and `index.txt` files to point to those links. If a package is available in more than one library tree, all the copies are linked, after the first with suffix `.1` etc.

Value

Logical, whether the function succeeded in recreating the files.

See Also

help.start
Description

With server = FALSE attempts to open a client socket to the specified port and host. With server = TRUE listens on the specified port for a connection and then returns a server socket. It is a good idea to use on.exit to ensure that a socket is closed, as you only get 64 of them.

Usage

make.socket(host = "localhost", port, fail = TRUE, server = FALSE)

Arguments

host name of remote host
port port to connect to/listen on
fail failure to connect is an error?
server a server socket?

Value

An object of class "socket".

socket socket number. This is for internal use
port port number of the connection
host name of remote computer

Warning

I don’t know if the connecting host name returned when server = TRUE can be trusted. I suspect not.

Author(s)

Thomas Lumley

References

Adapted from Luke Tierney’s code for XLISP-Stat, in turn based on code from Robbins and Robbins "Practical UNIX Programming"

See Also

close.socket, read.socket
Examples

```r
daytime <- function(host = "localhost"){ 
a <- make.socket(host, 13)
on.exit(close.socket(a))read.socket(a)
}
## Official time (UTC) from US Naval Observatory
## Not run: daytime("tick.usno.navy.mil")
```

memory.size  

Report on Memory Allocation

Description

memory.size and memory.limit are used to manage the total memory allocation on Windows. On other platforms these are stubs which report infinity with a warning.

Usage

```r
memory.size(max = FALSE)
memory.limit(size = NA)
```

Arguments

- `max` logical. If true the maximum amount of memory obtained from the OS is reported, otherwise the amount currently in use.
- `size` numeric. If NA report the memory size, otherwise request a new limit, in Mb.

Details

To restrict memory usage on a Unix-alike use the facilities of the shell used to launch R, e.g. `limit` or `ulimit`.

Value

Size in bytes: always Inf.

See Also

- Memory-limits for other limits.
**menu**  
*Menu Interaction Function*

**Description**

`menu` presents the user with a menu of choices labelled from 1 to the number of choices. To exit without choosing an item one can select ‘0’.

**Usage**

```r
menu(choices, graphics = FALSE, title = "")
```

**Arguments**

- `choices`  
  a character vector of choices
- `graphics`  
  a logical indicating whether a graphics menu should be used if available.
- `title`  
  a character string to be used as the title of the menu. NULL is also accepted.

**Details**

If `graphics = TRUE` and a windowing system is available (Windows, MacOS X or X11 via Tcl/Tk) a listbox widget is used, otherwise a text menu.

Ten or fewer items will be displayed in a single column, more in multiple columns if possible within the current display width.

No title is displayed if `title` is NULL or "".

**Value**

The number corresponding to the selected item, or 0 if no choice was made.

**References**

**See Also**

`select.list`, which is used to implement the graphical menu, and allows multiple selections.

**Examples**

```r
## Not run:
switch(menu(c("List letters", "List LETTERS")) + 1,
        cat("Nothing done\n"), letters, LETTERS)
## End(Not run)
```
methods

List Methods for S3 Generic Functions or Classes

Description

List all available methods for an S3 generic function, or all methods for a class.

Usage

methods(generic.function, class)

Arguments

generic.function

a generic function, or a character string naming a generic function.

class

a symbol or character string naming a class: only used if

generic.function

is not supplied.

Details

Function methods can be used to find out about the methods for a particular generic function or class. The functions listed are those which are named like methods and may not actually be methods (known exceptions are discarded in the code). Note that the listed methods may not be user-visible objects, but often help will be available for them.

If class is used, we check that a matching generic can be found for each user-visible object named. If generic.function is given, there is a warning if it appears not to be a generic function. (The check for being generic used can be fooled.)

Value

An object of class "MethodsFunction", a character vector of function names with an "info" attribute. There is a print method which marks with an asterisk any methods which are not visible: such functions can be examined by getS3method or getAnywhere.

The "info" attribute is a data frame, currently with a logical column, visible and a factor column from (indicating where the methods were found).

Note

This scheme is called S3 (S version 3). For new projects, it is recommended to use the more flexible and robust S4 scheme provided in the methods package. Functions can have both S3 and S4 methods, and function showMethods will list the S4 methods (possibly none).

The original methods function was written by Martin Maechler.

References

See Also

S3Methods, class, getS3method
Examples

methods(summary)
methods(class = "aov")
methods("[[")  # uses C-internal dispatching
methods("$")
methods("$<-")  # replacement function
methods("*")   # binary operator
methods("Math")  # group generic
methods("axis")  # looks like it has methods, but not generic
## Not run:
methods(print)  # over 100
## End(Not run)

Description

Functions helping to maintain CRAN, some of them may also be useful for administrators of other repository networks.

Usage

mirror2html(mirrors = NULL, file = "mirrors.html",
head = "mirrors-head.html", foot = "mirrors-foot.html")
checkCRAN(method)

Arguments

mirrors  A data frame, by default the CRAN list of mirrors is used.
file    A connection object or a character string.
head    Name of optional header file.
foot    Name of optional footer file.
method  Download method, see download.file.

Details

mirror2html creates the HTML file for the CRAN list of mirrors and invisibly returns the HTML text.
checkCRAN performs a sanity checks on all CRAN mirrors.
modifyList  

Recursively Modify Elements of a List

Description

Modifies a possibly nested list recursively by changing a subset of elements at each level to match a second list.

Usage

modifyList(x, val)

Arguments

x  
a named list, possibly empty.

val  
a named list with components to replace corresponding components in x.

Value

A modified version of x, with the modifications determined as follows (here, list elements are identified by their names). Elements in val which are missing from x are added to x. For elements that are common to both but are not both lists themselves, the component in x is replaced by the one in val. For common elements that are both lists, x[[name]] is replaced by modifyList(x[[name]], val[[name]]).

Author(s)

Deepayan Sarkar (Deepayan.Sarkar@R-project.org)

Examples

foo <- list(a = 1, b = list(c = "a", d = FALSE))
bar <- modifyList(foo, list(e = 2, b = list(d = TRUE)))
str(foo)
str(bar)

normalizePath  

Express File Paths in Canonical Form

Description

Convert file paths to canonical form for the platform, to display them in a user-understandable form.

Usage

normalizePath(path)

Arguments

path  
character vector of file paths.
Details
Where the platform supports it this turns paths into absolute paths in their canonical form (no ./, .. / nor symbolic links).
If the path is not a real path the result is undefined but will most likely be the corresponding input element.

Value
A character vector.

Examples

\[
\text{cat(normalizePath(c(R.home(), tempdir())), sep = "\n")}
\]

nsl

Look up the IP Address by Hostname

Description
Interface to gethostbyname.

Usage

\[\text{nsl(hostname)}\]

Arguments

hostname the name of the host.

Value
The IP address, as a character string, or NULL if the call fails.

Note
This was included as a test of internet connectivity, to fail if the node running R is not connected. It will also return NULL if BSD networking is not supported, including the header file ‘arpa/inet.h’.

Examples

\[\text{## Not run: nsl("www.r-project.org")}\]
Report the Space Allocated for an Object

Description

Provides an estimate of the memory that is being used to store an R object.

Usage

object.size(x)

Arguments

x
An R object.

Details

Exactly which parts of the memory allocation should be attributed to which object is not clear-cut. This function merely provides a rough indication: it should be reasonably accurate for atomic vectors, but does not detect if elements of a list are shared, for example. (Sharing amongst elements of a character vector is taken into account.)

The calculation is of the size of the object, and excludes the space needed to store its name in the symbol table.

Associated space (e.g. the environment of a function and what the pointer in a EXTTPRSXP points to) is not included in the calculation.

Object sizes are larger on 64-bit platforms than 32-bit ones, but will very likely be the same on different platforms with the same word length and pointer size.

Value

An estimate of the memory allocation attributable to the object, in bytes.

See Also

Memory-limits for the design limitations on object size.

Examples

object.size(letters)
object.size(ls)
## find the 10 largest objects in the base package
z <- sapply(ls("package:base"), function(x)
  object.size(get(x, envir = baseenv()))
as.matrix(rev(sort(z))[1:10])
Create a Skeleton for a New Source Package

Description

`package.skeleton` automates some of the setup for a new source package. It creates directories, saves functions and data to appropriate places, and creates skeleton help files and a ‘Read-and-delete-me’ file describing further steps in packaging.

Usage

```
package.skeleton(name = "anRpackage", list, environment = .GlobalEnv,
                 path = ".", force = FALSE, namespace = FALSE,
                 code_files = character())
```

Arguments

- **name** character string: the directory name for your package.
- **list** character vector naming the R objects to put in the package.
- **environment** if `list` is omitted and `code_files` is empty, the contents of this environment are packaged.
- **path** path to put the package directory in.
- **force** If `FALSE` will not overwrite an existing directory.
- **namespace** a logical indicating whether to add a name space for the package.
- **code_files** a character vector with the paths to R code files to build the package around.

Details

The package sources are placed in subdirectory `name` of `path`.

This tries to create filenames valid for all OSes known to run R. Invalid characters are replaced by `'_`_, invalid names are preceded by `'zz'`, and finally the converted names are made unique by `make.unique(sep = "_")`. This can be done for code and help files but not data files (which are looked for by name). Also, the code and help files should have names starting with an ASCII letter or digit, and this is checked and if necessary z prepended.

If `code_files` are given, these are copied over to the package code directory (so that non-function code objects are not converted to data sets), and the corresponding help files are generated.

When you are done, delete the ‘Read-and-delete-me’ file, as it should not be distributed.

Value

used for its side-effects.

References

Read the Writing R Extensions manual for more details.

Once you have created a source package you need to install it: see the R Installation and Administration manual, INSTALL and install.packages.
### Examples

```r
## two functions and two "data sets":
f <- function(x,y) x+y
g <- function(x,y) x-y
d <- data.frame(a=1, b=2)
e <- rnorm(1000)

package.skeleton(list=c("f","g","d","e"), name="mypkg")
```

---

**packageDescription**  
**Package Description**

### Description

Parses and returns the ‘DESCRIPTION’ file of a package.

### Usage

```r
packageDescription(pkg, lib.loc = NULL, fields = NULL, drop = TRUE, encoding = "")
```

### Arguments

- `pkg`: a character string with the package name.
- `lib.loc`: a character vector of directory names of R libraries, or NULL. The default value of NULL corresponds to all libraries currently known. If the default is used, the loaded packages are searched before the libraries.
- `fields`: a character vector giving the tags of fields to return (if other fields occur in the file they are ignored).
- `drop`: If TRUE and the length of `fields` is 1, then a single character string with the value of the respective field is returned instead of an object of class "packageDescription".
- `encoding`: If there is an Encoding field, to what encoding should re-encoding be attempted? If NA, no re-encoding. The other values are as used by `iconv`, so the default "" indicates the encoding of the current locale.

### Details

A package will not be ‘found’ unless it has a ‘DESCRIPTION’ file which contains a valid Version field. Different warnings are given when no package directory is found and when there is a suitable directory but no valid ‘DESCRIPTION’ file.
Value

If a ‘DESCRIPTION’ file for the given package is found and can successfully be read, `packageDescription` returns an object of class "packageDescription", which is a named list with the values of the (given) fields as elements and the tags as names, unless `drop = TRUE`.

If parsing the ‘DESCRIPTION’ file was not successful, it returns a named list of NAs with the field tags as names if `fields` is not null, and NA otherwise.

See Also

`read.dcf`

Examples

```r
packageDescription("stats")
packageDescription("stats", fields = c("Package", "Version"))
packageDescription("stats", fields = "Version")
packageDescription("stats", fields = "Version", drop = FALSE)
```
packageStatus

 type  type of package distribution: see `install.packages`.

 object  an object of class "packageStatus" as returned by `packageStatus`.

 ask  if TRUE, the user is prompted which packages should be upgraded and which not.

 ...  currently not used.

Details

The URLs in repositories should be full paths to the appropriate contrib sections of the repositories. The default is `contrib.url(getOption("repos"))`.

There are `print` and `summary` methods for the "packageStatus" objects: the `print` method gives a brief tabular summary and the `summary` method prints the results.

The `update` method updates the "packageStatus" object. The `upgrade` method is similar to `update.packages`: it offers to install the current versions of those packages which are not currently up-to-date.

Value

An object of class "packageStatus". This is a list with two components

inst  a data frame with columns as the matrix returned by `installed.packages` plus "Status", a factor with levels c("ok", "upgrade"). Only the newest version of each package is reported, in the first repository in which it appears.

avail  a data frame with columns as the matrix returned by `available.packages` plus "Status", a factor with levels c("installed", "not installed", "unavailable")..

See Also

`installed.packages`, `available.packages`

Examples

```r
## Not run:
x <- packageStatus()
print(x)
summary(x)
upgrade(x)
x <- update(x)
print(x)
## End(Not run)
```
Invoke a Pager on an R Object

Description
Displays a representation of the object named by x in a pager via file.show.

Usage
page(x, method = c("dput", "print"), ...)

Arguments
x An R object, or a character string naming an object.
method The default method is to dump the object via dput. An alternative is to use
print and capture the output to be shown in the pager.
... additional arguments for dput.print or file.show (such as title).

Details
If x is a length-one character vector, it is used as the name of an object to look up in the environment
from which page is called. All other objects are displayed directly.
A default value of title is passed to file.show if one is not supplied in ....

See Also
file.show, edit, fix.
To go to a new page when graphing, see frame.

Examples
## Not run:
## four ways to look at the code of 'page'
page(page) # as an object
page("page") # a character string
v <- "page"; page(v) # a length-one character vector
page(utils::page) # a call
## End(Not run)

Person Names and Contact Information

Description
A class and utility methods for holding information about persons like name and email address.
Usage

```r
person(first = "", last = "", middle = "", email = "")
personList(...)
as.person(x)
as.personList(x)
```

```r
## S3 method for class 'person':
as.character(x, ...)
## S3 method for class 'personList':
as.character(x, ...)
```

```r
## S3 method for class 'person':
toBibtex(object, ...)
## S3 method for class 'personList':
toBibtex(object, ...)
```

Arguments

```r
first character string, first name
middle character string, middle name(s)
last character string, last name
email character string, email address
... for personList an arbitrary number of person objects
x a character string or an object of class person or personList
object an object of class person or personList
```

Examples

```r
## create a person object directly
p1 <- person("Karl", "Pearson", email = "pearson@stats.heaven")
p1
```

```r
## convert a string
p2 <- as.person("Ronald Aylmer Fisher")
p2
```

```r
## create one object holding both
p <- personList(p1, p2)
p
```

```r
## convert to BibTeX author field
toBibtex(p)
```
Utilities for checking whether the sources of an R add-on package work correctly, and for building a source or binary package from them.

**Usage**

```
R CMD build [options] pkgdirs
R CMD check [options] pkgdirs
```

**Arguments**

- **pkgdirs**: a list of names of directories with sources of R add-on packages.
- **options**: further options to control the processing, or for obtaining information about usage and version of the utility.

**Details**

- `R CMD check` checks R add-on packages from their sources, performing a wide variety of diagnostic checks.
- `R CMD build` builds R source or binary packages from their sources. The name(s) of the packages are taken from the ‘DESCRIPTION’ files and not from the directory names (as from R 2.5.0).
- Use `R CMD foo --help` to obtain usage information on utility `foo`.
- Several of the options to `build --binary` are passed to `INSTALL` so consult its help for the details.

**See Also**

- The sections on “Checking and building packages” and “Processing Rd format” in “Writing R Extensions” (see the ‘doc/manual’ subdirectory of the R source tree).
- `INSTALL` is called by `build --binary`.

---

**prompt**

*Produce Prototype of an R Documentation File*

Facilitate the constructing of files documenting R objects.

**Usage**

```
prompt(object, filename = NULL, name = NULL, ...)  # Default S3 method:
prompt(object, filename = NULL, name = NULL, force.function = FALSE, ...)  # S3 method for class 'data.frame':
prompt(object, filename = NULL, name = NULL, ...)  # S3 method for class 'data.frame':
```
Arguments

object     an R object, typically a function for the default method.
filename   usually, a connection or a character string giving the name of the file to which
the documentation shell should be written. The default corresponds to a file
whose name is name followed by ".Rd". Can also be NA (see below).
name       a character string specifying the name of the object.
force.function     a logical. If TRUE, treat object as function in any case.
...     further arguments passed to or from other methods.

Details

Unless filename is NA, a documentation shell for object is written to the file specified by
filename, and a message about this is given. For function objects, this shell contains the proper
function and argument names. R documentation files thus created still need to be edited and moved
into the ‘man’ subdirectory of the package containing the object to be documented.

If filename is NA, a list-style representation of the documentation shell is created and re-
turned. Writing the shell to a file amounts to cat(unlist(x), file = filename, sep = "\n"), where x is the list-style representation.

When prompt is used in for loops or scripts, the explicit name specification will be useful.

Value

If filename is NA, a list-style representation of the documentation shell. Otherwise, the name of
the file written to is returned invisibly.

Warning

The default filename may not be a valid filename under limited file systems (e.g. those on Windows).
Currently, calling prompt on a non-function object assumes that the object is in fact a data set and
hence documents it as such. This may change in future versions of R. Use promptData to create
documentation skeletons for data sets.

Note

The documentation file produced by prompt.data.frame does not have the same format as
many of the data frame documentation files in the base package. We are trying to settle on a
preferred format for the documentation.

Author(s)

Douglas Bates for prompt.data.frame

See Also

promptData, help and the chapter on “Writing R documentation” in “Writing R Extensions” (see the ‘doc/manual’ subdirectory of the R source tree).

For creation of many help pages (for a package), see package.skeleton.

To prompt the user for input, see readline.

Examples

```r
require(graphics)
prompt(plot.default)
prompt(interactive, force.function = TRUE)
unlink("plot.default.Rd")
unlink("interactive.Rd")
prompt(women) # data.frame
unlink("women.Rd")
prompt(sunspots) # non-data.frame data
unlink("sunspots.Rd")
```

---

promptData  Generate a Shell for Documentation of Data Sets

Description

Generates a shell of documentation for a data set.

Usage

```r
promptData(object, filename = NULL, name = NULL)
```

Arguments

- **object**: an R object to be documented as a data set.
- **filename**: usually, a connection or a character string giving the name of the file to which the documentation shell should be written. The default corresponds to a file whose name is `name` followed by `.Rd`. Can also be NA (see below).
- **name**: a character string specifying the name of the object.

Details

Unless `filename` is NA, a documentation shell for `object` is written to the file specified by `filename`, and a message about this is given.

If `filename` is NA, a list-style representation of the documentation shell is created and returned. Writing the shell to a file amounts to `cat(unlist(x), file = filename, sep = "\n")`, where `x` is the list-style representation.

Currently, only data frames are handled explicitly by the code.
Value

If `filename` is `NA`, a list-style representation of the documentation shell. Otherwise, the name of the file written to is returned invisibly.

Warning

This function is still experimental. Both interface and value might change in future versions. In particular, it may be preferable to use a character string naming the data set and optionally a specification of where to look for it instead of using `object/name` as we currently do. This would be different from `prompt`, but consistent with other prompt-style functions in package `methods`, and also allow prompting for data set documentation without explicitly having to load the data set.

`prompt`

Examples

```r
promptData(sunspots)
unlink("sunspots.Rd")
```

---

`promptPackage`  
*Generate a Shell for Documentation of a Package*

Description

Generates a shell of documentation for an installed or source package.

Usage

```r
promptPackage(package, lib.loc = NULL, filename = NULL, name = NULL, final = FALSE)
```

Arguments

- `package`: the name of an *installed or source* package to be documented.
- `lib.loc`: a character vector describing the location of R library trees to search through, or `NULL`. The default value of `NULL` corresponds to all libraries currently known. For a source package this should specify the parent directory of the package’s sources.
- `filename`: usually, a connection or a character string giving the name of the file to which the documentation shell should be written. The default corresponds to a file whose name is `name` followed by `".Rd"`. Can also be `NA` (see below).
- `name`: a character string specifying the name of the help topic, typically of the form `<pkg>-package`.
- `final`: a logical value indicating whether to attempt to create a usable version of the help topic, rather than just a shell.
Details

Unless `filename` is `NA`, a documentation shell for `package` is written to the file specified by `filename`, and a message about this is given.

If `filename` is `NA`, a list-style representation of the documentation shell is created and returned. Writing the shell to a file amounts to `cat(unlist(x), file = filename, sep = "\n")`, where `x` is the list-style representation.

If `final` is `TRUE`, the generated documentation will not include the place-holder slots for manual editing, it will be usable as-is. In most cases a manually edited file is preferable (but `final = TRUE` is certainly less work).

Value

If `filename` is `NA`, a list-style representation of the documentation shell. Otherwise, the name of the file written to is returned invisibly.

See Also

`prompt`

Examples

```r
filename <- tempfile()
promptPackage("utils", file=filename)
file.show(filename)
unlink(filename)
```

---

**Data Input from Spreadsheet**

Description

Reads a file in Data Interchange Format (DIF) and creates a data frame from it. DIF is a format for data matrices such as single spreadsheets.

Usage

```r
read.DIF(file, header = FALSE, 
          dec = ".", row.names, col.names, 
          as.is = !stringsAsFactors, 
          na.strings = "NA", colClasses = NA, nrows = -1, 
          skip = 0, check.names = TRUE, 
          blank.lines.skip = TRUE, 
          stringsAsFactors = default.stringsAsFactors())
```

Arguments

- `file` the name of the file which the data are to be read from, or a connection, or a complete URL.
a logical value indicating whether the spreadsheet contains the names of the variables as its first line. If missing, the value is determined from the file format: header is set to TRUE if and only if the first row contains only character values and the top left cell is empty.

dec
the character used in the file for decimal points.

row.names
a vector of row names. This can be a vector giving the actual row names, or a single number giving the column of the table which contains the row names, or character string giving the name of the table column containing the row names. If there is a header and the first row contains one fewer field than the number of columns, the first column in the input is used for the row names. Otherwise if row.names is missing, the rows are numbered. Using row.names = NULL forces row numbering.

col.names
a vector of optional names for the variables. The default is to use "V" followed by the column number.

as.is
the default behavior of read.DIF is to convert character variables (which are not converted to logical, numeric or complex) to factors. The variable as.is controls the conversion of columns not otherwise specified by colClasses. Its value is either a vector of logicals (values are recycled if necessary), or a vector of numeric or character indices which specify which columns should not be converted to factors.

Note: to suppress all conversions including those of numeric columns, set colClasses = "character".

Note that as.is is specified per column (not per variable) and so includes the column of row names (if any) and any columns to be skipped.

na.strings
a character vector of strings which are to be interpreted as NA values. Blank fields are also considered to be missing values in logical, integer, numeric and complex fields.

colClasses
character. A vector of classes to be assumed for the columns. Recycled as necessary, or if the character vector is named, unspecified values are taken to be NA.

Possible values are NA (when type.convert is used), "NULL" (when the column is skipped), one of the atomic vector classes (logical, integer, numeric, complex, character, raw), or "factor", "Date" or "POSIXct". Otherwise there needs to be an as method (from package methods) for conversion from "character" to the specified formal class.

Note that colClasses is specified per column (not per variable) and so includes the column of row names (if any).

nrows
the maximum number of rows to read in. Negative values are ignored.

skip
the number of lines of the data file to skip before beginning to read data.

check.names
logical. If TRUE then the names of the variables in the data frame are checked to ensure that they are syntactically valid variable names. If necessary they are adjusted (by make.names) so that they are, and also to ensure that there are no duplicates.

blank.lines.skip
logical: if TRUE blank lines in the input are ignored.

stringsAsFactors
logical: should character vectors be converted to factors?
Value

A data frame (data.frame) containing a representation of the data in the file. Empty input is an error unless col.names is specified, when a 0-row data frame is returned: similarly giving just a header line if header = TRUE results in a 0-row data frame.

Note

The columns referred to in as.is and colClasses include the column of row names (if any).

Less memory will be used if colClasses is specified as one of the six atomic vector classes.

References

The DIF format specification can be found by searching on http://www.wotsit.org/; the optional header fields are ignored. See also http://en.wikipedia.org/wiki/Data_Interchange_Format.

The term is likely to lead to confusion: Windows will have a ‘Windows Data Interchange Format (DIF) data format’ as part of its WinFX system, which may or may not be compatible.

See Also

The R Data Import/Export manual.

scan, type.convert, read.fwf for reading fixed width formatted input; read.table; data.frame.

----------

read.fortran  Read fixed-format data

Description

Read fixed-format data files using Fortran-style format specifications.

Usage

read.fortran(file, format, ..., as.is = TRUE, colClasses = NA)

Arguments

file  File or connection to read from
format  Character vector or list of vectors. See Details below.
...  Other arguments for read.table
as.is  Keep characters as characters?
colClasses  Variable classes to override defaults. See read.table for details.
Details

The format for a field is of one of the following forms: \( rFl.d, rDl.d, rXl, rAl, rIl \), where \( l \) is the number of columns, \( d \) is the number of decimal places, and \( r \) is the number of repeats. \( F \) and \( D \) are numeric formats, \( A \) is character, \( I \) is integer, and \( X \) indicates columns to be skipped. The repeat code \( r \) and decimal place code \( d \) are always optional. The length code \( l \) is required except for \( X \) formats when \( r \) is present.

For a single-line record, \texttt{format} should be a character vector. For a multiline record it should be a list with a character vector for each line.

Skipped (\( X \)) columns are not passed to \texttt{read.table}, so \texttt{colClasses}, \texttt{col.names}, and similar arguments passed to \texttt{read.table} should not reference these columns.

Value

A data frame

See Also

\texttt{read.fwf, read.csv}

Examples

```r
ff <- tempfile()
cat(file=ff, "123456", "987654", sep="\n")
read.fortran(ff, c("F2.1","F2.0","I2"))
read.fortran(ff, c("2F1.0","2X","2A1"))
unlink(ff)
cat(file=ff, "123456AB", "987654CD", sep="\n")
read.fortran(ff, list(c("2F3.1","A2"), c("3I2","2X")))
unlink(ff)
```

---

**read.fwf**

*Read Fixed Width Format Files*

Description

Read a “table” of fixed width formatted data into a \texttt{data.frame}.

Usage

```r
read.fwf(file, widths, header = FALSE, sep = "\t", as.is = FALSE,
    skip = 0, row.names, col.names, n = -1,
    buffersize = 2000, ...)
```

Arguments

- **file**
  - the name of the file which the data are to be read from.
  - Alternatively, \texttt{file} can be a \texttt{connection}, which will be opened if necessary, and if so closed at the end of the function call.

- **widths**
  - integer vector, giving the widths of the fixed-width fields (of one line), or list of integer vectors giving widths for multiline records.
header a logical value indicating whether the file contains the names of the variables as its first line. If present, the names must be delimited by sep.

sep character; the separator used internally; should be a character that does not occur in the file (except in the header).

as.is see read.table.

skip number of initial lines to skip; see read.table.

row.names see read.table.

col.names see read.table.

n the maximum number of records (lines) to be read, defaulting to no limit.

buffersize Maximum number of lines to read at one time

... further arguments to be passed to read.table. Useful further arguments include na.strings, colClasses and strip.white.

Details

Multiline records are concatenated to a single line before processing. Fields that are of zero-width or are wholly beyond the end of the line in file are replaced by NA.

Negative-width fields are used to indicate columns to be skipped, eg -5 to skip 5 columns. These fields are not seen by read.table and so should not be included in a col.names or colClasses argument (nor in the header line, if present).

Reducing the buffersize argument may reduce memory use when reading large files with long lines. Increasing buffersize may result in faster processing when enough memory is available.

Value

A data.frame as produced by read.table which is called internally.

Author(s)

Brian Ripley for R version: original Perl by Kurt Hornik.

See Also

scan and read.table.

Examples

ff <- tempfile()
cat(file=ff, "123456", "987654", sep="\n")
read.fwf(ff, width=c(1,2,3)) #> 1 23 456 \ 9 87 654
read.fwf(ff, width=c(1,-2,3)) #> 1 456 \ 9 654
unlink(ff)
cat(file=ff, "123", "987654", sep="\n")
read.fwf(ff, width=c(1,0, 2,3)) #> 1 NA 23 NA \ 9 NA 87 654
unlink(ff)
cat(file=ff, "123456", "987654", sep="\n")
read.fwf(ff, width=list(c(1,0, 2,3), c(2,2,2))) #> 1 NA 23 456 98 76 54
unlink(ff)
read.socket  

Read from or Write to a Socket

Description

read.socket reads a string from the specified socket, write.socket writes to the specified socket. There is very little error checking done by either.

Usage

read.socket(socket, maxlen = 256, loop = FALSE)
write.socket(socket, string)

Arguments

socket  a socket object
maxlen  maximum length of string to read
loop   wait for ever if there is nothing to read?
string  string to write to socket

Value

read.socket returns the string read.

Author(s)

Thomas Lumley

close.socket, make.socket

Examples

finger <- function(user, host = "localhost", port = 79, print = TRUE) 
{
  if (!is.character(user))
    stop("user name must be a string")
  user <- paste(user,"\r\n")
  socket <- make.socket(host, port)
  on.exit(close.socket(socket))
  write.socket(socket, user)
  output <- character(0)
  repeat{
    ss <- read.socket(socket)
    if (ss == ") break
    output <- paste(output, ss)
  }
  close.socket(socket)
  if (print) cat(output)
  invisible(output)
}
```r
## Not run:
finger("root")  ## only works if your site provides a finger daemon
## End(Not run)
```

## read.table  Data Input

### Description

Reads a file in table format and creates a data frame from it, with cases corresponding to lines and variables to fields in the file.

### Usage

```r
read.table(file, header = FALSE, sep = " ", quote = " ", dec = ".", row.names, col.names,
as.is = !stringsAsFactors,
na.strings = "NA", colClasses = NA, nrow = -1,
skip = 0, check.names = TRUE, fill = !blank.lines.skip,
strip.white = FALSE, blank.lines.skip = TRUE,
comment.char = ",", allowEscapes = FALSE, flush = FALSE,
stringsAsFactors = default.stringsAsFactors(),
encoding = "unknown")
```

```r
read.csv(file, header = TRUE, sep = ",", quote="", dec=".",
fill = TRUE, comment.char="", ...)
```

```r
read.csv2(file, header = TRUE, sep = ";", quote="", dec=".",
fill = TRUE, comment.char="", ...)
```

```r
read.delim(file, header = TRUE, sep = "\t", quote="", dec=".",
fill = TRUE, comment.char="", ...)
```

```r
read.delim2(file, header = TRUE, sep = "\t", quote="", dec=".",
fill = TRUE, comment.char="", ...)
```

### Arguments

- **file**: the name of the file which the data are to be read from. Each row of the table appears as one line of the file. If it does not contain an `absolute` path, the file name is `relative` to the current working directory, `getwd()`. Tilde-expansion is performed where supported.

Alternatively, `file` can be a readable `connection` (which will be opened for reading if necessary, and if so closed at the end of the function call). If `stdin()` is used, the prompts for lines may be somewhat confusing. Terminate input with a blank line or an EOF signal, `Ctrl-D` on Unix and `Ctrl-Z` on Windows. Any pushback on `stdin()` will be cleared before return.

`file` can also be a complete URL.

To read a data file not in the current encoding (for example a Latin-1 file in a UTF-8 locale or conversely) use a `file` connection setting the `encoding` argument.
header
a logical value indicating whether the file contains the names of the variables as its first line. If missing, the value is determined from the file format: header is set to TRUE if and only if the first row contains one fewer field than the number of columns.

sep
the field separator character. Values on each line of the file are separated by this character. If sep = " " (the default for read.table) the separator is "white space", that is one or more spaces, tabs, newlines or carriage returns.

quote
the set of quoting characters. To disable quoting altogether, use quote = "". See scan for the behaviour on quotes embedded in quotes.

dec
the character used in the file for decimal points.

row.names
a vector of row names. This can be a vector giving the actual row names, or a single number giving the column of the table which contains the row names, or character string giving the name of the table column containing the row names. If there is a header and the first row contains one fewer field than the number of columns, the first column in the input is used for the row names. Otherwise if row.names is missing, the rows are numbered. Using row.names = NULL forces row numbering. Missing or NULL row.names generate row names that are considered to be 'automatic' (and not preserved by as.matrix).

col.names
a vector of optional names for the variables. The default is to use "V" followed by the column number.

as.is
the default behavior of read.table is to convert character variables (which are not converted to logical, numeric or complex) to factors. The variable as.is controls the conversion of columns not otherwise specified by colClasses. Its value is either a vector of logicals (values are recycled if necessary), or a vector of numeric or character indices which specify which columns should not be converted to factors.

Note: to suppress all conversions including those of numeric columns, set colClasses = "character".

Note that as.is is specified per column (not per variable) and so includes the column of row names (if any) and any columns to be skipped.

na.strings
a character vector of strings which are to be interpreted as NA values. Blank fields are also considered to be missing values in logical, integer, numeric and complex fields.

colClasses
character. A vector of classes to be assumed for the columns. Recycled as necessary, or if the character vector is named, unspecified values are taken to be NA.

Possible values are NA (when type.convert is used), "NULL" (when the column is skipped), one of the atomic vector classes (logical, integer, numeric, complex, character, raw), or "factor", "Date" or "POSIXct". Otherwise there needs to be an as method (from package methods) for conversion from "character" to the specified formal class.

Note that colClasses is specified per column (not per variable) and so includes the column of row names (if any).

nrows
integer: the maximum number of rows to read in. Negative and other invalid values are ignored.

skip
integer: the number of lines of the data file to skip before beginning to read data.
check.names  logical. If TRUE then the names of the variables in the data frame are checked to ensure that they are syntactically valid variable names. If necessary they are adjusted (by make.names) so that they are, and also to ensure that there are no duplicates.

fill  logical. If TRUE then in case the rows have unequal length, blank fields are implicitly added. See Details.

strip.white  logical. Used only when sep has been specified, and allows the stripping of leading and trailing white space from character fields (numeric fields are always stripped). See scan for further details, remembering that the columns may include the row names.

blank.lines.skip  logical: if TRUE blank lines in the input are ignored.

comment.char  character: a character vector of length one containing a single character or an empty string. Use "" to turn off the interpretation of comments altogether.

allowEscapes  logical. Should C-style escapes such as \n be processed or read verbatim (the default)? Note that if not within quotes these could be interpreted as a delimiter (but not as a comment character). For more details see scan.

flush  logical: if TRUE, scan will flush to the end of the line after reading the last of the fields requested. This allows putting comments after the last field.

stringsAsFactors  logical: should character vectors be converted to factors?

encoding  encoding to be assumed for input strings. It is used to mark character strings as known to be in Latin-1 or UTF-8: it is not used to re-encode the input.

...  Further arguments to be passed to read.table.

Details

This function is the principal means of reading tabular data into R.

A field or line is ‘blank’ if it contains nothing (except whitespace if no separator is specified) before a comment character or the end of the field or line.

If row.names is not specified and the header line has one less entry than the number of columns, the first column is taken to be the row names. This allows data frames to be read in from the format in which they are printed. If row.names is specified and does not refer to the first column, that column is discarded from such files.

The number of data columns is determined by looking at the first five lines of input (or the whole file if it has less than five lines), or from the length of col.names if it is specified and is longer. This could conceivably be wrong if fill or blank.lines.skip are true, so specify col.names if necessary.

read.csv and read.csv2 are identical to read.table except for the defaults. They are intended for reading “comma separated value” files (’.CSV’) or (read.csv2) the variant used in countries that use a comma as decimal point and a semicolon as field separator. Similarly, read.delim and read.delim2 are for reading delimited files, defaulting to the TAB character for the delimiter. Notice that header = TRUE and fill = TRUE in these variants, and that the comment character is disabled.

The rest of the line after a comment character is skipped; quotes are not processed in comments. Complete comment lines are allowed provided blank.lines.skip = TRUE; however, comment lines prior to the header must have the comment character in the first non-blank column.

Quoted fields with embedded newlines are supported except after a comment character.
Value

A data frame (\texttt{data.frame}) containing a representation of the data in the file.

Empty input is an error unless \texttt{col.names} is specified, when a 0-row data frame is returned: similarly giving just a header line if \texttt{header = TRUE} results in a 0-row data frame. Note that in either case the columns will logical unless \texttt{colClasses} was supplied.

Character strings in the result (including factor levels) will have a declared encoding if \texttt{encoding} is "latin1" or "UTF-8".

Note

The columns referred to in \texttt{as.is} and \texttt{colClasses} include the column of row names (if any). Less memory will be used if \texttt{colClasses} is specified as one of the six atomic vector classes. Using \texttt{nrows}, even as a mild over-estimate, will help memory usage.

Using \texttt{comment.char = "\"} will be appreciably faster.

\texttt{read.table} is not the right tool for reading large matrices, especially those with many columns: it is designed to read \texttt{data frames} which may have columns of very different classes. Use \texttt{scan} instead.

\begin{verbatim}
\textbf{readNEWS} \textit{Read R’s NEWS file or a Similar One}
\end{verbatim}

Description

Read R’s NEWS file or a similarly formatted one. This is an experimental feature, new in R 2.4.0 and may change in several ways.

Usage

\begin{verbatim}
readNEWS(file = file.path(R.home(), "NEWS"), trace = FALSE,
         chop = c("first", "1", "par1", "keepAll"))
\end{verbatim}
**Arguments**

- **file**: the name of the file which the data are to be read from. Alternatively, `file` can be a `connection`, which will be opened if necessary, and can also be a complete URL. For more details, see the `file` argument of `read.table`.

- **trace**: logical indicating if the recursive reading should be traced, i.e., print what it is doing.

- **chop**: a character string specifying how the news entries should be “chopped”; `chop = "keepAll"` saves the full entries.

**Value**

An (S3) object of class "newsTree"; effectively a list of lists which is a tree of NEWS entries. Note that this is still experimental and may change in the future.

**Examples**

```r
NEWStr <- readNEWS(trace = TRUE) # chop = "first" ( = "first non-empty")
## keep the full NEWS entry text i.e. "no chopping":
NEWStrA <- readNEWS(chop = "keepAll")
object.size(NEWStr)
object.size(NEWStrA) # (no chopping) ==> about double the size
str(NEWStr, max = 3)
str(NEWStr[[c("2.3", "2.3.1")]]), max=2, vec.len=1)
NEWStr [[c("2.3", "2.3.1", "NEW FEATURES")]]
NEWStrA[[c("2.4", "2.4.0", "NEW FEATURES")]]
```

---

**recover**  
**Browsing after an Error**

**Description**

This function allows the user to browse directly on any of the currently active function calls, and is suitable as an error option. The expression `options(error=recover)` will make this the error option.

**Usage**

```r
recover()
```

**Details**

When called, `recover` prints the list of current calls, and prompts the user to select one of them. The standard R `browser` is then invoked from the corresponding environment; the user can type ordinary S language expressions to be evaluated in that environment.

When finished browsing in this call, type c to return to `recover` from the browser. Type another frame number to browse some more, or type 0 to exit `recover`.

The use of `recover` largely supersedes `dump.frames` as an error option, unless you really want to wait to look at the error. If `recover` is called in non-interactive mode, it behaves like
dump.frames. For computations involving large amounts of data, `recover` has the advantage that it does not need to copy out all the environments in order to browse in them. If you do decide to quit interactive debugging, call `dump.frames` directly while browsing in any frame (see the examples).

**Value**

Nothing useful is returned. However, you can invoke `recover` directly from a function, rather than through the error option shown in the examples. In this case, execution continues after you type `0` to exit `recover`.

**Compatibility Note**

The R `recover` function can be used in the same way as the S-Plus function of the same name; therefore, the error option shown is a compatible way to specify the error action. However, the actual functions are essentially unrelated and interact quite differently with the user. The navigating commands `up` and `down` do not exist in the R version; instead, exit the browser and select another frame.

**References**

See the compatibility note above, however.

**See Also**

`browser` for details about the interactive computations; `options` for setting the error option;

`dump.frames` to save the current environments for later debugging.

**Examples**

```r
## Not run:
options(error = recover) # setting the error option

### Example of interaction

> myFit <- lm(y ~ x, data = xy, weights = w)
Error in lm.wfit(x, y, w, offset = offset, ...) :
  missing or negative weights not allowed

Enter a frame number, or 0 to exit
1:lm(y ~ x, data = xy, weights = w)
2:lm.wfit(x, y, w, offset = offset, ...) 
Selection: 2
Called from: eval(expr, envir, enclos)
Browse[1]> objects() # all the objects in this frame
[1] "method" "n" "ny" "offset" "tol" "w"
[7] 
Browse[1]> w
[1] -0.5013844 1.3112515 0.2939348 -0.8983705 -0.1538642
[6] -0.9772989 0.7888790 -0.1919154 -0.3026882
Browse[1]> dump.frames() # save for offline debugging
Browse[1]> c # exit the browser

Enter a frame number, or 0 to exit
```
### DESCRIPTION

Utility for removing add-on packages.

### Usage

```r
R CMD REMOVE [options] [-l lib] pkgs
```

### Arguments

- **pkgs**: a list with the names of the packages to be removed.
- **lib**: the path name of the R library tree to remove from. May be absolute or relative.
- **options**: further options.

### Details

If used as `R CMD REMOVE pkgs` without explicitly specifying `lib`, packages are removed from the library tree rooted at the first directory in the library path which would be used by R run in the current environment.

To remove from the library tree `lib`, use `R CMD REMOVE -l lib pkgs`.

Use `R CMD REMOVE --help` for more usage information.

### Note

Some binary distributions of R have `INSTALL` in a separate bundle, e.g. an R-devel RPM.

### See Also

`INSTALL`, `remove.packages`
remove.packages  \hspace{1em} \textit{Remove Installed Packages}

**Description**

Removes installed packages/bundles and updates index information as necessary.

**Usage**

```r
remove.packages(pkgs, lib, version)
```

**Arguments**

- `pkgs`: a character vector with the names of the package(s) or bundle(s) to be removed.
- `lib`: a character vector giving the library directories to remove the packages from. If missing, defaults to the first element in `.libPaths()`.
- `version`: A character vector specifying version(s) with versioned installs of the package(s) to remove. If none is provided, the system will remove an unversioned install of the package if one is found, otherwise the latest versioned install.

**Details**

If an element of `pkgs` matches a bundle name, all the packages in the bundle will be removed. This takes precedence over matching a package name.

`pkgs` and `version` will be recycled if necessary to the length of the longer one.

**See Also**

`REMOVE` for a command line version; `install.packages` for installing packages.

**RHOME**  \hspace{1em} \textit{R Home Directory}

**Description**

Returns the location of the R home directory, which is the root of the installed R tree.

**Usage**

```r
R RHOME
```
**roman**  
*Roman Numerals*

**Description**  
Manipulate integers as roman numerals.

**Usage**  
```r  
as.roman(x)  
```

**Arguments**  

*x*  
a numeric vector, or a character vector of arabic or roman numerals.

**Details**

`as.roman` creates objects of class "roman" which are internally represented as integers, and have suitable methods for printing, formatting, subsetting, and coercion to character.

Only numbers between 1 and 3899 have a unique representation as roman numbers.

**References**

**Examples**

```r  
## First five roman 'numbers'.
(y <- as.roman(1:5))
## Middle one.
y[3]
## Current year as a roman number.
(y <- as.roman(format(Sys.Date(), "%Y")))
## 10 years ago ...
y - 10  
```

---

**Rprof**  
*Enable Profiling of R’s Execution*

**Description**

Enable or disable profiling of the execution of R expressions.

**Usage**

```r  
Rprof(filename = "Rprof.out", append = FALSE, interval = 0.02, memory.profiling=FALSE)  
```
Arguments

filename              The file to be used for recording the profiling results. Set to NULL or "" to disable profiling.
append                logical: should the file be over-written or appended to?
interval              real: time interval between samples.
memory.profiling      logical: write memory use information to the file?

Details

Enabling profiling automatically disables any existing profiling to another or the same file.

Profiling works by writing out the call stack every interval seconds, to the file specified. Either the summaryRprof function or the Perl script `R CMD Rprof` can be used to process the output file to produce a summary of the usage; use `R CMD Rprof --help` for usage information.

Note that the timing interval cannot be too small: once the timer goes off, the information is not recorded until the next clock tick (probably every 10msecs). Thus the interval is rounded to the nearest integer number of clock ticks, and is made to be at least one clock tick (at which resolution the total time spent is liable to be underestimated).

Note

Profiling is not available on all platforms. By default, it is attempted to compile support for profiling. Configure R with ‘--disable-R-profiling’ to change this.

As R profiling uses the same mechanisms as C profiling, the two cannot be used together, so do not use `Rprof` in an executable built for profiling.

See Also

The chapter on “Tidying and profiling R code” in “Writing R Extensions” (see the ‘doc/manual’ subdirectory of the R source tree).

`summaryRprof`, `tracemem`, `Rprofmem` for other ways to track memory use.

Examples

```r
## Not run:
Rprof()
## some code to be profiled
Rprof(NULL)
## some code NOT to be profiled
Rprof(append=TRUE)
## some code to be profiled
Rprof(NULL)
...
## Now post-process the output as described in Details
## End(Not run)
```
Description

Enable or disable reporting of memory allocation in R.

Usage

Rprofmem(filename = "Rprofmem.out", append = FALSE, threshold = 0)

Arguments

filename  The file to be used for recording the memory allocations. Set to NULL or "" to disable reporting.
append    logical: should the file be over-written or appended to?
threshold numeric: allocations on R's "large vector" heap larger than this number of bytes will be reported.

Details

Enabling profiling automatically disables any existing profiling to another or the same file.

Profiling writes the call stack to the specified file every time malloc is called to allocate a large vector object or to allocate a page of memory for small objects. The size of a page of memory and the size above which malloc is used for vectors are compile-time constants, by default 2000 and 128 bytes respectively.

The profiler tracks allocations, some of which will be to previously used memory and will not increase the total memory use of R.

Value

None

Note

The memory profiler slows down R even when not in use, and so is a compile-time option. The memory profiler can be used at the same time as other R and C profilers.

See Also

The R sampling profiler, Rprof also collects memory information.
tracemem traces duplications of specific objects.

The "Writing R Extensions" manual section on "Tidying and profiling R code"
Examples

## Not run:
## not supported unless R is compiled to support it.
Rprofmem("Rprofmem.out", threshold=1000)
exmple(glm)
Rprofmem(NULL)
noquote(readLines("Rprofmem.out", n=5))
## End(Not run)

Description

This is an alternative front end for use in `#!` scripts and other scripting applications.

Usage

Rscript [options] [-e expression] file [args]

Arguments

options       A list of options beginning with `--`. These can be any of the options of the standard R front-end, and also those described in the details.
expression    a R expression.
file           The name of a file containing R commands. `--` indicates `stdin`.
args           Arguments to be passed to the script in file.

Details

Rscript --help gives details of usage, and Rscript --version gives the version of Rscript.

Other invocations invoke the R front-end with selected options. This front-end is convenient for writing `#!` scripts since it is an executable and takes file directly as an argument. Options --slave --no-restore are always supplied: these imply --no-save.

Either one or more `--e` options or file should be supplied.

Additional options accepted (before file or args) are

--verbose gives details of what Rscript is doing. Also passed on to R.

--default-packages=list where list is a comma-separated list of package names or NULL. Sets the environment variable R_DEFAULT_PACKAGES which determines the packages loaded on startup. The default for Rscript omits methods as it takes about 60% of the startup time.

Normally the version of R is determined at installation, but this can be overridden by setting the environment variable RHOME.

stdin() refers to the input file, and file("stdin") to the stdin file stream of the process.
Rscript is only supported on systems with the execv system call.

Examples

```r
## Not run:
Rscript -e 'date()' -e 'format(Sys.time(), "

## example #! script
#!/path/to/Rscript --vanilla --default-packages=utils
args <- commandArgs(); args <- args[-(1:match("--args", args))]
res <- try(install.packages(args))
if(inherits(res, "try-error")) q(status=1) else q()

## End(Not run)
```

RShowDoc

Show R Manuals and Other Documentation

Description

Utility function to find and display R documentation.

Usage

```r
RShowDoc(what, type = c("pdf", "html", "txt"), package)
```

Arguments

- **what**: a character string: see Details.
- **type**: an optional character string giving the preferred format.
- **package**: an optional character string specifying the name of a package within which to look for documentation.

Details

what can specify one of several different sources of documentation, including the R manuals (`R-admin`, `R-data`, `R-exts`, `R-intro`, `R-ints`, `R-lang`), NEWS, COPYING (the GPL licence), FAQ (also available as `R-FAQ`), and the files in `R_HOME/doc`.

If package is supplied, documentation is looked for in the `doc` and top-level directories of an installed package of that name.

If what is missing a brief usage message is printed.

The documentation types are tried in turn starting with the first specified in type (or "pdf" if none is specified).

Value

A invisible character string given the path to the file found.
Examples

```r
## Not run:
RShowDoc("R-lang")
RShowDoc("FAQ", type="html")
RShowDoc("frame", package="grid")
RShowDoc("changes.txt", package="grid")
RShowDoc("NEWS", package="MASS")
## End(Not run)
```

RSiteSearch

Search for Key Words or Phrases in the R-help Mailing List Archives
or Documentation

Description

Search for key words or phrases in the R-help mailing list archives, or R manuals and help pages, using the search engine at [http://search.r-project.org](http://search.r-project.org) and view them in a web browser.

Usage

```r
RSiteSearch(string, restrict = c("Rhelp02a", "functions", "docs"),
            format = c("normal", "short"),
            sortby = c("score", "date:late", "date:early",
                       "subject", "subject:descending",
                       "from", "from:descending",
                       "size", "size:descending"),
            matchesPerPage = 20)
```

Arguments

- `string`: word(s) or phrase to search. If the words are to be searched as one entity, enclose all words in braces (see example).
- `restrict`: a character vector, typically of length larger than one: What areas to search in: Rhelp02a for R-help mailing list archive since 2002, Rhelp01 for mailing list archive before 2002, docs for R manuals, functions for help pages. R-devel for R-devel mailing list. Use `c()` to specify more than one.
- `format`: normal or short (no excerpts); can be abbreviated.
- `sortby`: character string (can be abbreviated) indicating how to sort the search results: (score, date:late for sorting by date with latest results first, date:early for earliest first, subject for subject in alphabetical order, subject:descending for reverse alphabetical order, from or from:descending for sender (when applicable), size or size:descending for size.)
- `matchesPerPage`: How many items to show per page.
Details

This function is designed to work with the search site at http://search.r-project.org, and depends on that site continuing to be made available (thanks to Jonathan Baron and the School of Arts and Sciences of the University of Pennsylvania).

Unique partial matches will work for all arguments. Each new browser window will stay open unless you close it.

Value

(Invisibly) the complete URL passed to the browser, including the query string.

Author(s)

Andy Liaw and Jonathan Baron

See Also

help.search, help.start for local searches.
browseURL for how the help file is displayed.

Examples

## Not run:
# need Internet connection
RSiteSearch("logistic regression") # matches exact phrase
RSiteSearch("Baron Liaw", restr = "Rhelp02a")
## Search in R-devel archive and documents (and store the query-string):
fullquery <- RSiteSearch("S4", restr = c("R-dev", "docs"))
fullquery # a string of ~ 116 characters
## the latest purported bug reports
RSiteSearch("bug", restr = "R-devel", sortby = "date:late")
## End(Not run)

Rtangle

R Driver for Stangle

Description

A driver for Stangle that extracts R code chunks.

Usage

Rtangle()
RtangleSetup(file, syntax, output = NULL, annotate = TRUE,
                split = FALSE, prefix = TRUE, quiet = FALSE)
Arguments

- **file**: Name of Sweave source file.
- **syntax**: An object of class `SweaveSyntax`.
- **output**: Name of output file, default is to remove extension `.nw`, `.Rnw` or `.Snw` and to add extension `.R`. Any directory names in `file` are also removed such that the output is created in the current working directory.
- **annotate**: By default, code chunks are separated by comment lines specifying the names and numbers of the code chunks. If `FALSE`, only the code chunks without any decorating comments are extracted.
- **split**: Split output in single files per code chunk?
- **prefix**: If `split = TRUE`, prefix the chunk labels by the basename of the input file to get output file names?
- **quiet**: If `TRUE` all progress messages are suppressed.

Author(s)

Friedrich Leisch

References

http://www.ci.tuwien.ac.at/~leisch/Sweave

See Also

`Sweave`, `RweaveLatex`

RweaveLatex

R/\LaTeX{} Driver for Sweave

Description

A driver for Sweave that translates R code chunks in LaTeX files.

Usage

```r
RweaveLatex()

RweaveLatexSetup(file, syntax, output = NULL, quiet = FALSE, debug = FALSE, echo = TRUE, eval = TRUE, keep.source = FALSE, split = FALSE, stylepath = TRUE, pdf = TRUE, eps = TRUE)
```
Arguments

- **file**: Name of Sweave source file.
- **syntax**: An object of class `SweaveSyntax`.
- **output**: Name of output file, default is to remove extension `.nw`, `.Rnw` or `.Snw` and to add extension `.tex`. Any directory names in `file` are also removed such that the output is created in the current working directory.
- **quiet**: If TRUE all progress messages are suppressed.
- **debug**: If TRUE, input and output of all code chunks is copied to the console.
- **stylepath**: If TRUE, a hard path to the file `Sweave.sty` installed with this package is set, if FALSE, only `\usepackage{Sweave}` is written. The hard path makes the TeX file less portable, but avoids the problem of installing the current version of `Sweave.sty` to some place in your TeX input path. The argument is ignored if `\usepackage{Sweave}` is already present in the Sweave source file.
- **echo**: set default for option `echo`, see details below.
- **eval**: set default for option `eval`, see details below.
- **keep.source**: set default for option `keep.source`, see details below.
- **split**: set default for option `split`, see details below.
- **pdf**: set default for option `pdf`, see details below.
- **eps**: set default for option `eps`, see details below.

Supported Options

RweaveLatex supports the following options for code chunks (the values in parentheses show the default values):

- **echo**: logical (TRUE). Include S code in the output file?
- **keep.source**: logical (FALSE). When echoing, if `keep.source == TRUE` the original source is copied to the file. Otherwise, deparsed source is echoed.
- **eval**: logical (TRUE). If FALSE, the code chunk is not evaluated, and hence no text or graphical output produced.
- **results**: character string (verbatim). If `verbatim`, the output of S commands is included in the verbatim-like Soutput environment. If `tex`, the output is taken to be already proper latex markup and included as is. If `hide` then all output is completely suppressed (but the code executed during the weave).
- **print**: logical (FALSE). If TRUE, each expression in the code chunk is wrapped into a `print()` statement before evaluation, such that the values of all expressions become visible.
- **term**: logical (TRUE). If TRUE, visibility of values emulates an interactive R session: values of assignments are not printed, values of single objects are printed. If FALSE, output comes only from explicit `print` or `cat` statements.
- **split**: logical (FALSE). If TRUE, text output is written to separate files for each code chunk.
- **strip.white**: character string (false). If true, blank lines at the beginning and end of output are removed. If all, then all blank lines are removed from the output.
- **prefix**: logical (TRUE). If TRUE generated filenames of figures and output have a common prefix.
- **prefix.string**: a character string, default is the name of the `.Snw` source file.
- **include**: logical (TRUE), indicating whether input statements for text output and includegraphics statements for figures should be auto-generated. Use `include = FALSE` if the output should appear in a different place than the code chunk (by placing the input line manually).
fig: logical (FALSE), indicating whether the code chunk produces graphical output. Note that only one figure per code chunk can be processed this way.

eps: logical (TRUE), indicating whether EPS figures shall be generated. Ignored if \texttt{fig = FALSE}.

pdf: logical (TRUE), indicating whether PDF figures shall be generated. Ignored if \texttt{fig = FALSE}.

width: numeric (6), width of figures in inch.

height: numeric (6), height of figures in inch.

expand: logical (TRUE). Expand references to other chunks so that only R code appears in the output file. If FALSE, the chunk reference (e.g. \texttt{<<chunkname>>}) will appear. The \texttt{expand=FALSE} option requires \texttt{keep.source = TRUE} or it will have no effect.

concordance: logical (FALSE). Write a concordance file to link the input line numbers to the output line numbers. This is an experimental feature; see the source code for the output format, which is subject to change in future releases.

**savehistory**

*Load or Save or Display the Commands History*

**Description**

Load or save or display the commands history.

**Usage**

```r
loadhistory(file = "\.Rhistory")
savehistory(file = "\.Rhistory")
history(max.show = 25, reverse = FALSE, pattern, ...)
timestamp(stamp = date(),
           prefix = "##------- ", suffix = " -------##",
           quiet = FALSE)
```
savehistory

Arguments

file The name of the file in which to save the history, or from which to load it. The path is relative to the current working directory.

max.show The maximum number of lines to show. Inf will give all of the currently available history.

reverse logical. If true, the lines are shown in reverse order. Note: this is not useful when there are continuation lines.

pattern A character string to be matched against the lines of the history

... Arguments to be passed to grep when doing the matching.

stamp A value or vector of values to be written into the history.

prefix A prefix to apply to each line.

suffix A suffix to apply to each line.

quiet If TRUE, suppress printing timestamp to the console.

Details

There are several history mechanisms available for the different R consoles, which work in similar but not identical ways. Other uses of R, in particular embedded uses, may have no history. This works under the readline and GNOME and MacOS X consoles, but not otherwise (for example, in batch use or in an embedded application).

The readline history mechanism is controlled by two environment variables: R_HISTSIZE controls the number of lines that are saved (default 512), and R_HISTFILE sets the filename used for the loading/saving of history if requested at the beginning/end of a session (but not the default for these functions). There is no limit on the number of lines of history retained during a session, so setting R_HISTSIZE to a large value has no penalty unless a large file is actually generated.

These variables are read at the time of saving, so can be altered within a session by the use of Sys.setenv.

history shows only unique matching lines if pattern is supplied.

The timestamp function writes a timestamp (or other message) into the history and echos it to the console. On platforms that do not support a history mechanism (where the mechanism does not yet support timestamps) only the console message is printed.

Note

If you want to save the history (almost) every session, you can put a call to savehistory() in .Last. See the examples.

Examples

## Not run:
.Last <- function()
  if(interactive()) try(savehistory("~/.Rhistory"))
## End(Not run)
select.list  

Select Items from a List

Description

Select item(s) from a character vector.

Usage

```r
select.list(list, preselect = NULL, multiple = FALSE, title = NULL)
```

Arguments

- `list`: character. A list of items.
- `preselect`: a character vector, or NULL. If non-null and if the string(s) appear in the list, the item(s) are selected initially.
- `multiple`: logical: can more than one item be selected?
- `title`: optional character string for window title.

Details

Under the AQUA interface for MacOS X this brings up a modal dialog box with a (scrollable) list of items, which can be selected by the mouse.

Otherwise it displays a text list from which the user can choose by number(s). The `multiple = FALSE` case uses `menu`. Preselection is only supported for `multiple = TRUE`, where it is indicated by a "+" preceding the item.

Value

A character vector of selected items. If `multiple` is false and no item was selected (or Cancel was used), "" is returned. If `multiple` is true and no item was selected (or Cancel was used) then a character vector of length 0 is returned.

See Also

`menu, tk_select.list` for a graphical version using Tcl/Tk.

Examples

```r
## Not run:
select.list(sort(.packages(all.available = TRUE)))
## End(Not run)
```
sessionInfo

Collect Information About the Current R Session

Description
Print version information about R and attached packages.

Usage

sessionInfo(package=NULL)
## S3 method for class 'sessionInfo':
print(x, ...)
## S3 method for class 'sessionInfo':
toLatex(object, ...)

Arguments

package a character vector naming installed packages. By default all attached packages
are used.
x an object of class "sessionInfo".
object an object of class "sessionInfo".
... currently not used.

See Also
R.version

Examples

sessionInfo()
toLatex(sessionInfo())

setRepositories

Select Package Repositories

Description
Interact with the user to choose the package repositories to be used.

Usage

setRepositories(graphics = getOption("menu.graphics"))

Arguments

graphics Logical. If true and tcltk and an X server are available, use a Tk widget, or if
under the AQUA interface use a MacOS X widget, otherwise use a text list in
the console.
Details

The default list of known repositories is stored in the file ‘R_HOME/etc/repositories’. That file can be edited for a site, or a user can have a personal copy in ‘HOME/.R/repositories’ which will take precedence.

The items that are preselected are those that are currently in options("repos") plus those marked as default in the list of known repositories.

Value

This function is invoked mainly for its side effect of updating options("repos"). It returns (invisibly) the previous repos options setting (as a list with component repos) or NULL if no changes were applied.

chooseCRANmirror, install.packages.

---

SHLIB  Build Shared Library for Dynamic Loading

Description

Compile the given source files and then link all specified object files into a shared library which can be loaded into R using dyn.load or library.dynam.

Usage

R CMD SHLIB [options] [-o libname] files

Arguments

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>files</td>
<td>a list specifying the object files to be included in the shared library. You can also include the name of source files (for which the object files are automagically made from their sources) and library linking commands.</td>
</tr>
<tr>
<td>libname</td>
<td>the full name of the shared library to be built, including the extension (typically <code>.so</code> on Unix systems). If not given, the name of the library is taken from the first file.</td>
</tr>
<tr>
<td>options</td>
<td>Further options to control the processing. Use R CMD SHLIB --help for a current list.</td>
</tr>
</tbody>
</table>

Details

R CMD SHLIB is the mechanism used by INSTALL to compile source code in packages. Please consult section ‘Creating shared objects’ in the manual ‘Writing R Extensions’ for how to customize it (for example to add cpp flags and to add libraries to the link step) and for details of some of its quirks.

Items in files with extensions .c, .cpp, .cc, .C, .f, .f90, .f95, .m, .M and .mm are regarded as source files, and those with extension .o as object files. All other items are passed to the linker.
Note

Some binary distributions of R have SHLIB in a separate bundle, e.g. an R-devel RPM.

See Also

COMPILE, dyn.load, library.dynam.

The section on “Customizing compilation under Unix” in “R Administration and Installation” (see the ‘doc/manual’ subdirectory of the R source tree).

The ‘R Installation and Administration’ and ‘Writing R Extensions’ manuals.

Examples

```r
## Not run:
R CMD SHLIB -o mylib.so a.f b.f -L/opt/acml3.5.0/gnu64/lib -lacml

stack

Stack or Unstack Vectors from a Data Frame or List

Description

Stacking vectors concatenates multiple vectors into a single vector along with a factor indicating where each observation originated. Unstacking reverses this operation.

Usage

```r
stack(x, 
## Default S3 method:
stack(x, 
## S3 method for class 'data.frame':
stack(x, select, 

unstack(x, 
## Default S3 method:
unstack(x, form, 
## S3 method for class 'data.frame':
unstack(x, form, 
```

Arguments

- `x`  
  object to be stacked or unstacked
- `select`  
  expression, indicating variables to select from a data frame
- `form`  
  a two-sided formula whose left side evaluates to the vector to be unstacked and whose right side evaluates to the indicator of the groups to create. Defaults to `formula(x)` in `unstack.data.frame`
- `...`  
  further arguments passed to or from other methods.
Details

The `stack` function is used to transform data available as separate columns in a data frame or list into a single column that can be used in an analysis of variance model or other linear model. The `unstack` function reverses this operation.

Value

`unstack` produces a list of columns according to the formula `form`. If all the columns have the same length, the resulting list is coerced to a data frame.

`stack` produces a data frame with two columns:

- `values` the result of concatenating the selected vectors in `x`
- `ind` a factor indicating from which vector in `x` the observation originated

Douglas Bates

See Also

`lm`, `reshape`

Examples

```r
require(stats)
formula(PlantGrowth) # check the default formula
pg <- unstack(PlantGrowth) # unstack according to this formula
pg
stack(pg) # now put it back together
stack(pg, select = -ctrl) # omitting one vector
```

---

**str**

*Compactly Display the Structure of an Arbitrary R Object*

Description

Compactly display the internal structure of an R object, a “diagnostic” function and an alternative to `summary` (and to some extent, `dput`). Ideally, only one line for each “basic” structure is displayed. It is especially well suited to compactly display the (abbreviated) contents of (possibly nested) lists. The idea is to give reasonable output for any R object. It calls `args` for (non-primitive) function objects.

`strOptions()` is a convenience function for setting `options(str = .)`, see the examples.

Usage

```r
str(object, ...)
```

### S3 method for class 'data.frame':

```r
str(object, ...)
```

### Default S3 method:
str(object, max.level = NA,
    vec.len = str0$vec.len, digits.d = str0$digits.d,
    nchar.max = 128, give.attr = TRUE, give.length = TRUE,
    width = getOption("width"), nest.lev = 0,
    indent.str = paste(rep.int(" ", max(0, nest.lev + 1)),
                        collapse = ".."),
    comp.str="$ ", no.list = FALSE, envir = baseenv(),
    strict.width = str0$strict.width, ...) 
strOptions(strict.width = "no", digits.d = 3, vec.len = 4)

Arguments

object
any R object about which you want to have some information.

max.level
maximal level of nesting which is applied for displaying nested structures, e.g.,
a list containing sub lists. Default NA: Display all nesting levels.

vec.len
numeric (>= 0) indicating how many “first few” elements are displayed of each
vector. The number is multiplied by different factors (from .5 to 3) depending
on the kind of vector. Defaults to the vec.len component of option "str"
(see options) which defaults to 4.

digits.d
number of digits for numerical components (as for print). Defaults to the
digits.d component of option "str" which defaults to 3.

nchar.max
maximal number of characters to show for character strings. Longer strings
are truncated, see longch example below.

give.attr
logical; if TRUE (default), show attributes as sub structures.

give.length
logical; if TRUE (default), indicate length (as [1:...]).

width
the page width to be used. The default is the currently active
options("width"); note that this has only a weak effect, unless
strict.width is not "no".

nest.lev
current nesting level in the recursive calls to str.

indent.str
the indentation string to use.

comp.str
string to be used for separating list components.

no.list
logical; if true, no “list of...” is nor the class is printed.

envir
the environment to be used for promise (see delayedAssign) objects only.

strict.width
string indicating if the width argument’s specification should be followed
strictly, one of the values c("no", "cut", "wrap"). Defaults to the
strict.width component of option "str" (see options) which de-
defaults to "no" for back compatibility reasons; "wrap" uses strwrap(*,
width=width) whereas "cut" cuts directly to width. Note that a small
vec.length may be better than setting strict.width = "wrap".

...
potential further arguments (required for Method/Generic reasons).

Value

str does not return anything, for efficiency reasons. The obvious side effect is output to the
terminal.

*ls.str* for listing objects with their structure; *summary, args.*

**Examples**

```r
require(stats)
## The following examples show some of 'str' capabilities
str(1:12)
str(ls)
str(args) # more useful than args(args) !
str(freeny)
str(str)
str(.Machine, digits = 20)
str(lsfit(1:9,1:9))
str(lsfit(1:9,1:9), max = 1)
str(lsfit(1:9,1:9), width = 60, strict.width = "cut")
str(lsfit(1:9,1:9), width = 60, strict.width = "wrap")
op <- options(); str(op) # save first;
# otherwise internal options() is used.
need.dev <- !exists(".Device") || is.null(.Device) || .Device == "null device"
if(need.dev) postscript()
str(par())
if(need.dev) graphics.off()
ch <- letters[1:12]; is.na(ch) <- 3:5
str(ch) # character NA's
nchar(longch <- paste(rep(letters,100), collapse=""))
str(longch)
str(longch, nchar.max = 52)
str(longch, strict.width = "wrap")

## Settings for narrow transcript : 
op <- options(width = 60,
str <- strOptions(strict.width = "wrap"))
str(lsfit(1:9,1:9))
str(options())
## reset to previous:
options(op)

str(quote( { A+B; list(C,D) } ))

## S4 classes :
require(stats4)
x <- 0:10; y <- c(26, 17, 13, 12, 20, 5, 9, 8, 5, 4, 8)
l1 <- function(ymax=15, xh=6)

  -sum(dpois(y, lambda=ymax/(1+x/xh), log=TRUE))
fit <- mle(l1)
str(fit)
```
Summary of Output of R Sampling Profiler

Description

Summarise the output of the Rprof function to show the amount of time used by different R functions.

Usage

```r
summaryRprof(filename = "Rprof.out", chunksize = 5000,
             memory=c("none","both","tseries","stats"),
             index=2, diff=TRUE, exclude=NULL)
```

Arguments

- `filename` Name of a file produced by Rprof()
- `chunksize` Number of lines to read at a time
- `memory` Summaries for memory information. See Details below
- `index` How to summarize the stack trace for memory information. See Details below.
- `diff` If TRUE memory summaries use change in memory rather than current memory
- `exclude` Functions to exclude when summarizing the stack trace for memory summaries

Details

This function is an alternative to R CMD Rprof. It provides the convenience of an all-R implementation but will be slower for large files.

As the profiling output file could be larger than available memory, it is read in blocks of chunksize lines. Increasing chunksize will make the function run faster if sufficient memory is available.

When called with `memory.profiling=TRUE`, the profiler writes information on three aspects of memory use: vector memory in small blocks on the R heap, vector memory in large blocks (from malloc), memory in nodes on the R heap. It also records the number of calls to the internal function `duplicate` in the time interval. `duplicate` is called by C code when arguments need to be copied. Note that the profiler does not track which function actually allocated the memory.

With `memory="both"` the change in total memory (truncated at zero) is reported in addition to timing data.

With `memory="tseries"` or `memory="stats"` the index argument specifies how to summarize the stack trace. A positive number specifies that many calls from the bottom of the stack; a negative number specifies the number of calls from the top of the stack. With `memory="tseries"` the index is used to construct labels and may be a vector to give multiple sets of labels. With `memory="stats"` the index must be a single number and specifies how to aggregate the data to the maximum and average of the memory statistics. With both `memory="tseries"` and `memory="stats"` the argument `diff=TRUE` asks for summaries of the increase in memory use over the sampling interval and `diff=FALSE` asks for the memory use at the end of the interval.
Value

If `memory="none"`, a list with components

by.self Timings sorted by ‘self’ time
by.total Timings sorted by ‘total’ time
sampling.time Total length of profiling run

If `memory="both"` the same list but with memory consumption in Mb in addition to the timings.
If `memory="tseries"` a data frame giving memory statistics over time
If `memory="stats"` a by object giving memory statistics by function.

Examples

## Not run:
## Rprof() is not available on all platforms
Rprof(tmp <- tempfile())
extample(glm)
Rprof()
summaryRprof(tmp)
unlink(tmp)
## End(Not run)
Arguments

- **file**: Name of Sweave source file.
- **driver**: The actual workhorse, see details below.
- **syntax**: An object of class `SweaveSyntax` or a character string with its name. The default installation provides `SweaveSyntaxNoweb` and `SweaveSyntaxLatex`.
- ... Further arguments passed to the driver’s setup function.

Details

Automatic generation of reports by mixing word processing markup (like latex) and S code. The S code gets replaced by its output (text or graphs) in the final markup file. This allows to re-generate a report if the input data change and documents the code to reproduce the analysis in the same file that also produces the report.

Sweave combines the documentation and code chunks together (or their output) into a single document. Stangle extracts only the code from the Sweave file creating a valid S source file (that can be run using `source`). Code inside `\Sexpr{}` statements is ignored by Stangle. Stangle is just a frontend to Sweave using a simple driver by default, which discards the documentation and concatenates all code chunks the current S engine understands.

Hook Functions

Before each code chunk is evaluated, a number of hook functions can be executed. If `getOption("SweaveHooks")` is set, it is taken to be a collection of hook functions. For each logical option of a code chunk (echo, print, ...) a hook can be specified, which is executed if and only if the respective option is TRUE. Hooks must be named elements of the list returned by `getOption("SweaveHooks")` and be functions taking no arguments. E.g., if option "SweaveHooks" is defined as `list(fig = foo)`, and `foo` is a function, then it would be executed before the code in each figure chunk. This is especially useful to set defaults for the graphical parameters in a series of figure chunks.

Note that the user is free to define new Sweave options and associate arbitrary hooks with them. E.g., one could define a hook function for option `clean` that removes all objects in the global environment. Then all code chunks with `clean = TRUE` would start operating on an empty workspace.

Syntax Definition

Sweave allows a very flexible syntax framework for marking documentation and text chunks. The default is a noweb-style syntax, as alternative a latex-style syntax can be used. See the user manual for details.

SweaveSyntConv

Convert Sweave Syntax

Description

This function converts the syntax of files in Sweave format to another Sweave syntax definition.

Usage

SweaveSyntConv(file, syntax, output = NULL)

Arguments

file Name of Sweave source file.
syntax An object of class SweaveSyntax or a character string with its name giving the target syntax to which the file is converted.
output Name of output file, default is to remove the extension from the input file and to add the default extension of the target syntax. Any directory names in file are also removed such that the output is created in the current working directory.

Examples

```r
testfile <- system.file("Sweave", "Sweave-test-1.Rnw", package = "utils")

## convert the file to latex syntax
SweaveSyntConv(testfile, SweaveSyntaxLatex)

## and run it through Sweave
Sweave("Sweave-test-1.Stex")
```

---

**toLatex**

*Converting R Objects to BibTeX or LaTeX*

**Description**

These methods convert R objects to character vectors with BibTeX or LaTeX markup.

**Usage**

```r
toBibtex(object, ...)
toLatex(object, ...)
## S3 method for class 'Bibtex':
print(x, prefix="", ...,)
## S3 method for class 'Latex':
print(x, prefix="", ...,)
```

**Arguments**

- `object`: object of a class for which a `toBibtex` or `toLatex` method exists.
- `x`: object of class "Bibtex" or "Latex".
- `prefix`: a character string which is printed at the beginning of each line, mostly used to insert whitespace for indentation.
- `...`: currently not used in the print methods.

**Details**

Objects of class "Bibtex" or "Latex" are simply character vectors where each element holds one line of the corresponding BibTeX or LaTeX file.

`citEntry` and `sessionInfo` for examples
type.convert  

Type Conversion on Character Variables

Description

Convert a character vector to logical, integer, numeric, complex or factor as appropriate.

Usage

type.convert(x, na.strings = "NA", as.is = FALSE, dec = ".")

Arguments

x  a character vector.
na.strings a vector of strings which are to be interpreted as NA values. Blank fields are also considered to be missing values in logical, integer, numeric or complex vectors.
as.is logical. See Details.
dec the character to be assumed for decimal points.

Details

This is principally a helper function for read.table. Given a character vector, it attempts to convert it to logical, integer, numeric or complex, and failing that converts it to factor unless as.is = TRUE. The first type that can accept all the non-missing values is chosen.

Vectors which are entirely missing values are converted to logical, since NA is primarily logical.

Value

A vector of the selected class, or a factor.

update.packages  

Download Packages from CRAN-like repositories

Description

These functions can be used to automatically compare the version numbers of installed packages with the newest available version on the repositories and update outdated packages on the fly.
update.packages

Usage

update.packages(lib.loc = NULL, repos = getOption("repos"),
                contriburl = contrib.url(repos, type),
                method, instlib = NULL, ask = TRUE, available = NULL,
                ..., checkBuilt = FALSE,
                type = getOption("pkgType"))

available.packages(contriburl = contrib.url(getOption("repos")),
                    method, fields = NULL)

old.packages(lib.loc = NULL, repos = getOption("repos"),
              contriburl = contrib.url(repos),
              method, available = NULL, checkBuilt = FALSE)

new.packages(lib.loc = NULL, repos = getOption("repos"),
              contriburl = contrib.url(repos, type),
              method, available = NULL, ask = FALSE, ...
              type = getOption("pkgType"))

download.packages(pkgs, destdir, available = NULL,
                   repos = getOption("repos"),
                   contriburl = contrib.url(repos, type),
                   method, type = getOption("pkgType"))

install.packages(pkgs, lib, repos = getOption("repos"),
                 contriburl = contrib.url(repos, type),
                 method, available = NULL, destdir = NULL,
                 installWithVers = FALSE, dependencies = NA,
                 type = getOption("pkgType"),
                 configure.args = character(0),
                 clean = FALSE)

ccontrib.url(repos, type = getOption("pkgType"))

Arguments

lib.loc character vector describing the location of R library trees to search through (and
update packages therein).

repos character vector, the base URL(s) of the repositories to use, i.e., the URL of
the CRAN master such as "http://cran.r-project.org" or its Statlib
mirror, "http://lib.stat.cmu.edu/R/CRAN". Can be NULL to install
from local '.tar.gz' files.

contriburl URL(s) of the contrib sections of the repositories. Use this argument only if
your repository mirror is incomplete, e.g., because you burned only the 'contrib'
section on a CD. Overrides argument repos. Can also be NULL to install from
local '.tar.gz' files.

method Download method, see download.file.

pkgs character vector of the short names of packages/bundles whose current versions
should be downloaded from the repositories. If repos = NULL, a charac-
ter vector of file paths of '.tar.gz' files. These can be source archives or bi-
nary package/bundle archive files (as created by R CMD build --binary).
Tilde-expansion will be done on the file paths. If this is a zero-length character vector, a listbox of available packages (including those contained in bundles) is presented where possible.

defdir directory where downloaded packages are stored.

available an object listing packages available at the repositories as returned by available.packages.

lib character vector giving the library directories where to install the packages. Recycled as needed. If missing, defaults to .libPaths()[1].

ask logical indicating whether to ask user before packages are actually downloaded and installed, or the character string "graphics", which brings up a widget to allow the user to (de-)select from the list of packages which could be updated. The latter only works on systems with a GUI version of select.list, and is otherwise equivalent to ask = TRUE.

installWithVers If TRUE, will invoke the install of the package such that it can be referenced by package version.

checkBuilt If TRUE, a package built under an earlier minor version of R is considered to be 'old'.

instlib character string giving the library directory where to install the packages.

dependencies logical indicating to also install uninstalled packages on which these packages depend/suggest/import (and so on recursively). Not used if repos = NULL. Can also be a character vector, a subset of c("Depends", "Imports", "Suggests"). Only supported if lib is of length one (or missing), so it is unambiguous where to install the dependent packages.

The default, NA, means c("Depends", "Imports") if lib is unambiguous, and FALSE otherwise.

configure.args a character vector or a named list. If a character vector with no names is supplied, the elements are concatenated into a single string (separated by a space) and used as the value for the --configure-args flag in the call to R CMD INSTALL. If the character vector has names, these are assumed to identify values for --configure-args for individual packages. This allows one to specify settings for an entire collection of packages which will be used if any of those packages are installed. These settings can therefore be reused and act as default settings. A named list can be used also to the same effect, and that allows multi-element character strings for each package which are concatenated to a single string to be used as the value for --configure-args.

... (for update.packages). Arguments such as destdir, installWithVers and dependencies to be passed to install.packages.

... (for new.packages). Arguments such as destdir and dependencies to be passed to install.packages.

type character, indicating the type of package to download and install. Possible values are "source" (the default except under the CRAN Mac OS X build), "mac.binary" and "win.binary" (which can be downloaded but not installed).

clean a logical value indicating whether to specify to add the --clean flag to the call to R CMD INSTALL. This is sometimes used to perform additional operations at the end of the package installation in addition to removing intermediate files.
fields  a character vector giving the fields to extract from the PACKAGES file(s) in addition to the default ones, or NULL (default). Unavailable fields result in NA values.

Details

All of these functions work with the names of a package or bundle (and not the component packages of a bundle, except for install.packages if the repository provides the necessary information).

available.packages returns a matrix of details corresponding to packages/bundles currently available at one or more repositories. The current list of packages is downloaded over the internet (or copied from a local mirror). It returns only packages whose version requirements are met by the running version of R.

old.packages compares the information from available.packages with that from installed.packages and reports installed packages/bundles that have newer versions on the repositories or, if checkBuilt = TRUE, that were built under an earlier minor version of R (for example built under 2.0.x when running R 2.1.1).

new.packages does the same comparison but reports uninstalled packages/bundles that are available at the repositories. It will also give warnings about incompletely installed bundles (provided the information is available) and bundles whose contents has changed. If ask != FALSE it asks which packages should be installed in the first element of lib.loc. NB: versioned installs are not installs of a named package.

download.packages takes a list of package/bundle names and a destination directory, downloads the newest versions and saves them in destdir. If the list of available packages is not given as argument, it is obtained from repositories. If a repository is local, i.e., the URL starts with "file: ", then the packages are not downloaded but used directly. (Both "file:" and "file:///" are allowed as prefixes to a file path, the latter for an absolute file path.)

The main function of the set is update.packages. First a list of all packages/bundles found in lib.loc is created and compared with those available at the repositories. If ask = TRUE (the default) packages/bundles with a newer version are reported and for each one the user can specify if it should be updated. If so, the package sources are downloaded from the repositories and installed in the respective library path (or instlib if specified) using the R INSTALL mechanism.

install.packages can be used to install new packages/bundles. It takes a vector of names and a destination library, downloads the packages from the repositories and installs them. (If the library is omitted it defaults to the first directory in .libPaths(), with a warning if there is more than one.) If lib is omitted or is of length one and is not a (group) writeable directory, the code offers to create a personal library tree (the first element of Sys.getenv("R_LIBS_USER") and install there.

An attempt is made to install the packages in an order that respects their dependencies. This does assume that all the entries in lib are on the default library path for installs (set by R_LIBS).

contrib.url adds the appropriate type-specific path within a repository to each URL in repos.

For install.packages, destdir is the directory to which packages will be downloaded. If it is NULL (the default) a directory downloaded_packages of the session temporary directory will be used (and the files will be deleted at the end of the session).

If repos or contriburl is a vector of length greater than one, the newest version of the package compatible with this version of R is fetched from the first repository on the list within which it is found.
For `available.packages`, a matrix with one row per package/bundle, row names the package names and column names "Package", "Version", "Priority", "Bundle", "Depends", "Imports", "Suggests", "Contains" and "Repository". Additional columns can be specified using the `fields` argument.

For `old.packages`, `NULL` or a matrix with one row per package/bundle, row names the package names and column names "Package", "LibPath", "Installed" (the version), "Built" (the version built under), "ReposVer" and "Repository".

For `new.packages` a character vector of package/bundle names, after any have been installed.

For `download.packages`, a two-column matrix of names and destination file names, for those packages/bundles successfully downloaded. If packages are not available or there is a problem with the download, suitable warnings are given.

`install.packages` and `update.packages` have no return value.

**Warning**

Take care when using `dependencies` with `update.packages`, for it is unclear where new dependencies should be installed. The current implementation will only allow it if all the packages to be updated are in a single library, when that library will be used.

**Note**

Some binary distributions of R have `INSTALL` in a separate bundle, e.g. an R-devel RPM. `install.packages` will give an error if called on such a system.

**See Also**

`installed.packages`, `remove.packages`  
See `download.file` for how to handle proxies and other options to monitor file transfers.

`INSTALL`, `REMOVE`, `library`, `.packages`, `read.dcf`

**Examples**

```r
## Not run:
install.packages(c("XML_0.99-5.tar.gz", 
                      "./../Interfaces/Perl/RSPerl_0.8-0.tar.gz"), 
repos = NULL, 
configure.args = c("XML = '--with-xml-config=xml-config', 
                   RSPerl = "--with-modules='IO Fcntl'"))
## End(Not run)
```

---

**url.show**  
*Display a text URL*

**Description**

Extension of `file.show` to display text files from a remote server.
Usage

url.show(url, title = url, file = tempfile(),
         delete.file = TRUE, method, ...)

Arguments

url The URL to read from.
title Title for the browser.
file File to copy to.
delete.file Delete the file afterwards?
method File transfer method: see download.file
... Arguments to pass to file.show.

See Also

url, file.show, download.file

Examples

## Not run: url.show("http://lib.stat.cmu.edu/datasets/csb/ch3a.txt")

---

URLencode Encode or Decode a (partial) URL

Description

Functions to encode or decode characters in URLs.

Usage

URLencode(URL, reserved = FALSE)
URLdecode(URL)

Arguments

URL A character string.
reserved should reserved characters be encoded? See Details.

Details

Characters in a URL other than the English alphanumeric characters and $ - _ . + ! * ‘( ) , should be encoded as % plus a two-digit hexadecimal representation, and any single-byte character can be so encoded. (Multi-byte characters are encoded as byte-by-byte.)

In addition, ; / ? : @ = $ are reserved characters, and should be encoded unless used in their reserved sense, which is scheme specific. The default in URLencode is to leave them alone, which is appropriate for file:// URLs, but probably not for http:// ones.

Value

A character string.
References

Examples

\[(y \leftarrow \text{URLencode("a url with spaces and / and @")})\]
\[\text{URLdecode}(y)\]
\[(y \leftarrow \text{URLencode("a url with spaces and / and @", reserved=TRUE)})\]
\[\text{URLdecode}(y)\]
\[\text{URLdecode("ab%20cd")}\]

utils-deprecated  Deprecated Functions in Package utils

Description

These functions are provided for compatibility with older versions of R only, and may be defunct as soon as of the next release.

Usage

\[\text{CRAN.packages(CRAN = getOption("repos"), method, contriburl = contrib.url(CRAN))}\]

Arguments

- **CRAN**: character, an earlier way to specify a repository.
- **method**: Download method, see download.file.
- **contriburl**: URL(s) of the contrib section of the repositories. Use this argument only if your CRAN mirror is incomplete, e.g., because you burned only the ‘contrib’ section on a CD. Overrides argument repos.

See Also

Deprecated, Defunct

---

View  Invoke a Data Viewer

Description

Invoke a spreadsheet-style data viewer on a matrix-like R object.

Usage

\[\text{View}(x, \text{title})\]
vignette

Arguments

x an R object which can be coerced to a data frame with non-zero numbers of rows and columns.
title title for viewer window. Defaults to name of x.

Details

Object x is coerced (if possible) to a data frame, and all non-numeric columns are then coerced to character. The object is then viewed in a spreadsheet-like data viewer, a read-only version of data.entry.

If there are row names on the data frame that are not 1:nrow, they are displayed in a separate first column called row.names.

Objects with zero columns or zero rows are not accepted.

The array of cells can be navigated by the cursor keys and Home, End, Page Up and Page Down (where supported by X11) as well as Enter and Tab.

Value

Invisible NULL. The functions puts up a window and returns immediately: the window can be closed via its controls or menus.

See Also

edit.data.frame, data.entry.

vignette View or List Vignettes

Description

View a specified vignette, or list the available ones.

Usage

vignette(topic, package = NULL, lib.loc = NULL)

## S3 method for class 'vignette':
print(x, ...)
## S3 method for class 'vignette':
edit(name, ...)

Arguments

topic a character string giving the (base) name of the vignette to view. If omitted, all vignettes from all installed packages are listed.

package a character vector with the names of packages to search through, or NULL in which case all available packages in the library trees specified by lib.loc are searched.

lib.loc a character vector of directory names of R libraries, or NULL. The default value of NULL corresponds to all libraries currently known.
withVisible

x, name Object of class vignette.
...
Ignored by the print method, passed on to file.edit by the edit method.

Details

Function vignette returns an object of the same class, the print method opens a viewer for it. Currently, only PDF versions of vignettes can be viewed. The program specified by the pdfviewer option is used for this. If several vignettes have PDF versions with base name identical to topic, the first one found is used.

If no topics are given, all available vignettes are listed. The corresponding information is returned in an object of class "packageIQR".

The edit method extracts the R code from the vignette to a temporary file and opens the file in an editor (see edit). This makes it very easy to execute the commands line by line, modify them in any way you want to help you test variants, etc. An alternative way of extracting the R code from the vignette is to run Stangle on the source code of the vignette, see the examples below.

Examples

```r
## List vignettes from all *installed* packages (can take long!):
vignette()

## Not run:
## Open the grid intro vignette
vignette("grid")

## The same
v1 <- vignette("grid")
print(v1)

## Now let us have a closer look at the code
edit(v1)

## An alternative way of extracting the code,
## R file is written to current working directory
Stangle(v1$file)

## A package can have more than one vignette (package grid has several):
vignette(package="grid")
vignette("rotated")
## The same, but without searching for it:
vignette("rotated", package="grid")
## End(Not run)
```

withVisible Return both a value and its visibility

Description

This function evaluates an expression, returning it in a two element list containing its value and a flag showing whether it would automatically print.
withVisible(x)

x An expression to be evaluated.

The argument is evaluated in the caller’s context.

value The value of x after evaluation.
visible logical; whether the value would auto-print.

invisible, eval

Examples

x <- 1
withVisible(x <- 1)
x
withVisible(x)

# Wrap the call in evalq() for special handling
df <- data.frame(a=1:5, b=1:5)
evalq(withVisible(a + b), envir=df)

write.table prints its required argument x (after converting it to a data frame if it is not one nor a matrix) to a file or connection.

write.table(x, file = "", append = FALSE, quote = TRUE, sep = " ",
eol = "\n", na = "NA", dec = ".", row.names = TRUE, col.names = TRUE, qmethod = c("escape", "double"))

write.csv(...) write.csv2(...)
Arguments

x  the object to be written, preferably a matrix or data frame. If not, it is attempted
to coerce x to a data frame.

file  either a character string naming a file or a connection open for writing. "" indicates output to the console.

append  logical. If TRUE, the output is appended to the file. If FALSE, any existing file
of the name is destroyed.

quote  a logical value (TRUE or FALSE) or a numeric vector. If TRUE, any character
or factor columns will be surrounded by double quotes. If a numeric vector, its
elements are taken as the indices of columns to quote. In both cases, row and
column names are quoted if they are written. If FALSE, nothing is quoted.

sep  the field separator string. Values within each row of x are separated by this
string.

eol  the character(s) to print at the end of each line (row).

na  the string to use for missing values in the data.

dec  the string to use for decimal points in numeric or complex columns: must be a
single character.

row.names  either a logical value indicating whether the row names of x are to be written
along with x, or a character vector of row names to be written.

col.names  either a logical value indicating whether the column names of x are to be written
along with x, or a character vector of column names to be written. See the
section on 'CSV files' for the meaning of col.names = NA.

qmethod  a character string specifying how to deal with embedded double quote characters
when quoting strings. Must be one of "escape" (default), in which case the
quote character is escaped in C style by a backslash, or "double", in which
case it is doubled. You can specify just the initial letter.

...  arguments to write.table; col.names, sep, dec and qmethod cannot
be altered.

Details

If the table has no columns the rownames will be written only if row.names=TRUE, and vice
versa.

Real and complex numbers are written to the maximal possible precision.

If a data frame has matrix-like columns these will be converted to multiple columns in the result (via
as.matrix) and so a character col.names or a numeric quote should refer to the columns in
the result, not the input. Such matrix-like columns are unquoted by default.

Any columns in a data frame which are lists or have a class (e.g. dates) will be converted by the
appropriate as.character method: such columns are unquoted by default. On the other hand,
any class information for a matrix is discarded and non-atomic (e.g. list) matrices are coerced to
character.

Only columns which have been converted to character will be quoted if specified by quote.

The dec argument only applies to columns that are not subject to conversion to character because
they have a class or are part of a matrix-like column (or matrix), in particular to columns protected
by I(). Use options("OutDec") to control such conversions.

In almost all cases the conversion of numeric quantities is governed by the option "scipen" (see
options), but with the internal equivalent of digits=15. For finer control, use format to
make a character matrix/data frame, and call write.table on that.
These functions check for a user interrupt every 1000 lines of output.

If `file` is not open for writing, an attempt is made to open it and then close it after use.

**CSV files**

By default there is no column name for a column of row names. If `col.names = NA` and `row.names = TRUE` a blank column name is added, which is the convention used for CSV files to be read by spreadsheets.

`write.csv` and `write.csv2` provide convenience wrappers for writing CSV files. They set `sep`, `dec` and `qmethod`, and `col.names` to `NA` if `row.names = TRUE` and `TRUE` otherwise.

`write.csv` uses "." for the decimal point and a comma for the separator.

`write.csv2` uses a comma for the decimal point and a semicolon for the separator, the Excel convention for CSV files in some Western European locales.

These wrappers are deliberately inflexible: they are designed to ensure that the correct conventions are used to write a valid file. Attempts to change `col.names`, `sep`, `dec` or `qmethod` are ignored, with a warning.

**Note**

`write.table` can be slow for data frames with large numbers (hundreds or more) of columns: this is inevitable as each column could be of a different class and so must be handled separately. If they are all of the same class, consider using a matrix instead.

**See Also**

The ‘R Data Import/Export’ manual.

`read.table`, `write`,

`write.matrix` in package `MASS`.

**Examples**

```r
## Not run:
## To write a CSV file for input to Excel one might use
x <- data.frame(a = I("a \" quote"), b = pi)
write.table(x, file = "foo.csv", sep = ",", col.names = NA,
            qmethod = "double")
## and to read this file back into R one needs
read.table("foo.csv", header = TRUE, sep = ",", row.names = 1)
## NB: you do need to specify a separator if `qmethod = "double".

### Alternatively
write.csv(x, file = "foo.csv")
read.csv("foo.csv", row.names = 1)
## or without row names
write.csv(x, file = "foo.csv", row.names = FALSE)
read.csv("foo.csv")
## End(Not run)
```
zip.file.extract  Extract File from a Zip Archive

Description

This will extract the file named file from the zip archive, if possible, and write it in a temporary location.

Usage

```r
zip.file.extract(file, zipname = "R.zip", unzip = getOption("unzip"))
```

Arguments

- **file**: A file name. (If a path is given, see ‘Note’.)
- **zipname**: The file name (not path) of a zip archive, including the ".zip" extension if required.
- **unzip**: character string: the method to be used, an empty string indicates "internal".

Details

All platforms support an "internal" unzip: this is the default under Windows and the fall-back under Unix if no unzip program was found during configuration and R_UNZIPCMD is not set.

The file will be extracted if it is in the archive and any required unzip utility is available. It will be extracted to the directory given by tempdir, overwriting any existing file of that name.

Value

The name of the original or extracted file. Success is indicated by returning a different name.

Note

The "internal" method is very simple, and will not set file dates.

This is a helper function for help, example and data. As such, it handles file paths in an unusual way. Any path component of zipname is ignored, and the path to file is used only to determine the directory within which to find zipname.
Part II
Chapter 10

The KernSmooth package

bkde

Compute a Binned Kernel Density Estimate

Description

Returns x and y coordinates of the binned kernel density estimate of the probability density of the
data.

Usage

bkde(x, kernel = "normal", canonical = FALSE, bandwidth,
     gridsize = 401, range.x, truncate = TRUE)

Arguments

- **x**: vector of observations from the distribution whose density is to be estimated. Missing values are not allowed.
- **bandwidth**: the kernel bandwidth smoothing parameter. Larger values of bandwidth make smoother estimates, smaller values of bandwidth make less smooth estimates.
- **kernel**: character string which determines the smoothing kernel. kernel can be: "normal" - the Gaussian density function (the default). "box" - a rectangular box. "epanech" - the centred beta(2,2) density. "biweight" - the centred beta(3,3) density. "triweight" - the centred beta(4,4) density.
- **canonical**: logical flag: if TRUE, canonically scaled kernels are used.
- **gridsize**: the number of equally spaced points at which to estimate the density.
- **range.x**: vector containing the minimum and maximum values of x at which to compute the estimate. The default is the minimum and maximum data values, extended by the support of the kernel.
- **truncate**: logical flag: if TRUE, data with x values outside the range specified by range.x are ignored.
Details

This is the binned approximation to the ordinary kernel density estimate. Linear binning is used to obtain the bin counts. For each \( x \) value in the sample, the kernel is centered on that \( x \) and the heights of the kernel at each datapoint are summed. This sum, after a normalization, is the corresponding \( y \) value in the output.

Value

A list containing the following components:

- \( x \): vector of sorted \( x \) values at which the estimate was computed.
- \( y \): vector of density estimates at the corresponding \( x \).

Background

Density estimation is a smoothing operation. Inevitably there is a trade-off between bias in the estimate and the estimate’s variability: large bandwidths will produce smooth estimates that may hide local features of the density; small bandwidths may introduce spurious bumps into the estimate.

References

Examples

data(geyser, package="MASS")
x <- geyser$duration
est <- bkde(x, bandwidth=0.25)
plot(est, type="l")

bkde2D

Compute a 2D Binned Kernel Density Estimate

Description

Returns the set of grid points in each coordinate direction, and the matrix of density estimates over the mesh induced by the grid points. The kernel is the standard bivariate normal density.

Usage

\[
\text{bkde2D}(x, \text{bandwidth}, \text{gridsize}=c(51, 51), \text{range.x}, \text{truncate=TRUE})
\]
Arguments

- **x**: a two-column matrix containing the observations from the distribution whose density is to be estimated. Missing values are not allowed.
- **bandwidth**: vector containing the bandwidth to be used in each coordinate direction.
- **gridsize**: vector containing the number of equally spaced points in each direction over which the density is to be estimated.
- **range.x**: a list containing two vectors, where each vector contains the minimum and maximum values of \( x \) at which to compute the estimate for each direction. The default minimum in each direction is minimum data value minus 1.5 times the bandwidth for that direction. The default maximum is the maximum data value plus 1.5 times the bandwidth for that direction.
- **truncate**: logical flag: if TRUE, data with \( x \) values outside the range specified by \( \text{range.x} \) are ignored.

Value

A list containing the following components:

- **x1**: vector of values of the grid points in the first coordinate direction at which the estimate was computed.
- **x2**: vector of values of the grid points in the second coordinate direction at which the estimate was computed.
- **fhat**: matrix of density estimates over the mesh induced by \( x1 \) and \( x2 \).

Details

This is the binned approximation to the 2D kernel density estimate. Linear binning is used to obtain the bin counts and the Fast Fourier Transform is used to perform the discrete convolutions. For each \( x1,x2 \) pair the bivariate Gaussian kernel is centered on that location and the heights of the kernel, scaled by the bandwidths, at each datapoint are summed. This sum, after a normalization, is the corresponding \( fhat \) value in the output.

References

See Also

- `bkde`, `density`, `hist`.

Examples

data(geyser, package="MASS")
x <- cbind(geyser$duration, geyser$waiting)
est <- bkde2D(x, bandwidth=c(0.7,7))
contour(est$x1, est$x2, est$fhat)
persp(est$fhat)
**Description**

Returns an estimate of a binned approximation to the kernel estimate of the specified density functional. The kernel is the standard normal density.

**Usage**

```
bkfe(x, drv, bandwidth, gridsize = 401, range.x, binned = FALSE, truncate = TRUE)
```

**Arguments**

- `x` vector of observations from the distribution whose density is to be estimated. Missing values are not allowed.
- `drv` order of derivative in the density functional. Must be a non-negative even integer.
- `bandwidth` the kernel bandwidth smoothing parameter.
- `gridsize` the number of equally-spaced points over which binning is performed.
- `range.x` vector containing the minimum and maximum values of `x` at which to compute the estimate. The default is the minimum and maximum data values, extended by the support of the kernel.
- `binned` logical flag: if TRUE, then `x` and `y` are taken to be grid counts rather than raw data.
- `truncate` logical flag: if TRUE, data with `x` values outside the range specified by `range.x` are ignored.

**Details**

The density functional of order `drv` is the integral of the product of the density and its `drv`th derivative. The kernel estimates of such quantities are computed using a binned implementation, and the kernel is the standard normal density.

**Value**

the estimated functional.

**Background**

Estimates of this type were proposed by Sheather and Jones (1991).

**References**

Examples

data(geyser, package="MASS")
x <- geyser$duration
est <- bkfe(x, drv=4, bandwidth=0.3)

dpih

Select a Histogram Bin Width

Description

Uses direct plug-in methodology to select the bin width of a histogram.

Usage

dpih(x, scalest="minim", level=2, gridsize=401, range.x=range(x), truncate=TRUE)

Arguments

x vector containing the sample on which the histogram is to be constructed.
scalest estimate of scale.
  "stdev" - standard deviation is used.
  "iqr" - inter-quartile range divided by 1.349 is used.
  "minim" - minimum of "stdev" and "iqr" is used.
level number of levels of functional estimation used in the plug-in rule.
gridsize number of grid points used in the binned approximations to functional estimates.
rangep.range over which functional estimates are obtained. The default is the minimum
  and maximum data values.
truncate if truncate is TRUE then observations outside of the interval specified by
  range.x are omitted. Otherwise, they are used to weight the extreme grid
  points.

Details

The direct plug-in approach, where unknown functionals that appear in expressions for the asymptotically optimal bin width and bandwidths are replaced by kernel estimates, is used. The normal distribution is used to provide an initial estimate.

Value

the selected bin width.

Background

This method for selecting the bin width of a histogram is described in Wand (1995). It is an extension of the normal scale rule of Scott (1979) and uses plug-in ideas from bandwidth selection for kernel density estimation (e.g. Sheather and Jones, 1991).

dpik

Select a Bandwidth for Kernel Density Estimation

Description

Use direct plug-in methodology to select the bandwidth of a kernel density estimate.

Usage

dpik(x, scalest="minim", level=2, kernel="normal",
    canonical=FALSE, gridsize=401, range.x=range(x),
    truncate=TRUE)

Arguments

x
vector containing the sample on which the kernel density estimate is to be constructed.

scalest
estimate of scale.
"stdev" - standard deviation is used.
"iqr" - inter-quartile range divided by 1.349 is used.
"minim" - minimum of "stdev" and "iqr" is used.

level
number of levels of functional estimation used in the plug-in rule.

kernel
character string which determines the smoothing kernel. kernel can be:
"normal" - the Gaussian density function (the default).
"box" - a rectangular box.
"epanech" - the centred beta(2,2) density.
"biweight" - the centred beta(3,3) density.
"triweight" - the centred beta(4,4) density.

canonical
logical flag: if TRUE, canonically scaled kernels are used

gridsize
the number of equally-spaced points over which binning is performed to obtain kernel functional approximation.
dpill

range.x vector containing the minimum and maximum values of \( x \) at which to compute the estimate. The default is the minimum and maximum data values.

truncate logical flag: if TRUE, data with \( x \) values outside the range specified by range.x are ignored.

Details

The direct plug-in approach, where unknown functionals that appear in expressions for the asymptotically optimal bandwidths are replaced by kernel estimates, is used. The normal distribution is used to provide an initial estimate.

Value

the selected bandwidth.

Background

This method for selecting the bandwidth of a kernel density estimate was proposed by Sheather and Jones (1991) and is described in Section 3.6 of Wand and Jones (1995).

References

See Also

bkde, density, ksmooth

data(geyser, package="MASS")
x <- geyser$duration
h <- dpik(x)
est <- bkde(x, bandwidth=h)
plot(est, type="l")

-----------------------------
dpill  Select a Bandwidth for Local Linear Regression

Description

Use direct plug-in methodology to select the bandwidth of a local linear Gaussian kernel regression estimate, as described by Ruppert, Sheather and Wand (1995).

Usage

dpill(x, y, blockmax = 5, divisor = 20, trim = 0.01, proptrun = 0.05, gridsize = 401, range.x, truncate = TRUE)
Arguments

- **x**: vector of x data. Missing values are not accepted.
- **y**: vector of y data. This must be same length as x, and missing values are not accepted.
- **blockmax**: the maximum number of blocks of the data for construction of an initial parametric estimate.
- **divisor**: the value that the sample size is divided by to determine a lower limit on the number of blocks of the data for construction of an initial parametric estimate.
- **trim**: the proportion of the sample trimmed from each end in the x direction before application of the plug-in methodology.
- **proptrun**: the proportion of the range of x at each end truncated in the functional estimates.
- **gridsize**: number of equally-spaced grid points over which the function is to be estimated.
- **range.x**: vector containing the minimum and maximum values of x at which to compute the estimate. For density estimation the default is the minimum and maximum data values with 5% of the range added to each end. For regression estimation the default is the minimum and maximum data values.
- **truncate**: logical flag: if TRUE, data with x values outside the range specified by range.x are ignored.

Details

The direct plug-in approach, where unknown functionals that appear in expressions for the asymptotically optimal bandwidths are replaced by kernel estimates, is used. The kernel is the standard normal density. Least squares quartic fits over blocks of data are used to obtain an initial estimate. Mallow’s $C_p$ is used to select the number of blocks.

Value

the selected bandwidth.

Warning

If there are severe irregularities (i.e., outliers, sparse regions) in the x values then the local polynomial smooths required for the bandwidth selection algorithm may become degenerate and the function will crash. Outliers in the y direction may lead to deterioration of the quality of the selected bandwidth.

References

ksmooth, locpoly.
Examples

data(geyser, package = "MASS")
x <- geyser$duration
y <- geyser$waiting
plot(x, y)
h <- dpill(x, y)
fit <- locpoly(x, y, bandwidth = h)
lines(fit)

Description

Estimates a probability density function, regression function or their derivatives using local polynomials. A fast binned implementation over an equally-spaced grid is used.

Usage

locpoly(x, y, drv = 0, degree =, kernel = "normal",
bandwidth, gridsize = 401, bwdisc = 25,
range.x, binned = FALSE, truncate = TRUE)

Arguments

x vector of x data. Missing values are not accepted.
bandwidth the kernel bandwidth smoothing parameter. It may be a single number or an array having length gridsize, representing a bandwidth that varies according to the location of estimation.
y vector of y data. This must be same length as x, and missing values are not accepted.
drv order of derivative to be estimated.
degree degree of local polynomial used. Its value must be greater than or equal to the value of drv. The default value is of degree is drv + 1.
kernel "normal" - the Gaussian density function.
gridsize number of equally-spaced grid points over which the function is to be estimated.
bwdisc number of logarithmically-equally-spaced bandwidths on which bandwidth is discretised, to speed up computation.
range.x vector containing the minimum and maximum values of x at which to compute the estimate.
binned logical flag: if TRUE, then x and y are taken to be grid counts rather than raw data.
truncate logical flag: if TRUE, data with x values outside the range specified by range.x are ignored.
Value

if y is specified, a local polynomial regression estimate of E[Y|X] (or its derivative) is computed. If y is missing, a local polynomial estimate of the density of x (or its derivative) is computed.

a list containing the following components:

x vector of sorted x values at which the estimate was computed.

y vector of smoothed estimates for either the density or the regression at the corresponding x.

Details

Local polynomial fitting with a kernel weight is used to estimate either a density, regression function or their derivatives. In the case of density estimation, the data are binned and the local fitting procedure is applied to the bin counts. In either case, binned approximations over an equally-spaced grid is used for fast computation. The bandwidth may be either scalar or a vector of length gridsize.

addterm

Try All One-Term Additions to a Model

Description

Try fitting all models that differ from the current model by adding a single term from those supplied, maintaining marginality.

This function is generic; there exist methods for classes `lm` and `glm` and the default method will work for many other classes.

Usage

```r
addterm(object, ...)  
## Default S3 method:  
addterm(object, scope, scale = 0, test = c("none", "Chisq"),  
       k = 2, sorted = FALSE, trace = FALSE, ...)  
## S3 method for class 'lm':  
addterm(object, scope, scale = 0, test = c("none", "Chisq", "F"),  
       k = 2, sorted = FALSE, ...)  
## S3 method for class 'glm':  
addterm(object, scope, scale = 0, test = c("none", "Chisq", "F"),  
       k = 2, sorted = FALSE, trace = FALSE, ...)  
```

Arguments

- **object**: An object fitted by some model-fitting function.
- **scope**: a formula specifying a maximal model which should include the current one. All additional terms in the maximal model with all marginal terms in the original model are tried.
- **scale**: used in the definition of the AIC statistic for selecting the models, currently only for `lm`, `aov` and `glm` models. Specifying `scale` asserts that the residual standard error or dispersion is known.
- **test**: should the results include a test statistic relative to the original model? The F test is only appropriate for `lm` and `aov` models, and perhaps for some over-dispersed `glm` models. The Chisq test can be an exact test (`lm` models with known scale) or a likelihood-ratio test depending on the method.
- **k**: the multiple of the number of degrees of freedom used for the penalty. Only \( k=2 \) gives the genuine AIC: \( k = \log(n) \) is sometimes referred to as BIC or SBC.
- **sorted**: should the results be sorted on the value of AIC?
- **trace**: if TRUE additional information may be given on the fits as they are tried.
- **...**: arguments passed to or from other methods.
The definition of AIC is only up to an additive constant: when appropriate (\texttt{lm} models with specified scale) the constant is taken to be that used in Mallows’ Cp statistic and the results are labelled accordingly.

A table of class "\texttt{anova}" containing at least columns for the change in degrees of freedom and AIC (or Cp) for the models. Some methods will give further information, for example sums of squares, deviances, log-likelihoods and test statistics.

\texttt{dropterm, stepAIC}

\texttt{quine.hi} <- \texttt{aov(log(Days + 2.5) \sim .^4, quine)}
\texttt{quine.lo} <- \texttt{aov(log(Days+2.5) \sim 1, quine)}
\texttt{addterm(quine.lo, quine.hi, test="F")}

anorexia

Anorexia Data on Weight Change

Description

The anorexia data frame has 72 rows and 3 columns. Weight change data for young female anorexia patients.

Usage

anorexia

Format

This data frame contains the following columns:

- **Treat**: Factor of three levels: Cont (Control), CBT (Cognitive Behavioural Treatment) and FT (Family treatment).
- **Prewt**: Weight of patient before study period, in lbs.
- **Postwt**: Weight of patient after study period, in lbs.

Source

(Note that the original source mistakenly says that weights are in kg.)

References

anova.negbin

Likelihood Ratio Tests for Negative Binomial GLMs

Description

Method function to perform sequential likelihood ratio tests for Negative Binomial generalized linear models.

Usage

```r
## S3 method for class 'negbin':
anova(object, ..., test = "Chisq")
```
Arguments

- **object**: Fitted model object of class "negbin", inheriting from classes "glm" and "lm", specifying a Negative Binomial fitted GLM. Typically the output of `glm.nb()`.
- **...**: Zero or more additional fitted model objects of class "negbin". They should form a nested sequence of models, but need not be specified in any particular order.
- **test**: Argument to match the `test` argument of `anova.glm`. Ignored (with a warning if changed) if a sequence of two or more Negative Binomial fitted model objects is specified, but possibly used if only one object is specified.

Details

This function is a method for the generic function `anova()` for class "negbin". It can be invoked by calling `anova(x)` for an object `x` of the appropriate class, or directly by calling `anova.negbin(x)` regardless of the class of the object.

Note

If only one fitted model object is specified, a sequential analysis of deviance table is given for the fitted model. The `theta` parameter is kept fixed. If more than one fitted model object is specified they must all be of class "negbin" and likelihood ratio tests are done of each model within the next. In this case `theta` is assumed to have been re-estimated for each model.

`glm.nb`, `negative.binomial`, `summary.negbin`

Examples

```r
m1 <- glm.nb(Days ~ Eth*Age*Lrn*Sex, quine, link = log)
m2 <- update(m1, . ~ . - Eth:Age:Lrn:Sex)
anova(m2, m1)
anova(m2)
```

---

**area**

*Adaptive Numerical Integration*

Description

Integrate a function of one variable over a finite range using a recursive adaptive method. This function is mainly for demonstration purposes.

Usage

```r
area(f, a, b, ..., fa = f(a, ...), fb = f(b, ...),
     limit = 10, eps = 1e-05)
```
Arguments

- **f**: The integrand as an \( \mathbb{S} \) function object. The variable of integration must be the first argument.
- **a**: Lower limit of integration.
- **b**: Upper limit of integration.
- **\ldots**: Additional arguments needed by the integrand.
- **fa**: Function value at the lower limit.
- **fb**: Function value at the upper limit.
- **limit**: Limit on the depth to which recursion is allowed to go.
- **eps**: Error tolerance to control the process.

Details

The method divides the interval in two and compares the values given by Simpson’s rule and the trapezium rule. If these are within eps of each other the Simpson’s rule result is given, otherwise the process is applied separately to each half of the interval and the results added together.

Value

The integral from \( a \) to \( b \) of \( f(x) \).

References

Examples

```r
area(sin, 0, pi)  # integrate the sin function from 0 to pi.
```

---

*bacteria*  
*Presence of Bacteria after Drug Treatments*

Description

Tests of the presence of the bacteria \( H.\ influenzae \) in children with otitis media in the Northern Territory of Australia.

Usage

*bacteria*
bacteria

Format

This data frame has 220 rows and the following columns:

- y  presence or absence: a factor with levels n and y.
- ap  active/placebo: a factor with levels a and p.
- hilo  hi/low compliance: a factor with levels hi and lo.
- week  numeric: week of test.
- ID  subject ID: a factor.
- trt  a factor with levels placebo, drug and drug+, a re-coding of ap and hilo.

Details

Dr A. Leach tested the effects of a drug on 50 children with a history of otitis media in the Northern Territory of Australia. The children were randomized to the drug or the placebo, and also to receive active encouragement to comply with taking the drug.

The presence of *H. influenzae* was checked at weeks 0, 2, 4, 6 and 11: 30 of the checks were missing and are not included in this data frame.

Examples

```r
crosses(bacteria$trt) <- structure(contr.sdif(3),
    dimnames = list(NULL, c("drug", "encourage")))
## fixed effects analyses
summary(glm(y ~ trt * week, binomial, data = bacteria))
summary(glm(y ~ trt + week, binomial, data = bacteria))
summary(glm(y ~ trt + I(week > 2), binomial, data = bacteria))

## conditional random-effects analysis
library(survival)
bacteria$Time <- rep(1, nrow(bacteria))
coxph(Surv(Time, unclass(y)) ~ week + strata(ID),
    data = bacteria, method = "exact")
coxph(Surv(Time, unclass(y)) ~ factor(week) + strata(ID),
    data = bacteria, method = "exact")
coxph(Surv(Time, unclass(y)) ~ I(week > 2) + strata(ID),
    data = bacteria, method = "exact")

## PQL glmm analysis
library(nlme)
summary(glmmPQL(y ~ trt + I(week > 2), random = ~ 1 | ID,
    family = binomial, data = bacteria))
```
**bandwidth.nrd**  
*Bandwidth for density() via Normal Reference Distribution*

**Description**  
A well-supported rule-of-thumb for choosing the bandwidth of a Gaussian kernel density estimator.

**Usage**  
`bandwidth.nrd(x)`

**Arguments**  

- `x`  
  A data vector.

**Value**  
A bandwidth on a scale suitable for the `width` argument of `density`.

**References**  

**Examples**  
```r
# The function is currently defined as
function(x)
{
  r <- quantile(x, c(0.25, 0.75))
  h <- (r[2] - r[1])/1.34
  4 * 1.06 * min(sqrt(var(x)), h) * length(x)^(-1/5)
}
```

**bcv**  
*Biased Cross-Validation for Bandwidth Selection*

**Description**  
Uses biased cross-validation to select the bandwidth of a Gaussian kernel density estimator.

**Usage**  
`bcv(x, nb = 1000, lower, upper)`

**Arguments**  

- `x`  
  A numeric vector

- `nb`  
  Number of bins to use.

- `lower, upper`  
  Range over which to minimize. The default is almost always satisfactory.
Value

a bandwidth

**birthwt**

*Risk Factors Associated with Low Infant Birth Weight*

Description

The *birthwt* data frame has 189 rows and 10 columns. The data were collected at Baystate Medical Center, Springfield, Mass during 1986.

Usage

`birthwt`

Format

This data frame contains the following columns:

- `low` indicator of birth weight less than 2.5kg
- `age` mother’s age in years
- `lwt` mother’s weight in pounds at last menstrual period
- `race` mother’s race (1 = white, 2 = black, 3 = other)
- `smoke` smoking status during pregnancy
- `ptl` number of previous premature labours
- `ht` history of hypertension
- `ui` presence of uterine irritability
- `ftv` number of physician visits during the first trimester
- `bwt` birth weight in grams
Source

References

Examples

```

options(contrasts = c("contr.treatment", "contr.poly"))
glm(low ~ ., binomial, bwt)
```

---

**Boston**

*Housing Values in Suburbs of Boston*

**Description**

The *Boston* data frame has 506 rows and 14 columns.

**Usage**

*Boston*

**Format**

This data frame contains the following columns:

- **crim** per capita crime rate by town
- **zn** proportion of residential land zoned for lots over 25,000 sq.ft.
- **indus** proportion of non-retail business acres per town
- **chas** Charles River dummy variable (= 1 if tract bounds river; 0 otherwise)
- **nox** nitrogen oxides concentration (parts per 10 million)
- **rm** average number of rooms per dwelling
- **age** proportion of owner-occupied units built prior to 1940
- **dis** weighted mean of distances to five Boston employment centres
- **rad** index of accessibility to radial highways
- **tax** full-value property-tax rate per $10,000
- **ptratio** pupil-teacher ratio by town
- **black** $1000(Bk − 0.63)^2$ where Bk is the proportion of blacks by town
- **lstat** lower status of the population (percent)
- **medv** median value of owner-occupied homes in $1000
Description

Computes and optionally plots profile log-likelihoods for the parameter of the Box-Cox power transformation.

Usage

boxcox(object, ...)

## Default S3 method:
boxcox(object, lambda = seq(-2, 2, 1/10), plotit = TRUE, interp, eps = 1/50, xlab = expression(lambda), ylab = "log-Likelihood", ...)

## S3 method for class 'formula':
boxcox(object, lambda = seq(-2, 2, 1/10), plotit = TRUE, interp, eps = 1/50, xlab = expression(lambda), ylab = "log-Likelihood", ...)

## S3 method for class 'lm':
boxcox(object, lambda = seq(-2, 2, 1/10), plotit = TRUE, interp, eps = 1/50, xlab = expression(lambda), ylab = "log-Likelihood", ...)

Arguments

object       a formula or fitted model object. Currently only \texttt{lm} and \texttt{aov} objects are handled.
lambda       vector of values of \( \lambda \) – default \((\text{−}2, 2)\) in steps of 0.1.
plotit       logical which controls whether the result should be plotted.
interp       logical which controls whether spline interpolation is used. Default to \texttt{TRUE} if plotting with \( \lambda \) of length less than 100.
eps          Tolerance for \( \lambda = 0 \); defaults to 0.02.
xlab         defaults to \"lambda\".
ylab         defaults to \"log-Likelihood\".
...           additional parameters to be used in the model fitting.

Value

A list of the \( \lambda \) vector and the computed profile log-likelihood vector, invisibly if the result is plotted.
Side Effects

If plotit = TRUE plots loglik vs lambda and indicates a 95% confidence interval about the maximum observed value of lambda. If interp = TRUE, spline interpolation is used to give a smoother plot.

References

Examples

data(trees)
boxcox(Volume ~ log(Height) + log(Girth), data = trees,
     lambda = seq(-0.25, 0.25, length = 10))

boxcox(Days+1 ~ Eth*Sex*Age*Lrn, data = quine,
       lambda = seq(-0.05, 0.45, len = 20))

cabbages

Description

The cabbages data set has 60 observations and 4 variables

Usage

cabbages

Format

This data frame contains the following columns:

- **Cult** Factor giving the cultivar of the cabbage, two levels: c39 and c52.
- **Date** Factor specifying one of three planting dates: d16, d20 or d21.
- **HeadWt** Weight of the cabbage head, presumably in kg.
- **VitC** Ascorbic acid content, in undefined units.

Cars93

Data from 93 Cars on Sale in the USA in 1993

Description

The Cars93 data frame has 93 rows and 27 columns.

Usage

Cars93
Format

This data frame contains the following columns:

**Manufacturer**  Manufacturer

**Model**  Model

**Type**  Type: Small, Sporty, Compact, Midsize, Large, Van

**Min.Price**  Minimum Price (in $1,000) - price for a basic version

**Price**  Midrange Price (in $1,000) - average of Min.Price and Max.Price

**Max.Price**  Maximum Price (in $1,000) - price for “a premium version”

**MPG.city**  City MPG (miles per US gallon by EPA rating)

**MPG.highway**  Highway MPG

**AirBags**  Air Bags standard. Factor: none, driver only, or driver & passenger

**DriveTrain**  Drive train type: rear wheel, front wheel or 4WD; (factor).

**Cylinders**  Number of cylinders (missing for Mazda RX-7, which has a rotary engine).

**EngineSize**  Engine size (litres)

**Horsepower**  Horsepower (maximum)

**RPM**  RPM (revs per minute at maximum horsepower)

**Rev.per.mile**  Engine revolutions per mile (in highest gear)

**Man.trans.avail**  Is a manual transmission version available? (yes or no, Factor).

**Fuel.tank.capacity**  Fuel tank capacity (US gallons)

**Passengers**  Passenger capacity (persons)

**Length**  Length (inches)

**Wheelbase**  Wheelbase (inches)

**Width**  Width (inches)

**Turn.circle**  U-turn space (feet)

**Rear.seat.room**  Rear seat room (inches) (missing for 2-seater vehicles)

**Luggage.room**  Luggage capacity (cubic feet) (missing for vans)

**Weight**  Weight (pounds)

**Origin**  Of non-USA or USA company origins? (factor)

**Make**  Combination of Manufacturer and Model (character)

Details

Cars were selected at random from among 1993 passenger car models that were listed in both the *Consumer Reports* issue and the *PACE Buying Guide*. Pickup trucks and Sport/Utility vehicles were eliminated due to incomplete information in the *Consumer Reports* source. Duplicate models (e.g., Dodge Shadow and Plymouth Sundance) were listed at most once.

Further description can be found in Lock (1993). Use the URL [http://www.amstat.org/publications/jse/v1n1/datasets.lock.html](http://www.amstat.org/publications/jse/v1n1/datasets.lock.html)

Convert Lists to Data Frames for use by Trellis

Description

Convert lists to data frames for use by Trellis.

Usage

`con2tr(obj)`

Arguments

`obj`  
A list of components `x`, `y` and `z` as passed to `contour`

Details

`con2tr` repeats the `x` and `y` components suitably to match the vector `z`. 
Value

A data frame suitable for passing to Trellis functions.

References

---

**confint-MASS**

Confidence Intervals for Model Parameters

Description

Computes confidence intervals for one or more parameters in a fitted model. Package MASS adds methods for glm and nls fits.

Usage

```r
## S3 method for class 'glm':
confint(object, parm, level = 0.95, trace = FALSE, ...)

## S3 method for class 'nls':
confint(object, parm, level = 0.95, ...)
```

Arguments

- `object`: a fitted model object. Methods currently exist for the classes "glm", "nls" and for profile objects from these classes.
- `parm`: a specification of which parameters are to be given confidence intervals, either a vector of numbers or a vector of names. If missing, all parameters are considered.
- `level`: the confidence level required.
- `trace`: logical. Should profiling be traced?
- `...`: additional argument(s) for methods.

Details

`confint` is a generic function in package base.

These confint methods calls the appropriate profile method, then finds the confidence intervals by interpolation in the profile traces. If the profile object is already available it should be used as the main argument rather than the fitted model object itself.

Value

A matrix (or vector) with columns giving lower and upper confidence limits for each parameter. These will be labelled as (1-level)/2 and 1 - (1-level)/2 in % (by default 2.5% and 97.5%).

confint(budworm.lg0, "ldose")

contr.sdif

Successive Differences contrast coding

Description
A coding for unordered factors based on successive differences.

Usage
contr.sdif(n, contrasts = TRUE)

Arguments

n
  The number of levels required.

contrasts
  Should there be n - 1 columns orthogonal to the mean (the default) or n
  columns spanning the space.
Details

The contrast coefficients are chosen so that the coded coefficients in a one-way layout are the differences between the means of the second and first levels, the third and second levels, and so on.

Value

If contrasts is TRUE, a matrix with n rows and n - 1 columns, and the n by n identity matrix if contrasts is FALSE.

corresp(x, y, ...)  
## S3 method for class 'data.frame':  
corresp(x, ...)  
## S3 method for class 'xtabs':  
corresp(x, ...)  
## S3 method for class 'formula':  
corresp(formula, data, ...)  
```

Arguments

- `x, formula` The function is generic, accepting various forms of the principal argument for specifying a two-way frequency table. Currently accepted forms are matrices, data frames (coerced to frequency tables), objects of class "xtabs" and formulae of the form ~ F1 + F2, where F1 and F2 are factors.
- `nf` The number of factors to be computed. Note that although 1 is the most usual, one school of thought takes the first two singular vectors for a sort of biplot.
- `y` a second factor for a cross-classification
- `data` a data frame against which to preferentially resolve variables in the formula.
- `...` If the principal argument is a formula, a data frame may be specified as well from which variables in the formula are preferentially satisfied.

Details

See Venables & Ripley (2002). The `plot` method produces a graphical representation of the table if `nf=1`, with the `areas` of circles representing the numbers of points. If `nf` is two or more the `biplot` method is called, which plots the second and third columns of the matrices $A = Dr^{(-1/2)} U L$ and $B = Dc^{(-1/2)} V L$ where the singular value decomposition is $U L V$. Thus the x-axis is the canonical correlation times the row and column scores. Although this is called a biplot, it does not have any useful inner product relationship between the row and column scores. Think of this as an equally-scaled plot with two unrelated sets of labels. The origin is marked on the plot with a cross. (For other versions of this plot see the book.)
Value

An list object of class "correspondence" for which print, plot and biplot methods are supplied. The main components are the canonical correlation(s) and the row and column scores.

Examples

(ct <- corresp(~ Age + Eth, data = quine))
## Not run: plot(ct)
corresp(caith)
biplot(corresp(caith, nf = 2))

Description

Compute a multivariate location and scale estimate with a high breakdown point – this can be thought of as estimating the mean and covariance of the good part of the data. cov.mve and cov.mcd are compatibility wrappers.

Usage

cov.rob(x, cor = FALSE, quantile.used = floor((n + p + 1)/2),
method = c("mve", "mcd", "classical"),
nsamp = "best", seed)
cov.mve(...)
cov.mcd(...)

Arguments

x a matrix or data frame.
cor should the returned result include a correlation matrix?
quantile.used the minimum number of the data points regarded as good points.
method the method to be used – minimum volume ellipsoid, minimum covariance de-
terminant or classical product-moment. Using cov.mve or cov.mcd forces mve or mcd respectively.
the number of samples or "best" or "exact" or "sample". If "sample" the number chosen is \( \min(5p, 3000) \), taken from Rousseeuw and Hubert (1997). If "best" exhaustive enumeration is done up to 5000 samples: if "exact" exhaustive enumeration will be attempted however many samples are needed.

the seed to be used for random sampling: see \texttt{RNGkind}. The current value of \texttt{.Random.seed} will be preserved if it is set.

... arguments to \texttt{cov.rob} other than \texttt{method}.

**Details**

For method "mve", an approximate search is made of a subset of size \texttt{quantile.used} with an enclosing ellipsoid of smallest volume; in method "mcd" it is the volume of the Gaussian confidence ellipsoid, equivalently the determinant of the classical covariance matrix, that is minimized. The mean of the subset provides a first estimate of the location, and the rescaled covariance matrix a first estimate of scatter. The Mahalanobis distances of all the points from the location estimate for this covariance matrix are calculated, and those points within the 97.5\% point under Gaussian assumptions are declared to be good. The final estimates are the mean and rescaled covariance of the good points.

The rescaling is by the appropriate percentile under Gaussian data; in addition the first covariance matrix has an \textit{ad hoc} finite-sample correction given by Marazzi.

For method "mve" the search is made over ellipsoids determined by the covariance matrix of \( p \) of the data points. For method "mcd" an additional improvement step suggested by Rousseeuw and van Driessen (1999) is used, in which once a subset of size \texttt{quantile.used} is selected, an ellipsoid based on its covariance is tested (as this will have no larger a determinant, and may be smaller).

**Value**

A list with components

- **center**: the final estimate of location.
- **cov**: the final estimate of scatter.
- **cor**: (only is \texttt{cor = TRUE}) the estimate of the correlation matrix.
- **sing**: message giving number of singular samples out of total
- **crit**: the value of the criterion on log scale. For MCD this is the determinant, and for MVE it is proportional to the volume.
- **best**: the subset used. For MVE the best sample, for MCD the best set of size \texttt{quantile.used}.
- **n.obs**: total number of observations.

**Author(s)**

B.D. Ripley

**Examples**

```r
data(stackloss)
set.seed(123)
cov.rob(stackloss)
cov.rob(stack.x, method = "mcd", nsamp = "exact")
```

cov.trob

*Covariance Estimation for Multivariate t Distribution*

**Description**

Estimates a covariance or correlation matrix assuming the data came from a multivariate t distribution: this provides some degree of robustness to outlier without giving a high breakdown point.

**Usage**

```r
cov.trob(x, wt = rep(1, n), cor = FALSE, center = TRUE, nu = 5,
maxit = 25, tol = 0.01)
```

**Arguments**

- `x` data matrix. Missing values (NAs) are not allowed.
- `wt` A vector of weights for each case: these are treated as if the case i actually occurred wt[i] times.
- `cor` Flag to choose between returning the correlation (cor = TRUE) or covariance (cor = FALSE) matrix.
- `center` a logical value or a numeric vector providing the location about which the covariance is to be taken. If center = FALSE, no centering is done; if center = TRUE the MLE of the location vector is used.
- `nu` “degrees of freedom” for the multivariate t distribution. Must exceed 2 (so that the covariance matrix is finite).
- `maxit` Maximum number of iterations in fitting.
- `tol` Convergence tolerance for fitting.
Value

A list with the following components

- `cov`: the fitted covariance matrix.
- `center`: the estimated or specified location vector.
- `wt`: the specified weights: only returned if the `wt` argument was given.
- `n.obs`: the number of cases used in the fitting.
- `cor`: the fitted correlation matrix: only returned if `cor = TRUE`.
- `call`: The matched call.
- `iter`: The number of iterations used.

### cpus

A relative performance measure and characteristics of 209 CPUs.

#### Usage

cpus

#### Format

The components are:

- `name`: Manufacturer and model
- `syct`: cycle time in nanoseconds
- `mmin`: minimum main memory in kilobytes
- `mmax`: maximum main memory in kilobytes
- `cach`: cache size in kilobytes
- `chmin`: minimum number of channels
- `chmax`: maximum number of channels
- `perf`: published performance on a benchmark mix relative to an IBM 370/158-3
- `estperf`: estimated performance (by Ein-Dor & Feldmesser)
Morphological Measurements on Leptograpsus Crabs

Description
The crabs data frame has 200 rows and 8 columns, describing 5 morphological measurements on 50 crabs each of two colour forms and both sexes, of the species *Leptograpsus variegatus* collected at Fremantle, W. Australia.

Usage

```r
crabs
```

Format
This data frame contains the following columns:

- **sp** species - "B" or "O" for blue or orange
- **sex** as it says
- **index** index 1:50 within each of the four groups
- **FL** frontal lobe size (mm)
- **RW** rear width (mm)
- **CL** carapace length (mm)
- **CW** carapace width (mm)
- **BD** body depth (mm)

---

**denumerate**

Transform an Allowable Formula for 'loglm' into one for 'terms'

**Description**

*loglm* allows dimension numbers to be used in place of names in the formula. *denumerate* modifies such a formula into one that *terms* can process.

**Usage**

denumerate(x)

**Arguments**

x A formula conforming to the conventions of *loglm*, that is, it may allow dimension numbers to stand in for names when specifying a log-linear model.

**Details**

The model fitting function *loglm* fits log-linear models to frequency data using iterative proportional scaling. To specify the model the user must nominate the margins in the data that remain fixed under the log-linear model. It is convenient to allow the user to use dimension numbers, 1, 2, 3, ... for the first, second, third, ..., margins in a similar way to variable names. As the model formula has to be parsed by *terms*, which treats 1 in a special way and requires parsable variable names, these formulae have to be modified by giving genuine names for these margin, or dimension numbers. *denumerate* replaces these numbers with names of a special form, namely n is replaced by .vn. This allows *terms* to parse the formula in the usual way.
A linear model formula like that presented, except that where dimension numbers, say \( n \), have been used to specify fixed margins these are replaced by names of the form \(.vn\) which may be processed by terms.

dose.p

Predict Doses for Binomial Assay model

Description

Calibrate binomial assays, generalizing the calculation of LD50.

Usage

dose.p(obj, cf = 1:2, p = 0.5)

Arguments

- **obj**: A fitted model object of class inheriting from "glm".
- **cf**: The terms in the coefficient vector giving the intercept and coefficient of (log-)dose
- **p**: Probabilities at which to predict the dose needed.

Value

An object of class "glm.dose" giving the prediction (attribute "p") and standard error (attribute "SE") at each response probability.

References

Examples

```r
ldose <- rep(0:5, 2)
numdead <- c(1, 4, 9, 13, 18, 20, 0, 2, 6, 10, 12, 16)
sex <- factor(rep(c("M", "F"), c(6, 6)))
SF <- cbind(numdead, numalive = 20 - numdead)
budworm.lg0 <- glm(SF ~ sex + ldose - 1, family = binomial)
dose.p(budworm.lg0, cf = c(1,3), p = 1:3/4)
dose.p(update(budworm.lg0, family = binomial(link=probit)),
  cf = c(1,3), p = 1:3/4)
```
drivers

Description
A regular time series giving the monthly totals of car drivers in Great Britain killed or seriously injured Jan 1969 to Dec 1984. Compulsory wearing of seat belts was introduced on 31 Jan 1983.

Usage
drivers

Source

References

dropterm

Try All One-Term Deletions from a Model

Description
Try fitting all models that differ from the current model by dropping a single term, maintaining marginality.

This function is generic; there exist methods for classes lm and glm and the default method will work for many other classes.

Usage
dropterm (object, ...)

## Default S3 method:
dropterm(object, scope, scale = 0, test = c("none", "Chisq"),
  k = 2, sorted = FALSE, trace = FALSE, ...)

## S3 method for class 'lm':
dropterm(object, scope, scale = 0, test = c("none", "Chisq", "F"),
  k = 2, sorted = FALSE, trace = FALSE, ...)

## S3 method for class 'glm':
dropterm(object, scope, scale = 0, test = c("none", "Chisq", "F"),
  k = 2, sorted = FALSE, trace = FALSE, ...)
Arguments

- **object**: A object fitted by some model-fitting function.
- **scope**: a formula giving terms which might be dropped. By default, the model formula. Only terms that can be dropped and maintain marginality are actually tried.
- **scale**: used in the definition of the AIC statistic for selecting the models, currently only for `lm`, `aov` and `glm` models. Specifying `scale` asserts that the residual standard error or dispersion is known.
- **test**: should the results include a test statistic relative to the original model? The F test is only appropriate for `lm` and `aov` models, and perhaps for some over-dispersed `glm` models. The Chisq test can be an exact test (`lm` models with known scale) or a likelihood-ratio test depending on the method.
- **k**: the multiple of the number of degrees of freedom used for the penalty. Only \( k = 2 \) gives the genuine AIC: \( k = \log(n) \) is sometimes referred to as BIC or SBC.
- **sorted**: should the results be sorted on the value of AIC?
- **trace**: if TRUE additional information may be given on the fits as they are tried.
- ... arguments passed to or from other methods.

Details

The definition of AIC is only up to an additive constant: when appropriate (`lm` models with specified `scale`) the constant is taken to be that used in Mallows' Cp statistic and the results are labelled accordingly.

Value

A table of class "anova" containing at least columns for the change in degrees of freedom and AIC (or Cp) for the models. Some methods will give further information, for example sums of squares, deviances, log-likelihoods and test statistics.

prof <- profile(eagles.glm)
plot(prof)
pairs(prof)
Seizure Counts for Epileptics

Description
Thall and Vail (1990) give a data set on two-week seizure counts for 59 epileptics. The number of seizures was recorded for a baseline period of 8 weeks, and then patients were randomly assigned to a treatment group or a control group. Counts were then recorded for four successive two-week periods. The subject’s age is the only covariate.

Usage
epil

Format
This data frame has 236 rows and the following 9 columns:

- `y` The count for the 2-week period.
- `trt` The treatment, "placebo" or "progabide".
- `base` The counts in the baseline 8-week period.
- `age` The subject’s age, in years.
- `V4` 0/1 indicator variable of period 4.
- `subject` The subject number, 1 to 59.
- `period` The period, 1 to 4.
- `lbase` The log-counts for the baseline period, centred to have zero mean.
- `lage` The log-ages, centred to have zero mean.

Source

References

Examples
```r
summary(glm(y ~ lbase*trt + lage + V4, family = poisson, 
data = epil), cor = FALSE)
epil2 <- epil[epil$period == 1, ]
epil2["period"] <- rep(0, 59); epil2["y"] <- epil2["base"]
epil["time"] <- 1; epil2["time"] <- 4
epil2 <- rbind(epil, epil2)
epil2$pred <- unclass(epil2$trt) * (epil2$period > 0)
epil2$subject <- factor(epil2$subject)
epil3 <- aggregate(epil2, list(epil2$subject, epil2$period > 0), 
  function(x) if(is.numeric(x)) sum(x) else x[1])
```
eqscplot <- factor(eqscplot, 
    labels = c("base", "placebo", "drug"))

contrasts(eqscplot) <- structure(contr.sdif(3),
    dimnames = list(NULL, c("placebo-base", "drug-placebo")))

summary(glm(y ~ pred + factor(subject) + offset(log(time)),
    family = poisson, data = epil3), cor = FALSE)

summary(glmmPQL(y ~ lbase*trt + lage + V4,
    random = ~ 1 | subject,
    family = poisson, data = epil))

summary(glmmPQL(y ~ pred, random = ~1 | subject,
    family = poisson, data = epil3))

eqscplot

Plots with Geometrically Equal Scales

Description

Version of a scatterplot with scales chosen to be equal on both axes, that is 1cm represents the same units on each axis.

Usage

eqscplot(x, y, ratio = 1, tol = 0.04, uin, ...)

Arguments

x, y vector of x values, or a 2-column matrix, or a list with components x and y
ratio desired ratio of units on the axes. Units on the y axis are drawn at ratio times the size of units on the x axis. Ignored if uin is specified and of length 2.
tol proportion of white space at the margins of plot
uin desired values for the units-per-inch parameter. If of length 1, the desired units per inch on the x axis.
... further arguments for plot and graphical parameters. Note that par(xaxs="i", yaxs="i") is enforced, and xlim and ylim will be adjusted accordingly.

Details

Limits for the x and y axes are chosen so that they include the data. One of the sets of limits is then stretched from the midpoint to make the units in the ratio given by ratio. Finally both are stretched by 1 + tol to move points away from the axes, and the points plotted.

Value

invisibly, the values of uin used for the plot.

Side Effects

performs the plot.
Note
Arguments ratio and uin were suggested by Bill Dunlap.

plot, par

farms Ecological Factors in Farm Management

Description
The farms data frame has 20 rows and 4 columns. The rows are farms on the Dutch island of Terschelling and the columns are factors describing the management of grassland.

Usage
farms

Format
This data frame contains the following columns:

- **Mois** Five levels of soil moisture – level 3 does not occur at these 20 farms.
- **Manag** Grassland management type (SF = standard, BF = biological, HF = hobby farming, NM = nature conservation).
- **Use** Grassland use (U1 = hay production, U2 = intermediate, U3 = grazing)
- **Manure** Manure usage – classes C0 to C4.

Source

References

Examples
farms.mca <- mca(farms, abbrev = TRUE) # Use levels as names
eqscplot(farms.mca$cs, type = "n")

Measurements of Forensic Glass Fragments

Description
The `fgl` data frame has 214 rows and 10 columns. It was collected by B. German on fragments of glass collected in forensic work.

Usage
`fgl`

Format
This data frame contains the following columns:

- **RI** refractive index; more precisely the refractive index is 1.518xxxx.
  The remaining 8 measurements are percentages by weight of oxides.
- **Na** sodium
- **Mg** manganese
- **Al** aluminium
- **Si** silicon
- **K** potassium
- **Ca** calcium
- **Ba** barium
- **Fe** iron
- **type** The fragments were originally classed into seven types, one of which was absent in this dataset. The categories which occur are window float glass (`WinF`: 70), window non-float glass (`WinNF`: 76), vehicle window glass (`Veh`: 17), containers (`Con`: 13), tableware (`Tabl`: 9) and vehicle headlamps (`Head`: 29).

References

Maximum-likelihood Fitting of Univariate Distributions

Description
Maximum-likelihood fitting of univariate distributions, allowing parameters to be held fixed if desired.

Usage
`fitdistr(x, densfun, start, ...)`
Arguments

x
A numeric vector.

densfun
Either a character string or a function returning a density evaluated at its first argument.
Distributions "beta", "cauchy", "chi-squared", "exponential", "f", "gamma", "geometric", "log-normal", "lognormal", "logistic", "negative binomial", "normal", "Poisson", "t" and "weibull" are recognised, case being ignored.

start
A named list giving the parameters to be optimized with initial values. This can be omitted for some of the named distributions and must be for others (see Details).

...
Additional parameters, either for densfun or for optim. In particular, it can be used to specify bounds via lower or upper or both. If arguments of densfun (or the density function corresponding to a character-string specification) are included they will be held fixed.

Details

For the Normal, log-Normal, exponential and Poisson distributions the closed-form MLEs (and exact standard errors) are used, and start should not be supplied.

For all other distributions, direct optimization of the log-likelihood is performed using optim. The estimated standard errors are taken from the observed information matrix, calculated by a numerical approximation. For one-dimensional problems the Nelder-Mead method is used and for multi-dimensional problems the BFGS method, unless arguments named lower or upper are supplied when L-BFGS-B is used or method is supplied explicitly.

For the "t" named distribution the density is taken to be the location-scale family with location m and scale s.

For the following named distributions, reasonable starting values will be computed if start is omitted or only partially specified: "cauchy", "gamma", "logistic", "negative binomial" (parametrized by mu and size), "t" and "weibull". Note that these starting values may not be good enough if the fit is poor: in particular they are not resistant to outliers unless the fitted distribution is long-tailed.

There are print, coef and logLik methods for class "fitdistr".

Value

An object of class "fitdistr", a list with three components,

estimate the parameter estimates,

sd the estimated standard errors, and

loglik the log-likelihood.

Forbes’ Data on Boiling Points in the Alps

Description

A data frame with 17 observations on boiling point (degrees F) and barometric pressure in inches of mercury.

Usage

```r
forbes
```

Format

- `bp` boiling point (degrees F)
- `pres` barometric pressure in inches of mercury

Source

fractions

Rational Approximation

Description
Find rational approximations to the components of a real numeric object using a standard continued fraction method.

Usage
fractions(x, cycles = 10, max.denominator = 2000, ...)

Arguments
- **x**: Any object of mode numeric. Missing values are now allowed.
- **cycles**: The maximum number of steps to be used in the continued fraction approximation process.
- **max.denominator**: An early termination criterion. If any partial denominator exceeds max.denominator the continued fraction stops at that point.
- **...**: arguments passed to or from other methods.

Details
Each component is first expanded in a continued fraction of the form
\[ x = \text{floor}(x) + \frac{1}{(p_1 + \frac{1}{(p_2 + \ldots))}} \]
where \( p_1, p_2, \ldots \) are positive integers, terminating either at cycles terms or when a \( p_j > \) max.denominator. The continued fraction is then re-arranged to retrieve the numerator and denominator as integers.

The numerators and denominators are then combined into a character vector that becomes the "fracs" attribute and used in printed representations.

Arithmetic operations on "fractions" objects have full floating point accuracy, but the character representation printed out may not.

Value
An object of class "fractions". A structure with .Data component the same as the input numeric \( x \), but with the rational approximations held as a character vector attribute, "fracs". Arithmetic operations on "fractions" objects are possible.

```

GAGurine  

**Level of GAG in Urine of Children**

**Description**

Data were collected on the concentration of a chemical GAG in the urine of 314 children aged from zero to seventeen years. The aim of the study was to produce a chart to help a paediatrician to assess if a child’s GAG concentration is “normal”.

**Usage**

GAGurine

**Format**

This data frame contains the following columns:

- **Age**  age of child in years
- **GAG**  concentration of GAG (the units have been lost)

**Source**

Mrs Susan Prosser, Paediatrics Department, University of Oxford, via Department of Statistics Consulting Service.

**References**

galaxies

Description
A numeric vector of velocities in km/sec of 82 galaxies from 6 well-separated conic sections of an unfilled survey of the Corona Borealis region. Multimodality in such surveys is evidence for voids and superclusters in the far universe.

Usage
galaxies

Note
There is an 83rd measurement of 5607 km/sec in the Postman et al. paper which is omitted in Roeder (1990) and from the dataset here.
There is also a typo: this dataset has 78th observation 26690 which should be 26960.

Source

References

Examples
```r
gal <- galaxies/1000
c(width.SJ(gal, method = "dpi"), width.SJ(gal))
plot(x = c(0, 40), y = c(0, 0.3), type = "n", bty = "l",
     xlab = "velocity of galaxy (1000km/s)", ylab = "density")
rug(gal)
lines(density(gal, width = 3.25, n = 200), lty = 1)
lines(density(gal, width = 2.56, n = 200), lty = 3)
```

gamma.dispersion

Description
A front end to gamma.shape for convenience. Finds the reciprocal of the estimate of the shape parameter only.
Usage

\texttt{gamma.dispersion(object, \ldots)}

Arguments

\begin{itemize}
  \item \texttt{object} \quad Fitted model object giving the gamma fit.
  \item \texttt{\ldots} \quad Additional arguments passed on to \texttt{gamma.shape}.
\end{itemize}

Value

The MLE of the dispersion parameter of the gamma distribution.

References

See Also

\texttt{gamma.shape.glm}, including the example on its help page.

---

\textbf{gamma.shape} \quad \textit{Estimate the Shape Parameter of the Gamma Distribution in a GLM Fit}

Description

Find the maximum likelihood estimate of the shape parameter of the gamma distribution after fitting a Gamma generalized linear model.

Usage

\texttt{## S3 method for class 'glm':
  gamma.shape(object, it.lim = 10,
  eps.max = .Machine$double.eps^0.25, verbose = FALSE, \ldots)}

Arguments

\begin{itemize}
  \item \texttt{object} \quad Fitted model object from a Gamma family or quasi family with variance = "mu^2".
  \item \texttt{it.lim} \quad Upper limit on the number of iterations.
  \item \texttt{eps.max} \quad Maximum discrepancy between approximations for the iteration process to continue.
  \item \texttt{verbose} \quad If TRUE, causes successive iterations to be printed out. The initial estimate is taken from the deviance.
  \item \texttt{\ldots} \quad further arguments passed to or from other methods.
\end{itemize}

Details

A \texttt{glm} fit for a Gamma family correctly calculates the maximum likelihood estimate of the mean parameters but provides only a crude estimate of the dispersion parameter. This function takes the results of the \texttt{glm} fit and solves the maximum likelihood equation for the reciprocal of the dispersion parameter, which is usually called the shape (or exponent) parameter.
Value

List of two components

alpha the maximum likelihood estimate
SE the approximate standard error, the square-root of the reciprocal of the observed information.

Description

A data frame from a trial of 42 leukaemia patients. Some were treated with the drug 6-mercaptopurine and the rest are controls. The trial was designed as matched pairs, both withdrawn from the trial when either came out of remission.

Usage
gehan
Format

This data frame contains the following columns:

- **pair**: label for pair
- **time**: remission time in weeks
- **cens**: censoring, 0/1
- **treat**: treatment, control or 6-MP

Source

References

Examples

```r
library(survival)
gehan.surv <- survfit(Surv(time, cens) ~ treat, data = gehan,
  conf.type = "log-log")

survreg(Surv(time, cens) ~ factor(pair) + treat, gehan, dist = "exp")
summary(survreg(Surv(time, cens) ~ treat, gehan, dist = "exp"))
summary(survreg(Surv(time, cens) ~ treat, gehan))
gehan.cox <- coxph(Surv(time, cens) ~ treat, gehan)
summary(gehan.cox)
```

---

**genotype**  
**Rat Genotype Data**

Description

Data from a foster feeding experiment with rat mothers and litters of four different genotypes: A, B, I and J. Rice litters were separated from their natural mothers at birth and given to foster mothers to rear.

Usage

```r
genotype
```

Format

The data frame has the following components:

- **Litter**: The genotype of the litter
- **Mother**: The genotype of the foster mother
- **Wt**: Litter average weight gain of the litter, in grams at age 28 days. (The source states that the within-litter variability is negligible.)
Source

**geyser**

*Old Faithful Geyser Data*

**Description**

A version of the eruptions data from the ‘Old Faithful’ geyser in Yellowstone National Park, Wyoming. This version comes from Azzalini and Bowman (1990) and is of continuous measurement from August 1 to August 15, 1985.

Some nocturnal duration measurements were coded as 2, 3 or 4 minutes, having originally been described as ‘short’, ‘medium’ or ‘long’.

**Usage**

geyser

**Format**

A data frame with 299 observations on 2 variables.

<table>
<thead>
<tr>
<th>duration</th>
<th>numeric</th>
<th>Eruption time in mins</th>
</tr>
</thead>
<tbody>
<tr>
<td>waiting</td>
<td>numeric</td>
<td>Waiting time to next eruption</td>
</tr>

**gilgais**

*Line Transect of Soil in Gilgai Territory*
Description
This dataset was collected on a line transect survey in gilgai territory in New South Wales, Australia. Gilgais are natural gentle depressions in otherwise flat land, and sometimes seem to be regularly distributed. The data collection was stimulated by the question: are these patterns reflected in soil properties? At each of 365 sampling locations on a linear grid of 4 meters spacing, samples were taken at depths 0-10 cm, 30-40 cm and 80-90 cm below the surface. pH, electrical conductivity and chloride content were measured on a 1:5 soil:water extract from each sample.

Usage
gilgais

Format
This data frame contains the following columns:

- **pH00** pH at depth 0-10cm
- **pH30** pH at depth 30-40cm
- **pH80** pH at depth 80-90cm
- **e00** electrical conductivity in mS/cm (0-10 cm)
- **e30** electrical conductivity in mS/cm (30-40 cm)
- **e80** electrical conductivity in mS/cm (80-90 cm)
- **c00** chloride content in ppm (0-10 cm)
- **c30** chloride content in ppm (30-40 cm)
- **c80** chloride content in ppm (80-90 cm)

**ginv**

*Generalized Inverse of a Matrix*

Description
Calculates the Moore-Penrose generalized inverse of a matrix X.

Usage

```r
ginv(X, tol = sqrt(.Machine$double.eps))
```
glm.convert

Arguments

- **X**: Matrix for which the Moore-Penrose inverse is required.
- **tol**: A relative tolerance to detect zero singular values.

Value

A MP generalized inverse matrix for X.

References

See Also

solve, svd, eigen

Examples

```r
## Not run:
# The function is currently defined as
function(X, tol = sqrt(.Machine$double.eps))
{
  ## Generalized Inverse of a Matrix
  dnx <- dimnames(X)
  if(is.null(dnx)) dnx <- vector("list", 2)
  s <- svd(X)
  nz <- s$d > tol * s$d[1]
  structure(
    if(any(nz)) s$v[, nz] %*% (t(s$u[, nz])/s$d[nz]) else X,
    dimnames = dnx[2:1])
}
## End(Not run)
```

glm.convert

Change a Negative Binomial fit to a GLM fit

Description

This function modifies an output object from glm.nb() to one that looks like the output from glm() with a negative binomial family. This allows it to be updated keeping the theta parameter fixed.

Usage

```
glm.convert(object)
```

Arguments

- **object**: An object of class "negbin", typically the output from glm.nb().
**Details**

Convenience function needed to effect some low level changes to the structure of the fitted model object.

**Value**

An object of class "glm" with negative binomial family. The theta parameter is then fixed at its present estimate.

**See Also**

`glm.nb`, `negative.binomial`, `glm`

**Examples**

```r
quine.nb1 <- glm.nb(Days ~ Sex/(Age + Eth*Lrn), data = quine)
quine.nbA <- glm.convert(quine.nb1)
quine.nbB <- update(quine.nb1, . ~ . + Sex:Age:Lrn)
anova(quine.nbA, quine.nbB)
```

---

**glm.nb**

*Fit a Negative Binomial Generalized Linear Model*

**Description**

A modification of the system function `glm()` to include estimation of the additional parameter, theta, for a Negative Binomial generalized linear model.

**Usage**

```r
glm.nb(formula, data, weights, subset, na.action, 
start = NULL, etastart, mustart, 
control = glm.control(...), method = "glm.fit", 
model = TRUE, x = FALSE, y = TRUE, contrasts = NULL, ...) 
init.theta, link = log)
```

**Arguments**

- `formula, data, weights, subset, na.action, start, etastart, mustart, control, method, model, x, y, contrasts, ...`
  
  Arguments for the `glm()` function. Note that these exclude `family` and `offset` (but `offset()` can be used).

- `init.theta`  Optional initial value for the theta parameter. If omitted a moment estimator after an initial fit using a Poisson GLM is used.

- `link` The link function. Currently must be one of `log`, `sqrt` or `identity`. 
Details

An alternating iteration process is used. For given \( \theta \) the GLM is fitted using the same process as used by glm(). For fixed means the \( \theta \) parameter is estimated using score and information iterations. The two are alternated until convergence of both. (The number of alternations and the number of iterations when estimating \( \theta \) are controlled by the maxit parameter of glm.control.)

Setting \( \text{trace} > 0 \) traces the alternating iteration process. Setting \( \text{trace} > 1 \) traces the glm fit, and setting \( \text{trace} > 2 \) traces the estimation of \( \theta \).

Value

A fitted model object of class \( \text{negbin} \) inheriting from \( \text{glm} \) and \( \text{lm} \). The object is like the output of glm but contains three additional components, namely \( \theta \) for the ML estimate of \( \theta \), \( \text{SE.}\theta \) for its approximate standard error (using observed rather than expected information), and \( \text{twologlik} \) for twice the log-likelihood function.

References

See Also

glm, negative.binomial, anova.negbin, summary.negbin, theta.md

Examples

```r
quine.nb1 <- glm.nb(Days ~ Sex/(Age + Eth*Lrn), data = quine)
quine.nb2 <- update(quine.nb1, . ~ . + Sex:Age:Lrn)
quine.nb3 <- update(quine.nb2, Days ~ .^4)
anova(quine.nb1, quine.nb2, quine.nb3)
```
weights: optional case weights as in glm.
control: an optional argument to be passed to lme.
niter: maximum number of iterations.
verbose: logical: print out record of iterations?
... Further arguments for lme.

Details

glmmPQL works by repeated calls to lme, so package nlme will be loaded at first use if necessary.

Value

A object of class "lme": see lmeObject.

References

### hist.scott

*Plot a Histogram with Automatic Bin Width Selection*

**Description**

Plot a histogram with automatic bin width selection, using the Scott or Freedman–Diaconis formulae.

**Usage**

```r
hist.scott(x, prob = TRUE, xlab = deparse(substitute(x)), ...)
hist.FD(x, prob = TRUE, xlab = deparse(substitute(x)), ...)
```

**Arguments**

- `x` A data vector
- `prob` Should the plot have unit area, so be a density estimate?
- `xlab, ...` Further arguments to `hist`.

**Value**

For the `nclass.*` functions, the suggested number of classes.

**Side Effects**

Plot a histogram.

**References**

**See Also**

`hist`
Description

The `housing` data frame has 72 rows and 5 variables.

Usage

`housing`

Format

- **Sat**: Satisfaction of householders with their present housing circumstances, (High, Medium or Low, ordered factor).
- **Infl**: Perceived degree of influence householders have on the management of the property (High, Medium, Low).
- **Type**: Type of rental accommodation, (Tower, Atrium, Apartment, Terrace).
- **Cont**: Contact residents are afforded with other residents, (Low, High).
- **Freq**: Frequencies: the numbers of residents in each class.

**Insurance**

*Numbers of Car Insurance claims*

---

Description
The data given in data frame *Insurance* consist of the numbers of policyholders of an insurance company who were exposed to risk, and the numbers of car insurance claims made by those policyholders in the third quarter of 1973.

Usage

`Insurance`

Format
This data frame contains the following columns:

- **District** district of policyholder (1 to 4): 4 is major cities.
- **Group** group of car (1 to 4), <1 litre, 1–1.5 litre, 1.5–2 litre, >2 litre.
- **Age** of driver in 4 ordered groups, <25, 25–29, 30–35, >35.
- **Holders** numbers of policyholders
- **Claims** numbers of claims

Source

References
isoMDS

Examples

```r
## main-effects fit as Poisson GLM with offset
glm(Claims ~ District + Group + Age + offset(log(Holders)),
    data = Insurance, family = poisson)

# same via loglm
loglm(Claims ~ District + Group + Age + offset(log(Holders)),
     data = Insurance)
```

isoMDS

Kruskal’s Non-metric Multidimensional Scaling

Description

One form of non-metric multidimensional scaling

Usage

```r
isoMDS(d, y = cmdscale(d, k), k = 2, maxit = 50, trace = TRUE,
       tol = 1e-3, p = 2)

Shepard(d, x, p = 2)
```

Arguments

- `d`: distance structure of the form returned by `dist`, or a full, symmetric matrix. Data are assumed to be dissimilarities or relative distances, but must be positive except for self-distance. Both missing and infinite values are allowed.
- `y`: An initial configuration. If none is supplied, `cmdscale` is used to provide the classical solution, unless there are missing or infinite dissimilarities.
- `k`: The desired dimension for the solution, passed to `cmdscale`.
- `maxit`: The maximum number of iterations.
- `trace`: Logical for tracing optimization. Default `TRUE`.
- `tol`: convergence tolerance.
- `p`: Power for Minkowski distance in the configuration space.
- `x`: A final configuration.

Details

This chooses a k-dimensional (default k = 2) configuration to minimize the stress, the square root of the ratio of the sum of squared differences between the input distances and those of the configuration to the sum of configuration distances squared. However, the input distances are allowed a monotonic transformation.

An iterative algorithm is used, which will usually converge in around 10 iterations. As this is necessarily an $O(n^2)$ calculation, it is slow for large datasets. Further, since for the default $p = 2$ the configuration is only determined up to rotations and reflections (by convention the centroid is at the origin), the result can vary considerably from machine to machine.
Value

Two components:

- **points**: A k-column vector of the fitted configuration.
- **stress**: The final stress achieved (in percent).

Side Effects

If `trace` is true, the initial stress and the current stress are printed out every 5 iterations.

References

See Also

- `cmdscale`, `sammon`

Examples

```r
data(swiss)
swiss.x <- as.matrix(swiss[, -1])
swiss.dist <- dist(swiss.x)
swiss.mds <- isoMDS(swiss.dist)
plot(swiss.mds$points, type = "n")
text(swiss.mds$points, labels = as.character(1:nrow(swiss.x)))
swiss.sh <- Shepard(swiss.dist, swiss.mds$points)
plot(swiss.sh, pch = ".")
lines(swiss.sh$x, swiss.sh$yf, type = "S")
```

---

**kde2d**

Two-Dimensional Kernel Density Estimation

Description

Two-dimensional kernel density estimation with an axis-aligned bivariate normal kernel, evaluated on a square grid.

Usage

```r
kde2d(x, y, h, n = 25, lims = c(range(x), range(y)))
```

Arguments

- **x**: x coordinate of data
- **y**: y coordinate of data
- **h**: vector of bandwidths for x and y directions. Defaults to normal reference bandwidth (see `bandwidth.nrd`).
- **n**: Number of grid points in each direction.
- **lims**: The limits of the rectangle covered by the grid as `c(xl, xu, yl, yu)`. 
Value
A list of three components.

- **x, y**  The x and y coordinates of the grid points, vectors of length n.
- **z** An n x n matrix of the evaluated density.

References

Examples
```
attach(geyser)
plot(duration, waiting, xlim = c(0.5, 6), ylim = c(40, 100))
f1 <- kde2d(duration, waiting, n = 50, lims = c(0.5, 6, 40, 100))
image(f1, zlim = c(0, 0.05))
f2 <- kde2d(duration, waiting, n = 50, lims = c(0.5, 6, 40, 100),
          h = c(width.SJ(duration), width.SJ(waiting)))

detach("geyser")
```

---

**lda**  
*Linear Discriminant Analysis*

Description
Linear discriminant analysis.

Usage
```
lda(x, ...)  
```

```
## S3 method for class 'formula':
lda(formula, data, ..., subset, na.action)
```

```
## Default S3 method:
lda(x, grouping, prior = proportions, tol = 1.0e-4,
```
method, CV = FALSE, nu, ...)

## S3 method for class 'data.frame':
lda(x, ...)

## S3 method for class 'matrix':
lda(x, grouping, ..., subset, na.action)

Arguments

formula A formula of the form groups ~ x1 + x2 + ... That is, the response is the grouping factor and the right hand side specifies the (non-factor) discriminators.
data Data frame from which variables specified in formula are preferentially to be taken.
x (required if no formula is given as the principal argument.) a matrix or data frame or Matrix containing the explanatory variables.
grouping (required if no formula principal argument is given.) a factor specifying the class for each observation.
prior the prior probabilities of class membership. If unspecified, the class proportions for the training set are used. If present, the probabilities should be specified in the order of the factor levels.
tol A tolerance to decide if a matrix is singular; it will reject variables and linear combinations of unit-variance variables whose variance is less than \(\text{tol}^2\).
subset An index vector specifying the cases to be used in the training sample. (NOTE: If given, this argument must be named.)
na.action A function to specify the action to be taken if NAs are found. The default action is for the procedure to fail. An alternative is na.omit, which leads to rejection of cases with missing values on any required variable. (NOTE: If given, this argument must be named.)
method "moment" for standard estimators of the mean and variance, "mle" for MLEs, "mve" to use cov.mve, or "t" for robust estimates based on a \(t\) distribution.
CV If true, returns results (classes and posterior probabilities) for leave-one-out cross-validation. Note that if the prior is estimated, the proportions in the whole dataset are used.
nu degrees of freedom for method = "t".
... arguments passed to or from other methods.

Details

The function tries hard to detect if the within-class covariance matrix is singular. If any variable has within-group variance less than \(\text{tol}^2\) it will stop and report the variable as constant. This could result from poor scaling of the problem, but is more likely to result from constant variables.

Specifying the prior will affect the classification unless over-ridden in predict.lda. Unlike in most statistical packages, it will also affect the rotation of the linear discriminants within their space, as a weighted between-groups covariance matrix is used. Thus the first few linear discriminants emphasize the differences between groups with the weights given by the prior, which may differ from their prevalence in the dataset.

If one or more groups is missing in the supplied data, they are dropped with a warning, but the classifications produced are with respect to the original set of levels.
Value

If \( CV = \text{TRUE} \) the return value is a list with components `class`, the MAP classification (a factor), and `posterior`, posterior probabilities for the classes.

Otherwise it is an object of class "lda" containing the following components:

- **prior**: the prior probabilities used.
- **means**: the group means.
- **scaling**: a matrix which transforms observations to discriminant functions, normalized so that within groups covariance matrix is spherical.
- **svd**: the singular values, which give the ratio of the between- and within-group standard deviations on the linear discriminant variables. Their squares are the canonical F-statistics.
- **N**: The number of observations used.
- **call**: The (matched) function call.

Note

This function may be called giving either a formula and optional data frame, or a matrix and grouping factor as the first two arguments. All other arguments are optional, but `subset=` and `na.action=`, if required, must be fully named.

If a formula is given as the principal argument the object may be modified using `update()` in the usual way.

**ldahist**

**Histograms or Density Plots of Multiple Groups**

**Description**

Plot histograms or density plots of data on a single Fisher linear discriminant.

**Usage**

```r
ldahist(data, g, nbins = 25, h, x0 = -h/1000, breaks,
         xlim = range(breaks), ymax = 0, width,
         type = c("histogram", "density", "both"),
         sep = (type != "density"),
         col = 5, xlab = deparse(substitute(data)), bty = "n", ...)
```

**Arguments**

- `data` vector of data. Missing values (NAs) are allowed and omitted.
- `g` factor or vector giving groups, of the same length as `data`.
- `nbins` Suggested number of bins to cover the whole range of the data.
- `h` The bin width (takes precedence over `nbins`).
- `x0` Shift for the bins - the breaks are at `x0 + h * (..., -1, 0, 1, ...)`
- `breaks` The set of breakpoints to be used. (Usually omitted, takes precedence over `h` and `nbins`).
- `xlim` The limits for the x-axis.
- `ymax` The upper limit for the y-axis.
- `width` Bandwidth for density estimates. If missing, the Sheather-Jones selector is used for each group separately.
- `type` Type of plot.
- `sep` Whether there is a separate plot for each group, or one combined plot.
- `col` The colour number for the bar fill.
- `xlab` label for the plot x-axis. By default, this will be the name of `data`.
- `bty` The box type for the plot - defaults to `none`.
- `...` additional arguments to `polygon`.

**Side Effects**

Histogram and/or density plots are plotted on the current device.

`plot.lda`
Survival Times and White Blood Counts for Leukaemia Patients

Description
A data frame of data from 33 leukaemia patients.

Usage
leuk

Format
A data frame with columns:

- **wbc** white blood count
- **ag** a test result, "present" or "absent"
- **time** survival time in weeks

Details
Survival times are given for 33 patients who died from acute myelogenous leukaemia. Also measured was the patient’s white blood cell count at the time of diagnosis. The patients were also factored into 2 groups according to the presence or absence of a morphologic characteristic of white blood cells. Patients termed AG positive were identified by the presence of Auer rods and/or significant granulation of the leukaemic cells in the bone marrow at the time of diagnosis.

Source

Taken from

References

Examples
```r
library(survival)
plot(survfit(Surv(time) ~ ag, data = leuk), lty = 2:3, col = 2:3)

# now Cox models
leuk.cox <- coxph(Surv(time) ~ ag + log(wbc), leuk)
summary(leuk.cox)
```
lm.gls  

Fit Linear Models by Generalized Least Squares

Description

Fit linear models by Generalized Least Squares

Usage

lm.gls(formula, data, W, subset, na.action, inverse = FALSE, 
method = "qr", model = FALSE, x = FALSE, y = FALSE, 
contrasts = NULL, ...)

Arguments

formula  a formula expression as for regression models, of the form response ~ predictors. See the documentation of formula for other details.
data  an optional data frame in which to interpret the variables occurring in formula.
W  a weight matrix.
subset  expression saying which subset of the rows of the data should be used in the fit. All observations are included by default.
na.action  a function to filter missing data.
inverse  logical: if true \( W \) specifies the inverse of the weight matrix: this is appropriate if a variance matrix is used.
method  method to be used by \( \text{lm.fit} \).
model  should the model frame be returned?
x  should the design matrix be returned?
y  should the response be returned?
contrasts  a list of contrasts to be used for some or all of
...  additional arguments to \( \text{lm.fit} \).

Details

The problem is transformed to uncorrelated form and passed to \( \text{lm.fit} \).

Value

An object of class "lm.gls", which is similar to an "lm" object. There is no "weights" component, and only a few "lm" methods will work correctly. As from version 7.1-22 the residuals and fitted values refer to the untransformed problem.

See Also

gls, lm, lm.ridge
lm.ridge

Ridge Regression

Description

Fit a linear model by ridge regression.

Usage

```
lm.ridge(formula, data, subset, na.action, lambda = 0, model = FALSE, 
x = FALSE, y = FALSE, contrasts = NULL, ...)
```

Arguments

- **formula**: a formula expression as for regression models, of the form `response ~ predictors`. See the documentation of `formula` for other details.
- **data**: an optional data frame in which to interpret the variables occurring in `formula`.
- **subset**: expression saying which subset of the rows of the data should be used in the fit. All observations are included by default.
- **na.action**: a function to filter missing data.
- **lambda**: a scalar or vector of ridge constants.
- **model**: should the model frame be returned?
- **x**: should the design matrix be returned?
- **y**: should the response be returned?
- **contrasts**: a list of contrasts to be used for some or all of factor terms in the formula. See the `contrasts.arg` of `model.matrix.default`.
- **...**: additional arguments to `lm.fit`.

Details

If an intercept is present in the model, its coefficient is not penalized. (If you want to penalized an intercept, put in your own constant term and remove the intercept.)

Value

A list with components

- **coef**: matrix of coefficients, one row for each value of `lambda`. Note that these are not on the original scale and are for use by the `coef` method.
- **scales**: scalings used on the X matrix.
- **Inter**: was intercept included?
- **lambda**: vector of `lambda` values
- **ym**: mean of y
- **xm**: column means of x matrix
- **GCV**: vector of GCV values
- **kHKB**: HKB estimate of the ridge constant.
- **kLW**: L-W estimate of the ridge constant.
loglm: Fit Log-Linear Models by Iterative Proportional Scaling

Description

This function provides a front-end to the standard function, loglin, to allow log-linear models to be specified and fitted in a manner similar to that of other fitting functions, such as glm.

Usage

loglm(formula, data, subset, na.action, ...)

Arguments

formula A linear model formula specifying the log-linear model. If the left-hand side is empty, the data argument is required and must be a (complete) array of frequencies. In this case the variables on the right-hand side may be the names of the dimnames attribute of the frequency array, or may be the positive integers: 1, 2, 3, ... used as alternative names for the 1st, 2nd, 3rd, ...dimension (classifying factor). If the left-hand side is not empty it specifies a vector of frequencies. In this case the data argument, if present, must be a data frame from which the left-hand side vector and the classifying factors on the right-hand side are (preferentially) obtained. The usual abbreviation of a . to stand for ‘all other variables in the data frame’ is allowed. Any non-factors on the right-hand side of the formula are coerced to factor.

data Numeric array or data frame. In the first case it specifies the array of frequencies; in the second it provides the data frame from which the variables occurring in the formula are preferentially obtained in the usual way. This argument may be the result of a call to xtabs.

subset Specifies a subset of the rows in the data frame to be used. The default is to take all rows.

na.action Specifies a method for handling missing observations. The default is to fail if missing values are present.

... May supply other arguments to the function loglm.
Details

If the left-hand side of the formula is empty the data argument supplies the frequency array and the right-hand side of the formula is used to construct the list of fixed faces as required by loglin. Structural zeros may be specified by giving a start argument with those entries set to zero, as described in the help information for loglin.

If the left-hand side is not empty, all variables on the right-hand side are regarded as classifying factors and an array of frequencies is constructed. If some cells in the complete array are not specified they are treated as structural zeros. The right-hand side of the formula is again used to construct the list of faces on which the observed and fitted totals must agree, as required by loglin. Hence terms such as a:b, a*b and a/b are all equivalent.

Value

An object of class "loglm" conveying the results of the fitted log-linear model. Methods exist for the generic functions print, summary, deviance, fitted, coef, resid, anova and update, which perform the expected tasks. Only log-likelihood ratio tests are allowed using anova.

The deviance is simply an alternative name for the log-likelihood ratio statistic for testing the current model within a saturated model, in accordance with standard usage in generalized linear models.

Warning

If structural zeros are present, the calculation of degrees of freedom may not be correct. loglin itself takes no action to allow for structural zeros. loglm deducts one degree of freedom for each structural zero, but cannot make allowance for gains in error degrees of freedom due to loss of dimension in the model space. (This would require checking the rank of the model matrix, but since iterative proportional scaling methods are developed largely to avoid constructing the model matrix explicitly, the computation is at least difficult.)

When structural zeros (or zero fitted values) are present the estimated coefficients will not be available due to infinite estimates. The deviances will normally continue to be correct, though.

logtrans

*Estimate log Transformation Parameter*

**Description**

Find and optionally plot the marginal (profile) likelihood for alpha for a transformation model of the form $\log(y + \alpha) \sim x_1 + x_2 + \ldots$. 
**Usage**

```r
logtrans(object, ...)  
```

### Default S3 method:

```r
logtrans(object, ..., alpha = seq(0.5, 6, by = 0.25) - min(y),  
plotit = TRUE, interp =, xlab = "alpha",  
ylab = "log Likelihood")
```

### S3 method for class 'formula':

```r
logtrans(object, data, ...)
```

### S3 method for class 'lm':

```r
logtrans(object, ...)
```

**Arguments**

- **object**: Fitted linear model object, or formula defining the untransformed model that is `y ~ x1 + x2 + ...`. The function is generic.
- **...**: If `object` is a formula, this argument may specify a data frame as for `lm`.
- **alpha**: Set of values for the transformation parameter, alpha.
- **plotit**: Should plotting be done?
- **interp**: Should the marginal log-likelihood be interpolated with a spline approximation? (Default is `TRUE` if plotting is to be done and the number of real points is less than 100.)
- **xlab**: as for `plot`.
- **ylab**: as for `plot`.
- **data**: optional `data` argument for `lm` fit.

**Value**

List with components `x` (for alpha) and `y` (for the marginal log-likelihood values).

**Side Effects**

A plot of the marginal log-likelihood is produced, if requested, together with an approximate mle and 95% confidence interval.

**References**

**See Also**

- `boxcox`

**Examples**

```r
logtrans(Days ~ Age*Sex*Eth*Lrn, data = quine,  
alpha = seq(0.75, 6.5, len=20))
```
Resistant Regression

Description

Fit a regression to the good points in the dataset, thereby achieving a regression estimator with a high breakdown point. lmsreg and ltsreg are compatibility wrappers.

Usage

lqs(x, ...)

## S3 method for class 'formula':
lqs(formula, data, ..., method = c("lts", "lqs", "lms", "S", "model.frame"),
    subset, na.action, model = TRUE,
    x.ret = FALSE, y.ret = FALSE, contrasts = NULL)

## Default S3 method:
lqs(x, y, intercept = TRUE, method = c("lts", "lqs", "lms", "S"),
    quantile, control = lqs.control(...), k0 = 1.548, seed, ...)

lmsreg(...)
ltsreg(...)

Arguments

formula a formula of the form y ~ x1 + x2 + ....
data data frame from which variables specified in formula are preferentially to be taken.
subset an index vector specifying the cases to be used in fitting. (NOTE: If given, this argument must be named exactly.)
na.action function to specify the action to be taken if NAs are found. The default action is for the procedure to fail. Alternatives include na.omit and na.exclude, which lead to omission of cases with missing values on any required variable. (NOTE: If given, this argument must be named exactly.)
model, x.ret, y.ret logical. If TRUE the model frame, the model matrix and the response are returned, respectively.
contrasts an optional list. See the contrasts.arg of model.matrix.default.
x a matrix or data frame containing the explanatory variables.
y the response: a vector of length the number of rows of x.
intercept should the model include an intercept?
method the method to be used. model.frame returns the model frame: for the others see the Details section. Using lmsreg or ltsreg forces "lms" and "lts" respectively.
quantile the quantile to be used: see Details. This is over-ridden if method = "lms".
control additional control items: see Details.

k0 the cutoff / tuning constant used for $\chi()$ and $\psi()$ functions when method = "S", currently corresponding to Tukey’s “biweight”.

seed the seed to be used for random sampling: see .Random.seed. The current value of .Random.seed will be preserved if it is set.

... arguments to be passed to lqs.default or lqs.control. see control above and Details.

Details

Suppose there are $n$ data points and $p$ regressors, including any intercept.

The first three methods minimize some function of the sorted squared residuals. For methods "lqs" and "lms" is the quantile squared residual, and for "lts" it is the sum of the quantile smallest squared residuals. "lqs" and "lms" differ in the defaults for quantile, which are floor($(n+p+1)/2)$ and floor($(n+1)/2)$ respectively. For "lts" the default is floor($n/2$) + floor($p+1)/2$).

The "S" estimation method solves for the scale $s$ such that the average of a function chi of the residuals divided by $s$ is equal to a given constant.

The control argument is a list with components

**psamp:** the size of each sample. Defaults to $p$.

**nsamp:** the number of samples or "best" (the default) or "exact" or "sample". If "sample" the number chosen is min($5*p$, 3000), taken from Rousseeuw and Hubert (1997). If "best" exhaustive enumeration is done up to 5000 samples; if "exact" exhaustive enumeration will be attempted however many samples are needed.

**adjust:** should the intercept be optimized for each sample? Defaults to TRUE.

Value

An object of class "lqs". This is a list with components

**crit** the value of the criterion for the best solution found, in the case of method == "S" before IWLS refinement.

**sing** character. A message about the number of samples which resulted in singular fits.

**coefficients** of the fitted linear model

**bestone** the indices of those points fitted by the best sample found (prior to adjustment of the intercept, if requested).

**fitted.values** the fitted values.

**residuals** the residuals.

**scale** estimate(s) of the scale of the error. The first is based on the fit criterion. The second (not present for method == "S") is based on the variance of those residuals whose absolute value is less than 2.5 times the initial estimate.
Note

There seems no reason other than historical to use the `lms` and `lqs` options. LMS estimation is of low efficiency (converging at rate $n^{-1/3}$) whereas LTS has the same asymptotic efficiency as an M estimator with trimming at the quartiles (Marazzi, 1993, p.201). LQS and LTS have the same maximal breakdown value of $(\text{floor}((n-p)/2) + 1)/n$ attained if $\text{floor}((n+p)/2) \leq \text{quantile} \leq \text{floor}((n+p+1)/2)$. The only drawback mentioned of LTS is greater computation, as a sort was thought to be required (Marazzi, 1993, p.201) but this is not true as a partial sort can be used (and is used in this implementation).

Adjusting the intercept for each trial fit does need the residuals to be sorted, and may be significant extra computation if $n$ is large and $p$ small.

Opinions differ over the choice of `psamp`. Rousseeuw and Hubert (1997) only consider $p$; Marazzi (1993) recommends $p+1$ and suggests that more samples are better than adjustment for a given computational limit.

The computations are exact for a model with just an intercept and adjustment, and for LQS for a model with an intercept plus one regressor and exhaustive search with adjustment. For all other cases the minimization is only known to be approximate.

*Multiple Correspondence Analysis*

**Description**

Computes a multiple correspondence analysis of a set of factors.

**Usage**

```r
mca(df, nf = 2, abbrev = FALSE)
```

**Arguments**

- **df**  A data frame containing only factors
- **nf**  The number of dimensions for the MCA. Rarely 3 might be useful.
- **abbrev**  Should the vertex names be abbreviated? By default these are of the form “factor.level” but if `abbrev = TRUE` they are just “level” which will suffice if the factors have distinct levels.

**Value**

An object of class "mca", with components

- **rs**  The coordinates of the rows, in `nf` dimensions.
- **cs**  The coordinates of the column vertices, one for each level of each factor.
- **fs**  Weights for each row, used to interpolate additional factors in `predict.mca`.
- **p**  The number of factors
- **d**  The singular values for the `nf` dimensions.
- **call**  The matched call.

*Effect of Calcium Chloride on Muscle Contraction in Rat Hearts*

**Description**

The purpose of this experiment was to assess the influence of calcium in solution on the contraction of heart muscle in rats. The left auricle of 21 rat hearts was isolated and on several occasions a constant-length strip of tissue was electrically stimulated and dipped into various concentrations of calcium chloride solution, after which the shortening of the strip was accurately measured as the response.

**Usage**

`muscle`

**Format**

This data frame contains the following columns:

- **Strip** which heart muscle strip was used?
- **Conc** concentration of calcium chloride solution, in multiples of 2.2 mM.
- **Length** the change in length (shortening) of the strip, (allegedly) in mm.
**Source**

**References**

**Examples**

```r
A <- model.matrix(~ Strip - 1, data=muscle)
rats.nls1 <- nls(log(Length) ~ cbind(A, rho^Conc),
  data = muscle, start = c(rho=0.1), algorithm="plinear")
B <- coef(rats.nls1)

st <- list(alpha = B[2:22], beta = B[23], rho = B[1])
(rats.nls2 <- nls(log(Length) ~ alpha[Strip] + beta*rho^Conc,
  data = muscle, start = st))

attach(muscle)
Muscle <- expand.grid(Conc = sort(unique(Conc)),
  Strip = levels(Strip))
Muscle$Yhat <- predict(rats.nls2, Muscle)
ind <- match(paste(Strip, Conc),
  paste(Muscle$Strip, Muscle$Conc))
Muscle$logLength[ind] <- log(Length)
detach()

require(lattice)
xyplot(Yhat ~ Conc | Strip, Muscle, as.table = TRUE,
  ylim = range(c(Muscle$Yhat, Muscle$logLength), na.rm = TRUE),
  subscripts = TRUE, xlab = "Calcium Chloride concentration (mM)",
  ylab = "log(Length in mm)", panel =
  function(x, y, subscripts, ...){
    lines(spline(x, y))
    panel.xyplot(x, Muscle$logLength[subscripts], ...)
  })
```

---

**mvrnorm**

*Simulate from a Multivariate Normal Distribution*

**Description**

Produces one or more samples from the specified multivariate normal distribution.

**Usage**

```r
mvrnorm(n = 1, mu, Sigma, tol = 1e-6, empirical = FALSE)
```
negative.binomial

Arguments

n  the number of samples required.
mu  a vector giving the means of the variables.
Sigma  a positive-definite symmetric matrix specifying the covariance matrix of the variables.
tol  tolerance (relative to largest variance) for numerical lack of positive-definiteness in Sigma.
empirical  logical. If true, mu and Sigma specify the empirical not population mean and covariance matrix.

Details

The matrix decomposition is done via eigen; although a Choleski decomposition might be faster, the eigendecomposition is stabler.

Value

If n = 1 a vector of the same length as mu, otherwise an n by length(mu) matrix with one sample in each row.

Side Effects

Causes creation of the dataset .Random.seed if it does not already exist, otherwise its value is updated.

rnorm

Examples

Sigma <- matrix(c(10,3,3,2),2,2)
Sigma
var(mvrnorm(n=1000, rep(0, 2), Sigma))
var(mvrnorm(n=1000, rep(0, 2), Sigma, empirical = TRUE))

Description

Specifies the information required to fit a Negative Binomial generalized linear model, with known theta parameter, using glm().

Usage

negative.binomial(theta = stop("'theta' must be specified"), link = "log")
Arguments

theta
   The known value of the additional parameter, theta.

link
   The link function, as a character string, name or one-element character vector
   specifying one of log, sqrt or identity, or an object of class "link-
   glm".

Value

An object of class "family", a list of functions and expressions needed by glm() to fit a Negative
Binomial generalized linear model.

newcomb
Newcomb’s Measurements of the Passage Time of Light

Description

A numeric vector giving the Third Series of measurements of the passage time of light recorded
by Newcomb in 1882. The given values divided by 1000 plus 24 give the time in millionths of a
second for light to traverse a known distance. The “true” value is now considered to be 33.02.

Usage

newcomb

Source

Eighth-Grade Pupils in the Netherlands

Description
Snijders and Bosker (1999) use as a running example a study of 2287 eighth-grade pupils (aged about 11) in 132 classes in 131 schools in the Netherlands. Only the variables used in our examples are supplied.

Usage
nlschools

Format
This data frame contains 2287 rows and the following columns:

- **lang** language test score
- **IQ** Verbal IQ
- **class** class ID
- **GS** Class size: number of eighth-grade pupils recorded in the class (there may be others: see COMB, and some may have been omitted with missing values).
- **SES** Social-economic status of pupil’s family.
- **COMB** were the pupils taught in a multi-grade class (0/1)? Classes which contained pupils from grades 7 and 8 are coded 1, but only eighth-graders were tested.

Source

References

Examples
```r
library(nlme)
n11 <- nlschools
attach(n11)
classMeans <- tapply(IQ, class, mean)
n11$IQave <- classMeans[as.character(class)]
n11$IQ <- n11$IQ - n11$IQave
detach()
cen <- c("IQ", "IQave", "SES")
n11[cen] <- scale(n11[cen], center = TRUE, scale = FALSE)

nl.lme <- lme(lang ~ IQ*COMB + IQave + SES,
              random = ~ IQ | class, data = n11)
summary(nl.lme)
```
**Description**

A classical N, P, K (nitrogen, phosphate, potassium) factorial experiment on the growth of peas conducted on 6 blocks. Each half of a fractional factorial design confounding the NPK interaction was used on 3 of the plots.

**Usage**

npk

**Format**

The npk data frame has 24 rows and 5 columns:

- **block** which block (label 1 to 6).
- **N** indicator (0/1) for the application of nitrogen.
- **P** indicator (0/1) for the application of phosphate.
- **K** indicator (0/1) for the application of potassium.
- **yield** Yield of peas, in pounds/plot (the plots were (1/70) acre).

**Source**

**References**

**Examples**

```r
options(contrasts = c("contr.sum", "contr.poly"))
npk.aov <- aov(yield ~ block + N*P*K, npk)
npk.aov
summary(npk.aov)
alias(npk.aov)
coef(npk.aov)
options(contrasts = c("contr.treatment", "contr.poly"))
npk.aov1 <- aov(yield ~ block + N + K, data = npk)
summary.lm(npk.aov1)
se.contrast(npk.aov1, list(N="0", N="1"), data = npk)
model.tables(npk.aov1, type = "means", se = TRUE)
```
npr1  

US Naval Petroleum Reserve No. 1 data

Description

Data on the locations, porosity and permeability (a measure of oil flow) on 104 oil wells in the US Naval Petroleum Reserve No. 1 in California.

Usage

npr1

Format

This data frame contains the following columns:

- **x, y**  x and y coordinates, in miles from an arbitrary origin
- **perm** permeability in milli-Darcies
- **por** porosity (%)

Source

Null  

Null Spaces of Matrices

Description

Given a matrix, $M$, find a matrix $N$ giving a basis for the null space. That is $t(N) \ %*\ % M$ is the zero and $N$ has the maximum number of linearly independent columns.

Usage

Null($M$)

Arguments

- **M**  Input matrix. A vector is coerced to a 1-column matrix.

Value

The matrix $N$ with the basis for the null space, or an empty vector if the matrix $M$ is square and of maximal rank.
References

### oats

**Data from an Oats Field Trial**

**Description**

The yield of oats from a split-plot field trial using three varieties and four levels of manurial treatment. The experiment was laid out in 6 blocks of 3 main plots, each split into 4 sub-plots. The varieties were applied to the main plots and the manurial treatments to the sub-plots.

**Usage**

```r
oats
```

**Format**

This data frame contains the following columns:

- **B** Blocks, levels I, II, III, IV, V and VI
- **V** Varieties, 3 levels.
- **N** Nitrogen (manurial) treatment, levels 0.0cwt, 0.2cwt, 0.4cwt and 0.6cwt, showing the application in cwt/acre.
- **Y** Yields in 1/4lbs per sub-plot, each of area 1/80 acre.

**Source**

**References**

Examples

```r
oats$Nf <- ordered(oats$N, levels = sort(levels(oats$N)))
oats.aov <- aov(Y ~ Nf*V + Error(B/V), data = oats, qr = TRUE)
summary(oats.aov)

qqline(oats.pr[[4]][,"Residuals"])
par(mfrow = c(1,1), pty = "m")
oats.aov2 <- aov(Y ~ N + V + Error(B/V), data = oats, qr = TRUE)
model.tables(oats.aov2, type = "means", se = TRUE)
```

Tests of Auditory Perception in Children with OME

**Description**

Experiments were performed on children on their ability to differentiate a signal in broad-band noise. The noise was played from a pair of speakers and a signal was added to just one channel; the subject had to turn his/her head to the channel with the added signal. The signal was either coherent (the amplitude of the noise was increased for a period) or incoherent (independent noise was added for the same period to form the same increase in power).

The threshold used in the original analysis was the stimulus loudness needs to get 75% correct responses. Some of the children had suffered from otitis media with effusion (OME).

**Usage**

```r
OME
```

**Format**

The `OME` data frame has 1129 rows and 7 columns:

- **ID** Subject ID (1 to 99, with some IDs missing). A few subjects were measured at different ages.
- **OME** "low" or "high" or "N/A" (at ages other than 30 and 60 months).
- **Age** Age of the subject (months).
- **Loud** Loudness of stimulus, in decibels.
- **Noise** Whether the signal in the stimulus was "coherent" or "incoherent".
- **Correct** Number of correct responses from Trials trials.
- **Trials** Number of trials performed.
Background
The experiment was to study otitis media with effusion (OME), a very common childhood condition where the middle ear space, which is normally air-filled, becomes congested by a fluid. There is a concomitant fluctuating, conductive hearing loss which can result in various language, cognitive and social deficits. The term “binaural hearing” is used to describe the listening conditions in which the brain is processing information from both ears at the same time. The brain computes differences in the intensity and/or timing of signals arriving at each ear which contributes to sound localisation and also to our ability to hear in background noise.

Some years ago, it was found that children of 7-8 years with a history of significant OME had significantly worse binaural hearing than children without such a history, despite having equivalent sensitivity. The question remained as to whether it was the timing, the duration, or the degree of severity of the otitis media episodes during critical periods, which affected later binaural hearing. In an attempt to begin to answer this question, 95 children were monitored for the presence of effusion every month since birth. On the basis of OME experience in their first two years, the test population was split into one group of high OME prevalence and one of low prevalence.

The Painter’s Data of de Piles

Description

The subjective assessment, on a 0 to 20 integer scale, of 54 classical painters. The painters were assessed on four characteristics: composition, drawing, colour and expression. The data is due to the Eighteenth century art critic, de Piles.

Usage

painters

Format

The row names of the data frame are the painters. The components are:

- **Composition** Composition score
- **Drawing** Drawing score
- **Colour** Colour score
- **Expression** Expression score
- **School** The school to which a painter belongs, as indicated by a factor level code as follows:
  - "A": Renaissance; "B": Mannerist; "C": Seicento; "D": Venetian; "E": Lombard; "F": Sixteenth Century; "G": Seventeenth Century; "H": French.

Source

References

Description

Pairwise scatterplot of the data on the linear discriminants.

Usage

```r
## S3 method for class 'lda':
pairs(x, labels = colnames(x), panel = panel.lda,
      dimen, abbrev = FALSE, ..., cex=0.7, type = c("std", "trellis"))
```

Arguments

- `x` Object of class "lda".
- `labels` vector of character strings for labelling the variables.
- `panel` panel function to plot the data in each panel.
- `dimen` The number of linear discriminants to be used for the plot; if this exceeds the number determined by `x` the smaller value is used.
- `abbrev` whether the group labels are abbreviated on the plots. If `abbrev > 0` this gives `minlength` in the call to `abbreviate`.
- `...` additional arguments for `pairs.default`.
- `cex` graphics parameter `cex` for labels on plots.
- `type` type of plot. The default is in the style of `pairs.default`; the style "trellis" uses the Trellis function `splom`.

Details

This function is a method for the generic function `pairs()` for class "lda". It can be invoked by calling `pairs(x)` for an object `x` of the appropriate class, or directly by calling `pairs.lda(x)` regardless of the class of the object.

`pairs`
Description
Parallel coordinates plot

Usage
parcoord(x, col = 1, lty = 1, var.label = FALSE, ...)

Arguments
- `x`: a matrix or data frame whose columns represent variables. Missing values are allowed.
- `col`: A vector of colours, recycled as necessary for each observation.
- `lty`: A vector of line types, recycled as necessary for each observation.
- `var.label`: If `TRUE`, each variable’s axis is labelled with maximum and minimum values.
- `...`: Further graphics parameters which are passed to `matplot`.

Side Effects
A parallel coordinates plot is drawn.

Author(s)
B. D. Ripley. Enhancements based on ideas and code by Fabian Scheipl.

References

Examples
```R
data(state)
parcoord(state.x77[, c(7, 4, 6, 2, 5, 3)])

data(iris3)
ir <- rbind(iris3[,1], iris3[,2], iris3[,3])
parcoord(log(ir)[, c(3, 4, 2, 1)], col = 1 + (0:149)/150)
```
Description

The yield of a petroleum refining process with four covariates. The crude oil appears to come from only 10 distinct samples.

These data were originally used by Prater (1956) to build an estimation equation for the yield of the refining process of crude oil to gasoline.

Usage

petrol

Format

The variables are as follows

- **No**  Crude oil sample identification label. (factor)
- **SG**  Specific gravity, degrees API. (Constant within sample.)
- **VP**  Vapour pressure in psi. (Constant within sample.)
- **V10** Volatility of crude; ASTM 10% point. (Constant within sample.)
- **EP**  Desired volatility of gasoline. (The end point. Varies within sample.)
- **Y** Yield as a percentage of crude.

Source

This dataset is also given in D. J. Hand, F. Daly, K. McConway, D. Lunn and E. Ostrowski (eds) (1994) *A Handbook of Small Data Sets*. Chapman & Hall.

               random = ~ 1 | No, data = Petrol)
pet3.lme <- update(pet3.lme, method = "ML")
pet4.lme <- update(pet3.lme, fixed = Y ~ V10 + EP)
anova(pet4.lme, pet3.lme)
```
Diabetes in Pima Indian Women

Description

A population of women who were at least 21 years old, of Pima Indian heritage and living near Phoenix, Arizona, was tested for diabetes according to World Health Organization criteria. The data were collected by the US National Institute of Diabetes and Digestive and Kidney Diseases. We used the 532 complete records after dropping the (mainly missing) data on serum insulin.

Usage

Pima.tr
Pima.tr2
Pima.te

Format

These data frames contains the following columns:

- npreg  number of pregnancies
- glu    plasma glucose concentration in an oral glucose tolerance test
- bp     diastolic blood pressure (mm Hg)
- skin   triceps skin fold thickness (mm)
- bmi    body mass index (weight in kg/(height in m)^2)
- ped    diabetes pedigree function
- age    age in years
- type   Yes or No, for diabetic according to WHO criteria

Details

The training set Pima.tr contains a randomly selected set of 200 subjects, and Pima.te contains the remaining 322 subjects. Pima.tr2 contains Pima.tr plus 100 subjects with missing values in the explanatory variables.

Source

**plot.lda**  
*Plot Method for Class 'lda'*

**Description**  
Plots a set of data on one, two or more linear discriminants.

**Usage**  
```r  
## S3 method for class 'lda':  
plot(x, panel = panel.lda, ..., cex = 0.7, dimen,  
    abbrev = FALSE, xlab = "LD1", ylab = "LD2")  
```

**Arguments**  
- `x`: An object of class "lda".  
- `panel`: the panel function used to plot the data.  
- `...`: additional arguments to `pairs.lda`, `ldahist` or `eqscplot`.  
- `cex`: graphics parameter `cex` for labels on plots.  
- `dimen`: The number of linear discriminants to be used for the plot; if this exceeds the number determined by `x` the smaller value is used.  
- `abbrev`: whether the group labels are abbreviated on the plots. If `abbrev > 0` this gives `minlength` in the call to `abbreviate`.  
- `xlab`: label for the x axis  
- `ylab`: label for the y axis

**Details**  
This function is a method for the generic function `plot()` for class "lda". It can be invoked by calling `plot(x)` for an object `x` of the appropriate class, or directly by calling `plot.lda(x)` regardless of the class of the object.

The behaviour is determined by the value of `dimen`. For `dimen > 2`, a `pairs` plot is used. For `dimen = 2`, an equiscaled scatter plot is drawn. For `dimen = 1`, a set of histograms or density plots are drawn. Use argument `type` to match "histogram" or "density" or "both".

**References**  

**See Also**  
`pairs.lda`, `ldahist`, `lda`, `predict.lda`
Description

Plot a multiple correspondence analysis.

Usage

## S3 method for class 'mca':
plot(x, rows = TRUE, col, cex = par("cex"), ...)

Arguments

x
An object of class "mca".

rows
Should the coordinates for the rows be plotted, or just the vertices for the levels?

col, cex
The colours and cex to be used for the row points and level vertices respectively.

...
Additional parameters to plot.

plot(mca(farms, abbrev = TRUE))

---

polr

Description

Fits a logistic or probit regression model to an ordered factor response. The default logistic case is proportional odds logistic regression, after which the function is named.

Usage

polr(formula, data, weights, start, ..., subset, na.action,
contrasts = NULL, Hess = FALSE, model = TRUE,
method = c("logistic", "probit", "cloglog", "cauchit"))
Arguments

**formula**

A formula expression as for regression models, of the form `response ~ predictors`. The response should be a factor (preferably an ordered factor), which will be interpreted as an ordinal response, with levels ordered as in the factor. A proportional odds model will be fitted. The model must have an intercept: attempts to remove one will lead to a warning and be ignored. An offset may be used. See the documentation of `formula` for other details.

**data**

An optional data frame in which to interpret the variables occurring in `formula`.

**weights**

Optional case weights in fitting. Default to 1.

**start**

Initial values for the parameters. This is in the format `c(coefficients, zeta)`; see the Values section.

**...**

Additional arguments to be passed to `optim`, most often a `control` argument.

**subset**

Expression saying which subset of the rows of the data should be used in the fit. All observations are included by default.

**na.action**

A function to filter missing data.

**contrasts**

A list of contrasts to be used for some or all of the factors appearing as variables in the model formula.

**Hess**

Logical for whether the Hessian (the observed information matrix) should be returned.

**model**

Logical for whether the model matrix should be returned.

**method**

Logistic or probit or complementary log-log or cauchit (corresponding to a Cauchy latent variable and only available in R >= 2.1.0).

Details

This model is what Agresti (2002) calls a *cumulative link* model. The basic interpretation is as a *coarsened* version of a latent variable \( Y_i \) which has a logistic or normal or extreme-value or Cauchy distribution with scale parameter one and a linear model for the mean. The ordered factor which is observed is which bin \( Y_i \) falls into with breakpoints

\[
\zeta_0 = -\infty < \zeta_1 < \cdots < \zeta_K = \infty
\]

This leads to the model

\[
\text{logit} P(Y \leq k|x) = \zeta_k - \eta
\]

with `logit` replaced by `probit` for a normal latent variable, and \( \eta \) being the linear predictor, a linear function of the explanatory variables (with no intercept). Note that it is quite common for other software to use the opposite sign for \( \eta \).

In the logistic case, the left-hand side of the last display is the log odds of category \( k \) or less, and since these are log odds which differ only by a constant for different \( k \), the odds are proportional. Hence the term *proportional odds logistic regression*.

In the complementary log-log case, we have a *proportional hazards* model for grouped survival times.

There are methods for the standard model-fitting functions, including `predict, summary, vcov, anova, model.frame` and an `extractAIC` method for use with `stepAIC`. There are also `profile` and `confint` methods.
Value

A object of class "polr". This has components

coefficients  the coefficients of the linear predictor, which has no intercept.
zeta        the intercepts for the class boundaries.
deviance     the residual deviance.
fitted.values  a matrix, with a column for each level of the response.
lev          the names of the response levels.
terms        the terms structure describing the model.
df.residual  the number of residual degrees of freedoms, calculated using the weights.
edf          the (effective) number of degrees of freedom used by the model
n, nobs      the (effective) number of observations, calculated using the weights. (nobs is for use by stepAIC.
call         the matched call.
method       the matched method used.
convergence  the convergence code returned by optim.
niter        the number of function and gradient evaluations used by optim.
Hessian      (if Hess is true).
model        (if model is true).

predict.glmmPQL  Predict Method for glmmPQL Fits

Description

Obtains predictions from a fitted generalized linear model with random effects.

Usage

## S3 method for class 'glmmPQL':
predict(object, newdata = NULL, type = c("link", "response"),
        level, na.action = na.pass, ...)

Arguments

object  a fitted object of class inheriting from "glmmPQL".
newdata optionally, a data frame in which to look for variables with which to predict.
type the type of prediction required. The default is on the scale of the linear predictors; the alternative "response" is on the scale of the response variable. Thus for a default binomial model the default predictions are of log-odds (probabilities on logit scale) and type = "response" gives the predicted probabilities.
level an optional integer vector giving the level(s) of grouping to be used in obtaining the predictions. Level values increase from outermost to innermost grouping, with level zero corresponding to the population predictions. Defaults to the highest or innermost level of grouping.
na.action function determining what should be done with missing values in newdata. The default is to predict NA.
... further arguments passed to or from other methods.

Value

If level is a single integer, a vector otherwise a data frame.

See Also

glmmPQL, predict.lme.

Examples

fit <- glmmPQL(y ~ trt + I(week > 2), random = ~1 | ID,
               family = binomial, data = bacteriA) predict(fit, bacteria, level = 0, type="response") predict(fit, bacteria, level = 1, type="response")
predict.lda

Classify Multivariate Observations by Linear Discrimination

Description

Classify multivariate observations in conjunction with lda, and also project data onto the linear discriminants.

Usage

## S3 method for class 'lda':
predict(object, newdata, prior = object$prior, dimen,
method = c("plug-in", "predictive", "debiased"), ...)

Arguments

object          object of class "lda"
newdata         data frame of cases to be classified or, if object has a formula, a data frame
                with columns of the same names as the variables used. A vector will be interpreted as a row vector. If newdata is missing, an attempt will be made to retrieve the data used to fit the lda object.
prior           The prior probabilities of the classes, by default the proportions in the training set or what was set in the call to lda.
dimen           the dimension of the space to be used. If this is less than \( \min(p, ng-1) \), only the first \( \text{dimen} \) discriminant components are used (except for method="predictive"), and only those dimensions are returned in \( x \).
method          This determines how the parameter estimation is handled. With "plug-in" (the default) the usual unbiased parameter estimates are used and assumed to be correct. With "debiased" an unbiased estimator of the log posterior probabilities is used, and with "predictive" the parameter estimates are integrated out using a vague prior.
...             arguments based from or to other methods

Details

This function is a method for the generic function predict() for class "lda". It can be invoked by calling predict(x) for an object x of the appropriate class, or directly by calling predict.lda(x) regardless of the class of the object.

Missing values in newdata are handled by returning NA if the linear discriminants cannot be evaluated. If newdata is omitted and the na.action of the fit omitted cases, these will be omitted on the prediction.

This version centres the linear discriminants so that the weighted mean (weighted by prior) of the group centroids is at the origin.

Value

a list with components

  class          The MAP classification (a factor)
  posterior      posterior probabilities for the classes
  x              the scores of test cases on up to \( \text{dimen} \) discriminant variables

z <- lda(train, cl)
predict(z, test)$class

predict.lqs

Predict from an lqs Fit

Description

Predict from a resistant regression fitted by lqs.

Usage

## S3 method for class 'lqs':
predict(object, newdata, na.action = na.pass, ...)

Arguments

- **object**: object inheriting from class "lqs"
- **newdata**: matrix or data frame of cases to be predicted or, if object has a formula, a data frame with columns of the same names as the variables used. A vector will be interpreted as a row vector. If newdata is missing, an attempt will be made to retrieve the data used to fit the lqs object.
- **na.action**: function determining what should be done with missing values in newdata. The default is to predict NA.
- **...**: arguments to be passed from or to other methods.

Details

This function is a method for the generic function predict() for class lqs. It can be invoked by calling predict(x) for an object x of the appropriate class, or directly by calling predict.lqs(x) regardless of the class of the object.

Missing values in newdata are handled by returning NA if the linear fit cannot be evaluated. If newdata is omitted and the na.action of the fit omitted cases, these will be omitted on the prediction.
Value
A vector of predictions.

```

**predict.mca**

## S3 method for class 'mca':
predict(object, newdata, type = c("row", "factor"), ...)

**Arguments**

- **object** An object of class "mca", usually the result of a call to `mca`
- **newdata** A data frame containing either additional rows of the factors used to fit `object` or additional factors for the cases used in the original fit.
- **type** Are predictions required for further rows or for new factors?
- **...** Additional arguments from `predict`: unused.

**Value**

- If `type = "row"`, the coordinates for the additional rows.
- If `type = "factor"`, the coordinates of the column vertices for the levels of the new factors.

predict.qda

Classify from Quadratic Discriminant Analysis

Description

Classify multivariate observations in conjunction with qda

Usage

## S3 method for class 'qda':
predict(object, newdata, prior = object$prior,
         method = c("plug-in", "predictive", "debiased", "looCV"), ...)

Arguments

object
  object of class "qda"

newdata
  data frame of cases to be classified or, if object has a formula, a data frame
  with columns of the same names as the variables used. A vector will be interpreted
  as a row vector. If newdata is missing, an attempt will be made to retrieve
  the data used to fit the qda object.

prior
  The prior probabilities of the classes, by default the proportions in the training
  set or what was set in the call to qda.

method
  This determines how the parameter estimation is handled. With "plug-in" (the default)
  the usual unbiased parameter estimates are used and assumed to be correct. With "debiased"
  an unbiased estimator of the log posterior probabilities is used, and with "predictive"
  the parameter estimates are integrated out using a vague prior. With "looCV" the leave-one-out cross-validation
  fits to the original dataset are computed and returned.

... arguments based from or to other methods

Details

This function is a method for the generic function predict() for class "qda". It can be in-
voked by calling predict(x) for an object x of the appropriate class, or directly by calling
predict.qda(x) regardless of the class of the object.

Missing values in newdata are handled by returning NA if the quadratic discriminants cannot be
evaluated. If newdata is omitted and the na.action of the fit omitted cases, these will be
omitted on the prediction.

Value

a list with components

class
  The MAP classification (a factor)

posterior
  posterior probabilities for the classes

qz <- qda(train, cl)
predict(qz, test)$class

qda

Quadratic Discriminant Analysis

Description
Quadratic discriminant analysis.

Usage
qda(x, ...)

## S3 method for class 'formula':
qda(formula, data, ..., subset, na.action)

## Default S3 method:
qda(x, grouping, prior = proportions, 
method, CV = FALSE, nu, ...)

## S3 method for class 'data.frame':
qda(x, ...)

## S3 method for class 'matrix':
qda(x, grouping, ..., subset, na.action)

Arguments
formula A formula of the form groups ~ x1 + x2 + ... That is, the response is 
the grouping factor and the right hand side specifies the (non-factor) discrimina-
tors.
data Data frame from which variables specified in formula are preferentially to be 
taken.
x (required if no formula is given as the principal argument.) a matrix or data 
frame or Matrix containing the explanatory variables.
grouping (required if no formula principal argument is given.) a factor specifying the class 
for each observation.
prior the prior probabilities of class membership. If unspecified, the class proportions 
for the training set are used. If specified, the probabilities should be specified in 
the order of the factor levels.
subset An index vector specifying the cases to be used in the training sample. (NOTE: If given, this argument must be named.)

na.action A function to specify the action to be taken if NAs are found. The default action is for the procedure to fail. An alternative is na.omit, which leads to rejection of cases with missing values on any required variable. (NOTE: If given, this argument must be named.)

method "moment" for standard estimators of the mean and variance, "mle" for MLEs, "mve" to use cov.mve, or "t" for robust estimates based on a t distribution.

CV If true, returns results (classes and posterior probabilities) for leave-out-out cross-validation. Note that if the prior is estimated, the proportions in the whole dataset are used.

nu degrees of freedom for method = "t".

... arguments passed to or from other methods.

Details

Uses a QR decomposition which will give an error message if the within-group variance is singular for any group.

Value

an object of class "qda" containing the following components:

prior the prior probabilities used.
means the group means.
scaling for each group i, scaling[,i] is an array which transforms observations so that within-groups covariance matrix is spherical.
ldet a vector of half log determinants of the dispersion matrix.
lev the levels of the grouping factor.
terms (if formula is a formula) an object of mode expression and class term summarizing the formula.
call the (matched) function call.
class The MAP classification (a factor)
posterior posterior probabilities for the classes

**Examples**

```r
data(iris3)
tr <- sample(1:50, 25)
train <- rbind(iris3[tr,,1], iris3[tr,,2], iris3[tr,,3])
test <- rbind(iris3[-tr,,1], iris3[-tr,,2], iris3[-tr,,3])
cl <- factor(c(rep("s",25), rep("c",25), rep("v",25)))
z <- qda(train, cl)
predict(z,test)$class
```

**Description**

The `quine` data frame has 146 rows and 5 columns. Children from Walgett, New South Wales, Australia, were classified by Culture, Age, Sex and Learner status and the number of days absent from school in a particular school year was recorded.

**Usage**

`quine`

**Format**

This data frame contains the following columns:

- **Eth**: Ethnic background: Aboriginal or Not, ("A" or "N").
- **Sex**: Sex factor: ("F" or "M").
- **Age**: Age group: Primary ("F0"), or forms "F1", "F2" or "F3".
- **Lrn**: Learner status factor: Average or Slow learner, ("AL" or "SL").
- **Days**: Days absent from school in the year.

**Source**

Rabbit -- Blood Pressure in Rabbits

Description

Five rabbits were studied on two occasions, after treatment with saline (control) and after treatment with the $5 - HT_3$ antagonist MDL 72222. After each treatment ascending doses of phenylbiguanide were injected intravenously at 10 minute intervals and the responses of mean blood pressure measured. The goal was to test whether the cardiogenic chemoreflex elicited by phenylbiguanide depends on the activation of $5 - HT_3$ receptors.

Usage

Rabbit

Format

This data frame contains 60 rows and the following variables:

- **BPchange**: change in blood pressure relative to the start of the experiment
- **Dose**: dose of Phenylbiguanide in micrograms
- **Run**: label of run ("C1" to "C5", then "M1" to "M5")
- **Treatment**: placebo or the $5 - HT_3$ antagonist MDL 72222
- **Animal**: label of animal used ("R1" to "R5")

Source

[The numerical data are not in the paper but were supplied by Professor Ludbrook]

References

rational -- Rational Approximation

Description

Find rational approximations to the components of a real numeric object using a standard continued fraction method.

Usage

rational(x, cycles = 10, max.denominator = 2000, ...)

Arguments

- **x**: Any object of mode numeric. Missing values are now allowed.
- **cycles**: The maximum number of steps to be used in the continued fraction approximation process.
- **max.denominator**: An early termination criterion. If any partial denominator exceeds `max.denominator` the continued fraction stops at that point.
- ... arguments passed to or from other methods.

Details

Each component is first expanded in a continued fraction of the form

\[ x = \text{floor}(x) + \frac{1}{(p_1 + \frac{1}{(p_2 + \ldots)})} \]

where \( p_1, p_2, \ldots \) are positive integers, terminating either at `cycles` terms or when a \( p_j > max.denominator \). The continued fraction is then re-arranged to retrieve the numerator and denominator as integers and the ratio returned as the value.

Value

A numeric object with the same attributes as \( x \) but with entries rational approximations to the values. This effectively rounds relative to the size of the object and replaces very small entries by zero.

```
renumerate  

Convert a Formula Transformed by 'denumerate'

**Description**

*denumerate* converts a formula written using the conventions of *loglm* into one that *terms* is able to process. *renumerate* converts it back again to a form like the original.

**Usage**

renumerate(x)

**Arguments**

x  
A formula, normally as modified by *denumerate*.

**Details**

This is an inverse function to *denumerate*. It is only needed since *terms* returns an expanded form of the original formula where the non-marginal terms are exposed. This expanded form is mapped back into a form corresponding to the one that the user originally supplied.

**Value**

A formula where all variables with names of the form *.vn*, where *n* is an integer, converted to numbers, *n*, as allowed by the formula conventions of *loglm*.

**See Also**

denumerate

**Examples**

denumerate(~(1+2+3)^3 + a/b)  
## ~ (.v1 + .v2 + .v3)^3 + a/b  
renumerate(.Last.value)  
## ~ (1 + 2 + 3)^3 + a/b

---

**rlm**

Robust Fitting of Linear Models

**Description**

Fit a linear model by robust regression using an M estimator.
**Usage**

```r
rlm(x, ...)
```

```
## S3 method for class 'formula':
rlm(formula, data, weights, ..., subset, na.action,
    method = c("M", "MM", "model.frame"),
    wt.method = c("inv.var", "case"),
    model = TRUE, x.ret = TRUE, y.ret = FALSE, contrasts = NULL)
```

```
## Default S3 method:
rlm(x, y, weights, ..., w = rep(1, nrow(x)),
    init, psi = psi.huber, scale.est, k2 = 1.345,
    method = c("M", "MM"), wt.method = c("inv.var", "case"),
    maxit = 20, acc = 1e-4, test.vec = "resid", lqs.control = NULL)
```

`
psi.huber(u, k = 1.345, deriv = 0)
psi.hampel(u, a = 2, b = 4, c = 8, deriv = 0)
psi.bisquare(u, c = 4.685, deriv = 0)
```

**Arguments**

- `formula` a formula of the form `y ~ x1 + x2 + ....`
- `data` data frame from which variables specified in `formula` are preferentially to be taken.
- `weights` a vector of prior weights for each case.
- `subset` An index vector specifying the cases to be used in fitting.
- `na.action` A function to specify the action to be taken if NAs are found. The default action is for the procedure to fail. An alternative is `na.omit`, which leads to omission of cases with missing values on any required variable.
- `x` a matrix or data frame containing the explanatory variables.
- `y` the response: a vector of length the number of rows of `x`.
- `method` currently either M-estimation or find the model frame. MM estimation is M-estimation with Tukey’s biweight initialized by a specific S-estimator. See the details section.
- `wt.method` are the weights case weights (giving the relative importance of case, so a weight of 2 means there are two of these) or the inverse of the variances, so a weight of two means this error is half as variable?
- `model` should the model frame be returned in the object?
- `x.ret` should the model matrix be returned in the object?
- `y.ret` should the response be returned in the object?
- `contrasts` optional contrast specifications: see `lm`.
- `w` (optional) initial down-weighting for each case.
- `init` (optional) initial values for the coefficients OR a method to find initial values OR the result of a fit with a `coef` component. Known methods are "ls" (the default) for an initial least-squares fit using weights `w*weights`, and "lts" for an unweighted least-trimmed squares fit with 200 samples.
- `psi` the psi function is specified by this argument. It must give (possibly by name) a function `g(x, ..., deriv)` that for `deriv=0` returns `psi(x)/x` and for `deriv=1` returns `psi'(x)`. Tuning constants will be passed in via `....`
scale.est  method of scale estimation: re-scaled MAD of the residuals or Huber's proposal 2 (which can be selected by either "Huber" or "proposal 2").
k2 tuning constant used for Huber proposal 2 scale estimation.
maxit the limit on the number of IWLS iterations.
acc the accuracy for the stopping criterion.
test.vec the stopping criterion is based on changes in this vector.
... additional arguments to be passed to rlm.default or to the psi function.
lqs.control An optional list of control values for lqs.
u numeric vector of evaluation points.
k,a,b,c tuning constants
deriv 0 or 1: compute values of the psi function or of its first derivative.

Details

Fitting is done by iterated re-weighted least squares (IWLS).

Psi functions are supplied for the Huber, Hampel and Tukey bisquare proposals as psi.huber, psi.hampel and psi.bisquare. Huber’s corresponds to a convex optimization problem and gives a unique solution (up to collinearity). The other two will have multiple local minima, and a good starting point is desirable.

Selecting method = "MM" selects a specific set of options which ensures that the estimator has a high breakdown point. The initial set of coefficients and the final scale are selected by an S-estimator with \( k0 = 1.548 \); this gives (for \( n \gg p \)) breakdown point 0.5. The final estimator is an M-estimator with Tukey’s biweight and fixed scale that will inherit this breakdown point provided \( c > k0 \); this is true for the default value of \( c \) that corresponds to 95% relative efficiency at the normal. Case weights are not supported for method = "MM".

Value

An object of class "rlm" inheriting from "lm". The additional components not in an lm object are

s the robust scale estimate used
w the weights used in the IWLS process
psi the psi function with parameters substituted
conv the convergence criteria at each iteration
converged did the IWLS converge?
wresid a working residual, weighted for "inv.var" weights only.

lm, lqs.

Examples

data(stackloss)
summary(rlm(stack.loss ~ ., stackloss))
rlm(stack.loss ~ ., stackloss, psi = psi.hampel, init = "lts")
rlm(stack.loss ~ ., stackloss, psi = psi.bisquare)

Description

Calculates the root mean square parameter effects and intrinsic relative curvatures, \( c^\theta \) and \( c^\iota \), for a fitted nonlinear regression, as defined in Bates & Watts, section 7.3, p. 253 et seq.

Usage

rms.curv(obj)

Arguments

obj Fitted model object of class "nls". The model must be fitted using the default algorithm.

Details

The method of section 7.3.1 of Bates & Watts is implemented. The function deriv3 should be used to generate a model function with first derivative (gradient) matrix and second derivative (Hessian) array attributes. This function should then be used to fit the nonlinear regression model.

A print method, print.rms.curv, prints the pc and ic components only, suitably annotated. If either pc or ic exceeds some threshold (0.3 has been suggested) the curvature is unacceptably high for the planar assumption.

Value

A list of class rms.curv with components pc and ic for parameter effects and intrinsic relative curvatures multiplied by sqrt(F), ct and ci for \( c^\theta \) and \( c^\iota \) (unmultiplied), and C the C-array as used in section 7.3.1 of Bates & Watts.

##Parameter effects: c^theta x sqrt(F) = 0.2121
## Intrinsic: c^iota x sqrt(F) = 0.092

rnegbin

Simulate Negative Binomial Variates

Description

Function to generate random outcomes from a Negative Binomial distribution, with mean \( \mu \) and variance \( \mu + \mu^2/\theta \).

Usage

rnegbin(n, mu = n, theta = stop("'theta' must be specified"))

Arguments

- \( n \): If a scalar, the number of sample values required. If a vector, \( \text{length}(n) \) is the number required and \( n \) is used as the mean vector if \( \mu \) is not specified.
- \( \mu \): The vector of means. Short vectors are recycled.
- \( \theta \): Vector of values of the \( \theta \) parameter. Short vectors are recycled.

Details

The function uses the representation of the Negative Binomial distribution as a continuous mixture of Poisson distributions with Gamma distributed means. Unlike \texttt{rnbinom} the index can be arbitrary.

Value

Vector of random Negative Binomial variate values.

Side Effects

Changes \texttt{.Random.seed} in the usual way.

Examples

# Negative Binomials with means fitted(fm) and theta = 4.5
fm <- glm.nb(Days ~ ., data = quine)
dummy <- rnegbin(fitted(fm), theta = 4.5)
**Road Accident Deaths in US States**

**Description**

A data frame with the annual deaths in road accidents for half the US states. Components are:

**Usage**

**Format**

- `state` name
- `deaths` number of deaths
- `drivers` number of drivers (in 10,000’s)
- `popden` population density in people per square mile
- `rural` length of rural roads, in 1000’s of miles
- `temp` average daily maximum temperature in January
- `fuel` fuel consumption in 10,000,000 US gallons per year

**Rotifer**

**Numbers of Rotifers by Fluid Density**

**Description**

The data give the numbers of rotifers falling out of suspension for different fluid densities. There are two species, *pm* Polyarthra major and *kc*, Keratella cochlearis and for each species the number falling out and the total number are given.

**Usage**

**Format**

- `density` specific density of fluid
- `pm.y` number falling out for *P. major*
- `pm.total` total number of *P. major*
- `kc.y` number falling out for *K. cochlearis*
- `kc.tot` total number of *K. cochlearis*

sammon

**Sammon’s Non-Linear Mapping**

**Description**

One form of non-metric multidimensional scaling.

**Usage**

```r
sammon(d, y = cmdscale(d, k), k = 2, niter = 100, trace = TRUE, magic = 0.2, tol = 1e-4)
```
Arguments

- **d**: distance structure of the form returned by `dist`, or a full, symmetric matrix. Data are assumed to be dissimilarities or relative distances, but must be positive except for self-distance. This can contain missing values.

- **y**: An initial configuration. If none is supplied, `cmdscale` is used to provide the classical solution. (If there are missing values in `d`, an initial configuration must be provided.) This must not have duplicates.

- **k**: The dimension of the configuration.

- **niter**: The maximum number of iterations.

- **trace**: Logical for tracing optimization. Default `TRUE`.

- **magic**: initial value of the step size constant in diagonal Newton method.

- **tol**: Tolerance for stopping, in units of stress.

Details

This chooses a two-dimensional configuration to minimize the stress, the sum of squared differences between the input distances and those of the configuration, weighted by the distances, the whole sum being divided by the sum of input distances to make the stress scale-free.

An iterative algorithm is used, which will usually converge in around 50 iterations. As this is necessarily an \(O(n^5)\) calculation, it is slow for large datasets. Further, since the configuration is only determined up to rotations and reflections (by convention the centroid is at the origin), the result can vary considerably from machine to machine. In this release the algorithm has been modified by adding a step-length search (`magic`) to ensure that it always goes downhill.

Value

Two components:

- **points**: A two-column vector of the fitted configuration.

- **stress**: The final stress achieved.

Side Effects

If `trace` is true, the initial stress and the current stress are printed out every 10 iterations.

**snails**

*Snail Mortality Data*

Description

Groups of 20 snails were held for periods of 1, 2, 3 or 4 weeks in carefully controlled conditions of temperature and relative humidity. There were two species of snail, A and B, and the experiment was designed as a 4 by 3 by 4 by 2 completely randomized design. At the end of the exposure time the snails were tested to see if they had survived; the process itself is fatal for the animals. The object of the exercise was to model the probability of survival in terms of the stimulus variables, and in particular to test for differences between species.

The data are unusual in that in most cases fatalities during the experiment were fairly small.

Usage

```r
snails
```
Format

The data frame contains the following components:

- **Species**: Snail species A (1) or B (2)
- **Exposure**: Exposure in weeks
- **Rel. Hum**: Relative humidity (4 levels)
- **Temp**: Temperature, in degrees Celsius (3 levels)
- **Deaths**: Number of deaths
- **N**: Number of snails exposed

stepAIC

Choose a model by AIC in a Stepwise Algorithm

Description

Performs stepwise model selection by exact AIC.

Usage

stepAIC(object, scope, scale = 0,
       direction = c("both", "backward", "forward"),
       trace = 1, keep = NULL, steps = 1000, use.start = FALSE,
       k = 2, ...)

Arguments

object  
an object representing a model of an appropriate class. This is used as the initial
model in the stepwise search.

scope  
defines the range of models examined in the stepwise search. This should be
either a single formula, or a list containing components upper and lower,
both formulae. See the details for how to specify the formulae and how they are
used.

scale  
used in the definition of the AIC statistic for selecting the models, currently only
for lm and aov models (see extractAIC for details).

direction  
the mode of stepwise search, can be one of "both", "backward", or
"forward", with a default of "both". If the scope argument is missing
the default for direction is "backward".

trace  
if positive, information is printed during the running of stepAIC. Larger values
may give more information on the fitting process.

keep  
a filter function whose input is a fitted model object and the associated AIC
statistic, and whose output is arbitrary. Typically keep will select a subset
of the components of the object and return them. The default is not to keep
anything.

steps  
the maximum number of steps to be considered. The default is 1000 (essentially
as many as required). It is typically used to stop the process early.

use.start  
if true the updated fits are done starting at the linear predictor for the currently
selected model. This may speed up the iterative calculations for glm (and other
fits), but it can also slow them down. Not used in R.

k  
the multiple of the number of degrees of freedom used for the penalty. Only k
= 2 gives the genuine AIC: \( k = \log(n) \) is sometimes referred to as BIC or
SBC.

...  
any additional arguments to extractAIC. (None are currently used.)

References

Springer.
Details

The set of models searched is determined by the `scope` argument. The right-hand-side of its `lower` component is always included in the model, and right-hand-side of the model is included in the `upper` component. If `scope` is a single formula, it specifies the `upper` component, and the `lower` model is empty. If `scope` is missing, the initial model is used as the `upper` model.

Models specified by `scope` can be templates to update `object` as used by `update.formula`.

There is a potential problem in using `glm` fits with a variable `scale`, as in that case the deviance is not simply related to the maximized log-likelihood. The `glm` method for `extractAIC` makes the appropriate adjustment for a `gaussian` family, but may need to be amended for other cases. (The `binomial` and `poisson` families have fixed `scale` by default and do not correspond to a particular maximum-likelihood problem for variable `scale`.)

Where a conventional deviance exists (e.g. for `lm`, `aov` and `glm` fits) this is quoted in the analysis of variance table: it is the `unscaled` deviance.

Value

the stepwise-selected model is returned, with up to two additional components. There is an "anova" component corresponding to the steps taken in the search, as well as a "keep" component if the `keep` argument was supplied in the call. The "Resid. Dev" column of the analysis of deviance table refers to a constant minus twice the maximized log likelihood: it will be a deviance only in cases where a saturated model is well-defined (thus excluding `lm`, `aov` and `survreg` fits, for example).

Note

The model fitting must apply the models to the same dataset. This may be a problem if there are missing values and an `na.action` other than `na.fail` is used (as is the default in R). We suggest you remove the missing values first.

```
The Stormer Viscometer Data

Description

The Stormer viscometer measures the viscosity of a fluid by measuring the time taken for an inner cylinder in the mechanism to perform a fixed number of revolutions in response to an actuating weight. The viscometer is calibrated by measuring the time taken with varying weights while the mechanism is suspended in fluids of accurately known viscosity. The data comes from such a calibration, and theoretical considerations suggest a nonlinear relationship between time, weight and viscosity, of the form \( \text{Time} = \frac{B_1 \times \text{Viscosity}}{\text{Weight} - B_2} + E \) where \( B_1 \) and \( B_2 \) are unknown parameters to be estimated, and \( E \) is error.

Usage

stormer

Format

The data frame contains the following components:

- **Viscosity** Viscosity of fluid
- **Wt** Actuating weight
- **Time** Time taken

**summary.negbin**

**Details**

This function is a method for the generic function `summary()` for class "loglm". It can be invoked by calling `summary(x)` for an object `x` of the appropriate class, or directly by calling `summary.loglm(x)` regardless of the class of the object.

**Value**

A list is returned for use by `print.summary.loglm`. This has components

- **formula**: the formula used to produce `object`
- **tests**: the table of test statistics (likelihood ratio, Pearson) for the fit.
- **oe**: if `fitted = TRUE`, an array of the observed and expected frequencies, otherwise NULL.

**References**

**See Also**

`loglm`, `summary`

---

**summary.negbin**

*Summary Method Function for Objects of Class 'negbin'*

**Description**

Identical to `summary(glm)`, but with three lines of additional output: the ML estimate of theta, its standard error, and twice the log-likelihood function.

**Usage**

```r
## S3 method for class 'negbin':
summary(object, dispersion = 1, correlation = TRUE, ...)
```

**Arguments**

- **object**: Fitted model object of class `negbin` inheriting from `glm` and `lm`. Typically the output of `glm.nb`.
- **dispersion**: as for `summary.glm`, with a default of 1.
- **correlation**: as for `summary.glm`.
- **...**: arguments passed to or from other methods.

**Details**

`summary.glm` is used to produce the majority of the output and supply the result. This function is a method for the generic function `summary()` for class "negbin". It can be invoked by calling `summary(x)` for an object `x` of the appropriate class, or directly by calling `summary.negbin(x)` regardless of the class of the object.
Value

As for `summary.glm`; the additional lines of output are not included in the resultant object.

Side Effects

A summary table is produced as for `summary.glm`, with the additional information described above.

**summary.rlm**  
*Summary Method for Robust Linear Models*

### Description

`summary` method for objects of class "rlm"

### Usage

```r
## S3 method for class 'rlm':
summary(object, method = c("XtX", "XtWX"), correlation = TRUE, ...)
```

### Arguments

- **object**
  - the fitted model. This is assumed to be the result of some fit that produces an object inheriting from the class `rlm`, in the sense that the components returned by the `rlm` function will be available.

- **method**
  - Should the weighted (by the IWLS weights) or unweighted cross-products matrix be used?

- **correlation**
  - logical. Should correlations be computed (and printed)?

- **...**
  - arguments passed to or from other methods.

### Details

This function is a method for the generic function `summary()` for class "rlm". It can be invoked by calling `summary(x)` for an object `x` of the appropriate class, or directly by calling `summary.rlm(x)` regardless of the class of the object.
Value

If printing takes place, only a null value is returned. Otherwise, a list is returned with the following components. Printing always takes place if this function is invoked automatically as a method for the \texttt{summary} function.

\textbf{correlation} \hspace{1em} The computed correlation coefficient matrix for the coefficients in the model.

\textbf{cov.unscaled} \hspace{1em} The unscaled covariance matrix; i.e., a matrix such that multiplying it by an estimate of the error variance produces an estimated covariance matrix for the coefficients.

\textbf{sigma} \hspace{1em} The scale estimate.

\textbf{stddev} \hspace{1em} A scale estimate used for the standard errors.

\textbf{df} \hspace{1em} The number of degrees of freedom for the model and for residuals.

\textbf{coefficients} \hspace{1em} A matrix with three columns, containing the coefficients, their standard errors and the corresponding $t$ statistic.

\textbf{terms} \hspace{1em} The terms object used in fitting this model.

         [1] -0.994
\end{verbatim}
Student Survey Data

Description

This data frame contains the responses of 237 Statistics I students at the University of Adelaide to a number of questions.

Usage

survey

Format

The components of the data frame are:

- **Sex**: The sex of the student. (Factor with levels "Male" and "Female").
- **Wr.Hnd**: The span (distance from tip of thumb to tip of little finger of spread hand) of writing hand, in centimetres.
- **NW.Hnd**: Span of non-writing hand.
- **W.Hnd**: Writing hand of student. (Factor, with levels "Left" and "Right").
- **Fold**: "Fold your arms! Which is on top" (Factor, with levels "R on L", "L on R", "Neither").
- **Pulse**: Pulse rate of student (beats per minute).
- **Clap**: "Clap your hands! Which hand is on top?" (Factor, with levels "Right", "Left", "Neither").
- **Exer**: How often the student exercises. (Factor, with levels "Freq" (frequently), "Some", "None").
- **Smoke**: How much the student smokes. (Factor, levels "Heavy", "Regul" (regularly), "Occas" (occasionally), "Never").
- **Height**: The height of the student, in centimetres.
- **M.I**: Indicates whether the student expressed height in imperial (feet/inches) or metric (centimetres/metres) units. (Factor, levels "Metric", "Imperial").
- **Age**: Age of the student, in years.

**Synthetic Classification Problem**

**Description**

The `synth.tr` data frame has 250 rows and 3 columns. The `synth.te` data frame has 100 rows and 3 columns. It is intended that `synth.tr` be used from training and `synth.te` for testing.

**Usage**

```r
synth.tr
synth.te
```

**Format**

These data frames contains the following columns:

- **xs**: x-coordinate
- **ys**: y-coordinate
- **yc**: class, coded as 0 or 1.

**Source**

---

**Estimate theta of the Negative Binomial**

**Description**

Given the estimated mean vector, estimate `theta` of the Negative Binomial Distribution.

**Usage**

```r
theta.md(y, mu, dfr, weights, limit = 20, eps = .Machine$double.eps^0.25)
theta.ml(y, mu, n, weights, limit = 10, eps = .Machine$double.eps^0.25, trace = FALSE)
theta.mm(y, mu, dfr, weights, limit = 10, eps = .Machine$double.eps^0.25)
```
Arguments

\( y \) Vector of observed values from the Negative Binomial.

\( \mu \) Estimated mean vector.

\( n \) Number of data points (defaults to the sum of weights)

\( dfr \) Residual degrees of freedom (assuming \( \theta \) known). For a weighted fit this is the sum of the weights minus the number of fitted parameters.

\( \text{weights} \) Case weights. If missing, taken as 1.

\( \text{limit} \) Limit on the number of iterations.

\( \epsilon \) Tolerance to determine convergence.

\( \text{trace} \) logical: should iteration progress be printed?

Details

\( \theta.md \) estimates by equating the deviance to the residual degrees of freedom, an analogue of a moment estimator.

\( \theta.ml \) uses maximum likelihood.

\( \theta.mm \) calculates the moment estimator of \( \theta \) by equating the Pearson chi-square \( \sum \left( (y - \mu)^2 / (\mu + \mu^2 / \theta) \right) \) to the residual degrees of freedom.

Value

The required estimate of \( \theta \), as a scalar. For \( \theta.ml \), the standard error is given as attribute "SE".

**Traffic**  
_Effect of Swedish Speed Limits on Accidents_

**Description**

An experiment was performed in Sweden in 1961-2 to assess the effect of a speed limit on the motorway accident rate. The experiment was conducted on 92 days in each year, matched so that day \( j \) in 1962 was comparable to day \( j \) in 1961. On some days the speed limit was in effect and enforced, while on other days there was no speed limit and cars tended to be driven faster. The speed limit days tended to be in contiguous blocks.

**Usage**

`Traffic`

**Format**

This data frame contains the following columns:

- **year**: 1961 or 1962
- **day** of year
- **limit**: was there a speed limit?
- **y**: traffic accident count for that day
Source

Statistics*, 9, 697–704.

References

Springer.

---

**truehist**  
*Plot a Histogram*

**Description**

Creates a histogram on the current graphics device.

**Usage**

```
truehist(data, nbins = "Scott", h, x0 = -h/1000,
breaks, prob = TRUE, xlim = range(breaks),
ymax = max(est), col,
xlab = deparse(substitute(data)), bty = "n", ...)
```

**Arguments**

- **data** numeric vector of data for histogram. Missing values (NAs) are allowed and omitted.
- **nbins** The suggested number of bins. Either a positive integer, or a character string naming a rule: "Scott" or "Freedman-Diaconis" or "FD". (Case is ignored.)
- **h** The bin width, a strictly positive number (takes precedence over nbins).
- **x0** Shift for the bins - the breaks are at x0 + h * (...) -1, 0, 1, ...
- **breaks** The set of breakpoints to be used. (Usually omitted, takes precedence over h and nbins).
- **prob** If true (the default) plot a true histogram. The vertical axis has a relative frequency density scale, so the product of the dimensions of any panel gives the relative frequency. Hence the total area under the histogram is 1 and it is directly comparable with most other estimates of the probability density function. If false plot the counts in the bins.
- **xlim** The limits for the x-axis.
- **ymax** The upper limit for the y-axis.
- **col** The colour number for the bar fill.
- **xlab** label for the plot x-axis. By default, this will be the name of data.
- **bty** The box type for the plot - defaults to none.
- **...** additional arguments to `rect` or `plot`.
Details

This plots a true histogram, a density estimate of total area 1. If `breaks` is specified, those break-points are used. Otherwise if `h` is specified, a regular grid of bins is used with width `h`. If neither `breaks` nor `h` is specified, `nbins` is used to select a suitable `h`.

Side Effects

A histogram is plotted on the current device.

UScrime

Description

Criminologists are interested in the effect of punishment regimes on crime rates. This has been studied using aggregate data on 47 states of the USA for 1960 given in this data frame. The variables seem to have been re-scaled to convenient numbers.

Usage

UScrime

Format

This data frame contains the following columns:

- **M**: percentage of males aged 14-24
- **So**: indicator variable for a southern state
- **Ed**: mean years of schooling
- **Po1**: police expenditure in 1960
- **Po2**: police expenditure in 1959
- **LF**: labour force participation rate
- **M.F**: number of males per 1000 females
- **Pop**: state population
- **NW**: number of nonwhites per 1000 people
- **U1**: unemployment rate of urban males 14-24
- **U2**: unemployment rate of urban males 35-39
- **GDP**: gross domestic product per head
- **Ineq**: income inequality
- **Prob**: probability of imprisonment
- **Time**: average time served in state prisons
- **y**: rate of crimes in a particular category per head of population

plot(corresp(waders, nf=2))
```
Description

Mr Derek Whiteside of the UK Building Research Station recorded the weekly gas consumption and average external temperature at his own house in south-east England for two heating seasons, one of 26 weeks before, and one of 30 weeks after cavity-wall insulation was installed. The object of the exercise was to assess the effect of the insulation on gas consumption.

Usage

whiteside

Format

The whiteside data frame has 56 rows and 3 columns:

Insul A factor, before or after insulation.

Temp Purportedly the average outside temperature in degrees Celsius. (These values is far too low for any 56-week period in the 1960s in South-East England. It might be the weekly average of daily minima.)

Gas The weekly gas consumption in 1000s of cubic feet.

width.SJ

Bandwidth Selection by Pilot Estimation of Derivatives

Description

Uses the method of Sheather & Jones (1991) to select the bandwidth of a Gaussian kernel density estimator.

Usage

width.SJ(x, nb = 1000, lower, upper, method = c("ste", "dpi"))

Arguments

  x       a numeric vector
  nb      number of bins to use.
  upper, lower range over which to search for solution if method = "ste".
  method  Either "ste" ("solve-the-equation") or "dpi" ("direct plug-in").

Value

  a bandwidth.

  width.SJ(galaxies)
write.matrix  Write a Matrix or Data Frame

Description

Writes a matrix or data frame to a file or the console, using column labels and a layout respecting columns.

Usage

`write.matrix(x, file = "", sep = " ", blocksize)`

Arguments

- `x`: matrix or data frame.
- `file`: name of output file. The default (""") is the console.
- `sep`: The separator between columns.
- `blocksize`: If supplied and positive, the output is written in blocks of blocksize rows. Choose as large as possible consistent with the amount of memory available.

Details

If `x` is a matrix, supplying `blocksize` is more memory-efficient and enables larger matrices to be written, but each block of rows might be formatted slightly differently.

If `x` is a data frame, the conversion to a matrix may negate the memory saving.

Side Effects

A formatted file is produced, with column headings (if `x` has them) and columns of data.

                data = wtloss, start = list(b0=90, b1=95, th=120),
                trace = TRUE)
```
Chapter 12

The boot package

abc.ci Nonparametric ABC Confidence Intervals

Description

Calculate equi-tailed two-sided nonparametric approximate bootstrap confidence intervals for a parameter, given a set of data and an estimator of the parameter, using numerical differentiation.

Usage

abc.ci(data, statistic, index=1, strata=rep(1, n), conf=0.95, eps=0.001/n, ...)

Arguments

data A data set expressed as a vector, matrix or data frame.

statistic A function which returns the statistic of interest. The function must take at least 2 arguments; the first argument should be the data and the second a vector of weights. The weights passed to statistic will be normalized to sum to 1 within each stratum. Any other arguments should be passed to abc.ci as part of the ...() argument.

index If statistic returns a vector of length greater than 1, then this indicates the position of the variable of interest within that vector.

strata A factor or numerical vector indicating to which sample each observation belongs in multiple sample problems. The default is the one-sample case.

conf A scalar or vector containing the confidence level(s) of the required interval(s).

eps The value of epsilon to be used for the numerical differentiation.

... Any other arguments for statistic. These will be passed unchanged to statistic each time it is called within abc.ci.
Details

This function is based on the function `abcnon` written by R. Tibshirani. A listing of the original function is available in DiCiccio and Efron (1996). The function uses numerical differentiation for the first and second derivatives of the statistic and then uses these values to approximate the bootstrap BCa intervals. The total number of evaluations of the statistic is \(2 + n + 2 + 2 \times \text{length}(\text{conf})\) where \(n\) is the number of data points (plus calculation of the original value of the statistic). The function works for the multiple sample case without the need to rewrite the statistic in an artificial form since the stratified normalization is done internally by the function.

Value

A `length(conf)` by 3 matrix where each row contains the confidence level followed by the lower and upper end-points of the ABC interval at that level.

**aids**  
*Delay in AIDS Reporting in England and Wales*

Description

The *aids* data frame has 570 rows and 6 columns.

Although all cases of AIDS in England and Wales must be reported to the Communicable Disease Surveillance Centre, there is often a considerable delay between the time of diagnosis and the time that it is reported. In estimating the prevalence of AIDS, account must be taken of the unknown number of cases which have been diagnosed but not reported. The data set here records the reported cases of AIDS diagnosed from July 1983 and until the end of 1992. The data are cross-classified by the date of diagnosis and the time delay in the reporting of the cases.

Usage

aids

Format

This data frame contains the following columns:

- **year**: The year of the diagnosis.
- **quarter**: The quarter of the year in which diagnosis was made.
- **delay**: The time delay (in months) between diagnosis and reporting. 0 means that the case was reported within one month. Longer delays are grouped in 3 month intervals and the value of delay is the midpoint of the interval (therefore a value of 2 indicates that reporting was delayed for between 1 and 3 months).
dud  An indicator of censoring. These are categories for which full information is not yet available and the number recorded is a lower bound only.

time  The time interval of the diagnosis. That is the number of quarters from July 1983 until the end of the quarter in which these cases were diagnosed.

y  The number of AIDS cases reported.

Source

**aircondit**  
*Failures of Air-conditioning Equipment*

**Description**

Proschan (1963) reported on the times between failures of the air-conditioning equipment in 10 Boeing 720 aircraft. The **aircondit** data frame contains the intervals for the ninth aircraft while **aircondit7** contains those for the seventh aircraft.

Both data frames have just one column. Note that the data have been sorted into increasing order.

**Usage**

**aircondit**

**Format**

The data frames contain the following column:

**hours**  The time interval in hours between successive failures of the air-conditioning equipment

**Source**

The data were taken from

**References**

Description

The *amis* data frame has 8437 rows and 4 columns.

In a study into the effect that warning signs have on speeding patterns, Cambridgeshire County Council considered 14 pairs of locations. The locations were paired to account for factors such as traffic volume and type of road. One site in each pair had a sign erected warning of the dangers of speeding and asking drivers to slow down. No action was taken at the second site. Three sets of measurements were taken at each site. Each set of measurements was nominally of the speeds of 100 cars but not all sites have exactly 100 measurements. These speed measurements were taken before the erection of the sign, shortly after the erection of the sign, and again after the sign had been in place for some time.

Usage

*amis*

Format

This data frame contains the following columns:

- **speed**: Speeds of cars (in miles per hour).
- **period**: A numeric column indicating the time that the reading was taken. A value of 1 indicates a reading taken before the sign was erected, a 2 indicates a reading taken shortly after erection of the sign and a 3 indicates a reading taken after the sign had been in place for some time.
- **warning**: A numeric column indicating whether the location of the reading was chosen to have a warning sign erected. A value of 1 indicates presence of a sign and a value of 2 indicates that no sign was erected.
- **pair**: A numeric column giving the pair number at which the reading was taken. Pairs were numbered from 1 to 14.

Source

The data were kindly made available by Mr. Graham Amis, Cambridgeshire County Council, U.K.

References

Description

The `aml` data frame has 23 rows and 3 columns.

A clinical trial to evaluate the efficacy of maintenance chemotherapy for acute myelogenous leukaemia was conducted by Embury et al. (1977) at Stanford University. After reaching a stage of remission through treatment by chemotherapy, patients were randomized into two groups. The first group received maintenance chemotherapy and the second group did not. The aim of the study was to see if maintenance chemotherapy increased the length of the remission. The data here formed a preliminary analysis which was conducted in October 1974.

Usage

`aml`

Format

This data frame contains the following columns:

- **time**: The length of the complete remission (in weeks).
- **cens**: An indicator of right censoring. 1 indicates that the patient had a relapse and so `time` is the length of the remission. 0 indicates that the patient had left the study or was still in remission in October 1974, that is the length of remission is right-censored.
- **group**: The group into which the patient was randomized. Group 1 received maintenance chemotherapy, group 2 did not.

Note

Package `survival` also has a dataset `aml`. It is the same data with different names and with `group` replaced by a factor `x`.

**beaver**  

*Beaver Body Temperature Data*

**Description**

The `beaver` data frame has 100 rows and 4 columns. It is a multivariate time series of class "ts" and also inherits from class "data.frame".

This data set is part of a long study into body temperature regulation in beavers. Four adult female beavers were live-trapped and had a temperature-sensitive radiotransmitter surgically implanted. Readings were taken every 10 minutes. The location of the beaver was also recorded and her activity level was dichotomized by whether she was in the retreat or outside of it since high-intensity activities only occur outside of the retreat.

The data in this data frame are those readings for one of the beavers on a day in autumn.

**Usage**

`beaver`

**Format**

This data frame contains the following columns:

- **day** The day number. The data includes only data from day 307 and early 308.
- **time** The time of day formatted as hour-minute.
- **temp** The body temperature in degrees Celsius.
- **activ** The dichotomized activity indicator. 1 indicates that the beaver is outside of the retreat and therefore engaged in high-intensity activity.

bigcity  Population of U.S. Cities

Description

The bigcity data frame has 49 rows and 2 columns.
The city data frame has 10 rows and 2 columns.
The measurements are the population (in 1000's) of 49 U.S. cities in 1920 and 1930. The 49 cities are a random sample taken from the 196 largest cities in 1920. The city data frame consists of the first 10 observations in bigcity.

Usage

bigcity

Format

This data frame contains the following columns:

u  The 1920 population.
x  The 1930 population.

Source

The data were obtained from

References

boot  Bootstrap Resampling

Description

Generate R bootstrap replicates of a statistic applied to data. Both parametric and nonparametric resampling are possible. For the nonparametric bootstrap, possible resampling methods are the ordinary bootstrap, the balanced bootstrap, antithetic resampling, and permutation. For nonparametric multi-sample problems stratified resampling is used. This is specified by including a vector of strata in the call to boot. Importance resampling weights may be specified.

Usage

boot(data, statistic, R, sim="ordinary", stype="i",
    strata=rep(1,n), L=NULL, m=0, weights=NULL,
    ran.gen=function(d, p) d, mle=NULL, ...)
Arguments

- **data**: The data as a vector, matrix or data frame. If it is a matrix or data frame then each row is considered as one multivariate observation.

- **statistic**: A function which when applied to data returns a vector containing the statistic(s) of interest. When `sim="parametric"`, the first argument to `statistic` must be the data. For each replicate a simulated dataset returned by `ran.gen` will be passed. In all other cases `statistic` must take at least two arguments. The first argument passed will always be the original data. The second will be a vector of indices, frequencies or weights which define the bootstrap sample. Further, if predictions are required, then a third argument is required which would be a vector of the random indices used to generate the bootstrap predictions. Any further arguments can be passed to `statistic` through the `...()` argument.

- **R**: The number of bootstrap replicates. Usually this will be a single positive integer. For importance resampling, some resamples may use one set of weights and others use a different set of weights. In this case `R` would be a vector of integers where each component gives the number of resamples from each of the rows of weights.

- **sim**: A character string indicating the type of simulation required. Possible values are "ordinary" (the default), "parametric", "balanced", "permutation", or "antithetic". Importance resampling is specified by including importance weights; the type of importance resampling must still be specified but may only be "ordinary" or "balanced" in this case.

- **stype**: A character string indicating what the second argument of `statistic` represents. Possible values of `stype` are "i" (indices - the default), "f" (frequencies), or "w" (weights).

- **strata**: An integer vector or factor specifying the strata for multi-sample problems. This may be specified for any simulation, but is ignored when `sim` is "parametric". When `strata` is supplied for a nonparametric bootstrap, the simulations are done within the specified strata.

- **L**: Vector of influence values evaluated at the observations. This is used only when `sim` is "antithetic". If not supplied, they are calculated through a call to `empinf`. This will use the infinitesimal jackknife provided that `stype` is "w", otherwise the usual jackknife is used.

- **m**: The number of predictions which are to be made at each bootstrap replicate. This is most useful for (generalized) linear models. This can only be used when `sim` is "ordinary". `m` will usually be a single integer but, if there are strata, it may be a vector with length equal to the number of strata, specifying how many of the errors for prediction should come from each strata. The actual predictions should be returned as the final part of the output of `statistic`, which should also take a vector of indices of the errors to be used for the predictions.

- **weights**: Vector or matrix of importance weights. If a vector then it should have as many elements as there are observations in `data`. When simulation from more than one set of weights is required, `weights` should be a matrix where each row of the matrix is one set of importance weights. If `weights` is a matrix then `R` must be a vector of length `nrow(weights)`. This parameter is ignored if `sim` is not "ordinary" or "balanced".

- **ran.gen**: This function is used only when `sim` is "parametric" when it describes how random values are to be generated. It should be a function of two arguments.
The first argument should be the observed data and the second argument consists of any other information needed (e.g. parameter estimates). The second argument may be a list, allowing any number of items to be passed to ran.gen. The returned value should be a simulated data set of the same form as the observed data which will be passed to statistic to get a bootstrap replicate. It is important that the returned value be of the same shape and type as the original dataset. If ran.gen is not specified, the default is a function which returns the original data in which case all simulation should be included as part of statistic. Use of sim="parametric" with a suitable ran.gen allows the user to implement any types of nonparametric resampling which are not supported directly.

The second argument to be passed to ran.gen. Typically these will be maximum likelihood estimates of the parameters. For efficiency mle is often a list containing all of the objects needed by ran.gen which can be calculated using the original data set only.

Any other arguments for statistic which are passed unchanged each time it is called. Any such arguments to statistic must follow the arguments which statistic is required to have for the simulation.

Details

The statistic to be bootstrapped can be as simple or complicated as desired as long as its arguments correspond to the dataset and (for a nonparametric bootstrap) a vector of indices, frequencies or weights. statistic is treated as a black box by the boot function and is not checked to ensure that these conditions are met.

The first order balanced bootstrap is described in Davison, Hinkley and Schechtman (1986). The antithetic bootstrap is described by Hall (1989) and is experimental, particularly when used with strata. The other non-parametric simulation types are the ordinary bootstrap (possibly with unequal probabilities), and permutation which returns random permutations of cases. All of these methods work independently within strata if that argument is supplied.

For the parametric bootstrap it is necessary for the user to specify how the resampling is to be conducted. The best way of accomplishing this is to specify the function ran.gen which will return a simulated data set from the observed data set and a set of parameter estimates specified in mle.

Value

The returned value is an object of class "boot", containing the following components:

- `t0` The observed value of statistic applied to data.
- `t` A matrix with R rows each of which is a bootstrap replicate of statistic.
- `R` The value of R as passed to boot.
- `data` The data as passed to boot.
- `seed` The value of .Random.seed when boot was called.
- `statistic` The function statistic as passed to boot.
- `sim` Simulation type used.
- `stype` Statistic type as passed to boot.
- `call` The original call to boot.
- `strata` The strata used. This is the vector passed to boot, if it was supplied or a vector of ones if there were no strata. It is not returned if sim is "parametric".
weights The importance sampling weights as passed to \texttt{boot} or the empirical distribution function weights if no importance sampling weights were specified. It is omitted if \texttt{sim} is not one of "ordinary" or "balanced".

pred.i If predictions are required (m>0) this is the matrix of indices at which predictions were calculated as they were passed to statistic. Omitted if m is 0 or \texttt{sim} is not "ordinary".

L The influence values used when \texttt{sim} is "antithetic". If no such values were specified and \texttt{stype} is not "w" then \texttt{L} is returned as consecutive integers corresponding to the assumption that data is ordered by influence values. This component is omitted when \texttt{sim} is not "antithetic".

ran.gen The random generator function used if \texttt{sim} is "parametric". This component is omitted for any other value of \texttt{sim}.

mle The parameter estimates passed to \texttt{boot} when \texttt{sim} is "parametric". It is omitted for all other values of \texttt{sim}.

References
There are many references explaining the bootstrap and its variations. Among them are:

      else out <- lgamma(k)-k*(log(k)-1-para[1]+para[2])
      out
    }
    khat <- nlm(ll,ybar^2/var(data$hours))$estimate
    c(ybar, khat)
  }
air.rg <- function(data, mle)
  # Function to generate random exponential variates. mle will contain
  # the mean of the original data
  { out <- data
    out$hours <- rexp(nrow(out), 1/mle)
    out
  }
air.boot <- boot(aircondit, air.fun, R=999, sim="parametric",
  ran.gen=air.rg, mle=mean(aircondit$hours))

# The bootstrap p-value can then be approximated by
sum(abs(air.boot$t[,2]-1) > abs(air.boot$t0[2]-1))/(1+air.boot$R)

---

**boot.array**

### Bootstrap Resampling Arrays

**Description**

This function takes a bootstrap object calculated by one of the functions `boot`, `censboot`, or `tilt.boot` and returns the frequency (or index) array for the the bootstrap resamples.

**Usage**

```r
go.boot.array(boot.out, indices=)
```

**Arguments**

- `boot.out`: An object of class "boot" returned by one of the generation functions for such an object.
- `indices`: A logical argument which specifies whether to return the frequency array or the raw index array. The default is `indices=FALSE` unless `boot.out` was created by `tsboot` in which case the default is `indices=TRUE`.

**Details**

The process by which the original index array was generated is repeated with the same value of `.Random.seed`. If the frequency array is required then `freq.array` is called to convert the index array to a frequency array.
A resampling array can only be returned when such a concept makes sense. In particular it cannot be found for any parametric or model-based resampling schemes. Hence for objects generated by `censboot` the only resampling scheme for which such an array can be found is ordinary case resampling. Similarly if `boot.out$sim` is "parametric" in the case of `boot` or "model" in the case of `tsboot` the array cannot be found. Note also that for post-blackened bootstraps from `tsboot` the indices found will relate to those prior to any post-blackening and so will not be useful.

Frequency arrays are used in many post-bootstrap calculations such as the jackknife-after-bootstrap and finding importance sampling weights. They are also used to find empirical influence values through the regression method.

**Value**

A matrix with `boot.out$R` rows and `n` columns where `n` is the number of observations in `boot.out$data`. If `indices` is `FALSE` then this will give the frequency of each of the original observations in each bootstrap resample. If `indices` is `TRUE` it will give the indices of the bootstrap resamples in the order in which they would have been passed to the statistic.

**Side Effects**

This function temporarily resets `.Random.seed` to the value in `boot.out$seed` and then returns it to its original value at the end of the function.

**See Also**

`boot`, `censboot`, `freq.array`, `tilt.boot`, `tsboot`

**Examples**

```r
# A frequency array for a nonparametric bootstrap
city.boot <- boot(city, corr, R=40, stype="w")
boot.array(city.boot)

perm.cor <- function(d,i)
cor(d$x,d$u[i])
city.perm <- boot(city, perm.cor, R=40, sim="permutation")
boot.array(city.perm, indices=TRUE)
```

---

**Description**

This function generates 5 different types of equi-tailed two-sided nonparametric confidence intervals. These are the first order normal approximation, the basic bootstrap interval, the studentized bootstrap interval, the bootstrap percentile interval, and the adjusted bootstrap percentile (BCa) interval. All or a subset of these intervals can be generated.

**Usage**

```r
boot.ci(boot.out, conf = 0.95, type = "all",
       index = 1:min(2,length(boot.out$t0)), var.t0 = NULL,
       var.t = NULL, t0 = NULL, t = NULL, L = NULL, h = function(t) t,
       hdot = function(t) rep(1,length(t)), hinv = function(t) t, ...)```
Arguments

**boot.out**
An object of class "boot" containing the output of a bootstrap calculation.

**conf**
A scalar or vector containing the confidence level(s) of the required interval(s).

**type**
A vector of character strings representing the type of intervals required. The value should be any subset of the values c("norm", "basic", "stud", "perc", "bca") or simply "all" which will compute all five types of intervals.

**index**
This should be a vector of length 1 or 2. The first element of index indicates the position of the variable of interest in boot.out$t0 and the relevant column in boot.out$t. The second element indicates the position of the variance of the variable of interest. If both var.t0 and var.t are supplied then the second element of index (if present) is ignored. The default is that the variable of interest is in position 1 and its variance is in position 2 (as long as there are 2 positions in boot.out$t0).

**var.t0**
If supplied, a value to be used as an estimate of the variance of the statistic for the normal approximation and studentized intervals. If it is not supplied and length(index) is 2 then var.t0 defaults to boot.out$t0[index[2]] otherwise var.t0 is undefined. For studentized intervals var.t0 must be defined. For the normal approximation, if var.t0 is undefined it defaults to var(t). If a transformation is supplied through the argument h then var.t0 should be the variance of the untransformed statistic.

**var.t**
This is a vector (of length boot.out$R) of variances of the bootstrap replicates of the variable of interest. It is used only for studentized intervals. If it is not supplied and length(index) is 2 then var.t defaults to boot.out$t[, index[2]], otherwise its value is undefined which will cause an error for studentized intervals. If a transformation is supplied through the argument h then var.t should be the variance of the untransformed bootstrap statistics.

**t0**
The observed value of the statistic of interest. The default value is boot.out$t0[index[1]]. Specification of t0 and t allows the user to get intervals for a transformed statistic which may not be in the bootstrap output object. See the second example below. An alternative way of achieving this would be to supply the functions h, hdot, and hinv below.

**t**
The bootstrap replicates of the statistic of interest. It must be a vector of length boot.out$R. It is an error to supply one of t0 or t but not the other. Also if studentized intervals are required and t0 and t are supplied then so should be var.t0 and var.t. The default value is boot.out$t[, index].

**L**
The empirical influence values of the statistic of interest for the observed data. These are used only for BCa intervals. If a transformation is supplied through the parameter h then L should be the influence values for t; the values for h(t) are derived from these and hdot within the function. If L is not supplied then the values are calculated using empinf if they are needed.

**h**
A function defining a transformation. The intervals are calculated on the scale of h(t) and the inverse function hinv applied to the resulting intervals. It must be a function of one variable only and for a vector argument, it must return a vector of the same length, i.e. h(c(t1,t2,t3)) should return c(h(t1),h(t2),h(t3)). The default is the identity function.
hdot

A function of one argument returning the derivative of \( h \). It is a required argument if \( h \) is supplied and normal, studentized or BCa intervals are required. The function is used for approximating the variances of \( h(t_0) \) and \( h(t) \) using the delta method, and also for finding the empirical influence values for BCa intervals. Like \( h \) it should be able to take a vector argument and return a vector of the same length. The default is the constant function 1.

hinv

A function, like \( h \), which returns the inverse of \( h \). It is used to transform the intervals calculated on the scale of \( h(t) \) back to the original scale. The default is the identity function. If \( h \) is supplied but \( hinv \) is not, then the intervals returned will be on the transformed scale.

... Any extra arguments that \( \text{boot.out}\$\text{statistic} \) is expecting. These arguments are needed only if BCa intervals are required and \( L \) is not supplied since in that case \( L \) is calculated through a call to \( \text{empinf} \) which calls \( \text{boot.out}\$\text{statistic} \).

Details

The formulae on which the calculations are based can be found in Chapter 5 of Davison and Hinkley (1997). Function \( \text{boot} \) must be run prior to running this function to create the object to be passed as \( \text{boot.out} \).

Variance estimates are required for studentized intervals. The variance of the observed statistic is optional for normal theory intervals. If it is not supplied then the bootstrap estimate of variance is used. The normal intervals also use the bootstrap bias correction.

Interpolation on the normal quantile scale is used when a non-integer order statistic is required. If the order statistic used is the smallest or largest of the \( R \) values in \( \text{boot.out} \) a warning is generated and such intervals should not be considered reliable.

Value

An object of type "\( \text{boot.ci} \)" which contains the intervals. It has components

\( R \) The number of bootstrap replicates on which the intervals were based.
\( t_0 \) The observed value of the statistic on the same scale as the intervals.
\( \text{call} \) The call to \( \text{boot.ci} \) which generated the object.
\( \text{normal} \) A matrix of intervals calculated using the normal approximation. It will have 3 columns, the first being the level and the other two being the upper and lower endpoints of the intervals.
\( \text{basic} \) The intervals calculated using the basic bootstrap method.
\( \text{student} \) The intervals calculated using the studentized bootstrap method.
\( \text{percent} \) The intervals calculated using the bootstrap percentile method.
\( \text{bca} \) The intervals calculated using the adjusted bootstrap percentile (BCa) method. These latter four components will be matrices with 5 columns, the first column containing the level, the next two containing the indices of the order statistics used in the calculations and the final two the calculated endpoints themselves.

### brambles

**Spatial Location of Bramble Canes**

**Description**

The `brambles` data frame has 823 rows and 3 columns.

The location of living bramble canes in a 9m square plot was recorded. We take 9m to be the unit of distance so that the plot can be thought of as a unit square. The bramble canes were also classified by their age.

**Usage**

`brambles`

**Format**

This data frame contains the following columns:

- **x** The x coordinate of the position of the cane in the plot.
- **y** The y coordinate of the position of the cane in the plot.
- **age** The age classification of the canes; 0 indicates a newly emerged cane, 1 indicates a one year old cane and 2 indicates a two year old cane.

**Source**

The data were obtained from

**References**

**breslow**

*Smoking Deaths Among Doctors*

**Description**

The breslow data frame has 10 rows and 5 columns.

In 1961 Doll and Hill sent out a questionnaire to all men on the British Medical Register enquiring about their smoking habits. Almost 70% of such men replied. Death certificates were obtained for medical practitioners and causes of death were assigned on the basis of these certificates. The breslow data set contains the person-years of observations and deaths from coronary artery disease accumulated during the first ten years of the study.

**Usage**

breslow

**Format**

This data frame contains the following columns:

- **age**: The mid-point of the 10 year age-group for the doctors.
- **smoke**: An indicator of whether the doctors smoked (1) or not (0).
- **n**: The number of person-years in the category.
- **y**: The number of deaths attributed to coronary artery disease.
- **ns**: The number of smoker years in the category (smoke*n).

**Source**

The data were obtained from

calcium  

*Calcium Uptake Data*

**Description**

The calcium data frame has 27 rows and 2 columns.

Howard Grimes from the Botany Department, North Carolina State University, conducted an experiment for biochemical analysis of intracellular storage and transport of calcium across plasma membrane. Cells were suspended in a solution of radioactive calcium for a certain length of time and then the amount of radioactive calcium that was absorbed by the cells was measured. The experiment was repeated independently with 9 different times of suspension each replicated 3 times.

**Usage**

`calcium`

**Format**

This data frame contains the following columns:

- `time` The time (in minutes) that the cells were suspended in the solution.
- `cal` The amount of calcium uptake (nmoles/mg).

**Source**

The data were obtained from

**References**

cane  

*Sugar-cane Disease Data*

**Description**

The cane data frame has 180 rows and 5 columns. The data frame represents a randomized block design with 45 varieties of sugar-cane and 4 blocks.

**Usage**

`cane`
### capability

**Format**

This data frame contains the following columns:

- **n** The total number of shoots in each plot.
- **r** The number of diseased shoots.
- **x** The number of pieces of the stems, out of 50, planted in each plot.
- **var** A factor indicating the variety of sugar-cane in each plot.
- **block** A factor for the blocks.

**Details**

The aim of the experiment was to classify the varieties into resistant, intermediate and susceptible to a disease called "coal of sugar-cane" (carvao da cana-de-acucar). This is a disease that is common in sugar-cane plantations in certain areas of Brazil.

For each plot, fifty pieces of sugar-cane stem were put in a solution containing the disease agent and then some were planted in the plot. After a fixed period of time, the total number of shoots and the number of diseased shoots were recorded.

**Source**

The data were kindly supplied by Dr. C.G.B. Demetrio of Escola Superior de Agricultura, Universidade de Sao Paolo, Brazil.

**References**

### capability

*Simulated Manufacturing Process Data*

**Description**

The *capability* data frame has 75 rows and 1 columns.

The data are simulated successive observations from a process in equilibrium. The process is assumed to have specification limits (5.49, 5.79).

**Usage**

*capability*

**Format**

This data frame contains the following column:

- **y** The simulated measurements.

**Source**

The data were obtained from

catsM: Weight Data for Domestic Cats

Description

The catsM data frame has 97 rows and 3 columns.

144 adult (over 2kg in weight) cats used for experiments with the drug digitalis had their heart and body weight recorded. 47 of the cats were female and 97 were male. The catsM data frame consists of the data for the male cats. The full data are in dataset cats in package MASS.

Usage
cats

Format

This data frames contain the following columns:

- **Sex** A factor for the sex of the cat (levels are F and M).
- **Bwt** Body weight in kg.
- **Hwt** Heart weight in g.

Source

The data were obtained from

### cav

**Position of Muscle Caveolae**

**Description**

The `cav` data frame has 138 rows and 2 columns.

The data gives the positions of the individual caveolae in a square region with sides of length 500 units. This grid was originally on a 2.65μm square of muscle fibre. The data are those points falling in the lower left hand quarter of the region used for the dataset `caveolae.dat` in the `spatial` library by B.D. Ripley (1994) which is available from Statlib

**Usage**

`cav`

**Format**

This data frame contains the following columns:

- `x` The x coordinate of the caveola’s position in the region.
- `y` The y coordinate of the caveola’s position in the region.

### cd4

**CD4 Counts for HIV-Positive Patients**

**Description**

The `cd4` data frame has 20 rows and 2 columns.

CD4 cells are carried in the blood as part of the human immune system. One of the effects of the HIV virus is that these cells die. The count of CD4 cells is used in determining the onset of full-blown AIDS in a patient. In this study of the effectiveness of a new anti-viral drug on HIV, 20 HIV-positive patients had their CD4 counts recorded and then were put on a course of treatment with this drug. After using the drug for one year, their CD4 counts were again recorded. The aim of the experiment was to show that patients taking the drug had increased CD4 counts which is not generally seen in HIV-positive patients.

**Usage**

`cd4`
Format

This data frame contains the following columns:

- **baseline**: The CD4 counts (in 100’s) on admission to the trial.
- **oneyear**: The CD4 counts (in 100’s) after one year of treatment with the new drug.

Source

The data were obtained from DiCiccio, T.J. and Efron B. (1996) Bootstrap confidence intervals (with Discussion). *Statistical Science, 11*, 189–228.

censboot

*Bootstrap for Censored Data*

Description

This function applies types of bootstrap resampling which have been suggested to deal with right-censored data. It can also do model-based resampling using a Cox regression model.

Usage

censboot(data, statistic, R, F.surv, G.surv, strata=matrix(1,n,2), sim="ordinary", cox=NULL, index=c(1, 2), ...)

censboot

Arguments

data
The data frame or matrix containing the data. It must have at least two columns, one of which contains the times and the other the censoring indicators. It is allowed to have as many other columns as desired (although efficiency is reduced for large numbers of columns) except for sim="weird" when it should only have two columns - the times and censoring indicators. The columns of data referenced by the components of index are taken to be the times and censoring indicators.

statistic
A function which operates on the data frame and returns the required statistic. Its first argument must be the data. Any other arguments that it requires can be passed using the ...{} argument. In the case of sim="weird", the data passed to statistic only contains the times and censoring indicator regardless of the actual number of columns in data. In all other cases the data passed to statistic will be of the same form as the original data. When sim="weird", the actual number of observations in the resampled data sets may not be the same as the number in data. For this reason, if sim="weird" and strata is supplied, statistic should also take a numeric vector indicating the strata. This allows the statistic to depend on the strata if required.

R
The number of bootstrap replicates.

F.surv
An object returned from a call to survfit giving the survivor function for the data. This is a required argument unless sim="ordinary" or sim="model" and cox is missing.

G.surv
Another object returned from a call to survfit but with the censoring indicators reversed to give the product-limit estimate of the censoring distribution. Note that for consistency the uncensored times should be reduced by a small amount in the call to survfit. This is a required argument whenever sim="cond" or when sim="model" and cox is supplied.

strata
The strata used in the calls to survfit. It can be a vector or a matrix with 2 columns. If it is a vector then it is assumed to be the strata for the survival distribution, and the censoring distribution is assumed to be the same for all observations. If it is a matrix then the first column is the strata for the survival distribution and the second is the strata for the censoring distribution. When sim="weird" only the strata for the survival distribution are used since the censoring times are considered fixed. When sim="ordinary", only one set of strata is used to stratify the observations, this is taken to be the first column of strata when it is a matrix.

sim
The simulation type. Possible types are "ordinary" (case resampling), "model" (equivalent to "ordinary" if cox is missing, otherwise it is model based resampling), "weird" (the weird bootstrap - this cannot be used if cox is supplied), and "cond" (the conditional bootstrap, in which censoring times are resampled from the conditional censoring distribution).

cox
An object returned from coxph. If it is supplied, then F.surv should have been generated by a call of the form survfit(cox).

index
A vector of length two giving the positions of the columns in data which correspond to the times and censoring indicators respectively.

Details

The various types of resampling are described in Davison and Hinkley (1997) in sections 3.5 and 7.3. The simplest is case resampling which simply resamples with replacement from the observa-
The conditional bootstrap simulates failure times from the estimate of the survival distribution. Then, for each observation its simulated censoring time is equal to the observed censoring time if the observation was censored and generated from the estimated censoring distribution conditional on being greater than the observed failure time if the observation was uncensored. If the largest value is censored then it is given a nominal failure time of \( \text{Inf} \) and conversely if it is uncensored it is given a nominal censoring time of \( \text{Inf} \). This is necessary to allow the largest observation to be in the resamples.

If a Cox regression model is fitted to the data and supplied, then the failure times are generated from the survival distribution using that model. In this case the censoring times can either be simulated from the estimated censoring distribution (sim="model") or from the conditional censoring distribution as in the previous paragraph (sim="cond").

The weird bootstrap holds the censored observations as fixed and also the observed failure times. It then generates the number of events at each failure time using a binomial distribution with mean 1 and denominator the number of failures that could have occurred at that time in the original data set. In our implementation we insist that there is a least one simulated event in each stratum for every bootstrap dataset.

When there are strata involved and sim is either "model" or "cond" the situation becomes more difficult. Since the strata for the survival and censoring distributions are not the same it is possible that for some observations both the simulated failure time and the simulated censoring time are infinite. To see this consider an observation in stratum 1F for the survival distribution and stratum 1G for the censoring distribution. Now if the largest value in stratum 1F is censored it is given a nominal failure time of \( \text{Inf} \), also if the largest value in stratum 1G is uncensored it is given a nominal censoring time of \( \text{Inf} \) and so both the simulated failure and censoring times could be infinite. When this happens the simulated value is considered to be a failure at the time of the largest observed failure time in the stratum for the survival distribution.

Value

An object of class "boot" containing the following components:

- **t0**: The value of statistic when applied to the original data.
- **t**: A matrix of bootstrap replicates of the values of statistic.
- **R**: The number of bootstrap replicates performed.
- **sim**: The simulation type used. This will usually be the input value of sim unless that was "model" but cox was not supplied, in which case it will be "ordinary".
- **data**: The data used for the bootstrap. This will generally be the input value of data unless sim="weird", in which case it will just be the columns containing the times and the censoring indicators.
- **seed**: The value of .Random.seed when censboot was called.
- **statistic**: The input value of statistic.
- **strata**: The strata used in the resampling. When sim="ordinary" this will be a vector which stratifies the observations, when sim="weird" it is the strata for the survival distribution and in all other cases it is a matrix containing the strata for the survival distribution and the censoring distribution.
- **call**: The original call to censboot.

Description

The channing data frame has 462 rows and 5 columns.

Channing House is a retirement centre in Palo Alto, California. These data were collected between the opening of the house in 1964 until July 1, 1975. In that time 97 men and 365 women passed through the centre. For each of these, their age on entry and also on leaving or death was recorded. A large number of the observations were censored mainly due to the resident being alive on July 1, 1975 when the data was collected. Over the time of the study 130 women and 46 men died at Channing House. Differences between the survival of the sexes, taking age into account, was one of the primary concerns of this study.

Usage

channing

Format

This data frame contains the following columns:

- **sex**: A factor for the sex of each resident ("Male" or "Female").
- **entry**: The residents age (in months) on entry to the centre.
- **exit**: The age (in months) of the resident on death, leaving the centre or July 1, 1975 whichever event occurred first.
- **time**: The length of time (in months) that the resident spent at Channing House.\(^{(time=exit-entry)}\)
- **cens**: The indicator of right censoring. 1 indicates that the resident died at Channing House, 0 indicates that they left the house prior to July 1, 1975 or that they were still alive and living in the centre at that date.

Description

The claridge data frame has 37 rows and 2 columns.

The data are from an experiment which was designed to look for a relationship between a certain genetic characteristic and handedness. The 37 subjects were women who had a son with mental retardation due to inheriting a defective X-chromosome. For each such mother a genetic measurement of their DNA was made. Larger values of this measurement are known to be linked to the defective gene and it was hypothesized that larger values might also be linked to a progressive shift away from right-handedness. Each woman also filled in a questionnaire regarding which hand they used for various tasks. From these questionnaires a measure of hand preference was found for each mother. The scale of this measure goes from 1, indicating someone who always favours their right hand, to 8, indicating someone who always favours their left hand. Between these two extremes are people who favour one hand for some tasks and the other for other tasks.

Usage

claridge

Format

This data frame contains the following columns:

- **dnan**: The genetic measurement on each woman’s DNA.
- **hand**: The measure of left-handedness on an integer scale from 1 to 8.

Source

The data were kindly made available by Dr. Gordon S. Claridge from the Department of Experimental Psychology, University of Oxford.

**co.transfer**

*Carbon Monoxide Transfer*

**Description**

The `co.transfer` data frame has 7 rows and 2 columns. Seven smokers with chickenpox had their levels of carbon monoxide transfer measured on entry to hospital and then again after 1 week. The main question being whether one week of hospitalization has changed the carbon monoxide transfer factor.

**Usage**

`co.transfer`

**Format**

This data frame contains the following columns:

- **entry** Carbon monoxide transfer factor on entry to hospital.
- **week** Carbon monoxide transfer one week after admittance to hospital.

**Source**

The data were obtained from

### coal

**Dates of Coal Mining Disasters**

**Description**

The `coal` data frame has 191 rows and 1 columns.

This data frame gives the dates of 191 explosions in coal mines which resulted in 10 or more fatalities. The time span of the data is from March 15, 1851 until March 22, 1962.

**Usage**

`coal`

**Format**

This data frame contains the following column:

- **date** The date of the disaster. The integer part of `date` gives the year. The day is represented as the fraction of the year that had elapsed on that day.

**Source**

The data were obtained from

### control

**Control Variate Calculations**

**Description**

This function will find control variate estimates from a bootstrap output object. It can either find the adjusted bias estimate using post-simulation balancing or it can estimate the bias, variance, third cumulant and quantiles, using the linear approximation as a control variate.

**Usage**

```r
control(boot.out, L = NULL, distn = NULL, index = 1, t0 = NULL, t = NULL, bias.adj = FALSE, alpha = NULL, ...)
```
control

Arguments

boot.out A bootstrap output object returned from boot. The bootstrap replicates must have been generated using the usual nonparametric bootstrap.

L The empirical influence values for the statistic of interest. If L is not supplied then empinf is called to calculate them from boot.out.

distn If present this must be the output from smooth.spline giving the distribution function of the linear approximation. This is used only if bias.adj is FALSE. Normally this would be found using a saddlepoint approximation. If it is not supplied in that case then it is calculated by saddle.distn.

index The index of the variable of interest in the output of boot.out$statistic.

t0 The observed value of the statistic of interest on the original data set boot.out$data. This argument is used only if bias.adj is FALSE. The input value is ignored if t is not also supplied. The default value is boot.out$t0[index].

t The bootstrap replicate values of the statistic of interest. This argument is used only if bias.adj is FALSE. The input is ignored if t0 is not supplied also. The default value is boot.out$t[,index].

bias.adj A logical variable which if TRUE specifies that the adjusted bias estimate using post-simulation balance is all that is required. If bias.adj is FALSE (default) then the linear approximation to the statistic is calculated and used as a control variate in estimates of the bias, variance and third cumulant as well as quantiles.

alpha The alpha levels for the required quantiles if bias.adj is FALSE.

... Any additional arguments that boot.out$statistic requires. These are passed unchanged every time boot.out$statistic is called. boot.out$statistic is called once if bias.adj is TRUE, otherwise it may be called by empinf for empirical influence calculations if L is not supplied.

Details

If bias.adj is FALSE then the linear approximation to the statistic is found and evaluated at each bootstrap replicate. Then using the equation \(T^* = Tl^* + (T^* - Tl^*)\), moment estimates can be found. For quantile estimation the distribution of the linear approximation to \(t\) is approximated very accurately by saddlepoint methods, this is then combined with the bootstrap replicates to approximate the bootstrap distribution of \(t\) and hence to estimate the bootstrap quantiles of \(t\).

Value

If bias.adj is TRUE then the returned value is the adjusted bias estimate.

If bias.adj is FALSE then the returned value is a list with the following components

L The empirical influence values used. These are the input values if supplied, and otherwise they are the values calculated by empinf.

tL The linear approximations to the bootstrap replicates of the statistic of interest.

bias The control estimate of bias using the linear approximation to \(t\) as a control variate.

var The control estimate of variance using the linear approximation to \(t\) as a control variate.
The control estimate of the third cumulant using the linear approximation to $t$ as a control variate.

A matrix with two columns; the first column are the alpha levels used for the quantiles and the second column gives the corresponding control estimates of the quantiles using the linear approximation to $t$ as a control variate.

An output object from smooth.spline describing the saddlepoint approximation to the bootstrap distribution of the linear approximation to $t$. If distn was supplied on input then this is the same as the input otherwise it is calculated by a call to saddle.distn.

Examples

# Use of control variates for the variance of the air-conditioning data
mean.fun <- function(d, i)
{ m <- mean(d$hours[i])
  n <- nrow(d)
  v <- (n-1) * var(d$hours[i]) / n^2
  c(m, v)
}
air.boot <- boot(aircondit, mean.fun, R = 999)
control(air.boot, index = 2, bias.adj = TRUE)
air.cont <- control(air.boot, index = 2)
# Now let us try the variance on the log scale.
air.cont1 <- control(air.boot, t0=log(air.boot$t0[2]),
                     t=log(air.boot$t[,2]))

corr

Correlation Coefficient

description

Calculates the weighted correlation given a data set and a set of weights.

Usage

corr(d, w=rep(1,nrow(d))/nrow(d))
Arguments

d  A matrix with two columns corresponding to the two variables whose correlation we wish to calculate.
w  A vector of weights to be applied to each pair of observations. The default is equal weights for each pair. Normalization takes place within the function so \( \sum(w) \) need not equal 1.

Details

This function finds the correlation coefficient in weighted form. This is often useful in bootstrap methods since it allows for numerical differentiation to get the empirical influence values. It is also necessary to have the statistic in this form to find ABC intervals.

Value

The correlation coefficient between \( d[,1] \) and \( d[,2] \).

See Also

cor

cum3

Calculate Third Order Cumulants

Description

Calculates an estimate of the third cumulant, or skewness, of a vector. Also, if more than one vector is specified, a product-moment of order 3 is estimated.

Usage

cum3(a, b=a, c=a, unbiased=TRUE)

Arguments

a  A vector of observations.
b  Another vector of observations, if not supplied it is set to the value of \( a \). If supplied then it must be the same length as \( a \).
c  Another vector of observations, if not supplied it is set to the value of \( a \). If supplied then it must be the same length as \( a \).
unbiased  A logical value indicating whether the unbiased estimator should be used.

Details

The unbiased estimator uses a multiplier of \( n/((n-1)*(n-2)) \) where \( n \) is the sample size, if \( \text{unbiased} \) is \( \text{FALSE} \) then a multiplier of \( 1/n \) is used. This is multiplied by \( \sum((a-\text{mean}(a))*(b-\text{mean}(b))*(c-\text{mean}(c))) \) to give the required estimate.

Value

The required estimate.
cv.glm

Cross-validation for Generalized Linear Models

Description

This function calculates the estimated K-fold cross-validation prediction error for generalized linear models.

Usage

cv.glm(data, glmfit, cost, K)

Arguments

data
A matrix or data frame containing the data. The rows should be cases and the columns correspond to variables, one of which is the response.

glmfit
An object of class "glm" containing the results of a generalized linear model fitted to data.

cost
A function of two vector arguments specifying the cost function for the cross-validation. The first argument to cost should correspond to the observed responses and the second argument should correspond to the predicted or fitted responses from the generalized linear model. cost must return a non-negative scalar value. The default is the average squared error function.

K
The number of groups into which the data should be split to estimate the cross-validation prediction error. The value of K must be such that all groups are of approximately equal size. If the supplied value of K does not satisfy this criterion then it will be set to the closest integer which does and a warning is generated specifying the value of K used. The default is to set K equal to the number of observations in data which gives the usual leave-one-out cross-validation.

Details

The data is divided randomly into K groups. For each group the generalized linear model is fit to data omitting that group, then the function cost is applied to the observed responses in the group that was omitted from the fit and the prediction made by the fitted models for those observations.

When K is the number of observations leave-one-out cross-validation is used and all the possible splits of the data are used. When K is less than the number of observations the K splits to be used are found by randomly partitioning the data into K groups of approximately equal size. In this latter case a certain amount of bias is introduced. This can be reduced by using a simple adjustment (see equation 6.48 in Davison and Hinkley, 1997). The second value returned in delta is the estimate adjusted by this method.

Value

The returned value is a list with the following components.

call
The original call to cv.glm.

K
The value of K used for the K-fold cross-validation.
delta A vector of length two. The first component is the raw cross-validation estimate of prediction error. The second component is the adjusted cross-validation estimate. The adjustment is designed to compensate for the bias introduced by not using leave-one-out cross-validation.

seed The value of .Random.seed when cv.glm was called.

Side Effects

The value of .Random.seed is updated.

cv.11.err <- cv.glm(nodal, nodal.glm, cost, K=11)$delta
```
**Darwin’s Plant Height Differences**

**Description**

The `darwin` data frame has 15 rows and 1 column. Charles Darwin conducted an experiment to examine the superiority of cross-fertilized plants over self-fertilized plants. 15 pairs of plants were used. Each pair consisted of one cross-fertilized plant and one self-fertilized plant which germinated at the same time and grew in the same pot. The plants were measured at a fixed time after planting and the difference in heights between the cross- and self-fertilized plants are recorded in eighths of an inch.

**Usage**

```r
darwin
```

**Format**

This data frame contains the following column:

- `y` The difference in heights for the pairs of plants (in units of 0.125 inches).

**Source**

downs.bc  
*Incidence of Down’s Syndrome in British Columbia*

Description
The `downs.bc` data frame has 30 rows and 3 columns.

Down’s syndrome is a genetic disorder caused by an extra chromosome 21 or a part of chromosome 21 being translocated to another chromosome. The incidence of Down’s syndrome is highly dependent on the mother’s age and rises sharply after age 30. In the 1960's a large scale study of the effect of maternal age on the incidence of Down’s syndrome was conducted at the British Columbia Health Surveillance Registry. These are the data which was collected in that study.

Mothers were classified by age. Most groups correspond to the age in years but the first group comprises all mothers with ages in the range 15-17 and the last is those with ages 46-49. No data for mothers over 50 or below 15 were collected.

Usage
`downs.bc`

Format
This data frame contains the following columns:

- **age** The average age of all mothers in the age category.
- **m** The total number of live births to mothers in the age category.
- **r** The number of cases of Down’s syndrome.

Source
The data were obtained from

References
The ducks data frame has 11 rows and 2 columns. Each row of the data frame represents a male duck who is a second generation cross of mallard and pintail ducks. For 11 such ducks a behavioural and plumage index were calculated. These were measured on scales devised for this experiment which was to examine whether there was any link between which species the ducks resembled physically and which they resembled in behaviour. The scale for the physical appearance ranged from 0 (identical in appearance to a mallard) to 20 (identical to a pintail). The behavioural traits of the ducks were on a scale from 0 to 15 with lower numbers indicating closer to mallard-like in behaviour.

Usage

ducks

Format

This data frame contains the following columns:

- **plumage**: The index of physical appearance based on the plumage of individual ducks.
- **behaviour**: The index of behavioural characteristics of the ducks.

Source

The data were obtained from

References

Usage

\begin{verbatim}
EEF.profile(y, tmin=min(y) + 0.1, tmax=max(y) - 0.1, n.t=25,
    u=function(y, t) { y-t})
EL.profile(y, tmin = min(y) + 0.1, tmax = max(y) - 0.1, n.t = 25,
    u = function(y, t) y - t)
\end{verbatim}

Arguments

- **y**: A vector or matrix of data.
- **tmin**: The minimum value of the range over which the likelihood should be computed. This must be larger than \text{min}(y).
- **tmax**: The maximum value of the range over which the likelihood should be computed. This must be smaller than \text{max}(y).
- **n.t**: The number of points between \text{tmin} and \text{tmax} at which the value of the log-likelihood should be computed.
- **u**: A function of the data and the parameter.

Details

These functions calculate the log likelihood for a mean using either an empirical likelihood or an empirical exponential family likelihood. They are supplied as part of the package \texttt{boot} for demonstration purposes with the practicals in chapter 10 of Davison and Hinkley (1997). The functions are not intended for general use and are not supported as part of the \texttt{boot} package. For more general and more robust code to calculate empirical likelihoods see Professor A. B. Owen’s empirical likelihood home page at the URL \url{http://www-stat.stanford.edu/~owen/empirical/}.

Value

A matrix with \text{n.t} rows. The first column contains the values of the parameter used. The second column of the output of \texttt{EL.profile} contains the values of the empirical log likelihood. The second and third columns of the output of \texttt{EEF.profile} contain two versions of the empirical exponential family log-likelihood. The final column of the output matrix contains the values of the Lagrange multiplier used in the optimization procedure.

Author(s)

Angelo J. Canty

References

Description

This function calculates the empirical influence values for a statistic applied to a data set. It allows four types of calculation, namely the infinitesimal jackknife (using numerical differentiation), the usual jackknife estimates, the "positive" jackknife estimates and a method which estimates the empirical influence values using regression of bootstrap replicates of the statistic. All methods can be used with one or more samples.

Usage

```r
empinf(boot.out = NULL, data = NULL, statistic = NULL,
      type = NULL, stype = NULL ,index = 1, t = NULL,
      strata = rep(1, n), eps = 0.001, ...)
```

Arguments

- `boot.out`: A bootstrap object created by the function `boot`. If `type` is "reg" then this argument is required. For any of the other types it is an optional argument. If it is included when optional then the values of `data, statistic, stype, and strata` are taken from the components of `boot.out` and any values passed to `empinf` directly are ignored.
- `data`: A vector, matrix or data frame containing the data for which empirical influence values are required. It is a required argument if `boot.out` is not supplied. If `boot.out` is supplied then `data` is set to `boot.out$data` and any value supplied is ignored.
- `statistic`: The statistic for which empirical influence values are required. It must be a function of at least two arguments, the data set and a vector of weights, frequencies or indices. The nature of the second argument is given by the value of `stype`. Any other arguments that it takes must be supplied to `empinf` and will be passed to `statistic` unchanged. This is a required argument if `boot.out` is not supplied, otherwise its value is taken from `boot.out` and any value supplied here will be ignored.
- `type`: The calculation type to be used for the empirical influence values. Possible values of `type` are "inf" (infinitesimal jackknife), "jack" (usual jackknife), "pos" (positive jackknife), and "reg" (regression estimation). The default value depends on the other arguments. If `t` is supplied then the default value of `type` is "reg" and `boot.out` should be present so that its frequency array can be found. If `t` is not supplied then if `stype` is "w", the default value of `type` is "inf"; otherwise, if `boot.out` is present the default is "reg". If none of these conditions apply then the default is "jack". Note that it is an error for `type` to be "reg" if `boot.out` is missing or to be "inf" if `stype` is not "w".
- `stype`: A character variable giving the nature of the second argument to `statistic`. It can take on three values: "w" (weights), "f" (frequencies), or "i" (indices). If `boot.out` is supplied the value of `stype` is set to `boot.out$stype` and any value supplied here is ignored. Otherwise it is an optional argument which defaults to "w". If `type` is "inf" then `stype` MUST be "w".
**empinf**

index  
An integer giving the position of the variable of interest in the output of statistic.

t  
A vector of length `boot.out$R` which gives the bootstrap replicates of the statistic of interest. t is used only when type is `reg` and it defaults to `boot.out$t[,index]`.

strata  
An integer vector or a factor specifying the strata for multi-sample problems. If `boot.out` is supplied the value of strata is set to `boot.out$strata`. Otherwise it is an optional argument which has default corresponding to the single sample situation.

eps  
This argument is used only if type is "inf". In that case the value of epsilon to be used for numerical differentiation will be eps divided by the number of observations in data.

...  
Any other arguments that statistic takes. They will be passed unchanged to statistic every time that it is called.

**Details**

If type is "inf" then numerical differentiation is used to approximate the empirical influence values. This makes sense only for statistics which are written in weighted form (i.e. stype is "w"). If type is "jack" then the usual leave-one-out jackknife estimates of the empirical influence are returned. If type is "pos" then the positive (include-one-twice) jackknife values are used. If type is "reg" then a bootstrap object must be supplied. The regression method then works by regressing the bootstrap replicates of statistic on the frequency array from which they were derived. The bootstrap frequency array is obtained through a call to `boot.array`. Further details of the methods are given in Section 2.7 of Davison and Hinkley (1997).

Empirical influence values are often used frequently in nonparametric bootstrap applications. For this reason many other functions call `empinf` when they are required. Some examples of their use are for nonparametric delta estimates of variance, BCa intervals and finding linear approximations to statistics for use as control variates. They are also used for antithetic bootstrap resampling.

**Value**

A vector of the empirical influence values of statistic applied to data. The values will be in the same order as the observations in data.

**Warning**

All arguments to `empinf` must be passed using the name = value convention. If this is not followed then unpredictable errors can occur.

empinf(boot.out=grav.boot,t=grav.z)

envelope

Confidence Envelopes for Curves

Description

This function calculates overall and pointwise confidence envelopes for a curve based on bootstrap replicates of the curve evaluated at a number of fixed points.

Usage

envelope(boot.out=NULL, mat=NULL, level=0.95, index=1:ncol(mat))
envelope

Arguments

- **boot.out**: An object of class "boot" for which `boot.out$t` contains the replicates of the curve at a number of fixed points.
- **mat**: A matrix of bootstrap replicates of the values of the curve at a number of fixed points. This is a required argument if `boot.out` is not supplied and is set to `boot.out$t` otherwise.
- **level**: The confidence level of the envelopes required. The default is to find 95% confidence envelopes. It can be a scalar or a vector of length 2. If it is scalar then both the pointwise and the overall envelopes are found at that level. If is a vector then the first element gives the level for the pointwise envelope and the second gives the level for the overall envelope.
- **index**: The numbers of the columns of `mat` which contain the bootstrap replicates. This can be used to ensure that other statistics which may have been calculated in the bootstrap are not considered as values of the function.

Details

The pointwise envelope is found by simply looking at the quantiles of the replicates at each point. The overall error for that envelope is then calculated using equation (4.17) of Davison and Hinkley (1997). A sequence of pointwise envelopes is then found until one of them has overall error approximately equal to the level required. If no such envelope can be found then the envelope returned will just contain the extreme values of each column of `mat`.

Value

A list with the following components:

- **point**: A matrix with two rows corresponding to the values of the upper and lower pointwise confidence envelope at the same points as the bootstrap replicates were calculated.
- **overall**: A matrix similar to `point` but containing the envelope which controls the overall error.
- **k.pt**: The quantiles used for the pointwise envelope.
- **err.pt**: A vector with two components, the first gives the pointwise error rate for the pointwise envelope, and the second the overall error rate for that envelope.
- **k.ov**: The quantiles used for the overall envelope.
- **err.ov**: A vector with two components, the first gives the pointwise error rate for the overall envelope, and the second the overall error rate for that envelope.
- **err.nom**: A vector of length 2 giving the nominal error rates for the pointwise and the overall envelopes.

exp.tilt

Explosive Tilting

Description

This function calculates exponentially tilted multinomial distributions such that the resampling distributions of the linear approximation to a statistic have the required means.

Usage

exp.tilt(L, theta=NULL, t0=0, lambda=NULL,
         strata=rep(1, length(L)))

Arguments

L
  The empirical influence values for the statistic of interest based on the observed
data. The length of L should be the same as the size of the original data set.
  Typically L will be calculated by a call to empinf.
theta
  The value at which the tilted distribution is to be centred. This is not required if
lambda is supplied but is needed otherwise.
t0
  The current value of the statistic. The default is that the statistic equals 0.
lambda
  The Lagrange multiplier(s). For each value of lambda a multinomial distribution
  is found with probabilities proportional to exp(lambda * L). In general
lambda is not known and so theta would be supplied, and the corresponding
value of lambda found. If both lambda and theta are supplied then
lambda is ignored and the multipliers for tilting to theta are found.
strata
  A vector or factor of the same length as L giving the strata for the observed data
  and the empirical influence values L.
Details

Exponential tilting involves finding a set of weights for a data set to ensure that the bootstrap distribution of the linear approximation to a statistic of interest has mean $\theta$. The weights chosen to achieve this are given by $p[j]$ proportional to $\exp(\lambda L[j]/n)$, where $n$ is the number of data points. $\lambda$ is then chosen to make the mean of the bootstrap distribution, of the linear approximation to the statistic of interest, equal to the the required value $\theta$. Thus $\lambda$ is defined as the solution of a nonlinear equation. The equation is solved by minimizing the Euclidean distance between the left and right hand sides of the equation using the function *nlmin*. If this minimum is not equal to zero then the method fails.

Typically exponential tilting is used to find suitable weights for importance resampling. If a small tail probability or quantile of the distribution of the statistic of interest is required then a more efficient simulation is to centre the resampling distribution close to the point of interest and then use the functions *imp.prob* or *imp.quantile* to estimate the required quantity.

Another method of achieving a similar shifting of the distribution is through the use of *smooth.f*. The function *tilt.boot* uses *exp.tilt* or *smooth.f* to find the weights for a tilted bootstrap.

Value

A list with the following components:

- **p**  
  The tilted probabilities. There will be $m$ distributions where $m$ is the length of $\theta$ (or $\lambda$ if supplied). If $m$ is 1 then $p$ is a vector of length($L$) probabilities. If $m$ is greater than 1 then $p$ is a matrix with $m$ rows, each of which contain length($L$) probabilities. In this case the vector $p[i,]$ is the distribution tilted to $\theta[i]$. $p$ is in the form required by the argument *weights* of the function *boot* for importance resampling.

- **lambda**  
  The Lagrange multiplier used in the equation to determine the tilted probabilities. $\lambda$ is a vector of the same length as $\theta$.

- **theta**  
  The values of $\theta$ to which the distributions have been tilted. In general this will be the input value of $\theta$ but if $\lambda$ was supplied then this is the vector of the corresponding $\theta$ values.

Examples

```r
# Example 9.8 of Davison and Hinkley (1997) requires tilting the resampling
# distribution of the studentized statistic to be centred at the observed
# value of the test statistic 1.84. This can be achieved as follows.
grav1 <- gravity[as.numeric(gravity[,2])>=7,]
grav.fun <- function(dat, w, orig)
{  strata <- tapply(dat[,2], as.numeric(dat[,2]))
   d <- dat[,1]
   ...}
```
The `fir` data frame has 50 rows and 3 columns. The number of balsam-fir seedlings in each quadrant of a grid of 50 five foot square quadrants were counted. The grid consisted of 5 rows of 10 quadrants in each row.

### Usage

`fir`

### Format

This data frame contains the following columns:

- **count**: The number of seedlings in the quadrant.
- **row**: The row number of the quadrant.
- **col**: The quadrant number within the row.

### Source

freq.array

Bootstrap Frequency Arrays

Description

Take a matrix of indices for nonparametric bootstrap resamples and return the frequencies of the original observations in each resample.

Usage

freq.array(i.array)

Arguments

i.array

This will be a matrix of integers between 1 and n, where n is the number of observations in a data set. The matrix will have n columns and R rows where R is the number of bootstrap resamples. Such matrices are found by boot when doing nonparametric bootstraps. They can also be found after a bootstrap has been run through the function boot.array.

Value

A matrix of the same dimensions as the input matrix. Each row of the matrix corresponds to a single bootstrap resample. Each column of the matrix corresponds to one of the original observations and specifies its frequency in each bootstrap resample. Thus the first column tells us how often the first observation appeared in each bootstrap resample. Such frequency arrays are often useful for diagnostic purposes such as the jackknife-after-bootstrap plot. They are also necessary for the regression estimates of empirical influence values and for finding importance sampling weights.

boot.array

frets

Head Dimensions in Brothers

Description

The frets data frame has 25 rows and 4 columns.

The data consist of measurements of the length and breadth of the heads of pairs of adult brothers in 25 randomly sampled families. All measurements are expressed in millimetres.

Usage

frets
Format

This data frame contains the following columns:

11  The head length of the eldest son.
12  The head length of the second son.
b1  The head breadth of the eldest son.
b2  The head breadth of the second son.

Source

The data were obtained from

**glm.diag**  
*Generalized Linear Model Diagnostics*

Description

Calculates jackknife deviance residuals, standardized deviance residuals, standardized Pearson residuals, approximate Cook statistic, leverage and estimated dispersion.

Usage

`glm.diag(glmfit)`

Arguments

- `glmfit`  
  `glmfit` is a `glm.object` - the result of a call to `glm()`

Value

Returns a list with the following components

- `res`  
  The vector of jackknife deviance residuals.
- `rd`  
  The vector of standardized deviance residuals.
- `rp`  
  The vector of standardized Pearson residuals.
- `cook`  
  The vector of approximate Cook statistics.
- `h`  
  The vector of leverages of the observations.
- `sd`  
  The value used to standardize the residuals. This is the the estimate of residual standard deviation in the Gaussian family and is the square root of the estimated shape parameter in the Gamma family. In all other cases it is 1.
glm.diag.plots

Note
See the help file for glm.diag.plots for an example of the use of glm.diag.

References

See Also
glm, glm.diag.plots, summary.glm

glm.diag.plots  Diagnostics plots for generalized linear models

Description
Makes plot of jackknife deviance residuals against linear predictor, normal scores plots of standardized deviance residuals, plot of approximate Cook statistics against leverage/(1-leverage), and case plot of Cook statistic.

Usage
glm.diag.plots(glmfit, glmdiag=glm.diag(glmfit),
subset=NULL, iden=FALSE, labels=NULL, ret=FALSE)

Arguments

glmfit  glm.object: the result of a call to glm()

glmdiag  Diagnostics of glmfit obtained from a call to glm.diag. If it is not supplied then it is calculated.

subset  Subset of data for which glm fitting performed: should be the same as the subset option used in the call to glm() which generated glmfit. Needed only if the subset= option was used in the call to glm.

iden  A logical argument. If TRUE then, after the plots are drawn, the user will be prompted for an integer between 0 and 4. A positive integer will select a plot and invoke identify() on that plot. After exiting identify(), the user is again prompted, this loop continuing until the user responds to the prompt with 0. If iden is FALSE (default) the user cannot interact with the plots.

labels  A vector of labels for use with identify() if iden is TRUE. If it is not supplied then the labels are derived from glmfit.

ret  A logical argument indicating if glmdiag should be returned. The default is FALSE.
Details

The diagnostics required for the plots are calculated by `glm.diag`. These are then used to produce the four plots on the current graphics device.

The plot on the top left is a plot of the jackknife deviance residuals against the fitted values.

The plot on the top right is a normal QQ plot of the standardized deviance residuals. The dotted line is the expected line if the standardized residuals are normally distributed, i.e. it is the line with intercept 0 and slope 1.

The bottom two panels are plots of the Cook statistics. On the left is a plot of the Cook statistics against the standardized leverages. In general there will be two dotted lines on this plot. The horizontal line is at $8/(n-2p)$ where $n$ is the number of observations and $p$ is the number of parameters estimated. Points above this line may be points with high influence on the model. The vertical line is at $2p/(n-2p)$ and points to the right of this line have high leverage compared to the variance of the raw residual at that point. If all points are below the horizontal line or to the left of the vertical line then the line is not shown.

The final plot again shows the Cook statistic this time plotted against case number enabling us to find which observations are influential.

Use of `iden=T` is encouraged for proper exploration of these four plots as a guide to how well the model fits the data and whether certain observations have an unduly large effect on parameter estimates.

Value

If `ret` is `TRUE` then the value of `glmdiag` is returned otherwise there is no returned value.

Side Effects

The current device is cleared and four plots are plotted by use of `split.screen(c(2,2))`. If `iden` is `TRUE`, interactive identification of points is enabled. All screens are closed, but not cleared, on termination of the function.

**Gravity**

*Acceleration Due to Gravity*

### Description

The `gravity` data frame has 81 rows and 2 columns. The `grav` data set has 26 rows and 2 columns.

Between May 1934 and July 1935, the National Bureau of Standards in Washington D.C. conducted a series of experiments to estimate the acceleration due to gravity, \( g \), at Washington. Each experiment produced a number of replicate estimates of \( g \) using the same methodology. Although the basic method remained the same for all experiments, that of the reversible pendulum, there were changes in configuration.

The `gravity` data frame contains the data from all eight experiments. The `grav` data frame contains the data from the experiments 7 and 8. The data are expressed as deviations from 980.000 in centimetres per second squared.

### Usage

`gravity`

### Format

This data frame contains the following columns:

- **\( g \)** The deviation of the estimate from 980.000 centimetres per second squared.
- **series** A factor describing from which experiment the estimate was derived.

### Source

The data were obtained from

Imp.Estimates Importance Sampling Estimates

Description

Central moment, tail probability, and quantile estimates for a statistic under importance resampling.

Usage

imp.moments(boot.out=NULL, index=1, t=boot.out$t[, index],
w=NULL, def=TRUE, q=NULL)
imp.prob(boot.out=NULL, index=1, t0=boot.out$t0[index],
t=boot.out$t[, index], w=NULL, def=TRUE, q=NULL)
imp.quantile(boot.out=NULL, alpha=NULL, index=1,
t=boot.out$t[, index], w=NULL, def=TRUE, q=NULL)

Arguments

boot.out A object of class "boot" generated by a call to boot or tilt.boot. Use of these functions makes sense only when the bootstrap resampling used unequal weights for the observations. If the importance weights w are not supplied then boot.out is a required argument. It is also required if t is not supplied.
alpha The alpha levels for the required quantiles. The default is to calculate the 1%, 2.5%, 5%, 10%, 90%, 95%, 97.5% and 99% quantiles.
index The index of the variable of interest in the output of boot.out$statistic. This is not used if the argument t is supplied.
Imp.Estimates

The values at which tail probability estimates are required. For each value of $t_0[i]$ the function will estimate the bootstrap cdf evaluated at $t_0[i]$. If `imp.prob` is called without the argument $t_0$ then the bootstrap cdf evaluated at the observed value of the statistic is found.

The bootstrap replicates of a statistic. By default these are taken from the bootstrap output object `boot.out` but they can be supplied separately if required (e.g. when the statistic of interest is a function of the calculated values in `boot.out`). Either `boot.out` or `t` must be supplied.

The importance resampling weights for the bootstrap replicates. If they are not supplied then `boot.out` must be supplied, in which case the importance weights are calculated by a call to `imp.weights`.

A logical value indicating whether a defensive mixture is to be used for weight calculation. This is used only if `w` is missing and it is passed unchanged to `imp.weights` to calculate `w`.

A vector of probabilities specifying the resampling distribution from which any estimates should be found. In general this would correspond to the usual bootstrap resampling distribution which gives equal weight to each of the original observations. The estimates depend on this distribution only through the importance weights `w` so this argument is ignored if `w` is supplied. If `w` is missing then `q` is passed as an argument to `imp.weights` and used to find `w`.

A list with the following components:

- `alpha`: The alpha levels used for the quantiles, if `imp.quantile` is used.
- `t0`: The values at which the tail probabilities are estimated, if `imp.prob` is used.
- `raw`: The raw importance resampling estimates. For `imp.moments` this has length 2, the first component being the estimate of the mean and the second being the variance estimate. For `imp.prob`, `raw` is of the same length as `t0`, and for `imp.quantile` it is of the same length as `alpha`.
- `rat`: The ratio importance resampling estimates. In this method the weights `w` are rescaled to have average value one before they are used. The format of this vector is the same as `raw`.
- `reg`: The regression importance resampling estimates. In this method the weights which are used are derived from a regression of $t \times w$ on $w$. This choice of weights can be shown to minimize the variance of the weights and also the Euclidean distance of the weights from the uniform weights. The format of this vector is the same as `raw`.

References

### Examples

# Example 9.8 of Davison and Hinkley (1997) requires tilting the resampling distribution of the studentized statistic to be centred at the observed value of the test statistic, 1.84. In this example we show how certain estimates can be found using resamples taken from the tilted distribution.

```r
grav1 <- gravity[as.numeric(gravity[,2])>=7,]
grav.fun <- function(dat, w, orig)
{
  strata <- tapply(dat[, 2], as.numeric(dat[, 2]))
  d <- dat[, 1]
  ns <- tabulate(strata)
  w <- w/tapply(w, strata, sum)[strata]
  mns <- tapply(d * w, strata, sum)
  mn2 <- tapply(d * d * w, strata, sum)
  s2hat <- sum((mn2 - mns^2)/ns)
  as.vector(c(mns[2]-mns[1],s2hat,(mns[2]-mns[1]-orig)/sqrt(s2hat)))
}
grav.z0 <- grav.fun(grav1,rep(1,26),0)
grav.L <- empinf(data=grav1, statistic=grav.fun, stype="w", strata=grav1[,2], index=3, orig=grav.z0[1])
grav.tilt <- exp.tilt(grav.L,grav.z0[3],strata=grav1[,2])
grav.tilt.boot <- boot(grav1, grav.fun, R=199, stype="w", strata=grav1[,2], weights=grav.tilt$p, orig=grav.z0[1])
# Since the weights are needed for all calculations, we shall calculate them once only.
grav.w <- imp.weights(grav.tilt.boot)
grav.mom <- imp.moments(grav.tilt.boot, w=grav.w, index=3)
grav.p <- imp.prob(grav.tilt.boot, w=grav.w, index=3, t0=grav.z0[3])
grav.q <- imp.quantile(grav.tilt.boot, w=grav.w, index=3, alpha=c(0.9,0.95,0.975,0.99))
```

### Description

This function calculates the importance sampling weight required to correct for simulation from a distribution with probabilities \( p \) when estimates are required assuming that simulation was from an alternative distribution with probabilities \( q \).

### Usage

```r
imp.weights(boot.out, def=TRUE, q=NULL)
```
imp.weights

Arguments

boot.out  A object of class "boot" generated by boot or tilt.boot. Typically the bootstrap simulations would have been done using importance resampling and we wish to do our calculations under the assumption of sampling with equal probabilities.

def  A logical variable indicating whether the defensive mixture distribution weights should be calculated. This makes sense only in the case where the replicates in boot.out were simulated under a number of different distributions. If this is the case then the defensive mixture weights use a mixture of the distributions used in the bootstrap. The alternative is to calculate the weights for each replicate using knowledge of the distribution from which the bootstrap resample was generated.

q  A vector of probabilities specifying the resampling distribution from which we require inferences to be made. In general this would correspond to the usual bootstrap resampling distribution which gives equal weight to each of the original observations and this is the default. q must have length equal to the number of observations in the boot.out$data and all elements of q must be positive.

Details

The importance sampling weight for a bootstrap replicate with frequency vector f is given by \( \prod((q/p)^f) \). This reweights the replicates so that estimates can be found as if the bootstrap resamples were generated according to the probabilities q even though, in fact, they came from the distribution p.

Value

A vector of importance weights of the same length as boot.out$t. These weights can then be used to reweight boot.out$t so that estimates can be found as if the simulations were from a distribution with probabilities q.

Note

See the example in the help for imp.moments for an example of using imp.weights.

inv.logit  Inverse Logit Function

Description
Given a numeric object return the inverse logit of the values.

Usage
inv.logit(x)

Arguments
x  A numeric object. Missing values (NAs) are allowed.

Details
The inverse logit is defined by \( \exp(x)/(1+\exp(x)) \). Values in \( x \) of \(-\infty\) or \( \infty \) return logits of 0 or 1 respectively. Any NAs in the input will also be NAs in the output.

Value
An object of the same type as \( x \) containing the inverse logits of the input values.

See Also
logit, plogis which is the underlying function.

islay  Jura Quartzite Azimuths on Islay

Description
The islay data frame has 18 rows and 1 columns.
Measurements were taken of paleocurrent azimuths from the Jura Quartzite on the Scottish island of Islay.

Usage
islay

Format
This data frame contains the following column:

theta  The angle of the azimuth in degrees East of North.
jack.after.boot

1667

Source
The data were obtained from
Hand, D.J., Daly, F., Lunn, A.D., McConway, K.J. and Ostrowski, E. (1994) A Handbook of Small
Data Sets, Chapman and Hall.
References
University Press.

jack.after.boot

Jackknife-after-Bootstrap Plots

Description
This function calculates the jackknife influence values from a bootstrap output object and plots the
corresponding jackknife-after-bootstrap plot.
Usage
jack.after.boot(boot.out, index=1, t=NULL, L=NULL, useJ=TRUE,
stinf=TRUE, alpha=NULL, main="", ylab=NULL, ...)
Arguments
boot.out

An object of class "boot" which would normally be created by a call to
boot. It should represent a nonparametric bootstrap. For reliable results
boot.out$R should be reasonably large.

index

The index of the statistic of interest in the output of boot.out$statistic.

t

A vector of length boot.out$R giving the bootstrap replicates of the statistic of interest. This is useful if the statistic of interest is a function of
the calculated bootstrap output. If it is not supplied then the default is
boot.out$t[,index].

L

The empirical influence values for the statistic of interest. These are used only if
useJ is FALSE. If they are not supplied and are needed, they are calculated by a
call to empinf. If L is supplied then it is assumed that they are the infinitesimal
jackknife values.

useJ

A logical variable indicating if the jackknife influence values calculated from the
bootstrap replicates should be used. If FALSE the empirical influence values are
used. The default is TRUE.

stinf

A logical variable indicating whether to standardize the jackknife values before
plotting them. If TRUE then the jackknife values used are divided by their standard error.

alpha

The quantiles at which the plots are required. The default is c(0.05, 0.1,
0.16, 0.5, 0.84, 0.9, 0.95).

main

A character string giving the main title for the plot.


yalab The label for the Y axis. If the default values of alpha are used and ylab is not supplied then a label indicating which percentiles are plotted is used. If alpha is supplied then the default label will not say which percentiles were used.

... Any extra arguments required by boot.out$statistic. These are required only if useJ is FALSE and L is not supplied, in which case they are passed to empinf for use in calculation of the empirical influence values.

Details

The centred jackknife quantiles for each observation are estimated from those bootstrap samples in which the particular observation did not appear. These are then plotted against the influence values. If useJ is TRUE then the influence values are found in the same way as the difference between the mean of the statistic in the samples excluding the observations and the mean in all samples. If useJ is FALSE then empirical influence values are calculated by calling empinf.

The resulting plots are useful diagnostic tools for looking at the way individual observations affect the bootstrap output.

The plot will consist of a number of horizontal dotted lines which correspond to the quantiles of the centred bootstrap distribution. For each data point the quantiles of the bootstrap distribution calculated by omitting that point are plotted against the (possibly standardized) jackknife values. The observation number is printed below the plots. To make it easier to see the effect of omitting points on quantiles, the plotted quantiles are joined by line segments. These plots provide a useful diagnostic tool in establishing the effect of individual observations on the bootstrap distribution. See the references below for some guidelines on the interpretation of the plots.

Value

There is no returned value but a plot is generated on the current graphics display.

Side Effects

A plot is created on the current graphics device.

---

**k3.linear**

*Linear Skewness Estimate*

**Description**

Estimates the skewness of a statistic from its empirical influence values.

**Usage**

k3.linear(L, strata=NULL)

**Arguments**

L

Vector of the empirical influence values of a statistic. These will usually be calculated by a call to `empinf`.

strata

A numeric vector or factor specifying which observations (and hence which components of L) come from which strata.

**Value**

The skewness estimate calculated from L.

**References**

**See Also**

`empinf`, `linear.approx`, `var.linear`
Examples

```r
# To estimate the skewness of the ratio of means for the city data.
ratio <- function(d,w)
  sum(d$x * w)/sum(d$u * w)
k3.linear(empinf(data=city,statistic=ratio))
```

linear.approx  

**Linear Approximation of Bootstrap Replicates**

Description

This function takes a bootstrap object and for each bootstrap replicate it calculates the linear approximation to the statistic of interest for that bootstrap sample.

Usage

```r
linear.approx(boot.out, L=NULL, index=1, type=NULL, t0=NULL, t=NULL, ...)
```

Arguments

- `boot.out`: An object of class "boot" representing a nonparametric bootstrap. It will usually be created by the function `boot`.
- `L`: A vector containing the empirical influence values for the statistic of interest. If it is not supplied then `L` is calculated through a call to `empinf`.
- `index`: The index of the variable of interest within the output of `boot.out$statistic`.
- `type`: This gives the type of empirical influence values to be calculated. It is not used if `L` is supplied. The possible types of empirical influence values are described in the helpfile for `empinf`.
- `t0`: The observed value of the statistic of interest. The input value is used only if one of `t` or `L` is also supplied. The default value is `boot.out$t0[index]`. If `t0` is supplied but neither `t` nor `L` are supplied then `t0` is set to `boot.out$t0[index]` and a warning is generated.
- `t`: A vector of bootstrap replicates of the statistic of interest. If `t0` is missing then `t` is not used, otherwise it is used to calculate the empirical influence values (if they are not supplied in `L`).
- `...`: Any extra arguments required by `boot.out$statistic`. These are needed if `L` is not supplied as they are used by `empinf` to calculate empirical influence values.

Details

The linear approximation to a bootstrap replicate with frequency vector `f` is given by `t0 + sum(L * f)/n` in the one sample with an easy extension to the stratified case. The frequencies are found by calling `boot.array`. 
**Value**

A vector of length \( \text{boot.out$R} \) with the linear approximations to the statistic of interest for each of the bootstrap samples.

**References**

**See Also**

`boot`, `empinf`, `control`

**Examples**

```r
# Using the city data let us look at the linear approximation to the
# ratio statistic and its logarithm. We compare these with the
# corresponding plots for the bigcity data

ratio <- function(d, w)
  sum(d$x * w) / sum(d$u * w)
city.boot <- boot(city, ratio, R=499, stype="w")
bigcity.boot <- boot(bigcity, ratio, R=499, stype="w")
par(pty="s")
par(mfrow=c(2,2))

# The first plot is for the city data ratio statistic.
city.lin1 <- linear.approx(city.boot)
lim <- range(c(city.boot$t, city.lin1))
plot(city.boot$t, city.lin1, xlim=lim, ylim=lim,
     main="Ratio; n=10", xlab="t *", ylab="tL *")
abline(0,1)

# Now for the log of the ratio statistic for the city data.
city.lin2 <- linear.approx(city.boot, t0=log(city.boot$t0),
                           t=log(city.boot$t))
lim <- range(c(log(city.boot$t), city.lin2))
plot(log(city.boot$t), city.lin2, xlim=lim, ylim=lim,
     main="Log(Ratio); n=10", xlab="t *", ylab="tL *")
abline(0,1)

# The ratio statistic for the bigcity data.
bigcity.lin1 <- linear.approx(bigcity.boot)
lim <- range(c(bigcity.boot$t, bigcity.lin1))
plot(bigcity.lin1,bigcity.boot$t, xlim=lim, ylim=lim,
     main="Ratio; n=49", xlab="t *", ylab="tL *")
abline(0,1)

# Finally the log of the ratio statistic for the bigcity data.
bigcity.lin2 <- linear.approx(bigcity.boot, t0=log(bigcity.boot$t0),
                           t=log(bigcity.boot$t))
lim <- range(c(log(bigcity.boot$t), bigcity.lin2))
plot(bigcity.lin2,log(bigcity.boot$t), xlim=lim, ylim=lim,
     main="Log(Ratio); n=49", xlab="t *", ylab="tL *")
abline(0,1)
```

par(mfrow=c(1,1))

lines.saddle.distn  Add a Saddlepoint Approximation to a Plot

Description

This function adds a line corresponding to a saddlepoint density or distribution function approximation to the current plot.

Usage

## S3 method for class 'saddle.distn':
lines(x, dens = TRUE, h = function(u) u, J = function(u) 1,
npts = 50, lty = 1, ...)

Arguments

x  An object of class "saddle.distn" (see saddle.distn.object representing a saddlepoint approximation to a distribution.

dens A logical variable indicating whether the saddlepoint density (TRUE; the default) or the saddlepoint distribution function (FALSE) should be plotted.

h  Any transformation of the variable that is required. Its first argument must be the value at which the approximation is being performed and the function must be vectorized.

J  When dens=TRUE this function specifies the Jacobian for any transformation that may be necessary. The first argument of J must the value at which the approximation is being performed and the function must be vectorized. If h is supplied J must also be supplied and both must have the same argument list.

npts  The number of points to be used for the plot. These points will be evenly spaced over the range of points used in finding the saddlepoint approximation.

lty  The line type to be used.

... Any additional arguments to h and J.

Details

The function uses smooth.spline to produce the saddlepoint curve. When dens=TRUE the spline is on the log scale and when dens=FALSE it is on the probit scale.

Value

sad.d is returned invisibly.

Side Effects

A line is added to the current plot.

References

logit

Description

This function calculates the logit of proportions.

Usage

logit(p)

Arguments

p

A numeric Splus object, all of whose values are in the range [0,1]. Missing values (NAs) are allowed.

Details

If any elements of p are outside the unit interval then an error message is generated. Values of p equal to 0 or 1 (to within machine precision) will return -Inf or Inf respectively. Any NAs in the input will also be NAs in the output.

Value

A numeric object of the same type as p containing the logits of the input values.

inv.logit
**Average Heights of the Rio Negro river at Manaus**

**Description**

The manaus time series is of class "ts" and has 1080 observations on one variable. The data values are monthly averages of the daily stages (heights) of the Rio Negro at Manaus. Manaus is 18km upstream from the confluence of the Rio Negro with the Amazon but because of the tiny slope of the water surface and the lower courses of its flatland affluents, they may be regarded as a good approximation of the water level in the Amazon at the confluence. The data here cover 90 years from January 1903 until December 1992.

The Manaus gauge is tied in with an arbitrary bench mark of 100m set in the steps of the Municipal Prefecture; gauge readings are usually referred to sea level, on the basis of a mark on the steps leading to the Parish Church (Matriz), which is assumed to lie at an altitude of 35.874 m according to observations made many years ago under the direction of Samuel Pereira, an engineer in charge of the Manaus Sanitation Committee. Whereas such an altitude cannot, by any means, be considered to be a precise datum point, observations have been provisionally referred to it. The measurements are in metres.

**Source**

The data were kindly made available by Professors H. O’Reilly Sternberg and D. R. Brillinger of the University of California at Berkeley.

**References**

**Survival from Malignant Melanoma**

**Description**

The melanoma data frame has 205 rows and 7 columns. The data consist of measurements made on patients with malignant melanoma. Each patient had their tumour removed by surgery at the Department of Plastic Surgery, University Hospital of Odense, Denmark during the period 1962 to 1977. The surgery consisted of complete removal of the tumour together with about 2.5cm of the surrounding skin. Among the measurements taken were the thickness of the tumour and whether it was ulcerated or not. These are thought to be important prognostic variables in that patients with a thick and/or ulcerated tumour have an increased chance of death from melanoma. Patients were followed until the end of 1977.
**Format**

This data frame contains the following columns:

- **time** Survival time in days since the operation, possibly censored.
- **status** The patients status at the end of the study. 1 indicates that they had died from melanoma, 2 indicates that they were still alive and 3 indicates that they had died from causes unrelated to their melanoma.
- **sex** The patients sex; 1=male, 2=female.
- **age** Age in years at the time of the operation.
- **year** Year of operation.
- **thickness** Tumour thickness in mm.
- **ulcer** Indicator of ulceration; 1=present, 0=absent.

**Note**

This dataset is not related to the dataset in the **lattice** package with the same name.

**Source**

The data were obtained from

**References**

---

**Description**

The **motor** data frame has 94 rows and 4 columns. The rows are obtained by removing replicate values of **time** from the dataset **mcycle**. Two extra columns are added to allow for strata with a different residual variance in each stratum.

**Usage**

**motor**
Format

This data frame contains the following columns:

- **times** The time in milliseconds since impact.
- **accel** The recorded head acceleration (in g).
- **strata** A numeric column indicating to which of the three strata (numbered 1, 2 and 3) the observations belong.
- **v** An estimate of the residual variance for the observation. **v** is constant within the strata but a different estimate is used for each of the three strata.

*Neurophysiological Point Process Data*

Description

**neuro** is a matrix containing times of observed firing of a neuron in windows of 250ms either side of the application of a stimulus to a human subject. Each row of the matrix is a replication of the experiment and there were a total of 469 replicates.

Note

There are a lot of missing values in the matrix as different numbers of firings were observed in different replicates. The number of firings observed varied from 2 to 6.

Source

The data were collected and kindly made available by Dr. S.J. Boniface of the Neurophysiology Unit at the Radcliffe Infirmary, Oxford.

References

Description

The nitrofen data frame has 50 rows and 5 columns.

Nitrofen is a herbicide that was used extensively for the control of broad-leaved and grass weeds in cereals and rice. Although it is relatively non-toxic to adult mammals, nitrofen is a significant tetrogenic and mutagen. It is also acutely toxic and reproductively toxic to cladoceran zooplankton. Nitrofen is no longer in commercial use in the U.S., having been the first pesticide to be withdrawn due to tetrogenic effects.

The data here come from an experiment to measure the reproductive toxicity of nitrofen on a species of zooplankton (*Ceriodaphnia dubia*). 50 animals were randomized into batches of 10 and each batch was put in a solution with a measured concentration of nitrofen. Then the number of live offspring in each of the three broods to each animal was recorded.

Usage

nitrofen

Format

This data frame contains the following columns:

- **conc**: The nitrofen concentration in the solution (mug/litre).
- **brood1**: The number of live offspring in the first brood.
- **brood2**: The number of live offspring in the second brood.
- **brood3**: The number of live offspring in the third brood.
- **total**: The total number of live offspring in the first three broods.

Description

The nodal data frame has 53 rows and 7 columns.

The treatment strategy for a patient diagnosed with cancer of the prostate depend highly on whether the cancer has spread to the surrounding lymph nodes. It is common to operate on the patient to get samples from the nodes which can then be analysed under a microscope but clearly it would be preferable if an accurate assessment of nodal involvement could be made without surgery.

For a sample of 53 prostate cancer patients, a number of possible predictor variables were measured before surgery. The patients then had surgery to determine nodal involvement. It was required to see if nodal involvement could be accurately predicted from the predictor variables and which ones were most important.

Usage

nodal

Format

This data frame contains the following columns:

- **m** A column of ones.
- **r** An indicator of nodal involvement.
- **aged** The patients age dichotomized into less than 60 (0) and 60 or over 1.
- **stage** A measurement of the size and position of the tumour observed by palpation with the fingers via the rectum. A value of 1 indicates a more serious case of the cancer.
- **grade** Another indicator of the seriousness of the cancer, this one is determined by a pathology reading of a biopsy taken by needle before surgery. A value of 1 indicates a more serious case of the cancer.
- **xray** A third measure of the seriousness of the cancer taken from an X-ray reading. A value of 1 indicates a more serious case of the cancer.
- **acid** The level of acid phosphatase in the blood serum.

Source

The data were obtained from

References

Description

Using the normal approximation to a statistic, calculate equi-tailed two-sided confidence intervals.

Usage

```r
norm.ci(boot.out=NULL, conf=0.95, index=1, var.t0=NULL,
t0=NULL, t=NULL, L=NULL, h=function(t) t,
hdot=function(t) 1, hinv=function(t) t)
```

Arguments

- **boot.out**: A bootstrap output object returned from a call to `boot`. If `t0` is missing then `boot.out` is a required argument. It is also required if both `var.t0` and `t` are missing.
- **conf**: A scalar or vector containing the confidence level(s) of the required interval(s).
- **index**: The index of the statistic of interest within the output of a call to `boot.out$statistic`. It is not used if `boot.out` is missing, in which case `t0` must be supplied.
- **var.t0**: The variance of the statistic of interest. If it is not supplied then `var(t)` is used.
- **t0**: The observed value of the statistic of interest. If it is missing then it is taken from `boot.out` which is required in that case.
- **t**: Bootstrap replicates of the variable of interest. These are used to estimate the variance of the statistic of interest if `var.t0` is not supplied. The default value is `boot.out$t[,index]`.
- **L**: The empirical influence values for the statistic of interest. These are used to calculate `var.t0` if neither `var.t0` nor `boot.out` are supplied. If a transformation is supplied through `h` then the influence values must be for the untransformed statistic `t0`.
- **h**: A function defining a monotonic transformation, the intervals are calculated on the scale of `h(t)` and the inverse function `hinv` is applied to the resulting intervals. `h` must be a function of one variable only and must be vectorized. The default is the identity function.
- **hdot**: A function of one argument returning the derivative of `h`. It is a required argument if `h` is supplied and is used for approximating the variance of `h(t0)`. The default is the constant function 1.
- **hinv**: A function, like `h`, which returns the inverse of `h`. It is used to transform the intervals calculated on the scale of `h(t)` back to the original scale. The default is the identity function. If `h` is supplied but `hinv` is not, then the intervals returned will be on the transformed scale.
Details

It is assumed that the statistic of interest has an approximately normal distribution with variance \( \text{var.t0} \) and so a confidence interval of length \( 2 \times qnorm((1+\text{conf})/2) \times \sqrt{\text{var.t0}} \) is found. If \( \text{boot.out} \) or \( t \) are supplied then the interval is bias-corrected using the bootstrap bias estimate, and so the interval would be centred at \( 2 \times t0 - \text{mean}(t) \). Otherwise the interval is centred at \( t0 \).

Value

If \( \text{length(\text{conf})} \) is 1 then a vector containing the confidence level and the endpoints of the interval is returned. Otherwise, the returned value is a matrix where each row corresponds to a different confidence level.

Note

This function is primarily designed to be called by \texttt{boot.ci} to calculate the normal approximation after a bootstrap but it can also be used without doing any bootstrap calculations as long as \( t0 \) and \( \text{var.t0} \) can be supplied. See the examples below.

nuclear  

Nuclear Power Station Construction Data
Description

The `nuclear` data frame has 32 rows and 11 columns.

The data relate to the construction of 32 light water reactor (LWR) plants constructed in the U.S.A in the late 1960's and early 1970's. The data was collected with the aim of predicting the cost of construction of further LWR plants. 6 of the power plants had partial turnkey guarantees and it is possible that, for these plants, some manufacturers' subsidies may be hidden in the quoted capital costs.

Usage

`nuclear`

Format

This data frame contains the following columns:

- **cost**: The capital cost of construction in millions of dollars adjusted to 1976 base.
- **date**: The date on which the construction permit was issued. The data are measured in years since January 1 1990 to the nearest month.
- **t1**: The time between application for and issue of the construction permit.
- **t2**: The time between issue of operating license and construction permit.
- **cap**: The net capacity of the power plant (MWe).
- **pr**: A binary variable where 1 indicates the prior existence of a LWR plant at the same site.
- **ne**: A binary variable where 1 indicates that the plant was constructed in the north-east region of the U.S.A.
- **ct**: A binary variable where 1 indicates the use of a cooling tower in the plant.
- **bw**: A binary variable where 1 indicates that the nuclear steam supply system was manufactured by Babcock-Wilcox.
- **cum.n**: The cumulative number of power plants constructed by each architect-engineer.
- **pt**: A binary variable where 1 indicates those plants with partial turnkey guarantees.

Neurotransmission in Guinea Pig Brains

Description

The paulsen data frame has 346 rows and 1 columns.
Sections were prepared from the brain of adult guinea pigs. Spontaneous currents that flowed into individual brain cells were then recorded and the peak amplitude of each current measured. The aim of the experiment was to see if the current flow was quantal in nature (i.e. that it is not a single burst but instead is built up of many smaller bursts of current). If the current was indeed quantal then it would be expected that the distribution of the current amplitude would be multimodal with modes at regular intervals. The modes would be expected to decrease in magnitude for higher current amplitudes.

Usage

paulsen

Format

This data frame contains the following column:

y  The current flowing into individual brain cells. The currents are measured in pico-amperes.

Source

The data were kindly made available by Dr. O. Paulsen from the Department of Pharmacology at the University of Oxford.

References

plot.boot  Plots of the Output of a Bootstrap Simulation

Description

This takes a bootstrap object and produces plots for the bootstrap replicates of the variable of interest.

Usage

## S3 method for class 'boot':
plot(x, index=1, t0=NULL, t=NULL, jack=FALSE, qdist="norm",
    nclass=NULL, df, ...)
Arguments

x  An object of class "boot" returned from one of the bootstrap generation functions.

index  The index of the variable of interest within the output of boot.out. This is ignored if t and t0 are supplied.

t0  The original value of the statistic. This defaults to boot.out$t0[index] unless t is supplied when it defaults to NULL. In that case no vertical line is drawn on the histogram.

t  The bootstrap replicates of the statistic. Usually this will take on its default value of boot.out$t[,index], however it may be useful sometimes to supply a different set of values which are a function of boot.out$t.

jack  A logical value indicating whether a jackknife-after-bootstrap plot is required. The default is not to produce such a plot.

qdist  The distribution against which the Q-Q plot should be drawn. At present "norm" (normal distribution - the default) and "chisq" (chi-squared distribution) are the only possible values.

nclass  An integer giving the number of classes to be used in the bootstrap histogram. The default is the integer between 10 and 100 closest to ceiling(length(t)/25).

df  If qdist is "chisq" then this is the degrees of freedom for the chi-squared distribution to be used. It is a required argument in that case.

...  When jack is TRUE additional parameters to jack.after.boot can be supplied. See the help file for jack.after.boot for details of the possible parameters.

Details

This function will generally produce two side-by-side plots. The left plot will be a histogram of the bootstrap replicates. Usually the breaks of the histogram will be chosen so that t0 is at a breakpoint and all intervals are of equal length. A vertical dotted line indicates the position of t0. This cannot be done if t is supplied but t0 is not and so, in that case, the breakpoints are computed by hist using the nclass argument and no vertical line is drawn.

The second plot is a Q-Q plot of the bootstrap replicates. The order statistics of the replicates can be plotted against normal or chi-squared quantiles. In either case the expected line is also plotted. For the normal, this will have intercept mean(t) and slope sqrt(var(t)) while for the chi-squared it has intercept 0 and slope 1.

If jack is TRUE a third plot is produced beneath these two. That plot is the jackknife-after-bootstrap plot. This plot may only be requested when nonparametric simulation has been used. See jack.after.boot for further details of this plot.

Value

boot.out is returned invisibly.

Side Effects

All screens are closed and cleared and a number of plots are produced on the current graphics device. Screens are closed but not cleared at termination of this function.

**print.boot**  

**Print a Summary of a Bootstrap Object**

**Description**

This is a method for the function print for objects of the class "boot".

**Usage**

```r
## S3 method for class 'boot':
print(x, digits = getOption("digits"),
       index = 1:ncol(boot.out$t), ...)
```
print.bootci

Arguments

  x A bootstrap output object of class "boot" generated by one of the bootstrap functions.

  digits The number of digits to be printed in the summary statistics.

  index Indices indicating for which elements of the bootstrap output summary statistics are required.

  ... further arguments passed to or from other methods.

Details

For each statistic calculated in the bootstrap the original value and the bootstrap estimates of its bias and standard error are printed. If `boot.out$t0` is missing (such as when it was created by a call to `tsboot` with `orig.t=FALSE`) the bootstrap mean and standard error are printed. If resampling was done using importance resampling weights, then the bootstrap estimates are reweighted as if uniform resampling had been done. The ratio importance sampling estimates are used and if there were a number of distributions then defensive mixture distributions are used. In this case an extra column with the mean of the observed bootstrap statistics is also printed.

Value

The bootstrap object is returned invisibly.

See Also

  `boot`, `censboot`, `imp.moments`, `plot.boot`, `tilt.boot`, `tsboot`

---

Description

This is a method for the function `print()` to print objects of the class "bootci".

Usage

```r
## S3 method for class 'bootci':
print(x, hinv = NULL, ...)
```

Arguments

  x The output from a call to `boot.ci`.

  hinv A transformation to be made to the interval end-points before they are printed.

  ... further arguments passed to or from other methods.
print.saddle.distn

Details
This function prints out the results from boot.ci in a "nice" format. It also notes whether the scale of the intervals is the original scale of the input to boot.ci or a different scale and whether the calculations were done on a transformed scale. It also looks at the order statistics that were used in calculating the intervals. If the smallest or largest values were used then it prints a message

Warning : Intervals used Extreme Quantiles
Such intervals should be considered very unstable and not relied upon for inferences. Even if the extreme values are not used, it is possible that the intervals are unstable if they used quantiles close to the extreme values. The function alerts the user to intervals which use the upper or lower 10 order statistics with the message

Some intervals may be unstable

Value
The object ci.out is returned invisibly.

See Also
boot.ci

print.saddle.distn  Print Quantiles of Saddlepoint Approximations

Description
This is a method for the function print() to print objects of class "saddle.distn".

Usage
## S3 method for class 'saddle.distn':
print(x, ...)

Arguments
x  An object of class "saddle.distn" created by a call to saddle.distn.
...  further arguments passed to or from other methods.

Details
The quantiles of the saddlepoint approximation to the distribution are printed along with the original call and some other useful information.

Value
The input is returned invisibly.

See Also
lines.saddle.distn, saddle.distn
Description

This is a method for the function `print()` to print objects of class "simplex".

Usage

```r
## S3 method for class 'simplex':
print(x, ...)  
```

Arguments

- `x`: An object of class "simplex" created by calling the function `simplex` to solve a linear programming problem.
- `...`: Further arguments passed to or from other methods.

Details

The coefficients of the objective function are printed. If a solution to the linear programming problem was found then the solution and the optimal value of the objective function are printed. If a feasible solution was found but the maximum number of iterations was exceeded then the last feasible solution and the objective function value at that point are printed. If no feasible solution could be found then a message stating that is printed.

Value

- `x` is returned silently.

saddle

**Saddlepoint Approximations for Bootstrap Statistics**

Description

This function calculates a saddlepoint approximation to the distribution of a linear combination of \( W \) at a particular point \( u \), where \( W \) is a vector of random variables. The distribution of \( W \) may be multinomial (default), Poisson or binary. Other distributions are possible also if the adjusted cumulant generating function and its second derivative are given. Conditional saddlepoint approximations to the distribution of one linear combination given the values of other linear combinations of \( W \) can be calculated for \( W \) having binary or Poisson distributions.

Usage

```
saddle(A=NULL, u=NULL, wdist="m", type="simp", d=NULL, d1=1, init=rep(0.1, d), mu=rep(0.5, n), LR=FALSE, strata=NULL, K.adj=NULL, K2=NULL)
```

Arguments

- **A**: A vector or matrix of known coefficients of the linear combinations of \( W \). It is a required argument unless \( K.\text{adj} \) and \( K2 \) are supplied, in which case it is ignored.
- **u**: The value at which it is desired to calculate the saddlepoint approximation to the distribution of the linear combination of \( W \). It is a required argument unless \( K.\text{adj} \) and \( K2 \) are supplied, in which case it is ignored.
- **wdist**: The distribution of \( W \). This can be one of "m" (multinomial), "p" (Poisson), "b" (binary) or "o" (other). If \( K.\text{adj} \) and \( K2 \) are given \( wdist \) is set to "o".
- **type**: The type of saddlepoint approximation. Possible types are "simp" for simple saddlepoint and "cond" for the conditional saddlepoint. When \( wdist \) is "o" or "m", \( \text{type} \) is automatically set to "simp", which is the only type of saddlepoint currently implemented for those distributions.
This specifies the dimension of the whole statistic. This argument is required only when \texttt{wdist}="c" and defaults to 1 if not supplied in that case. For other distributions it is set to \texttt{ncol(A)}.

\texttt{d1}

When \texttt{type} is "cond" this is the dimension of the statistic of interest which must be less than \texttt{length(u)}. Then the saddlepoint approximation to the conditional distribution of the first \texttt{d1} linear combinations given the values of the remaining combinations is found. Conditional distribution function approximations can only be found if the value of \texttt{d1} is 1.

\texttt{init}

Used if \texttt{wdist} is either "m" or "o", this gives initial values to \texttt{nlmin} which is used to solve the saddlepoint equation.

\texttt{mu}

The values of the parameters of the distribution of \texttt{W} when \texttt{wdist} is "m", "p" or "b". \texttt{mu} must be of the same length as \texttt{W} (i.e. \texttt{ncol(A)}). The default is that all values of \texttt{mu} are equal and so the elements of \texttt{W} are identically distributed.

\texttt{LR}

If \texttt{TRUE} then the Lugananni-Rice approximation to the cdf is used, otherwise the approximation used is based on Barndorff-Nielsen's \texttt{r*}.

\texttt{strata}

The strata for stratified data.

\texttt{K.adj}

The adjusted cumulant generating function used when \texttt{wdist} is "o". This is a function of a single parameter, \texttt{zeta}, which calculates \( K(zeta) - u \% \%* \% zeta \), where \( K(zeta) \) is the cumulant generating function of \( W \).

\texttt{K2}

This is a function of a single parameter \texttt{zeta} which returns the matrix of second derivatives of \( K(zeta) \) for use when \texttt{wdist} is "o". If \texttt{K.adj} is given then this must be given also. It is called only once with the calculated solution to the saddlepoint equation being passed as the argument. This argument is ignored if \texttt{K.adj} is not supplied.

Details

If \texttt{wdist} is "o" or "m", the saddlepoint equations are solved using \texttt{nlmin} to minimize \texttt{K.adj} with respect to its parameter \texttt{zeta}. For the Poisson and binary cases, a generalized linear model is fitted such that the parameter estimates solve the saddlepoint equations. The response variable 'y' for the \texttt{glm} must satisfy the equation \( t(A) \% \%* \% y = u \) (t() being the transpose function). Such a vector can be found as a feasible solution to a linear programming problem. This is done by a call to \texttt{simplex}. The covariate matrix for the \texttt{glm} is given by \texttt{A}.

Value

A list consisting of the following components

\texttt{spa}

The saddlepoint approximations. The first value is the density approximation and the second value is the distribution function approximation.

\texttt{zeta.hat}

The solution to the saddlepoint equation. For the conditional saddlepoint this is the solution to the saddlepoint equation for the numerator.

\texttt{zeta2.hat}

If \texttt{type} is "cond" this is the solution to the saddlepoint equation for the denominator. This component is not returned for any other value of \texttt{type}.

Examples

```r
# To evaluate the bootstrap distribution of the mean failure time of
# air-conditioning equipment at 80 hours
saddle(A=aircondit$hours/12, u=80)

# Alternatively this can be done using a conditional poisson
saddle(A=cbind(aircondit$hours/12,1), u=c(80,12), wdist="p", type="cond")

# To use the Lugananni-Rice approximation to this
saddle(A=cbind(aircondit$hours/12,1), u=c(80,12), wdist="p", type="cond",
       LR = TRUE)

# Example 9.16 of Davison and Hinkley (1997) calculates saddlepoint
# approximations to the distribution of the ratio statistic for the
# city data. Since the statistic is not in itself a linear combination
# of random Variables, its distribution cannot be found directly.
# Instead the statistic is expressed as the solution to a linear
# estimating equation and hence its distribution can be found. We
# get the saddlepoint approximation to the pdf and cdf evaluated at
# t=1.25 as follows.
jacobian <- function(dat,t,zeta)
{  p <- exp(zeta *(dat$x-t*dat$u))
    abs(sum(dat$u*p)/sum(p))
}
city.sp1 <- saddle(A=city$x-1.25 *city$u, u=0)
city.sp1$spa[1] <- jacobian(city, 1.25, city.sp1$zeta.hat) * city.sp1$spa[1]
city.sp1
```

`saddle.distn`  
*Saddlepoint Distribution Approximations for Bootstrap Statistics*

Description

Approximate an entire distribution using saddlepoint methods. This function can calculate simple and conditional saddlepoint distribution approximations for a univariate quantity of interest. For the simple saddlepoint the quantity of interest is a linear combination of $W$ where $W$ is a vector of random variables. For the conditional saddlepoint we require the distribution of one linear combination given the values of any number of other linear combinations. The distribution of $W$ must be one of multinomial, Poisson or binary. The primary use of this function is to calculate quantiles of bootstrap distributions using saddlepoint approximations. Such quantiles are required by the library function `control` to approximate the distribution of the linear approximation to a statistic.
saddle.distn

Usage

saddle.distn(A, u=NULL, alpha=NULL, wdist="m",
    type="simp", npts=20, t=NULL, t0=NULL,
    init=rep(0.1, d), mu=rep(0.5, n), LR=FALSE,
    strata=NULL, ...)

Arguments

A
This is a matrix of known coefficients or a function which returns such a matrix. If a function then its first argument must be the point \( t \) at which a saddlepoint is required. The most common reason for \( A \) being a function would be if the statistic is not itself a linear combination of the \( W \) but is the solution to a linear estimating equation.

u
If \( A \) is a function then \( u \) must also be a function returning a vector with length equal to the number of columns of the matrix returned by \( A \). Usually all components other than the first will be constants as the other components are the values of the conditioning variables. If \( A \) is a matrix with more than one column (such as when \( wdist="cond" \)) then \( u \) should be a vector with length one less than \( ncol(A) \). In this case \( u \) specifies the values of the conditioning variables. If \( A \) is a matrix with one column or a vector then \( u \) is not used.

alpha
The alpha levels for the quantiles of the distribution which should be returned. By default the 0.1, 0.5, 1, 2.5, 5, 10, 20, 50, 80, 90, 95, 97.5, 99, 99.5 and 99.9 percentiles are calculated.

wdist
The distribution of \( W \). Possible values are "m" (multinomial), "p" (Poisson), or "b" (binary).

type
The type of saddlepoint to be used. Possible values are "simp" (simple saddlepoint) and "cond" (conditional). If \( wdist="m", type \) is set to "simp".

npts
The number of points at which the saddlepoint approximation should be calculated and then used to fit the spline.

t
A vector of points at which the saddlepoint approximations are calculated. These points should extend beyond the extreme quantiles required but still be in the possible range of the bootstrap distribution. The observed value of the statistic should not be included in \( t \) as the distribution function approximation breaks down at that point. The points should, however, cover the entire effective range of the distribution including close to the centre. If \( t \) is supplied then \( npts \) is set to \( length(t) \). When \( t \) is not supplied, the function attempts to find the effective range of the distribution and then selects points to cover this range.

t0
If \( t \) is not supplied then a vector of length 2 should be passed as \( t0 \). The first component of \( t0 \) should be the centre of the distribution and the second should be an estimate of spread (such as a standard error). These two are then used to find the effective range of the distribution. The range finding mechanism does rely on an accurate estimate of location in \( t0[1] \).

init
When \( wdist="m", \) this vector should contain the initial values to be passed to \( nlmin \) when it is called to solve the saddlepoint equations.

mu
The vector of parameter values for the distribution. The default is that the components of \( W \) are identically distributed.

LR
A logical flag. When \( LR \) is TRUE the Lugananini-Rice cdf approximations are calculated and used to fit the spline. Otherwise the cdf approximations used are based on Barndorff-Nielsen’s \( r^* \).
strata  A vector giving the strata when the rows of A relate to stratified data. This is used only when wdist is "m".

... When A and u are functions any additional arguments are passed unchanged each time one of them is called.

Details

The range at which the saddlepoint is used is such that the cdf approximation at the endpoints is more extreme than required by the extreme values of alpha. The lower endpoint is found by evaluating the saddlepoint at the points \( t0[1] - 2 \times t0[2], t0[1] - 4 \times t0[2], t0[1] - 8 \times t0[2] \) etc. until a point is found with a cdf approximation less than \( \min(alpha)/10 \). Then a bisection method is used to find the endpoint which has cdf approximation in the range \( (\min(alpha)/1000, \min(alpha)/10) \). Then a number of, equally spaced, points are chosen between the lower endpoint and \( t0[1] \) until a total of \( npts/2 \) approximations have been made. The remaining \( npts/2 \) points are chosen to the right of \( t0[1] \) in a similar manner. Any points which are very close to the centre of the distribution are then omitted as the cdf approximations are not reliable at the centre. A smoothing spline is then fitted to the probit of the saddlepoint distribution function approximations at the remaining points and the required quantiles are predicted from the spline.

Sometimes the function will terminate with the message "Unable to find range". There are two main reasons why this may occur. One is that the distribution is too discrete and/or the required quantiles too extreme, this can cause the function to be unable to find a point within the allowable range which is beyond the extreme quantiles. Another possibility is that the value of \( t0[2] \) is too small and so too many steps are required to find the range. The first problem cannot be solved except by asking for less extreme quantiles, although for very discrete distributions the approximations may not be very good. In the second case using a larger value of \( t0[2] \) will usually solve the problem.

Value

The returned value is an object of class "saddle.distn". See the help file for saddle.distn.object for a description of such an object.

### Saddlepoint Distribution Approximation Objects

#### Description

Class of objects that result from calculating saddlepoint distribution approximations by a call to `saddle.distn`.

#### Generation

This class of objects is returned from calls to the function `saddle.distn`.

#### Methods

The class "saddle.distn" has methods for the functions `lines` and `print`.

#### Structure

Objects of class "saddle.distn" are implemented as a list with the following components.

- **quantiles**: A matrix with 2 columns. The first column contains the probabilities alpha and the second column contains the estimated quantiles of the distribution at those probabilities derived from the spline.

- **points**: A matrix of evaluations of the saddlepoint approximation. The first column contains the values of t which were used, the second and third contain the density and cdf approximations at those points and the rest of the columns contain the solutions to the saddlepoint equations. When `type` is "simp", there is only one of those. When `type` is "cond" there are 2*d-1 where d is the
number of columns in \( A \) or the output of \( A(t, \ldots()) \). The first \( d \) of these correspond to the numerator and the remainder correspond to the denominator.

distn  An object of class \texttt{smooth.spline}. This corresponds to the spline fitted to the saddlepoint cdf approximations in points in order to approximate the entire distribution. For the structure of the object see \texttt{smooth.spline}.

call  The original call to \texttt{saddle.distn} which generated the object.

LR  A logical variable indicating whether the Lugananni-Rice approximations were used.

**salinity**  
*Water Salinity and River Discharge*

**Description**

The \texttt{salinity} data frame has 28 rows and 4 columns.

Biweekly averages of the water salinity and river discharge in Pamlico Sound, North Carolina were recorded between the years 1972 and 1977. The data in this set consists only of those measurements in March, April and May.

**Usage**

\texttt{salinity}

**Format**

This data frame contains the following columns:

- \texttt{sal}  The average salinity of the water over two weeks.
- \texttt{lag}  The average salinity of the water lagged two weeks. Since only spring is used, the value of \texttt{lag} is not always equal to the previous value of \texttt{sal}.
- \texttt{trend}  A factor indicating in which of the 6 biweekly periods between March and May, the observations were taken. The levels of the factor are from 0 to 5 with 0 being the first two weeks in March.
- \texttt{dis}  The amount of river discharge during the two weeks for which \texttt{sal} is the average salinity.

**Source**

The data were obtained from

**References**

**Description**

This function will optimize the linear function $a \times x$ subject to the constraints $A_1 \times x \leq b_1$, $A_2 \times x \geq b_2$, $A_3 \times x = b_3$ and $x \geq 0$. Either maximization or minimization is possible but the default is minimization.

**Usage**

```r
simplex(a, A1 = NULL, b1 = NULL, A2 = NULL, b2 = NULL, A3 = NULL, b3 = NULL, maxi = FALSE, n.iter = n + 2 * m, eps = 1e-10)
```

**Arguments**

- **a**: A vector of length $n$ which gives the coefficients of the objective function.
- **A1**: An $m_1$ by $n$ matrix of coefficients for the "$\leq$" type of constraints.
- **b1**: A vector of length $m_1$ giving the right hand side of the "$\leq$" constraints. This argument is required if $A1$ is given and ignored otherwise. All values in $b1$ must be non-negative.
- **A2**: An $m_2$ by $n$ matrix of coefficients for the "$\geq$" type of constraints.
- **b2**: A vector of length $m_2$ giving the right hand side of the "$\geq$" constraints. This argument is required if $A2$ is given and ignored otherwise. All values in $b2$ must be non-negative. Note that the constraints $x \geq 0$ are included automatically and so should not be repeated here.
- **A3**: An $m_3$ by $n$ matrix of coefficients for the equality constraints.
- **b3**: A vector of length $m_3$ giving the right hand side of equality constraints. This argument is required if $A3$ is given and ignored otherwise. All values in $b3$ must be non-negative.
- **maxi**: A logical flag which specifies minimization if FALSE (default) and maximization otherwise. If maxi is TRUE then the maximization problem is recast as a minimization problem by changing the objective function coefficients to their negatives.
- **n.iter**: The maximum number of iterations to be conducted in each phase of the simplex method. The default is $n + 2 * (m_1 + m_2 + m_3)$.
- **eps**: The floating point tolerance to be used in tests of equality.

**Details**

The method employed by this function is the two phase tableau simplex method. If there are "$\geq$" or equality constraints an initial feasible solution is not easy to find. To find a feasible solution an artificial variable is introduced into each "$\geq$" or equality constraint and an auxiliary objective function is defined as the sum of these artificial variables. If a feasible solution to the set of constraints exists then the auxiliary objective will be minimized when all of the artificial variables are 0. These are then discarded and the original problem solved starting at the solution to the auxiliary problem. If the only constraints are of the "$\leq$" form, the origin is a feasible solution and so the first stage can be omitted.
Value

An object of class "simplex": see \texttt{simplex.object}.

Note

The method employed here is suitable only for relatively small systems. Also if possible the number of constraints should be reduced to a minimum in order to speed up the execution time which is approximately proportional to the cube of the number of constraints. In particular if there are any constraints of the form $x[i] \geq b2[i]$ they should be omitted by setting $x[i] = x[i] - b2[i]$, changing all the constraints and the objective function accordingly and then transforming back after the solution has been found.

\end{verbatim}

\texttt{simplex.object} \hspace{1cm} \textit{Linear Programming Solution Objects}

Description

Class of objects that result from solving a linear programming problem using \texttt{simplex}.

Generation

This class of objects is returned from calls to the function \texttt{simplex}.

Methods

The class "\texttt{saddle.distn}" has a method for the function \texttt{print}.  

\texttt{simplex.object}
Structure

Objects of class "simplex" are implemented as a list with the following components.

- **soln**: The values of \( x \) which optimize the objective function under the specified constraints provided those constraints are jointly feasible.

- **solved**: This indicates whether the problem was solved. A value of \(-1\) indicates that no feasible solution could be found. A value of \(0\) that the maximum number of iterations was reached without termination of the second stage. This may indicate an unbounded function or simply that more iterations are needed. A value of \(1\) indicates that an optimal solution has been found.

- **value**: The value of the objective function at soln.

- **val.aux**: This is NULL if a feasible solution is found. Otherwise it is a positive value giving the value of the auxiliary objective function when it was minimized.

- **obj**: The original coefficients of the objective function.

- **a**: The objective function coefficients re-expressed such that the basic variables have coefficient zero.

- **a.aux**: This is NULL if a feasible solution is found. Otherwise it is the re-expressed auxiliary objective function at the termination of the first phase of the simplex method.

- **A**: The final constraint matrix which is expressed in terms of the non-basic variables. If a feasible solution is found then this will have dimensions \(m1+m2+m3\) by \(n+m1+m2\), where the final \(m1+m2\) columns correspond to slack and surplus variables. If no feasible solution is found there will be an additional \(m1+m2+m3\) columns for the artificial variables introduced to solve the first phase of the problem.

- **basic**: The indices of the basic (non-zero) variables in the solution. Indices between \(n+1\) and \(n+m1\) correspond to slack variables, those between \(n+m1+1\) and \(n+m2\) correspond to surplus variables and those greater than \(n+m2\) are artificial variables. Indices greater than \(n+m2\) should occur only if solved is \(-1\) as the artificial variables are discarded in the second stage of the simplex method.

- **slack**: The final values of the \(m1\) slack variables which arise when the "\(<=\)" constraints are re-expressed as the equalities \(A1\%*%x + \text{slack} = b1\).

- **surplus**: The final values of the \(m2\) surplus variables which arise when the "\(<=\)" constraints are re-expressed as the equalities \(A2\%*%x - \text{surplus} = b2\).

- **artificial**: This is NULL if a feasible solution can be found. If no solution can be found then this contains the values of the \(m1+m2+m3\) artificial variables which minimize their sum subject to the original constraints. A feasible solution exists only if all of the artificial variables can be made \(0\) simultaneously.

print.simplex, simplex
Smooth Distributions on Data Points

Description

This function uses the method of frequency smoothing to find a distribution on a data set which has a required value, \( \theta \), of the statistic of interest. The method results in distributions which vary smoothly with \( \theta \).

Usage

\[
\text{smooth.f}(\theta, \text{boot.out}, \text{index}=1, t=\text{boot.out}\$t[, \text{index}], \text{width}=0.5)
\]

Arguments

- \( \theta \): The required value for the statistic of interest. If \( \theta \) is a vector, a separate distribution will be found for each element of \( \theta \).
- \( \text{boot.out} \): A bootstrap output object returned by a call to \text{boot}.
- \( \text{index} \): The index of the variable of interest in the output of \text{boot.out}\$statistic. This argument is ignored if \( t \) is supplied. \( \text{index} \) must be a scalar.
- \( t \): The bootstrap values of the statistic of interest. This must be a vector of length \( \text{boot.out}\$R \) and the values must be in the same order as the bootstrap replicates in \text{boot.out}.
- \( \text{width} \): The standardized width for the kernel smoothing. The smoothing uses a value of \( \text{width} \times s \) for \( \epsilon \), where \( s \) is the bootstrap estimate of the standard error of the statistic of interest. \( \text{width} \) should take a value in the range (0.2, 1) to produce a reasonable smoothed distribution. If \( \text{width} \) is too large then the distribution becomes closer to uniform.

Details

The new distributional weights are found by applying a normal kernel smoother to the observed values of \( t \) weighted by the observed frequencies in the bootstrap simulation. The resulting distribution may not have parameter value exactly equal to the required value \( \theta \) but it will typically have a value which is close to \( \theta \). The details of how this method works can be found in Davison, Hinkley and Worton (1995) and Section 3.9.2 of Davison and Hinkley (1997).

Value

If \( \text{length}(\theta) \) is 1 then a vector with the same length as the data set \( \text{boot.out}\$data \) is returned. The value in position \( i \) is the probability to be given to the data point in position \( i \) so that the distribution has parameter value approximately equal to \( \theta \). If \( \text{length}(\theta) \) is bigger than 1 then the returned value is a matrix with \( \text{length}(\theta) \) rows each of which corresponds to a distribution with the parameter value approximately equal to the corresponding value of \( \theta \).

  d <- dat[, 1]
  ns <- tabulate(strata)
  w <- w/tapply(w, strata, sum)[strata]
  mns <- tapply(d * w, strata, sum)
  mn2 <- tapply(d * d * w, strata, sum)
  s2hat <- sum((mn2 - mns^2)/ns)
  c(mns[2]-mns[1], s2hat, (mns[2]-mns[1]-orig)/sqrt(s2hat))
}
grav.z0 <- grav.fun(grav1,rep(1,26),0)
grav.boot <- boot(grav1, grav.fun, R=499, stype="w",
  strata=grav1[,2], orig=grav.z0[1])
grav.sm <- smooth.f(grav.z0[3], grav.boot, index=3)
# Now we can run another bootstrap using these weights
grav.boot2 <- boot(grav1, grav.fun, R=499, stype="w",
  strata=grav1[,2], orig=grav.z0[1],
  weights=grav.sm)
# Estimated p-values can be found from these as follows
mean(grav.boot$t[,3] >= grav.z0[3])
imp.prob(grav.boot2,t0=-grav.z0[3],t=-grav.boot2$t[,3])
# Note that for the importance sampling probability we must multiply everything by -1 to ensure that we find the correct probability. Raw resampling is not reliable for probabilities greater than 0.5. Thus
1-imp.prob(grav.boot2,index=3,t0=grav.z0[3])$raw
# can give very strange results (negative probabilities).
```

sunspot  

Annual Mean Sunspot Numbers
Description

sunspot is a time series of class "rts" and contains 289 observations.

The Zurich sunspot numbers have been analyzed in almost all books on time series analysis as well as numerous papers. The data set, usually attributed to Rudolf Wolf, consists of means of daily relative numbers of sunspot sightings. The relative number for a day is given by k(f+10g) where g is the number of sunspot groups observed, f is the total number of spots within the groups and k is a scaling factor relating the observer and telescope to a baseline. The relative numbers are then averaged to give an annual figure. See Inzenman (1983) for a discussion of the relative numbers. The figures are for the years 1700-1988.

Note

These data are not related to dataset of the same name in the trellis library. They are, however, similar to the S-Plus dataset sunspots except that this set contains annual averages instead of monthly averages and it is for a longer period of time.

tau                    Tau Particle Decay Modes

Description
The tau data frame has 60 rows and 2 columns.

The tau particle is a heavy electron-like particle discovered in the 1970’s by Martin Perl at the Stanford Linear Accelerator Center. Soon after its production the tau particle decays into various collections of more stable particles. About 86% of the time the decay involves just one charged particle. This rate has been measured independently 13 times.

The one-charged-particle event is made up of four major modes of decay as well as a collection of other events. The four main types of decay are denoted rho, pi, e and mu. These rates have been measured independently 6, 7, 14 and 19 times respectively. Due to physical constraints each experiment can only estimate the composite one-charged-particle decay rate or the rate of one of the major modes of decay.

Each experiment consists of a major research project involving many years work. One of the goals of the experiments was to estimate the rate of decay due to events other than the four main modes of decay. These are uncertain events and so cannot themselves be observed directly.

Usage
tau

Format
This data frame contains the following columns:

*rate* The decay rate expressed as a percentage.

*decay* The type of decay measured in the experiment. It is a factor with levels rho, pi, e and mu.

tilt.boot

Non-parametric Tilted Bootstrap

Description

This function will run an initial bootstrap with equal resampling probabilities (if required) and will use the output of the initial run to find resampling probabilities which put the value of the statistic at required values. It then runs an importance resampling bootstrap using the calculated probabilities as the resampling distribution.

Usage

```r
tilt.boot(data, statistic, R, sim="ordinary", stype="i",
strata=rep(1, n), L=NULL, theta=NULL,
alpha=c(0.025, 0.975), tilt=TRUE, width=0.5,
index=1, ...)
```

Arguments

- **data**
  The data as a vector, matrix or data frame. If it is a matrix or data frame then each row is considered as one (multivariate) observation.

- **statistic**
  A function which when applied to data returns a vector containing the statistic(s) of interest. It must take at least two arguments. The first argument will always be `data` and the second should be a vector of indices, weights or frequencies describing the bootstrap sample. Any other arguments must be supplied to `tilt.boot` and will be passed unchanged to statistic each time it is called.

- **R**
  The number of bootstrap replicates required. This will generally be a vector, the first value stating how many uniform bootstrap simulations are to be performed at the initial stage. The remaining values of `R` are the number of simulations to be performed resampling from each reweighted distribution. The first value of `R` must always be present, a value of 0 implying that no uniform resampling is to be carried out. Thus `length(R)` should always equal `l+length(theta)`.

- **sim**
  This is a character string indicating the type of bootstrap simulation required. There are only two possible values that this can take: "ordinary" and "balanced". If other simulation types are required for the initial un-weighted bootstrap then it will be necessary to run `boot`, calculate the weights appropriately, and run `boot` again using the calculated weights.

- **stype**
  A character string indicating the type of second argument expected by `statistic`. The possible values that `stype` can take are "i" (indices), "w" (weights) and "f" (frequencies).

- **strata**
  An integer vector or factor representing the strata for multi-sample problems.
The empirical influence values for the statistic of interest. They are used only for exponential tilting when tilt is TRUE. If tilt is TRUE and they are not supplied then tilt.boot uses empinf to calculate them.

theta

The required parameter value(s) for the tilted distribution(s). There should be one value of theta for each of the non-uniform distributions. If R[1] is 0 theta is a required argument. Otherwise theta values can be estimated from the initial uniform bootstrap and the values in alpha.

alpha

The alpha level to which tilting is required. This parameter is ignored if R[1] is 0 or if theta is supplied, otherwise it is used to find the values of theta as quantiles of the initial uniform bootstrap. In this case R[1] should be large enough that min(c(alpha, 1-alpha)) * R[1] > 5, if this is not the case then a warning is generated to the effect that the theta are extreme values and so the tilted output may be unreliable.

tilt

A logical variable which if TRUE (the default) indicates that exponential tilting should be used, otherwise local frequency smoothing (smooth.f) is used. If tilt is FALSE then R[1] must be positive. In fact in this case the value of R[1] should be fairly large (in the region of 500 or more).

width

This argument is used only if tilt is FALSE, in which case it is passed unchanged to smooth.f as the standardized bandwidth for the smoothing operation. The value should generally be in the range (0.2, 1). See smooth.f for more details.

index

The index of the statistic of interest in the output from statistic. By default the first element of the output of statistic is used.

... Any additional arguments required by statistic. These are passed unchanged to statistic each time it is called.

Value

An object of class "boot" with the following components

t0

The observed value of the statistic on the original data.

t

The values of the bootstrap replicates of the statistic. There will be sum(R) of these, the first R[1] corresponding to the uniform bootstrap and the remainder to the tilted bootstrap(s).

R

The input vector of the number of bootstrap replicates.

data

The original data as supplied.

statistic

The statistic function as supplied.

sim

The simulation type used in the bootstrap(s), it can either be "ordinary" or "balanced".

stype

The type of statistic supplied, it is the same as the input value stype.

call

A copy of the original call to tilt.boot.

strata

The strata as supplied.

weights

The matrix of weights used. If R[1] is greater than 0 then the first row will be the uniform weights and each subsequent row the tilted weights. If R[1] equals 0 then the uniform weights are omitted and only the tilted weights are output.

theta

The values of theta used for the tilted distributions. These are either the input values or the values derived from the uniform bootstrap and alpha.

  tmp <- (d$market-mean(d$market)) * d.diag$res*d.diag$sd
  sr <- sqrt(sum(tmp^2))/SSx
  c(beta.b, sr, (beta.b-bhat)/sr)
}
a.b <- a.fun(acme,1:nrow(acme),0)
a.boot1 <- tilt.boot(acme, a.fun, R=c(499,250,250), stype="l", sim="balanced", alpha=c(0.05,0.95), tilt=TRUE, index=3, bhat=a.b[1])
```
tsboot

Bootstrapping of Time Series

Description

Generate R bootstrap replicates of a statistic applied to a time series. The replicate time series can be generated using fixed or random block lengths or can be model based replicates.

Usage

\texttt{tsboot(tseries, statistic, R, l=NULL, sim="model", endcorr=TRUE,}
\texttt{n.sim=NROW(tseries), orig.t=TRUE, ran.gen,}
\texttt{ran.args=NULL, norm=TRUE, ...)}

Arguments

- \texttt{tseries} A univariate or multivariate time series.
- \texttt{statistic} A function which when applied to \texttt{tseries} returns a vector containing the statistic(s) of interest. Each time \texttt{statistic} is called it is passed a time series of length \texttt{n.sim} which is of the same class as the original \texttt{tseries}. Any other arguments which \texttt{statistic} takes must remain constant for each bootstrap replicate and should be supplied through the ... argument to tsboot.
- \texttt{R} A positive integer giving the number of bootstrap replicates required.
- \texttt{sim} The type of simulation required to generate the replicate time series. The possible input values are "model" (model based resampling), "fixed" (block resampling with fixed block lengths of \texttt{l}), "geom" (block resampling with block lengths having a geometric distribution with mean \texttt{l}) or "scramble" (phase scrambling).
- \texttt{l} If \texttt{sim} is "fixed" then \texttt{l} is the fixed block length used in generating the replicate time series. If \texttt{sim} is "geom" then \texttt{l} is the mean of the geometric distribution used to generate the block lengths. \texttt{l} should be a positive integer less than the length of \texttt{tseries}. This argument is not required when \texttt{sim} is "model" but it is required for all other simulation types.
- \texttt{endcorr} A logical variable indicating whether end corrections are to be applied when \texttt{sim} is "fixed". When \texttt{sim} is "geom", \texttt{endcorr} is automatically set to \texttt{TRUE}; \texttt{endcorr} is not used when \texttt{sim} is "model" or "scramble".
- \texttt{n.sim} The length of the simulated time series. Typically this will be equal to the length of the original time series but there are situations when it will be larger. One obvious situation is if prediction is required. Another situation in which \texttt{n.sim} is larger than the original length is if \texttt{tseries} is a residual time series from fitting some model to the original time series. In this case, \texttt{n.sim} would usually be the length of the original time series.
- \texttt{orig.t} A logical variable which indicates whether \texttt{statistic} should be applied to \texttt{tseries} itself as well as the bootstrap replicate series. If \texttt{statistic} is expecting a longer time series than \texttt{tseries} or if applying \texttt{statistic} to \texttt{tseries} will not yield any useful information then \texttt{orig.t} should be set to \texttt{FALSE}. 
ran.gen This is a function of three arguments. The first argument is a time series. If sim is code"model" then it will always be tseries that is passed. For other simulation types it is the result of selecting n.sim observations from tseries by some scheme and converting the result back into a time series of the same form as tseries (although of length n.sim). The second argument to ran.gen is always the value n.sim, and the third argument is ran.args, which is used to supply any other objects needed by ran.gen. If sim is "model" then the generation of the replicate time series will be done in ran.gen (for example through use of arima.sim). For the other simulation types ran.gen is used for “post-blackening”. The default is that the function simply returns the time series passed to it.

ran.args This will be supplied to ran.gen each time it is called. If ran.gen needs any extra arguments then they should be supplied as components of ran.args. Multiple arguments may be passed by making ran.args a list. If ran.args is NULL then it should not be used within ran.gen but note that ran.gen must still have its third argument.

norm A logical argument indicating whether normal margins should be used for phase scrambling. If norm is FALSE then margins corresponding to the exact empirical margins are used.

... Any extra arguments to statistic may be supplied here.

Details

If sim is "fixed" then each replicate time series is found by taking blocks of length l, from the original time series and putting them end-to-end until a new series of length n.sim is created. When sim is "geom" a similar approach is taken except that now the block lengths are generated from a geometric distribution with mean l. Post-blackening can be carried out on these replicate time series by including the function ran.gen in the call to tsboot and having tseries as a time series of residuals.

Model based resampling is very similar to the parametric bootstrap and all simulation must be in one of the user specified functions. This avoids the complicated problem of choosing the block length but relies on an accurate model choice being made.

Phase scrambling is described in Section 8.2.4 of Davison and Hinkley (1997). The types of statistic for which this method produces reasonable results is very limited and the other methods seem to do better in most situations. Other types of resampling in the frequency domain can be accomplished using the function boot with the argument sim="parametric".

Value

An object of class "boot." with the following components.

t0 If orig.t is TRUE then t0 is the result of statistic(tseries,...{}) otherwise it is NULL.
t The results of applying statistic to the replicate time series.
R The value of R as supplied to tsboot.
tseries The original time series.
statistic The function statistic as supplied.
sim The simulation type used in generating the replicates.
endcorr The value of endcorr used. The value is meaningful only when sim is "fixed"; it is ignored for model based simulation or phase scrambling and is always set to TRUE if sim is "geom".
The value of \texttt{n.sim} used.

The value of \texttt{l} used for block based resampling. This will be \texttt{NULL} if block based resampling was not used.

The \texttt{ran.gen} function used for generating the series or for "post-blackening".

The extra arguments passed to \texttt{ran.gen}.

The original call to \texttt{tsboot}.

\texttt{boot}, \texttt{arima.sim}

Examples

\begin{verbatim}
lynx.fun <- function(tsb) {
  ar.fit <- ar(tsb, order.max=25)
  c(ar.fit$order, mean(tsb), tsb)
}

# the stationary bootstrap with mean block length 20
lynx.1 <- tsboot(log(lynx), lynx.fun, R=99, l=20, sim="geom")

# the fixed block bootstrap with length 20
lynx.2 <- tsboot(log(lynx), lynx.fun, R=99, l=20, sim="fixed")

# Now for model based resampling we need the original model
# Note that for all of the bootstraps which use the residuals as their
# data, we set \texttt{orig.t} to \texttt{FALSE} since the function applied to the residual
# time series will be meaningless.
lynx.ar <- ar(log(lynx))
lynx.model <- list(order=c(lynx.ar$order,0,0),ar=lynx.ar$ar)
lynx.res <- lynx.ar$resid[!is.na(lynx.ar$resid)]
lynx.res <- lynx.res - mean(lynx.res)

lynx.sim <- function(res,n.sim, ran.args) {
  # random generation of replicate series using arima.sim
  rg1 <- function(n, res) {
    sample(res, n, replace=TRUE)
    ts.orig <- ran.args$ts
    ts.mod <- ran.args$model
    mean(ts.orig)+ts(arima.sim(model=ts.mod, n=n.sim, rand.gen=rg1, res=as.vector(res)))
  }
  lynx.3 <- tsboot(lynx.res, lynx.fun, R=99, sim="model", n.sim=114,
                  orig.t=FALSE, ran.gen=lynx.sim,
\end{verbatim}
ran.args=list(ts=log(lynx), model=lynx.model))

# For "post-blackening" we need to define another function
lynx.black <- function(res, n.sim, ran.args)
{
  ts.orig <- ran.args$ts
  ts.mod <- ran.args$model
  mean(ts.orig) + ts(arima.sim(model=ts.mod, n=n.sim, innov=res))
}

# Now we can run apply the two types of block resampling again but this
# time applying post-blackening.
lynx.1b <- tsboot(lynx.res, lynx.fun, R=99, l=20, sim="fixed",
  n.sim=114, orig.t=FALSE, ran.gen=lynx.black,
  ran.args=list(ts=log(lynx), model=lynx.model))
lynx.2b <- tsboot(lynx.res, lynx.fun, R=99, l=20, sim="geom",
  n.sim=114, orig.t=FALSE, ran.gen=lynx.black,
  ran.args=list(ts=log(lynx), model=lynx.model))

# To compare the observed order of the bootstrap replicates we
# proceed as follows.
table(lynx.1$t[,1])
table(lynx.1b$t[,1])
table(lynx.2$t[,1])
table(lynx.2b$t[,1])
table(lynx.3$t[,1])

# Notice that the post-blackened and model-based bootstraps preserve
# the true order of the model (11) in many more cases than the others.

---

### tuna

#### Tuna Sighting Data

**Description**

The `tuna` data frame has 64 rows and 1 columns.

The data come from an aerial line transect survey of Southern Bluefin Tuna in the Great Australian Bight. An aircraft with two spotters on board flies randomly allocated line transects. Each school of tuna sighted is counted and its perpendicular distance from the transect measured. The survey was conducted in summer when tuna tend to stay on the surface.

**Usage**

tuna

**Format**

This data frame contains the following column:

| y | The perpendicular distance, in miles, from the transect for 64 independent sightings of tuna schools. |
Source

**urine**

*Urine Analysis Data*

**Description**

The urine data frame has 79 rows and 7 columns.

79 urine specimens were analyzed in an effort to determine if certain physical characteristics of the urine might be related to the formation of calcium oxalate crystals.

**Usage**

`urine`

**Format**

This data frame contains the following columns:

- `r` Indicator of the presence of calcium oxalate crystals.
- `gravity` The specific gravity of the urine.
- `ph` The pH reading of the urine.
- `osmo` The osmolarity of the urine. Osmolarity is proportional to the concentration of molecules in solution.
- `cond` The conductivity of the urine. Conductivity is proportional to the concentration of charged ions in solution.
- `urea` The urea concentration in millimoles per litre.
- `calc` The calcium concentration in millimoles per litre.

**var.linear**  
*Linear Variance Estimate*

**Description**
Estimates the variance of a statistic from its empirical influence values.

**Usage**

```r
var.linear(L, strata=NULL)
```

**Arguments**

- `L`: Vector of the empirical influence values of a statistic. These will usually be calculated by a call to `empinf`.
- `strata`: A numeric vector or factor specifying which observations (and hence empirical influence values) come from which strata.

**Value**
The variance estimate calculated from `L`.

**References**

**See Also**

`empinf`, `linear.approx`, `k3.linear`

**Examples**

```r
# To estimate the variance of the ratio of means for the city data.
ratio <- function(d,w)
  sum(d$x * w)/sum(d$u * w)
var.linear(empinf(data=city,statistic=ratio))
```

---

**wool**  
*Australian Relative Wool Prices*

**Description**

`wool` is a time series of class "*ts*" and contains 309 observations.

Each week that the market is open the Australian Wool Corporation set a floor price which determines their policy on intervention and is therefore a reflection of the overall price of wool for the week in question. Actual prices paid can vary considerably about the floor price. The series here is the log of the ratio between the price for fine grade wool and the floor price, each market week between July 1976 and Jun 1984.

Chapter 13

The class package

batchSOM

Self-Organizing Maps: Batch Algorithm

Description

Kohonen’s Self-Organizing Maps are a crude form of multidimensional scaling.

Usage

batchSOM(data, grid = somgrid(), radii, init)

Arguments

data          a matrix or data frame of observations, scaled so that Euclidean distance is appropriate.
grid          A grid for the representatives; see somgrid.
radii         the radii of the neighbourhood to be used for each pass: one pass is run for each element of radii.
init          the initial representatives. If missing, chosen (without replacement) randomly from data.

Details

The batch SOM algorithm of Kohonen(1995, section 3.14) is used.

Value

an object of class "SOM" with components

grid          the grid, an object of class "somgrid".
codes         a matrix of representatives.

References

crabs.grp <- factor(c("B", "b", "O", "o") [rep(1:4, rep(50,4))])
gr <- somgrid(topo = "hexagonal")
crabs.som <- batchSOM(lcrabs, gr, c(4, 4, 2, 2, 1, 1, 0, 0))
plot(crabs.som)

bins <- as.numeric(knn1(crabs.som$code, lcrabs, 0:47)))
plot(crabs.som$grid, type = "n")
symbols(crabs.som$grid$pts[, 1], crabs.som$grid$pts[, 2],
circles = rep(0.4, 48), inches = FALSE, add = TRUE)
text(crabs.som$grid$pts[bins, ] + rnorm(400, 0, 0.1),
as.character(crabs.grp))

condense

Condense training set for k-NN classifier

Description

Condense training set for k-NN classifier

Usage

condense(train, class, store, trace = TRUE)

Arguments

train matrix for training set
class vector of classifications for test set
store initial store set. Default one randomly chosen element of the set.
trace logical. Trace iterations?

Details

The store set is used to 1-NN classify the rest, and misclassified patterns are added to the store set. The whole set is checked until no additions occur.

Value

index vector of cases to be retained (the final store set).

Examples

data(iris3)
train <- rbind(iris3[1:25,,1], iris3[1:25,,2], iris3[1:25,,3])
test <- rbind(iris3[26:50,,1], iris3[26:50,,2], iris3[26:50,,3])
cl <- factor(c(rep("s", 25), rep("c", 25), rep("v", 25)))
keep <- condense(train, cl)
knn(train[keep, , drop=FALSE], test, cl[keep])
keep2 <- reduce.nn(train, keep, cl)
knn(train[keep2, , drop=FALSE], test, cl[keep2])

Description

k-nearest neighbour classification for test set from training set. For each row of the test set, the k nearest (in Euclidean distance) training set vectors are found, and the classification is decided by majority vote, with ties broken at random. If there are ties for the kth nearest vector, all candidates are included in the vote.

Usage

knn(train, test, cl, k = 1, l = 0, prob = FALSE, use.all = TRUE)

Arguments

train matrix or data frame of training set cases.
test matrix or data frame of test set cases. A vector will be interpreted as a row vector for a single case.
cl factor of true classifications of training set
k number of neighbours considered.
l minimum vote for definite decision, otherwise doubt. (More precisely, less than k–l dissenting votes are allowed, even if k is increased by ties.)
prob If this is true, the proportion of the votes for the winning class are returned as attribute prob.
use.all controls handling of ties. If true, all distances equal to the kth largest are included. If false, a random selection of distances equal to the kth is chosen to use exactly k neighbours.

Value

factor of classifications of test set. doubt will be returned as NA.

Examples

data(iris3)
train <- rbind(iris3[1:25,,1], iris3[1:25,,2], iris3[1:25,,3])
test <- rbind(iris3[26:50,,1], iris3[26:50,,2], iris3[26:50,,3])
cl <- factor(c(rep("s",25), rep("c",25), rep("v",25)))
knn(train, test, cl, k = 3, prob=TRUE)
attributes(.Last.value)

knn.cv

k-Nearest Neighbour Cross-Validatory Classification

Description

k-nearest neighbour cross-validatory classification from training set.

Usage

knn.cv(train, cl, k = 1, l = 0, prob = FALSE, use.all = TRUE)

Arguments

- train: matrix or data frame of training set cases.
- cl: factor of true classifications of training set.
- k: number of neighbours considered.
- l: minimum vote for definite decision, otherwise doubt. (More precisely, less than k-l dissenting votes are allowed, even if k is increased by ties.)
- prob: If this is true, the proportion of the votes for the winning class are returned as attribute prob.
- use.all: controls handling of ties. If true, all distances equal to the kth largest are included. If false, a random selection of distances equal to the kth is chosen to use exactly k neighbours.

Details

This uses leave-one-out cross validation. For each row of the training set train, the k nearest (in Euclidean distance) other training set vectors are found, and the classification is decided by majority vote, with ties broken at random. If there are ties for the kth nearest vector, all candidates are included in the vote.

Value

factor of classifications of training set. doubt will be returned as NA.

attributes(.Last.value)

knn1

1-nearest neighbour classification

Description

Nearest neighbour classification for test set from training set. For each row of the test set, the nearest (by Euclidean distance) training set vector is found, and its classification used. If there is more than one nearest, a majority vote is used with ties broken at random.

Usage

knn1(train, test, cl)

Arguments

train matrix or data frame of training set cases.
test matrix or data frame of test set cases. A vector will be interpreted as a row vector for a single case.
cl factor of true classification of training set.

Value

factor of classifications of test set.

train <- rbind(iris3[1:25,,1], iris3[1:25,,2], iris3[1:25,,3])
test <- rbind(iris3[26:50,,1], iris3[26:50,,2], iris3[26:50,,3])
cl <- factor(c(rep("s",25), rep("c",25), rep("v",25)))
knn1(train, test, cl)
**Description**

Moves examples in a codebook to better represent the training set.

**Usage**

```r
lvq1(x, cl, codebk, niter = 100 * nrow(codebk$x), alpha = 0.03)
```

**Arguments**

- `x`: a matrix or data frame of examples
- `cl`: a vector or factor of classifications for the examples
- `codebk`: a codebook
- `niter`: number of iterations
- `alpha`: constant for training

**Details**

Selects `niter` examples at random with replacement, and adjusts the nearest example in the codebook for each.

**Value**

A codebook, represented as a list with components `x` and `cl` giving the examples and classes.

**References**

**See Also**

**Examples**

```r
data(iris3)
train <- rbind(iris3[1:25,,1], iris3[1:25,,2], iris3[1:25,,3])
test <- rbind(iris3[26:50,,1], iris3[26:50,,2], iris3[26:50,,3])
cl <- factor(c(rep("s",25), rep("c",25), rep("v",25)))
cd <- lvqinit(train, cl, 10)
lvqtest(cd, train)
cd0 <- olvq1(train, cl, cd)
lvqtest(cd0, train)
cd1 <- lvq1(train, cl, cd0)
lvqtest(cd1, train)
```
Description

Moves examples in a codebook to better represent the training set.

Usage

```r
lvq2(x, cl, codebk, niter = 100 * nrow(codebk$x), alpha = 0.03, win = 0.3)
```

Arguments

- **x**: a matrix or data frame of examples
- **cl**: a vector or factor of classifications for the examples
- **codebk**: a codebook
- **niter**: number of iterations
- **alpha**: constant for training
- **win**: a tolerance for the closeness of the two nearest vectors.

Details

Selects `niter` examples at random with replacement, and adjusts the nearest two examples in the codebook if one is correct and the other incorrect.

Value

A codebook, represented as a list with components `x` and `cl` giving the examples and classes.

### lvq3

**Learning Vector Quantization 3**

**Description**

Moves examples in a codebook to better represent the training set.

**Usage**

```r
lvq3(x, cl, codebk, niter = 100*nrow(codebk$x), alpha = 0.03,
     win = 0.3, epsilon = 0.1)
```

**Arguments**

- `x`: a matrix or data frame of examples
- `cl`: a vector or factor of classifications for the examples
- `codebk`: a codebook
- `niter`: number of iterations
- `alpha`: constant for training
- `win`: a tolerance for the closeness of the two nearest vectors.
- `epsilon`: proportion of move for correct vectors

**Details**

Selects `niter` examples at random with replacement, and adjusts the nearest two examples in the codebook for each.

**Value**

A codebook, represented as a list with components `x` and `cl` giving the examples and classes.

Examples

data(iris3)
train <- rbind(iris3[1:25,,1], iris3[1:25,,2], iris3[1:25,,3])
test <- rbind(iris3[26:50,,1], iris3[26:50,,2], iris3[26:50,,3])
cl <- factor(c(rep("s",25), rep("c",25), rep("v",25)))
cd <- lvqinit(train, cl, 10)
lvqtest(cd, train)
cd0 <- olvq1(train, cl, cd)
lvqtest(cd0, train)
cd3 <- lvq3(train, cl, cd0)
lvqtest(cd3, train)

lvqinit

Initialize a LVQ Codebook

Description

Construct an initial codebook for LVQ methods.

Usage

lvqinit(x, cl, size, prior, k = 5)

Arguments

x
a matrix or data frame of training examples, n by p.

cl
the classifications for the training examples. A vector or factor of length n.

size
the size of the codebook. Defaults to \( \min(round(0.4*ng*(ng-1 + p/2),0), n) \) where \( ng \) is the number of classes.

prior
Probabilities to represent classes in the codebook. Default proportions in the
training set.

k
k used for k-NN test of correct classification. Default is 5.

Details

Selects size examples from the training set without replacement with proportions proportional to
the prior or the original proportions.

Value

A codebook, represented as a list with components x and cl giving the examples and classes.

train <- rbind(iris3[1:25,,1], iris3[1:25,,2], iris3[1:25,,3])
test <- rbind(iris3[26:50,,1], iris3[26:50,,2], iris3[26:50,,3])
cl <- factor(c(rep("s",25), rep("c",25), rep("v",25)))
cd <- lvqinit(train, cl, 10)
lvqtest(cd, train)
cd1 <- olvq1(train, cl, cd)
lvqtest(cd1, train)
```

\textbf{Description}

Classify a test set by 1-NN from a specified LVQ codebook.

\textbf{Usage}

```
lvqtest(codebk, test)
```

\textbf{Arguments}

- \texttt{codebk} codebook object returned by other LVQ software
- \texttt{test} matrix of test examples

\textbf{Details}

uses 1-NN to classify each test example against the codebook.

\textbf{Value}

factor of classification for each row of \texttt{x}

\textbf{References}

\textbf{See Also}

\texttt{lvqinit, olvq1}

Multiedit for k-NN Classifier

Description
Multiedit for k-NN classifier

Usage
multiedit(x, class, k = 1, V = 3, I = 5, trace = TRUE)

Arguments
- x: matrix of training set.
- class: vector of classification of training set.
- k: number of neighbours used in k-NN.
- V: divide training set into V parts.
- I: number of null passes before quitting.
- trace: logical for statistics at each pass.

Value
index vector of cases to be retained.

length(ind2)
table(cl, knn(ntrain[ind2, , drop=FALSE], test, ncl[ind2], 1))
```
olvq1

**Optimized Learning Vector Quantization 1**

**Description**

Moves examples in a codebook to better represent the training set.

**Usage**

```r
olvq1(x, cl, codebk, niter = 40 * nrow(codebk$x), alpha = 0.3)
```

**Arguments**

- `x`: a matrix or data frame of examples
- `cl`: a vector or factor of classifications for the examples
- `codebk`: a codebook
- `niter`: number of iterations
- `alpha`: constant for training

**Details**

Selects `niter` examples at random with replacement, and adjusts the nearest example in the codebook for each.

**Value**

A codebook, represented as a list with components `x` and `cl` giving the examples and classes.

**References**

**See Also**

`lvqinit`, `lvqtest`, `lvq1`, `lvq2`, `lvq3`

**Examples**

lvqtest(cd1, train)
```
**reduce.nn**

Reduce Training Set for a k-NN Classifier

**Description**

Reduce training set for a k-NN classifier. Used after `condense`.

**Usage**

```r
reduce.nn(train, ind, class)
```

**Arguments**

- `train`: matrix for training set
- `ind`: Initial list of members of the training set (from `condense`).
- `class`: vector of classifications for test set

**Details**

All the members of the training set are tried in random order. Any which when dropped do not cause any members of the training set to be wrongly classified are dropped.

**Value**

index vector of cases to be retained.

**References**

**See Also**

`condense`, `multiedit`

**Examples**

```r
data(iris3)
train <- rbind(iris3[1:25,,1], iris3[1:25,,2], iris3[1:25,,3])
test <- rbind(iris3[26:50,,1], iris3[26:50,,2], iris3[26:50,,3])
cl <- factor(c(rep("s",25), rep("c",25), rep("v",25)))
keep <- condense(train, cl)
knn(train[keep,], test, cl[keep])
keep2 <- reduce.nn(train, keep, cl)
knn(train[keep2,], test, cl[keep2])
```
Self-Organizing Maps: Online Algorithm

Description

Kohonen’s Self-Organizing Maps are a crude form of multidimensional scaling.

Usage

SOM(data, grid = somgrid(), rlen = 10000, alpha, radii, init)

Arguments

data a matrix or data frame of observations, scaled so that Euclidean distance is appropriate.

grid A grid for the representatives: see somgrid.

rlen the number of updates: used only in the defaults for alpha and radii.

alpha the amount of change: one update is done for each element of alpha. Default is to decline linearly from 0.05 to 0 over rlen updates.

radii the radii of the neighbourhood to be used for each update: must be the same length as alpha. Default is to decline linearly from 4 to 1 over rlen updates.

init the initial representatives. If missing, chosen (without replacement) randomly from data.

Details

alpha and radii can also be lists, in which case each component is used in turn, allowing two- or more phase training.

Value

an object of class "SOM" with components

grid the grid, an object of class "somgrid".

codes a matrix of representatives.

References

See Also

somgrid, batchSOM
Examples

data(crabs, package = "MASS")

lcrabs <- log(crabs[, 4:8])
crabs.grp <- factor(c("B", "b", "O", "o") [rep(1:4, rep(50,4))])
gr <- somgrid(topo = "hexagonal")
crabs.som <- SOM(lcrabs, gr)
plot(crabs.som)

## 2-phase training

r <- rep(1:4, rep(50,4))
crabs.som2 <- SOM(lcrabs, gr,
    alpha = list(seq(0.05, 0, len = 1e4), seq(0.02, 0, len = 1e5)),
    radii = list(seq(8, 1, len = 1e4), seq(4, 1, len = 1e5)))
plot(crabs.som2)

---

somgrid

Plot SOM Fits

Description

Plotting functions for SOM results.

Usage

somgrid(xdim = 8, ydim = 6, topo = c("rectangular", "hexagonal"))

## S3 method for class 'somgrid':
plot(x, type = "p", ...)

## S3 method for class 'SOM':
plot(x, ...)

Arguments

xdim, ydim dimensions of the grid
topo the topology of the grid.
x an object inheriting from class "somgrid" or "SOM".
type, ... graphical parameters.

Details

The class "somgrid" records the coordinates of the grid to be used for (batch or on-line) SOM: this has a plot method.
The plot method for class "SOM" plots a stars plot of the representative at each grid point.

Value

For somgrid, an object of class "somgrid", a list with components

pts a two-column matrix giving locations for the grid points.
xdim, ydim, topo as in the arguments to somgrid.

Chapter 14

The cluster package

agnes

Agglomerative Nesting (Hierarchical Clustering)

Description

Computes agglomerative hierarchical clustering of the dataset.

Usage

agnes(x, diss = inherits(x, "dist"), metric = "euclidean",
       stand = FALSE, method = "average", par.method,
       keep.diss = n < 100, keep.data = !diss)

Arguments

x        data matrix or data frame, or dissimilarity matrix, depending on the value of the
diss argument.

In case of a matrix or data frame, each row corresponds to an observation, and
each column corresponds to a variable. All variables must be numeric. Missing
values (NAs) are allowed.

In case of a dissimilarity matrix, x is typically the output of daisy or dist.
Also a vector with length n*(n-1)/2 is allowed (where n is the number of ob-
servations), and will be interpreted in the same way as the output of the above-
mentioned functions. Missing values (NAs) are not allowed.

diss     logical flag: if TRUE (default for dist or dissimilarity objects), then x
         is assumed to be a dissimilarity matrix. If FALSE, then x is treated as a matrix
         of observations by variables.

metric   character string specifying the metric to be used for calculating dissimilarity-
ties between observations. The currently available options are "euclidean" and
"manhattan". Euclidean distances are root sum-of-squares of differences, and
manhattan distances are the sum of absolute differences. If x is already a dis-
similarity matrix, then this argument will be ignored.

stand    logical flag: if TRUE, then the measurements in x are standardized before calcu-

9731
agnes
(column), by subtracting the variable’s mean value and dividing by the variable’s mean absolute deviation. If \( x \) is already a dissimilarity matrix, then this argument will be ignored.

`method` character string defining the clustering method. The six methods implemented are "average" ([unweighted pair-]group average method, UPGMA), "single" (single linkage), "complete" (complete linkage), "ward" (Ward’s method), "weighted" (weighted average linkage) and its generalization "flexible" which uses a (constant version of) the Lance-Williams formula and the `par.method` argument. Default is "average".

`par.method` if `method == "flexible"`, numeric vector of length 1, 3, or 4, see in the details section.

`keep.diss`, `keep.data` logicals indicating if the dissimilarities and/or input data \( x \) should be kept in the result. Setting these to `FALSE` can give much smaller results and hence even save memory allocation time.

Details

`agnes` is fully described in chapter 5 of Kaufman and Rousseeuw (1990). Compared to other agglomerative clustering methods such as `hclust`, `agnes` has the following features: (a) it yields the agglomerative coefficient (see `agnes.object`) which measures the amount of clustering structure found; and (b) apart from the usual tree it also provides the banner, a novel graphical display (see `plot.agnes`).

The `agnes`-algorithm constructs a hierarchy of clusterings. At first, each observation is a small cluster by itself. Clusters are merged until only one large cluster remains which contains all the observations. At each stage the two nearest clusters are combined to form one larger cluster.

For `method="average"`, the distance between two clusters is the average of the dissimilarities between the points in one cluster and the points in the other cluster.

In `method="single"`, we use the smallest dissimilarity between a point in the first cluster and a point in the second cluster (nearest neighbor method).

When `method="complete"`, we use the largest dissimilarity between a point in the first cluster and a point in the second cluster (furthest neighbor method).

The `method = "flexible"` allows (and requires) more details: The Lance-Williams formula specifies how dissimilarities are computed when clusters are agglomerated (equation (32) in K.&R., p.237). If clusters \( C_1 \) and \( C_2 \) are agglomerated into a new cluster, the dissimilarity between their union and another cluster \( Q \) is given by

\[
D(C_1 \cup C_2, Q) = \alpha_1 * D(C_1, Q) + \alpha_2 * D(C_2, Q) + \beta * D(C_1, C_2) + \gamma * |D(C_1, Q) - D(C_2, Q)|,
\]

where the four coefficients \((\alpha_1, \alpha_2, \beta, \gamma)\) are specified by the vector `par.method`:

If `par.method` is of length 1, say \( \alpha \), `par.method` is extended to give the "Flexible Strategy" (K. & R., p.236 f) with Lance-Williams coefficients \((\alpha_1 = \alpha_2 = \alpha, \beta = 1 - 2\alpha, \gamma = 0)\).

If of length 3, \( \gamma = 0 \) is used.

Care and expertise is probably needed when using `method = "flexible"` particularly for the case when `par.method` is specified of longer length than one. The weighted average (method="weighted") is the same as `method="flexible"`, `par.method = 0.5`.

Value

an object of class "agnes" representing the clustering. See `agnes.object` for details.
BACKGROUND

Cluster analysis divides a dataset into groups (clusters) of observations that are similar to each other.

Hierarchical methods like agnes, diana, and mona construct a hierarchy of clusterings, with the number of clusters ranging from one to the number of observations.

Partitioning methods like pam, clara, and fanny require that the number of clusters be given by the user.

agnes.object

Agglomerative Nesting (AGNES) Object

Description

The objects of class "agnes" represent an agglomerative hierarchical clustering of a dataset.
A legitimate **agnes** object is a list with the following components:

- **order**: a vector giving a permutation of the original observations to allow for plotting, in the sense that the branches of a clustering tree will not cross.
- **order.lab**: a vector similar to `order`, but containing observation labels instead of observation numbers. This component is only available if the original observations were labelled.
- **height**: a vector with the distances between merging clusters at the successive stages.
- **ac**: the agglomerative coefficient, measuring the clustering structure of the dataset. For each observation i, denote by m(i) its dissimilarity to the first cluster it is merged with, divided by the dissimilarity of the merger in the final step of the algorithm. The ac is the average of all 1 - m(i). It can also be seen as the average width (or the percentage filled) of the banner plot. Because ac grows with the number of observations, this measure should not be used to compare datasets of very different sizes.
- **merge**: an (n-1) by 2 matrix, where n is the number of observations. Row i of `merge` describes the merging of clusters at step i of the clustering. If a number j in the row is negative, then the single observation |j| is merged at this stage. If j is positive, then the merger is with the cluster formed at stage j of the algorithm.
- **diss**: an object of class "dissimilarity" (see `dissimilarity.object`), representing the total dissimilarity matrix of the dataset.
- **data**: a matrix containing the original or standardized measurements, depending on the `stand` option of the function `agnes`. If a dissimilarity matrix was given as input structure, then this component is not available.

**METHODS**

The "agnes" class has methods for the following generic functions: `print`, `summary`, `plot`.

**INHERITANCE**

The class "agnes" inherits from "twins". Therefore, the generic functions `pltree` and `as.hclust` are available for `agnes` objects. After applying `as.hclust()`, all its methods are available, of course.

**See Also**

`agnes`, `diana`, `as.hclust`, `hclust`, `plot.agnes`, `twins.object`. 
Description

Gross National Product (GNP) per capita and percentage of the population working in agriculture for each country belonging to the European Union in 1993.

Usage

data(agriculture)

Format

A data frame with 12 observations on 2 variables:

<p>| | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>[,1]</td>
<td>numeric</td>
</tr>
<tr>
<td>[,2]</td>
<td>numeric</td>
</tr>
</tbody>
</table>

The row names of the data frame indicate the countries.

Details

The data seem to show two clusters, the “more agricultural” one consisting of Greece, Portugal, Spain, and Ireland.

`agnes`, `daisy`, `diana`.

Examples

data(agriculture)

```r
## Compute the dissimilarities using Euclidean metric and without
## standardization
daisy(agriculture, metric = "euclidean", stand = FALSE)

## 2nd plot is similar to Figure 3 in Struyf et al (1996)
plot(pam(agriculture, 2))

## Plot similar to Figure 7 in Struyf et al (1996)
```
## Not run: plot(agnes(agriculture), ask = TRUE)
## Plot similar to Figure 8 in Struyf et al (1996)
## Not run: plot(diana(agriculture), ask = TRUE)

### animals

#### Attributes of Animals

**Description**

This data set considers 6 binary attributes for 20 animals.

**Usage**

```r
data(animals)
```

**Format**

A data frame with 20 observations on 6 variables:

```
[, 1] war warm-blooded
[, 2] fly can fly
[, 3] ver vertebrate
[, 4] end endangered
[, 5] gro live in groups
[, 6] hai have hair
```

All variables are encoded as 1 = ‘no’, 2 = ‘yes’.

**Details**

This dataset is useful for illustrating monothetic (only a single variable is used for each split) hierarchical clustering.

**Source**

**References**

**Examples**

```r
data(animals)
apply(animals, 2, table) # simple overview
ma <- mona(animals)
```
bannerplot

ma
## Plot similar to Figure 10 in Struyf et al (1996)
plot(ma)

### Description

Draws a “banner”, i.e. basically a horizontal barplot visualizing the (agglomerative or divisive) hierarchical clustering or an other binary dendrogram structure.

### Usage

```r
bannerplot(x, w = rev(x$height), fromLeft = TRUE,
main=NULL, sub=NULL, xlab = "Height", adj = 0,
col = c(2, 0), border = 0, axes = TRUE, frame.plot = axes,
rev.xax = !fromLeft, xax.pretty = TRUE,
labels = NULL, nmax.lab = 35, max.strlen = 5,
yax.do = axes && length(x$order) <= nmax.lab,
yaxRight = fromLeft, y.mar = 2.4 + max.strlen/2.5, ...)
```

### Arguments

- **x**: a list with components `order`, `order.lab` and `height` when `w`, the next argument is not specified.
- **w**: non-negative numeric vector of bar widths.
- **fromLeft**: logical, indicating if the banner is from the left or not.
- **main, sub**: main and sub titles, see `title`.
- **xlab**: x axis label (with ‘correct’ default e.g. for `plot.agnes`).
- **adj**: passed to `title(main, sub)` for string adjustment.
- **col**: vector of length 2, for two horizontal segments.
- **border**: color for bar border; now defaults to background (no border).
- **axes**: logical indicating if axes (and labels) should be drawn at all.
- **frame.plot**: logical indicating the banner should be framed; mainly used when `border = 0` (as per default).
- **rev.xax**: logical indicating if the x axis should be reversed (as in `plot.diana`).
- **xax.pretty**: logical or integer indicating if `pretty()` should be used for the x axis. `xax.pretty = FALSE` is mainly for back compatibility.
- **labels**: labels to use on y-axis; the default is constructed from x.
- **nmax.lab**: integer indicating the number of labels which is considered too large for single-name labelling the banner plot.
- **max.strlen**: positive integer giving the length to which strings are truncated in banner plot labeling.
- **yax.do**: logical indicating if a y axis and banner labels should be drawn.
- **yaxRight**: logical indicating if the y axis is on the right or left.
variable y.mar

- positive number specifying the margin width to use when banners are labeled (along a y-axis). The default adapts to the string width and optimally would also dependend on the font.

... graphical parameters (see par) may also be supplied as arguments to this function.

Note

This is mainly a utility called from plot.agnes, plot.diana and plot.mona.

Author(s)

Martin Maechler (from original code of Kaufman and Rousseeuw).

Examples

data(agriculture)
bannerplot(agnes(agriculture), main = "Bannerplot")

——

data frame chorSub

Description

This is a small rounded subset of the C-horizon data chorizon from package mvoutlier.

Usage

data(chorSub)

Format

A data frame with 61 observations on 10 variables. The variables contain scaled concentrations of chemical elements.

Details

This data set was produced from chorizon via these statements:

data(chorizon, package = "mvoutlier")
chorSub <- round(100*scale(chorizon[,101:110]))[190:250,]
storage.mode(chorSub) <- "integer"
colnames(chorSub) <- gsub("._.*", '', colnames(chorSub))

Source

See Also

chorizon in package mvoutlier and other Kola data in the same package.
Examples

data(chorSub)
summary(chorSub)
pairs(chorSub, gap= .1)# some outliers

Description

Computes a "clara" object, a list representing a clustering of the data into \( k \) clusters.

Usage

clara(x, k, metric = "euclidean", stand = FALSE, samples = 5,
sampsize = min(n, 40 + 2 * k), trace = 0, medoids.x = TRUE,
keep.data = medoids.x, rngR = FALSE)

Arguments

x
data matrix or data frame, each row corresponds to an observation, and each column corresponds to a variable. All variables must be numeric. Missing values (NA) are allowed.

k
integer, the number of clusters. It is required that \( 0 < k < n \) where \( n \) is the number of observations (i.e., \( n = nrow(x) \)).

metric
character string specifying the metric to be used for calculating dissimilarities between observations. The currently available options are "euclidean" and "manhattan". Euclidean distances are root sum-of-squares of differences, and manhattan distances are the sum of absolute differences.

stand
logical, indicating if the measurements in \( x \) are standardized before calculating the dissimilarities. Measurements are standardized for each variable (column), by subtracting the variable's mean value and dividing by the variable's mean absolute deviation.

samples
integer, number of samples to be drawn from the dataset.

sampsize
integer, number of observations in each sample. sampsize should be higher than the number of clusters (\( k \)) and at most the number of observations (\( n = nrow(x) \)).

trace
integer indicating a trace level for diagnostic output during the algorithm.

medoids.x
logical indicating if the medoids should be returned, identically to some rows of the input data \( x \). If FALSE, keep.data must be false as well, and the medoid indices, i.e., row numbers of the medoids will still be returned (i.e., med component), and the algorithm saves space by needing one copy less of \( x \).

keep.data
logical indicating if the (scaled if stand is true) data should be kept in the result. Setting this to FALSE saves memory (and hence time), but disables clusplot() ing of the result. Use medoids.x = FALSE to save even more memory.

rngR
logical indicating if R's random number generator should be used instead of the primitive clara()-builtin one. If true, this also means that each call to clara() returns a different result – though only slightly different in good situations.
Details

c克拉 is fully described in chapter 3 of Kaufman and Rousseeuw (1990). Compared to other
partitioning methods such as pam, it can deal with much larger datasets. Internally, this is achieved
by considering sub-datasets of fixed size (sampsize) such that the time and storage requirements
become linear in \( n \) rather than quadratic.

Each sub-dataset is partitioned into \( k \) clusters using the same algorithm as in pam.
Once \( k \) representative objects have been selected from the sub-dataset, each observation of the
entire dataset is assigned to the nearest medoid.

The sum of the dissimilarities of the observations to their closest medoid is used as a measure of
the quality of the clustering. The sub-dataset for which the sum is minimal, is retained. A further
analysis is carried out on the final partition.

Each sub-dataset is forced to contain the medoids obtained from the best sub-dataset until then.
Randomly drawn observations are added to this set until sampsize has been reached.

Value

an object of class "clara" representing the clustering. See clara.object for details.

Note

By default, the random sampling is implemented with a very simple scheme (with period \( 2^{16} = 65536 \)) inside the Fortran code, independently of R's random number generation, and as a matter of fact, deterministically. Alternatively, we recommend setting \( \text{rngR} = \text{TRUE} \) which uses R's random number generators. Then, clara() results are made reproducible typically by using set.seed() before calling clara.

The storage requirement of clara computation (for small \( k \)) is about \( O(n \times p) + O(j^2) \) where \( j = \text{sampsize} \), and \( (n,p) = \text{dim}(x) \). The CPU computing time (again assuming small \( k \)) is about \( O(n \times p \times j^2 \times N) \), where \( N = \text{samples} \).

For “small” datasets, the function pam can be used directly. What can be considered small, is
really a function of available computing power, both memory (RAM) and speed. Originally (1990),
“small” meant less than 100 observations; later, the authors said “small (say with fewer than 200
observations)"...

Author(s)

Kaufman and Rousseeuw (see agnes), originally. All arguments from trace on, and most R
documentation and all tests by Martin Maechler.

}

---

**clara.object**

*Clustering Large Applications (CLARA) Object*

**Description**

The objects of class "clara" represent a partitioning of a large dataset into clusters and are typically returned from clara.

**Value**

A legitimate clara object is a list with the following components:

- **sample** labels or case numbers of the observations in the best sample, that is, the sample used by the clara algorithm for the final partition.

- **medoids** the medoids or representative objects of the clusters. It is a matrix with in each row the coordinates of one medoid. Possibly NULL, namely when the object resulted from clara(*, medoids.x=FALSE). Use the following i.med in that case.

- **i.med** the indices of the medoids above: medoids <- x[i.med,] where x is the original data matrix in clara(x,*).

- **clustering** the clustering vector, see partition.object.

- **objective** the objective function for the final clustering of the entire dataset.

- **clusinfo** matrix, each row gives numerical information for one cluster. These are the cardinality of the cluster (number of observations), the maximal and average dissimilarity between the observations in the cluster and the cluster’s medoid. The last column is the maximal dissimilarity between the observations in the
clusplot

clusplot

cluster and the cluster’s medoid, divided by the minimal dissimilarity between
the cluster’s medoid and the medoid of any other cluster. If this ratio is small,
the cluster is well-separated from the other clusters.

<table>

Methods, Inheritance

The "clara" class has methods for the following generic functions: print, summary.
The class "clara" inherits from "partition". Therefore, the generic functions plot and
clusplot can be used on a clara object.

See Also

clara, dissimilarity.object, partition.object, plot.partition.

clusplot

clusplot

Cluster Plot - Generic Function

Description

Draws a 2-dimensional “clusplot” on the current graphics device. This is a generic function with a
default and partition method.

Usage

clusplot(x, ...)

Arguments

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>x</td>
<td>an R object.</td>
</tr>
<tr>
<td>...</td>
<td>additional arguments for methods. Graphical parameters (see par) may also be supplied as arguments to this function.</td>
</tr>
</tbody>
</table>

Side Effects

a 2-dimensional clusplot is created on the current graphics device.

See Also

(for references and examples) clusplot.default, clusplot.partition, partition.object, pam, fanny, clara.
Bivariate Cluster Plot (clusplot) Default Method

Description

Creates a bivariate plot visualizing a partition (clustering) of the data. All observation are represented by points in the plot, using principal components or multidimensional scaling. Around each cluster an ellipse is drawn.

Usage

```r
# Default S3 method:
clusplot(x, clus, diss = FALSE, cor = TRUE, stand = FALSE,
        lines = 2, shade = FALSE, color = FALSE,
        labels = 0, plotchar = TRUE,
        col.p = "dark green", col.txt = col.p,
        col.clus = if(color) c(2, 4, 6, 3) else 5,
        span = TRUE, xlim = NULL, ylim = NULL,
        main = paste("CLUSPLOT(" , deparse(substitute(x)) , ")" ),
        sub = paste("These two components explain",
                    round(100 * var.dec, digits = 2), ", ": 
                    "% of the point variability." ),
        verbose = getOption("verbose"),
        ...)"n```

Arguments

- **x**: matrix or data frame, or dissimilarity matrix, depending on the value of the **diss** argument.
  - In case of a matrix (alike), each row corresponds to an observation, and each column corresponds to a variable. All variables must be numeric. Missing values (NAs) are allowed. They are replaced by the median of the corresponding variable. When some variables or some observations contain only missing values, the function stops with a warning message.
  - In case of a dissimilarity matrix, x is the output of `daisy` or `dist` or a symmetric matrix. Also, a vector of length \( n(n - 1)/2 \) is allowed (where \( n \) is the number of observations), and will be interpreted in the same way as the output of the above-mentioned functions. Missing values (NAs) are not allowed.

- **clus**: a vector of length \( n \) representing a clustering of \( x \). For each observation the vector lists the number or name of the cluster to which it has been assigned.
  - `clus` is often the clustering component of the output of `pam`, `fanny` or `clara`.

- **diss**: logical indicating if \( x \) will be considered as a dissimilarity matrix or a matrix of observations by variables (see x argument above).

- **cor**: logical flag, only used when working with a data matrix (diss = FALSE). If TRUE, then the variables are scaled to unit variance.

- **stand**: logical flag: if true, then the representations of the \( n \) observations in the 2-dimensional plot are standardized.

- **lines**: integer out of 0, 1, 2, used to obtain an idea of the distances between ellipses. The distance between two ellipses E1 and E2 is measured along the line connecting the centers \( m1 \) and \( m2 \) of the two ellipses.
In case $E_1$ and $E_2$ overlap on the line through $m_1$ and $m_2$, no line is drawn. Otherwise, the result depends on the value of `lines`: If

- `lines = 0`, no distance lines will appear on the plot;
- `lines = 1`, the line segment between $m_1$ and $m_2$ is drawn;
- `lines = 2`, a line segment between the boundaries of $E_1$ and $E_2$ is drawn (along the line connecting $m_1$ and $m_2$).

**shade**

Logical flag: if TRUE, then the ellipses are shaded in relation to their density. The density is the number of points in the cluster divided by the area of the ellipse.

**color**

Logical flag: if TRUE, then the ellipses are colored with respect to their density. With increasing density, the colors are light blue, light green, red and purple. To see these colors on the graphics device, an appropriate color scheme should be selected (we recommend a white background).

**labels**

Integer code, currently one of 0,1,2,3,4 and 5. If

- `labels= 0`, no labels are placed in the plot;
- `labels= 1`, points and ellipses can be identified in the plot (see `identify`);
- `labels= 2`, all points and ellipses are labelled in the plot;
- `labels= 3`, only the points are labelled in the plot;
- `labels= 4`, only the ellipses are labelled in the plot.
- `labels= 5`, the ellipses are labelled in the plot, and points can be identified.

The levels of the vector `clus` are taken as labels for the clusters. The labels of the points are the rownames of `x` if `x` is matrix like. Otherwise (`diss = TRUE`), `x` is a vector, point labels can be attached to `x` as a "Labels" attribute (attr(x, "Labels")), as is done for the output of `daisy`.

A possible `names` attribute of `clus` will not be taken into account.

**plotchar**

Logical flag: if TRUE, then the plotting symbols differ for points belonging to different clusters.

**span**

Logical flag: if TRUE, then each cluster is represented by the ellipse with smallest area containing all its points. (This is a special case of the minimum volume ellipsoid.)

If FALSE, the ellipse is based on the mean and covariance matrix of the same points. While this is faster to compute, it often yields a much larger ellipse. There are also some special cases: When a cluster consists of only one point, a tiny circle is drawn around it. When the points of a cluster fall on a straight line, `span=FALSE` draws a narrow ellipse around it and `span=TRUE` gives the exact line segment.

**col.p**

Color code(s) used for the observation points.

**col.txt**

Color code(s) used for the labels (if `labels` >= 2).

**col.clus**

Color code for the ellipses (and their labels); only one if color is false (as per default).

**xlim, ylim**

Numeric vectors of length 2, giving the x- and y- ranges as in `plot.default`.

**main**

Main title for the plot; by default, one is constructed.

**sub**

Subtitle for the plot; by default, one is constructed.

**verbose**

A logical indicating, if there should be extra diagnostic output; mainly for ‘debugging’.

Further graphical parameters may also be supplied, see `par`.
clusplot.default

Details

clusplot uses the functions princomp and cmdscale. These functions are data reduction techniques. They will represent the data in a bivariate plot. Ellipses are then drawn to indicate the clusters. The further layout of the plot is determined by the optional arguments.

Value

An invisible list with components:

Distances When lines is 1 or 2 we obtain a k by k matrix (k is the number of clusters). The element in [i,j] is the distance between ellipse i and ellipse j. If lines = 0, then the value of this component is NA.

Shading A vector of length k (where k is the number of clusters), containing the amount of shading per cluster. Let y be a vector where element i is the ratio between the number of points in cluster i and the area of ellipse i. When the cluster i is a line segment, y[i] and the density of the cluster are set to NA. Let z be the sum of all the elements of y without the NAs. Then we put shading = y/z * 37 + 3.

Side Effects

a visual display of the clustering is plotted on the current graphics device.

Note

When we have 4 or fewer clusters, then the color=TRUE gives every cluster a different color. When there are more than 4 clusters, clusplot uses the function pam to cluster the densities into 4 groups such that ellipses with nearly the same density get the same color. col.clus specifies the colors used.

The col.p and col.txt arguments, added for R, are recycled to have length the number of observations. If col.p has more than one value, using color = TRUE can be confusing because of a mix of point and ellipse colors.

# reset graphics
cpar(op)
```

clusplot.partition  Bivariate Clusplot of a Partitioning Object

Description

Clusplot (Clustering Plot) method for an object of class `partition`.

Usage

```r
## S3 method for class 'partition':
clusplot(x, main = NULL, dist = NULL, ...)
```

Arguments

- `x`  
an object of class "partition", e.g. created by the functions `pam, clara`, or `fanny`.
- `main`  
title for the plot; when NULL (by default), a title is constructed, using `x$call`.

dist  when x does not have a diss nor a data component, e.g., for 
pam(dist(*), keep.diss=FALSE), dist must specify the dissimilarity  
for the clusplot.

...  all optional arguments available for the clusplot.default function (except  
for the diss one) may also be supplied to this function. Graphical parameters  
(see par) may also be supplied as arguments to this function.

Details

This clusplot.partition() method relies on clusplot.default.

If the clustering algorithms pam, fanny and clara are applied to a data matrix of observations-
by-variables then a clusplot of the resulting clustering can always be drawn. When the data ma-
trix contains missing values and the clustering is performed with pam or fanny, the dissimi-
larity matrix will be given as input to clusplot. When the clustering algorithm clara was  
applied to a data matrix with NAs then clusplot will replace the missing values as described in  
clusplot.default, because a dissimilarity matrix is not available.

Value

An invisible list with components

Distances  When option lines is 1 or 2 we obtain a k by k matrix (k is the number of  
clusters). The element at row j and column s is the distance between ellipse j  
and ellipse s. If lines=0, then the value of this component is NA.

Shading  A vector of length k (where k is the number of clusters), containing the amount  
of shading per cluster. Let y be a vector where element i is the ratio between the  
number of objects in cluster i and the area of ellipse i. When the cluster i is a  
line segment, y[i] and the density of the cluster are set to NA. Let z be the sum  
of all the elements of y without the NAs. Then we put shading = y/z *37 + 3.

See Also

clusplot.default for references: partition.object, pam, pam.object, clara,  
clara.object, fanny, fanny.object.par.

Examples

## generate 25 objects, divided into 2 clusters.  
x <- rbind(cbind(rnorm(10,0,0.5), rnorm(10,0,0.5)),  
           cbind(rnorm(15,5,0.5), rnorm(15,5,0.5)))  
clusplot(pam(x, 2))  
## add noise, and try again :  
x4 <- cbind(x, rnorm(25), rnorm(25))  
clusplot(pam(x4, 2))
Agglomerative Coefficient for 'hclust' Objects

Description
Computes the “agglomerative coefficient”, measuring the clustering structure of the dataset.

For each observation i, denote by \( m(i) \) its dissimilarity to the first cluster it is merged with, divided by the dissimilarity of the merger in the final step of the algorithm. The agglomerative coefficient is the average of all \( 1 - m(i) \). It can also be seen as the average width (or the percentage filled) of the banner plot.

Because it grows with the number of observations, this measure should not be used to compare datasets of very different sizes.

Usage

```r
coef.hclust(object, ...)  
## S3 method for class 'hclust':
coef(object, ...)  
## S3 method for class 'twins':
coef(object, ...)
```

Arguments

- `object` an object of class "hclust" or "twins", i.e., typically the result of `hclust(.)`, `agnes(.)`, or `diana(.)`.
- `...` currently unused potential further arguments

Value

a number specifying the agglomerative (or divisive for diana objects) coefficient as defined by Kaufman and Rousseeuw, see `agnes.object$ac` or `diana.object$dc`.

Examples

```r
data(agriculture)  
aa <- agnes(agriculture)  
coef(aa) # really just extracts aa$ac  
coef(as.hclust(aa))# recomputes
```
daisy  

Dissimilarity Matrix Calculation

Description

Compute all the pairwise dissimilarities (distances) between observations in the data set. The original variables may be of mixed types.

Usage

daisy(x, metric = c("euclidean", "manhattan", "gower"),
    stand = FALSE, type = list())

Arguments

x  numeric matrix or data frame. Dissimilarities will be computed between the rows of x. Columns of mode numeric (i.e. all columns when x is a matrix) will be recognized as interval scaled variables, columns of class factor will be recognized as nominal variables, and columns of class ordered will be recognized as ordinal variables. Other variable types should be specified with the type argument. Missing values (NAs) are allowed.

metric character string specifying the metric to be used. The currently available options are "euclidean" (the default), "manhattan" and "gower". Euclidean distances are root sum-of-squares of differences, and manhattan distances are the sum of absolute differences. “Gower’s distance” is chosen by metric "gower" or automatically if some columns of x are not numeric. Also known as Gower’s coefficient (1971), expressed as a dissimilarity, this implies that a particular standardisation will be applied to each variable, and the “distance” between two units is the sum of all the variable-specific distances, see the details section.

stand logical flag: if TRUE, then the measurements in x are standardized before calculating the dissimilarities. Measurements are standardized for each variable (column), by subtracting the variable’s mean value and dividing by the variable’s mean absolute deviation. If not all columns of x are numeric, stand will be ignored and Gower’s standardization (based on the range) will be applied in any case, see argument metric, above, and the details section.

type list for specifying some (or all) of the types of the variables (columns) in x. The list may contain the following components: "ordratio" (ratio scaled variables to be treated as ordinal variables), "logratio" (ratio scaled variables that must be logarithmically transformed), "asymm" (asymmetric binary) and "symm" (symmetric binary variables). Each component’s value is a vector, containing the names or the numbers of the corresponding columns of x. Variables not mentioned in the type list are interpreted as usual (see argument x).

Details

daisy is fully described in chapter 1 of Kaufman and Rousseeuw (1990). Compared to dist whose input must be numeric variables, the main feature of daisy is its ability to handle other
variable types as well (e.g. nominal, ordinal, (a)symmetric binary) even when different types occur in the same data set.

The handling of nominal, ordinal, and (a)symmetric binary data is achieved by using the general dissimilarity coefficient of Gower (1971). If \( x \) contains any columns of these data-types, both arguments \texttt{metric} and \texttt{stand} will be ignored and Gower’s coefficient will be used as the metric. This can also be activated for purely numeric data by \texttt{metric = "gower"}. With that, each variable (column) is first standardized by dividing each entry by the range of the corresponding variable.

Note that setting the type to \texttt{symm} (symmetric binary) gives the same dissimilarities as using \texttt{nominal} (which is chosen for non-ordered factors) only when no missing values are present, and more efficiently.

Note that \texttt{daisy} now gives a warning when 2-valued numerical variables don’t have an explicit \texttt{type} specified, because the reference authors recommend to consider using \"asymm\".

In the \texttt{daisy} algorithm, missing values in a row of \( x \) are not included in the dissimilarities involving that row. There are two main cases,

1. If all variables are interval scaled, the metric is "euclidean", and \( ng \) is the number of columns in which neither row \( i \) and \( j \) have NAs, then the dissimilarity \( d(i,j) \) returned is \( \sqrt{\text{ncol}(x)/ng} \) times the Euclidean distance between the two vectors of length \( ng \) shortened to exclude NAs. The rule is similar for the "manhattan" metric, except that the coefficient is \( \text{ncol}(x)/ng \). If \( ng \) is zero, the dissimilarity is \( \text{NA} \).

2. When some variables have a type other than interval scaled, the dissimilarity between two rows is the weighted sum of the contributions of each variable. The weight becomes zero when that variable is missing in either or both rows, or when the variable is asymmetric binary and both values are zero. In all other situations, the weight of the variable is 1. The contribution of a nominal or binary variable to the total dissimilarity is 0 if both values are different, 1 otherwise. The contribution of other variables is the absolute difference of both values, divided by the total range of that variable. Ordinal variables are first converted to ranks.

If \( nok \) is the number of nonzero weights, the dissimilarity is multiplied by the factor \( 1/nok \) and thus ranges between 0 and 1. If \( nok = 0 \), the dissimilarity is set to \( \text{NA} \).

Value

an object of class "dissimilarity" containing the dissimilarities among the rows of \( x \). This is typically the input for the functions \texttt{pam}, \texttt{fanny}, \texttt{agnes} or \texttt{diana}. For more details, see \texttt{dissimilarity.object}.

Background

Dissimilarities are used as inputs to cluster analysis and multidimensional scaling. The choice of metric may have a large impact.

References

**diana**

**DIvisive ANAlysis Clustering**

**Description**

Computes a divisive hierarchical clustering of the dataset returning an object of class `diana`.

**Usage**

```r
diana(x, diss = inherits(x, "dist"), metric = "euclidean", stand = FALSE, keep.diss = n < 100, keep.data = !diss)
```

**Arguments**

- `x` data matrix or data frame, or dissimilarity matrix or object, depending on the value of the `diss` argument.
  
  In case of a matrix or data frame, each row corresponds to an observation, and each column corresponds to a variable. All variables must be numeric. Missing values (NAs) are allowed.
  
  In case of a dissimilarity matrix, `x` is typically the output of `daisy` or `dist`. Also a vector of length n*(n-1)/2 is allowed (where n is the number of observations), and will be interpreted in the same way as the output of the above-mentioned functions. Missing values (NAs) are not allowed.

- `diss` logical flag: if TRUE (default for `dist` or `dissimilarity` objects), then `x` will be considered as a dissimilarity matrix. If FALSE, then `x` will be considered as a matrix of observations by variables.

**Examples**

```r
data( agriculture)
## Example 1 in ref:
## Dissimilarities using Euclidean metric and without standardization
d.agr <- daisy( agriculture, metric = "euclidean", stand = FALSE)
d.agr
as.matrix(d.agr)[,"DK"] # via as.matrix.dist(.)
## compare with
as.matrix(daisy( agriculture, metric = "gower"))

data( flower)
## Example 2 in ref
summary(dfl1 <- daisy( flower, type = list( asymm = 3)))
summary(dfl2 <- daisy( flower, type = list( asymm = c(1, 3), ordratio = 7)))
## this failed earlier:
summary(dfl3 <- daisy( flower,
                     type = list( asymm = c("V1", "V3"), symm= 2,
                                ordratio= 7, logratio= 8))))
```

---

**Examples**

```r
data( agriculture)
## Example 1 in ref:
## Dissimilarities using Euclidean metric and without standardization
d.agr <- daisy( agriculture, metric = "euclidean", stand = FALSE)
d.agr
as.matrix(d.agr)[,"DK"] # via as.matrix.dist(.)
## compare with
as.matrix(daisy( agriculture, metric = "gower"))

data( flower)
## Example 2 in ref
summary(dfl1 <- daisy( flower, type = list( asymm = 3)))
summary(dfl2 <- daisy( flower, type = list( asymm = c(1, 3), ordratio = 7)))
## this failed earlier:
summary(dfl3 <- daisy( flower,
                     type = list( asymm = c("V1", "V3"), symm= 2,
                                ordratio= 7, logratio= 8))))
```

**Description**

Computes a divisive hierarchical clustering of the dataset returning an object of class `diana`.

**Usage**

```r
diana(x, diss = inherits(x, "dist"), metric = "euclidean", stand = FALSE, keep.diss = n < 100, keep.data = !diss)
```

**Arguments**

- `x` data matrix or data frame, or dissimilarity matrix or object, depending on the value of the `diss` argument.
  
  In case of a matrix or data frame, each row corresponds to an observation, and each column corresponds to a variable. All variables must be numeric. Missing values (NAs) are allowed.
  
  In case of a dissimilarity matrix, `x` is typically the output of `daisy` or `dist`. Also a vector of length n*(n-1)/2 is allowed (where n is the number of observations), and will be interpreted in the same way as the output of the above-mentioned functions. Missing values (NAs) are not allowed.

- `diss` logical flag: if TRUE (default for `dist` or `dissimilarity` objects), then `x` will be considered as a dissimilarity matrix. If FALSE, then `x` will be considered as a matrix of observations by variables.
character string specifying the metric to be used for calculating dissimilarities between observations. The currently available options are "euclidean" and "manhattan". Euclidean distances are root sum-of-squares of differences, and manhattan distances are the sum of absolute differences. If x is already a dissimilarity matrix, then this argument will be ignored.

logical; if true, the measurements in x are standardized before calculating the dissimilarities. Measurements are standardized for each variable (column), by subtracting the variable’s mean value and dividing by the variable’s mean absolute deviation. If x is already a dissimilarity matrix, then this argument will be ignored.

logicals indicating if the dissimilarities and/or input data x should be kept in the result. Setting these to FALSE can give much smaller results and hence even save memory allocation time.

The diana-algorithm constructs a hierarchy of clusterings, starting with one large cluster containing all n observations. Clusters are divided until each cluster contains only a single observation. At each stage, the cluster with the largest diameter is selected. (The diameter of a cluster is the largest dissimilarity between any two of its observations.) To divide the selected cluster, the algorithm first looks for its most disparate observation (i.e., which has the largest average dissimilarity to the other observations of the selected cluster). This observation initiates the "splinter group". In subsequent steps, the algorithm reassigns observations that are closer to the "splinter group" than to the "old party". The result is a division of the selected cluster into two new clusters.

A legitimate diana object is a list with the following components:

- order: a vector giving a permutation of the original observations to allow for plotting, in the sense that the branches of a clustering tree will not cross.
- order.lab: a vector similar to order, but containing observation labels instead of observation numbers. This component is only available if the original observations were labelled.
- height: a vector with the diameters of the clusters prior to splitting.
- dc: the divisive coefficient, measuring the clustering structure of the dataset. For each observation i, denote by d(i) the diameter of the last cluster to which it belongs (before being split off as a single observation), divided by the diameter of the whole dataset. The dc is the average of all 1 − d(i). It can also be
seen as the average width (or the percentage filled) of the banner plot. Because \( dc \) grows with the number of observations, this measure should not be used to compare datasets of very different sizes.

**merge**

an \((n-1)\) by 2 matrix, where \( n \) is the number of observations. Row \( i \) of merge describes the split at step \( n-i \) of the clustering. If a number \( j \) in row \( r \) is negative, then the single observation \( |j| \) is split off at stage \( n-r \). If \( j \) is positive, then the cluster that will be split at stage \( n-j \) (described by row \( j \)), is split off at stage \( n-r \).

**diss**

an object of class "dissimilarity", representing the total dissimilarity matrix of the dataset.

**data**

a matrix containing the original or standardized measurements, depending on the \( \text{stand} \) option of the function agnes. If a dissimilarity matrix was given as input structure, then this component is not available.

**See Also**

agnes also for background and references; cutree (and \text{as.hclust}) for grouping extraction; daisy, dist, plot.diana, twins.object.

**Examples**

data(votes.repub)
dv <- diana(votes.repub, metric = "manhattan", stand = TRUE)
print(dv)
plot(dv)

## Cut into 2 groups:
dv2 <- cutree(as.hclust(dv), k = 2)
table(dv2) # 8 and 42 group members
rownames(votes.repub)[dv2 == 1]

## For two groups, does the metric matter ?
dv0 <- diana(votes.repub, stand = TRUE) # default: Euclidean
dv.2 <- cutree(as.hclust(dv0), k = 2)
table(dv2 == dv.2)## identical group assignments

data(agriculture)
## Plot similar to Figure 8 in ref
## Not run: plot(diana(agriculture), ask = TRUE)
The dissimilarity matrix is symmetric, and hence its lower triangle (column wise) is represented as a vector to save storage space. If the object, is called do, and n the number of observations, i.e.,

\[ n \leftarrow \text{attr(do, "Size")}, \]

then for \( i < j \leq n \), the dissimilarity between (row) \( i \) and \( j \) is

\[ \text{do}[n*(i-1) - i*(i-1)/2 + j-i]. \]

The length of the vector is \( n*(n-1)/2 \), i.e., of order \( n^2 \).

"dissimilarity" objects also inherit from class \texttt{dist} and can use \texttt{dist} methods, in particular, \texttt{as.matrix}, such that \( d_{ij} \) from above is just \( \text{as.matrix(do)}[i,j] \).

The object has the following attributes:

- **Size**: the number of observations in the dataset.
- **Metric**: the metric used for calculating the dissimilarities. Possible values are "euclidean", "manhattan", "mixed" (if variables of different types were present in the dataset), and "unspecified".
- **Labels**: optionally, contains the labels, if any, of the observations of the dataset.
- **NA.message**: optionally, if a dissimilarity could not be computed, because of too many missing values for some observations of the dataset.
- **Types**: when a mixed metric was used, the types for each variable as one-letter codes (as in the book, e.g. p.54):
  - \( A \): Asymmetric binary
  - \( S \): Symmetric binary
  - \( N \): Nominal (factor)
  - \( O \): Ordinal (ordered factor)
  - \( I \): Interval scaled (numeric)
  - \( T \): raTio to be log transformed (positive numeric)

**GENERATION**

\texttt{daisy} returns this class of objects. Also the functions \texttt{pam}, \texttt{clara}, \texttt{fanny}, \texttt{agnes}, and \texttt{diana} return a dissimilarity object, as one component of their return objects.

**METHODS**

The "dissimilarity" class has methods for the following generic functions: \texttt{print}, \texttt{summary}.

**See Also**

\texttt{daisy}, \texttt{dist}, \texttt{pam}, \texttt{clara}, \texttt{fanny}, \texttt{agnes}, \texttt{diana}. 

ellipsoidhull

Compute the Ellipsoid Hull or Spanning Ellipsoid of a Point Set

Description

Compute the “ellipsoid hull” or “spanning ellipsoid”, i.e. the ellipsoid of minimal volume (‘area’ in 2D) such that all given points lie just inside or on the boundary of the ellipsoid.

Usage

ellipsoidhull(x, tol=0.01, maxit=5000,
  ret.wt = FALSE, ret.sqdist = FALSE, ret.pr = FALSE)

## S3 method for class 'ellipsoid':
print(x, digits = max(1, getOption("digits") - 2), ...)

Arguments

x
  the n p-dimensional points as numeric n x p matrix.

tol
  convergence tolerance for Titterington’s algorithm. Setting this to much smaller values may drastically increase the number of iterations needed, and you may want to increase maxit as well.

maxit
  integer giving the maximal number of iteration steps for the algorithm.

ret.wt, ret.sqdist, ret.pr
  logicals indicating if additional information should be returned, ret.wt specifying the weights, ret.sqdist the squared distances and ret.pr the final probabilities in the algorithms.

digits,...
  the usual arguments to print methods.

Details

The “spanning ellipsoid” algorithm is said to stem from Titterington(1976), in Pison et al(1999) who use it for clusplot.default. The problem can be seen as a special case of the “Min.Vol.” ellipsoid of which a more more flexible and general implementation is cov.mve in the MASS package.

Value

an object of class "ellipsoid", basically a list with several components, comprising at least

- cov
  p x p covariance matrix description the ellipsoid.

- loc
  p-dimensional location of the ellipsoid center.

- d2
  average squared radius. Further, d2 = \( t^2 \), where \( t \) is “the value of a t-statistic on the ellipse boundary” (from ellipse in the ellipse package), and hence, more usefully, \( d2 = qchisq(alpha, df = p) \), where \( alpha \) is the confidence level for p-variate normally distributed data with location and covariance loc and cov to lie inside the ellipsoid.

- wt
  the vector of weights iff ret.wt was true.

- sqdist
  the vector of squared distances iff ret.sqdist was true.

- prob
  the vector of algorithm probabilities iff ret.pr was true.
it 

number of iterations used.

tol, maxit 

just the input argument, see above.

eps 

the achieved tolerance which is the maximal squared radius minus $p$.

ierr 

error code as from the algorithm; 0 means ok.

conv 

logical indicating if the converged. This is defined as $it < \text{maxit} \land ierr == 0$.

Author(s)

Martin Maechler did the present class implementation; Rousseeuw et al did the underlying code.

References

A version of this is available as technical report from http://www.agoras.ua.ac.be/abstract/Disclu99.htm

See Also

predict.ellipsoid which is also the predict method for ellipsoid objects.

volume.ellipsoid for an example of ‘manual’ ellipsoid object construction;

further ellipse from package ellipse and ellipsePoints from package sfsmisc.

chull for the convex hull, clusplot which makes use of this; cov.mve.

Examples

```r
x <- rnorm(100)
xy <- unname(cbind(x, rnorm(100) + 2*x + 10))
ext <- ellipsoidhull(xy)
ext # >> calling print.ellipsoid()

plot(xy)
lines(predict(exy))
points(rbind(exy$loc), col = "red", cex = 3, pch = 13)

exy <- ellipsoidhull(xy, tol = 1e-7, ret.wt = TRUE, ret.sq = TRUE)
str(exy) # had small 'tol', hence many iterations
(ii <- which(zapsmall(exy$wt) > 1e-6)) # only about 4 to 6 points
round(exy$wt[ii],3); sum(exy$wt[ii]) # sum to 1
```

fanny

Fuzzy Analysis Clustering

Description

Computes a fuzzy clustering of the data into $k$ clusters.
Usage

fanny(x, k, diss = inherits(x, "dist"), memb.exp = 2,
metric = c("euclidean", "manhattan", "SqEuclidean"),
stand = FALSE, iniMem.p = NULL, cluster.only = FALSE,
keep.diss = !diss && !cluster.only && n < 100,
keep.data = !diss && !cluster.only,
maxit = 500, tol = 1e-15, trace.lev = 0)

Arguments

x
  data matrix or data frame, or dissimilarity matrix, depending on the value of the
diss argument.
In case of a matrix or data frame, each row corresponds to an observation, and
each column corresponds to a variable. All variables must be numeric. Missing
values (NAs) are allowed.
In case of a dissimilarity matrix, x is typically the output of daisy or dist.
Also a vector of length n*(n-1)/2 is allowed (where n is the number of obser-
vations), and will be interpreted in the same way as the output of the above-
mentioned functions. Missing values (NAs) are not allowed.
k
  integer giving the desired number of clusters. It is required that 0 < k < n/2
where n is the number of observations.
diss
  logical flag: if TRUE (default for dist or dissimilarity objects), then x
is assumed to be a dissimilarity matrix. If FALSE, then x is treated as a matrix
of observations by variables.
memb.exp
  number r strictly larger than 1 specifying the membership exponent used in the
fit criterion; see the "Details" below. Default: 2 which used to be hardwired
inside FANNY.
metric
  character string specifying the metric to be used for calculating dissimilarities
between observations. Options are "euclidean" (default), "manhattan",
and "SqEuclidean". Euclidean distances are root sum-of-squares of dif-
fferences, and manhattan distances are the sum of absolute differences, and
"SqEuclidean", the squared euclidean distances are sum-of-squares of dif-
fferences. Using this last option is equivalent (but somewhat slower) to comput-
ing so called "fuzzy C-means".
If x is already a dissimilarity matrix, then this argument will be ignored.
stand
  logical; if true, the measurements in x are standardized before calculating the
dissimilarities. Measurements are standardized for each variable (column), by
subtracting the variable’s mean value and dividing by the variable’s mean abso-
lute deviation. If x is already a dissimilarity matrix, then this argument will be
ignored.
iniMem.p
  numeric n × k matrix or NULL (by default); can be used to specify a starting
membership matrix, i.e., a matrix of non-negative numbers, each row sum-
ming to one.
cluster.only
  logical; if true, no silhouette information will be computed and returned, see
details.
keep.diss, keep.data
  logicals indicating if the dissimilarities and/or input data x should be kept in
the result. Setting these to FALSE can give smaller results and hence also save
memory allocation time.
maxit, tol  maximal number of iterations and default tolerance for convergence (relative convergence of the fit criterion) for the FANNY algorithm. The defaults maxit = 500 and tol = 1e-15 used to be hardwired inside the algorithm.

trace.lev  integer specifying a trace level for printing diagnostics during the C-internal algorithm. Default 0 does not print anything; higher values print increasingly more.

Details

In a fuzzy clustering, each observation is “spread out” over the various clusters. Denote by $u_{iv}$ the membership of observation $i$ to cluster $v$.

The memberships are nonnegative, and for a fixed observation $i$ they sum to 1. The particular method fanny stems from chapter 4 of Kaufman and Rousseeuw (1990) (see the references in daisy) and has been extended by Martin Maechler to allow user specified memb.exp, iniMem.p, maxit, tol, etc.

Fanny aims to minimize the objective function

$$
\sum_{i=1}^{k} \sum_{v=1}^{n} \sum_{j=1}^{n} u_{ir} u_{jv} d(i,j) \quad 2 \sum_{j=1}^{n} u_{jv}
$$

where $n$ is the number of observations, $k$ is the number of clusters, $r$ is the membership exponent memb.exp and $d(i,j)$ is the dissimilarity between observations $i$ and $j$.

Note that $r \to 1$ gives increasingly crisper clusterings whereas $r \to \infty$ leads to complete fuzzyness. K&R(1990), p.191 note that values too close to 1 can lead to slow convergence. Further note that even the default, $r = 2$ can lead to complete fuzzyness, i.e., memberships $u_{iv} \equiv 1/k$. In that case a warning is signalled and the user is advised to chose a smaller memb.exp ($< r$).

Compared to other fuzzy clustering methods, fanny has the following features: (a) it also accepts a dissimilarity matrix; (b) it is more robust to the spherical cluster assumption; (c) it provides a novel graphical display, the silhouette plot (see plot.partition).

Value

an object of class "fanny" representing the clustering. See fanny.object for details.

See Also

agnes for background and references; fanny.object, partition.object, plot.partition, daisy, dist.

Examples

```r
## generate 10+15 objects in two clusters, plus 3 objects lying 
## between those clusters.
x <- rbind(cbind(rnorm(10, 0, 0.5), rnorm(10, 0, 0.5)),
  cbind(rnorm(15, 5, 0.5), rnorm(15, 5, 0.5)),
  cbind(rnorm(3,3,2,0.5), rnorm(3,3,2,0.5)))
fannyx <- fanny(x, 2)
## Note that observations 26:28 are "fuzzy" (closer to # 2):
fannyx
summary(fannyx)
plot(fannyx)

(fan.x.15 <- fanny(x, 2, memb.exp = 1.5)) # 'crisper' for obs. 26:28
```
fanny.object

(fanny(x, 2, memb.exp = 3))  # more fuzzy in general

data(ruspini)
f4 <- fanny(ruspini, 4)
stopifnot(rle(f4$clustering)$lengths == c(20,23,17,15))
plot(f4, which = 1)
## Plot similar to Figure 6 in Stryuf et al (1996)
plot(fanny(ruspini, 5))

---

**fanny.object**  
**Fuzzy Analysis (FANNY) Object**

---

**Description**

The objects of class "fanny" represent a fuzzy clustering of a dataset.

**Value**

A legitimate fanny object is a list with the following components:

- **membership**: matrix containing the memberships for each pair consisting of an observation and a cluster.
- **memb.exp**: the membership exponent used in the fitting criterion.
- **coeff**: Dunn’s partition coefficient $F(k)$ of the clustering, where $k$ is the number of clusters. $F(k)$ is the sum of all squared membership coefficients, divided by the number of observations. Its value is between $1/k$ and 1.
  The normalized form of the coefficient is also given. It is defined as $(F(k) - 1/k)/(1 - 1/k)$, and ranges between 0 and 1. A low value of Dunn’s coefficient indicates a very fuzzy clustering, whereas a value close to 1 indicates a near-crisp clustering.
- **clustering**: the clustering vector of the nearest crisp clustering, see partition.object.
- **k.crisp**: integer ($\leq k$) giving the number of crisp clusters; can be less than $k$, where it’s recommended to decrease memb.exp.
- **objective**: named vector containing the minimal value of the objective function reached by the FANNY algorithm and the relative convergence tolerance tol used.
- **convergence**: named vector with iterations, the number of iterations needed and converged indicating if the algorithm converged (in maxit iterations within convergence tolerance tol).
- **diss**: an object of class "dissimilarity", see partition.object.
- **call**: generating call, see partition.object.
- **silinfo**: list with silhouette information of the nearest crisp clustering, see partition.object.
- **data**: matrix, possibly standardized, or NULL, see partition.object.

**GENERATION**

These objects are returned from fanny.
METHODS

The "fanny" class has methods for the following generic functions: print, summary.

INHERITANCE

The class "fanny" inherits from "partition". Therefore, the generic functions plot and clusplot can be used on a fanny object.

See Also

fanny, print.fanny, dissimilarity.object, partition.object, plot.partition.

---

flower

**Flower Characteristics**

Description

8 characteristics for 18 popular flowers.

Usage

data(flower)

Format

A data frame with 18 observations on 8 variables:

<p>| | | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>V1</td>
<td>factor</td>
<td>winters</td>
</tr>
<tr>
<td>V2</td>
<td>factor</td>
<td>shadow</td>
</tr>
<tr>
<td>V3</td>
<td>factor</td>
<td>tubers</td>
</tr>
<tr>
<td>V4</td>
<td>factor</td>
<td>color</td>
</tr>
<tr>
<td>V5</td>
<td>ordered</td>
<td>soil</td>
</tr>
<tr>
<td>V6</td>
<td>ordered</td>
<td>preference</td>
</tr>
<tr>
<td>V7</td>
<td>numeric</td>
<td>height</td>
</tr>
<tr>
<td>V8</td>
<td>numeric</td>
<td>distance</td>
</tr>
</tbody>
</table>

V1 winters, is binary and indicates whether the plant may be left in the garden when it freezes.

V2 shadow, is binary and shows whether the plant needs to stand in the shadow.

V3 tubers, is asymmetric binary and distinguishes between plants with tubers and plants that grow in any other way.

V4 color, is nominal and specifies the flower’s color (1 = white, 2 = yellow, 3 = pink, 4 = red, 5 = blue).

V5 soil, is ordinal and indicates whether the plant grows in dry (1), normal (2), or wet (3) soil.

V6 preference, is ordinal and gives someone’s preference ranking going from 1 to 18.

V7 height, is interval scaled, the plant’s height in centimeters.

V8 distance, is interval scaled, the distance in centimeters that should be left between the plants.

lower.to.upper.tri.inds

*Permute Indices for Triangular Matrices*

Description

Compute index vectors for extracting or reordering of lower or upper triangular matrices that are stored as contiguous vectors.

Usage

lower.to.upper.tri.inds(n)
upper.to.lower.tri.inds(n)

Arguments

n  integer larger than 1.

Value

integer vector containing a permutation of 1:N where $N = n(n - 1)/2$.

Note

these functions are mainly for internal use in the cluster package, and may not remain available (unless we see a good reason).

See Also

*upper.tri, lower.tri* with a related purpose.
Examples

```r
m5 <- matrix(NA, 5, 5)
m <- m5; m[lower.tri(m)] <- upper.to.lower.tri.ind(5); m
m <- m5; m[upper.tri(m)] <- lower.to.upper.tri.ind(5); m
```

```r
stopifnot(lower.to.upper.tri.ind(2) == 1,
          lower.to.upper.tri.ind(3) == 1:3,
          upper.to.lower.tri.ind(3) == 1:3,
          sort(upper.to.lower.tri.ind(5)) == 1:10,
          sort(lower.to.upper.tri.ind(6)) == 1:15)
```

Description

Returns a list representing a divisive hierarchical clustering of a dataset with binary variables only.

Usage

```r
mona(x)
```

Arguments

- `x`: data matrix or data frame in which each row corresponds to an observation, and each column corresponds to a variable. All variables must be binary. A limited number of missing values (NAs) is allowed. Every observation must have at least one value different from NA. No variable should have half of its values missing. There must be at least one variable which has no missing values. A variable with all its non-missing values identical, is not allowed.

Details

`mona` is fully described in chapter 7 of Kaufman and Rousseeuw (1990). It is “monothetic” in the sense that each division is based on a single (well-chosen) variable, whereas most other hierarchical methods (including `agnes` and `diana`) are “polythetic”, i.e. they use all variables together.

The `mona`-algorithm constructs a hierarchy of clusterings, starting with one large cluster. Clusters are divided until all observations in the same cluster have identical values for all variables. At each stage, all clusters are divided according to the values of one variable. A cluster is divided into one cluster with all observations having value 1 for that variable, and another cluster with all observations having value 0 for that variable.

The variable used for splitting a cluster is the variable with the maximal total association to the other variables, according to the observations in the cluster to be splitted. The association between variables f and g is given by \( a(f, g) * d(f, g) - b(f, g) * c(f, g) \), where \( a(f, g), b(f, g), c(f, g), \) and \( d(f, g) \) are the numbers in the contingency table of \( f \) and \( g \). [That is, \( a(f, g) \) (resp. \( d(f, g) \)) is the number of observations for which \( f \) and \( g \) both have value 0 (resp. value 1); \( b(f, g) \) (resp. \( c(f, g) \)) is the number of observations for which \( f \) has value 0 (resp. 1) and \( g \) has value 1 (resp. 0).] The total association of a variable \( f \) is the sum of its associations to all variables.

This algorithm does not work with missing values, therefore the data are revised, e.g. all missing values are filled in. To do this, the same measure of association between variables is used as in the algorithm. When variable \( f \) has missing values, the variable \( g \) with the largest absolute association
to f is looked up. When the association between f and g is positive, any missing value of f is replaced by the value of g for the same observation. If the association between f and g is negative, then any missing value of f is replaced by the value of 1-g for the same observation.

Value

an object of class "mona" representing the clustering. See mona.object for details.

See Also

agnes for background and references; mona.object, plot.mona.

Examples

data(animals)
ma <- mona(animals)
ma
## Plot similar to Figure 10 in Struyf et al (1996)
plot(ma)

mona.object Monothetic Analysis (MONA) Object

Description

The objects of class "mona" represent the divisive hierarchical clustering of a dataset with only binary variables (measurements). This class of objects is returned from mona.

Value

A legitimate mona object is a list with the following components:

- data matrix with the same dimensions as the original data matrix, but with factors coded as 0 and 1, and all missing values replaced.
- order a vector giving a permutation of the original observations to allow for plotting, in the sense that the branches of a clustering tree will not cross.
- order.lab a vector similar to order, but containing observation labels instead of observation numbers. This component is only available if the original observations were labelled.
- variable vector of length n-1 where n is the number of observations, specifying the variables used to separate the observations of order.
- step vector of length n-1 where n is the number of observations, specifying the separation steps at which the observations of order are separated.

METHODS

The "mona" class has methods for the following generic functions: print, summary, plot.

See Also

mona for examples etc, plot.mona.
Partitioning (clustering) of the data into \( k \) clusters "around medoids", a more robust version of K-means.

**Usage**

```r
pam(x, k, diss = inherits(x, "dist"), metric = "euclidean",
    medoids = NULL, stand = FALSE, cluster.only = FALSE,
    keep.diss = !diss && !cluster.only && n < 100,
    keep.data = !diss && !cluster.only, trace.lev = 0)
```

**Arguments**

- **x**
  - data matrix or data frame, or dissimilarity matrix or object, depending on the value of the `diss` argument.
  - In case of a matrix or data frame, each row corresponds to an observation, and each column corresponds to a variable. All variables must be numeric. Missing values (NAs) are allowed—as long as every pair of observations has at least one case not missing.
  - In case of a dissimilarity matrix, \( x \) is typically the output of `daisy` or `dist`. Also a vector of length \( n \times (n-1)/2 \) is allowed (where \( n \) is the number of observations), and will be interpreted in the same way as the output of the above-mentioned functions. Missing values (NAs) are not allowed.

- **k**
  - positive integer specifying the number of clusters, less than the number of observations.

- **diss**
  - logical flag: if TRUE (default for `dist` or dissimilarity objects), then \( x \) will be considered as a dissimilarity matrix. If FALSE, then \( x \) will be considered as a matrix of observations by variables.

- **metric**
  - character string specifying the metric to be used for calculating dissimilarities between observations.
  - The currently available options are "euclidean" and "manhattan". Euclidean distances are root sum-of-squares of differences, and manhattan distances are the sum of absolute differences. If \( x \) is already a dissimilarity matrix, then this argument will be ignored.

- **medoids**
  - NULL (default) or length-\( k \) vector of integer indices (in \( 1:n \)) specifying initial medoids instead of using the 'build' algorithm.

- **stand**
  - logical; if true, the measurements in \( x \) are standardized before calculating the dissimilarities. Measurements are standardized for each variable (column), by subtracting the variable’s mean value and dividing by the variable’s mean absolute deviation. If \( x \) is already a dissimilarity matrix, then this argument will be ignored.

- **cluster.only**
  - logical; if true, only the clustering will be computed and returned, see details.

- **keep.diss, keep.data**
  - logicals indicating if the dissimilarities and/or input data \( x \) should be kept in the result. Setting these to FALSE can give much smaller results and hence even save memory allocation time.
trace.lev  integer specifying a trace level for printing diagnostics during the build and swap phase of the algorithm. Default 0 does not print anything; higher values print increasingly more.

Details

pam is fully described in chapter 2 of Kaufman and Rousseeuw (1990). Compared to the k-means approach in kmeans, the function pam has the following features: (a) it also accepts a dissimilarity matrix; (b) it is more robust because it minimizes a sum of dissimilarities instead of a sum of squared euclidean distances; (c) it provides a novel graphical display, the silhouette plot (see plot.partition) (d) it allows to select the number of clusters using mean(silhouette(pr)) on the result pr <- pam(..), or directly its component pr$silinfo$avg.width, see also pam.object.

When cluster.only is true, the result is simply a (possibly named) integer vector specifying the clustering, i.e.,
pam(x,k, cluster.only=TRUE) is the same as
pam(x,k)$clustering but computed more efficiently.

The pam-algorithm is based on the search for k representative objects or medoids among the observations of the dataset. These observations should represent the structure of the data. After finding a set of k medoids, k clusters are constructed by assigning each observation to the nearest medoid. The goal is to find k representative objects which minimize the sum of the dissimilarities of the observations to their closest representative object.

By default, when medoids are not specified, the algorithm first looks for a good initial set of medoids (this is called the build phase). Then it finds a local minimum for the objective function, that is, a solution such that there is no single switch of an observation with a medoid that will decrease the objective (this is called the swap phase).

When the medoids are specified, their order does not matter; in general, the algorithms have been designed to not depend on the order of the observations.

Value

an object of class "pam" representing the clustering. See ?pam.object for details.

Note

For datasets larger than (say) 200 observations, pam will take a lot of computation time. Then the function clara is preferable.

See Also

agnes for background and references; pam.object, clara, daisy, partition.object, plot.partition, dist.

Examples

## generate 25 objects, divided into 2 clusters.
x <- rbind(cbind(rnorm(10,0,0.5), rnorm(10,0,0.5)),
           cbind(rnorm(15,5,0.5), rnorm(15,5,0.5)))
pamx <- pam(x, 2)
pamx
summary(pamx)
plot(pamx)
## use obs. 1 & 16 as starting medoids -- same result (typically)
(p2m <- pam(x, 2, medoids = c(1,16)))

p3m <- pam(x, 3, trace = 2)
## rather stupid initial medoids:
(p3m. <- pam(x, 3, medoids = 3:1, trace = 1))

pam(daisy(x, metric = "manhattan"), 2, diss = TRUE)
data(ruspini)
## Plot similar to Figure 4 in Stryuf et al (1996)
## Not run: plot(pam(ruspini, 4), ask = TRUE)

---

**pam.object**

*Partitioning Around Medoids (PAM) Object*

**Description**

The objects of class "pam" represent a partitioning of a dataset into clusters.

**Value**

A legitimate pam object is a list with the following components:

- **medoids**
  - the medoids or representative objects of the clusters. If a dissimilarity matrix was given as input to pam, then a vector of numbers or labels of observations is given, else medoids is a matrix with in each row the coordinates of one medoid.

- **id.med**
  - integer vector of indices giving the medoid observation numbers.

- **clustering**
  - the clustering vector, see partition.object.

- **objective**
  - the objective function after the first and second step of the pam algorithm.

- **isolation**
  - vector with length equal to the number of clusters, specifying which clusters are isolated clusters (L- or L*-clusters) and which clusters are not isolated. A cluster is an L*-cluster iff its diameter is smaller than its separation. A cluster is an L-cluster iff for each observation i the maximal dissimilarity between i and any other observation of the cluster is smaller than the minimal dissimilarity between i and any observation of another cluster. Clearly each L*-cluster is also an L-cluster.

- **clusinfo**
  - matrix, each row gives numerical information for one cluster. These are the cardinality of the cluster (number of observations), the maximal and average dissimilarity between the observations in the cluster and the cluster’s medoid, the diameter of the cluster (maximal dissimilarity between two observations of the cluster), and the separation of the cluster (minimal dissimilarity between an observation of the cluster and an observation of another cluster).

- **silinfo**
  - list with silhouette width information, see partition.object.

- **diss**
  - dissimilarity (maybe NULL), see partition.object.

- **call**
  - generating call, see partition.object.

- **data**
  - (possibily standardized) see partition.object.
**partition.object**

**Description**

The objects of class "partition" represent a partitioning of a dataset into clusters.

**Value**

a "partition" object is a list with the following (and typically more) components:

- **clustering**: the clustering vector. An integer vector of length `n`, the number of observations, giving for each observation the number (‘id’) of the cluster to which it belongs.
- **call**: the matched `call` generating the object.
- **silinfo**: a list with all silhouette information, only available when the number of clusters is non-trivial, i.e., `1 < k < n` and then has the following components, see `silhouette`

---

**GENERATION**

These objects are returned from `pam`.

**METHODS**

The "pam" class has methods for the following generic functions: `print`, `summary`.

**INHERITANCE**

The class "pam" inherits from "partition". Therefore, the generic functions `plot` and `clusplot` can be used on a `pam` object.

**Examples**

```r
## Use the silhouette widths for assessing the best number of clusters,
## following a one-dimensional example from Christian Hennig :
##
x <- c(rnorm(50), rnorm(50,mean=5), rnorm(30,mean=15))
asw <- numeric(20)
## Note that "k=1" won't work!
for (k in 2:20)
  asw[k] <- pam(x, k) $ silinfo $ avg.width
k.best <- which.max(asw)
cat("silhouette-optimal number of clusters:", k.best, 
plot(1:20, asw, type= "h", main = "pam() clustering assessment",
xlab= "k (# clusters)", ylab = "average silhouette width")
axis(1, k.best, paste("best",k.best,sep=" 
```

---

**See Also**

`pam`, `dissimilarity.object`, `partition.object`, `plot.partition`.

**widths** an (n x 3) matrix, as returned by `silhouette()`, with for each observation i the cluster to which i belongs, as well as the neighbor cluster of i (the cluster, not containing i, for which the average dissimilarity between its observations and i is minimal), and the silhouette width $s(i)$ of the observation.

**clus.avg.widths** the average silhouette width per cluster.

**avg.width** the average silhouette width for the dataset, i.e., simply the average of $s(i)$ over all observations $i$.

This information is also needed to construct a silhouette plot of the clustering, see `plot.partition`.

Note that `avg.width` can be maximized over different clusterings (e.g. with varying number of clusters) to choose an optimal clustering.

**objective** value of criterion maximized during the partitioning algorithm, may more than one entry for different stages.

**diss** an object of class "dissimilarity", representing the total dissimilarity matrix of the dataset (or relevant subset, e.g. for `clara`).

**data** a matrix containing the original or standardized data. This might be missing to save memory or when a dissimilarity matrix was given as input structure to the clustering method.

### GENERATION

These objects are returned from `pam`, `clara` or `fanny`.

### METHODS

The "partition" class has a method for the following generic functions: `plot`, `clusplot`.

### INHERITANCE

The following classes inherit from class "partition": "pam", "clara" and "fanny". See `pam.object`, `clara.object` and `fanny.object` for details.

**See Also**

`pam`, `clara`, `fanny`.

---

**plantTraits**

*Plant Species Traits Data*

**Description**

This dataset constitutes a description of 136 plant species according to biological attributes (morphological or reproductive)

**Usage**

`data(plantTraits)`
Format

A data frame with 136 observations on the following 31 variables.

**pdias** Diaspore mass (mg)

**longindex** Seed bank longevity

**durflow** Flowering duration

**height** Plant height, an ordered factor with levels $1 < 2 < \ldots < 8$.

**begflow** Time of first flowering, an ordered factor with levels $1 < 2 < 3 < 4 < 5 < 6 < 7 < 8 < 9$

**mycor** Mycorrhizas, an ordered factor with levels $0$never $< 1$ sometimes $< 2$always

**vegaer** aerial vegetative propagation, an ordered factor with levels $0$never $< 1$ present but limited $< 2$important.

**vegsout** underground vegetative propagation, an ordered factor with 3 levels identical to vegaer above.

**autopoll** selfing pollination, an ordered factor with levels $0$never $< 1$rare $< 2$often $< 3$ the rule

**insects** insect pollination, an ordered factor with 5 levels $0 < \ldots < 4$.

**wind** wind pollination, an ordered factor with 5 levels $0 < \ldots < 4$.

**lign** a binary factor with levels $0 : 1$, indicating if plant is woody.

**piq** a binary factor indicating if plant is thorny.

**ros** a binary factor indicating if plant is rosette.

**semiros** semi-rosette plant, a binary factor ($0$: no; $1$: yes).

**leafy** leafy plant, a binary factor.

**suman** summer annual, a binary factor.

**winan** winter annual, a binary factor.

**monocarp** monocarpic perennial, a binary factor.

**polycarp** polycarpic perennial, a binary factor.

**seasaes** seasonal aestival leaves, a binary factor.

**seashiv** seasonal hibernal leaves, a binary factor.

**seasver** seasonal vernal leaves, a binary factor.

**everalw** leaves always evergreen, a binary factor.

**everparti** leaves partially evergreen, a binary factor.

**elaio** fruits with an elaiosome (dispersed by ants), a binary factor.

**endozoo** endozoochorous fruits, a binary factor.

**epizoo** epizoocchorous fruits, a binary factor.

**aquat** aquatic dispersal fruits, a binary factor.

**windgl** wind dispersed fruits, a binary factor.

**unsp** unspecialized mechanism of seed dispersal, a binary factor.

Details

Most of factor attributes are not disjunctive. For example, a plant can be usually pollinated by insects but sometimes self-pollination can occurred.
library(cluster)

dai.b <- daisy(plantTraits, type = list(ordratio = 4:11, symm = 12:13, asymm = 14:31))

agn.trts <- agnes(dai.b, method="ward")

plot(agn.trts, which.plots = 2, cex = 0.6)

plot(agn.trts, which.plots = 1)

cutree6 <- cutree(agn.trts, k=6)
cutree6

## Principal Coordinate Analysis

cmdsdai.b <- cmdscale(dai.b, k=6)

plot(cmdsdai.b[, 1:2], asp = 1, col = cutree6)

## S3 method for class 'agnes':
plot(x, ask = FALSE, which.plots = NULL, main = NULL,
     sub = paste("Agglomerative Coefficient = ",round(x$ac, digits = 2)),
     adj = 0, nmax.lab = 35, max.strlen = 5, xax.pretty = TRUE, ...)

x an object of class "agnes", typically created by agnes(.)

ask logical; if true and which.plots is NULL, plot.agnes operates in interactive mode, via menu.

which.plots integer vector or NULL (default), the latter producing both plots. Otherwise, which.plots must contain integers of 1 for a banner plot or 2 for a dendrogram or "clustering tree".

main, sub main and sub title for the plot, with convenient defaults. See documentation for these arguments in plot.default.

adj for label adjustment in bannerplot().
### plot.agnes

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>nmax.lab</code></td>
<td>integer indicating the number of labels which is considered too large for single-name labelling the banner plot.</td>
</tr>
<tr>
<td><code>max.strlen</code></td>
<td>positive integer giving the length to which strings are truncated in banner plot labeling.</td>
</tr>
<tr>
<td><code>xax.pretty</code></td>
<td>logical or integer indicating if <code>pretty(*, n = xax.pretty)</code> should be used for the x axis. <code>xax.pretty = FALSE</code> is for back compatibility.</td>
</tr>
</tbody>
</table>

... graphical parameters (see `par`) may also be supplied and are passed to `bannerplot()` or `pltree()`, respectively.

### Details

When `ask = TRUE`, rather than producing each plot sequentially, `plot.agnes` displays a menu listing all the plots that can be produced. If the menu is not desired but a pause between plots is still wanted one must set `par(ask = TRUE)` before invoking the plot command.

The banner displays the hierarchy of clusters, and is equivalent to a tree. See Rousseeuw (1986) or chapter 5 of Kaufman and Rousseeuw (1990). The banner plots distances at which observations and clusters are merged. The observations are listed in the order found by the `agnes` algorithm, and the numbers in the `height` vector are represented as bars between the observations.

The leaves of the clustering tree are the original observations. Two branches come together at the distance between the two clusters being merged.

For more customization of the plots, rather call `bannerplot` and `pltree` directly with corresponding arguments, e.g., `xlab` or `ylab`.

### Side Effects

Appropriate plots are produced on the current graphics device. This can be one or both of the following choices:

- Banner
- Clustering tree

### Note

In the banner plot, observation labels are only printed when the number of observations is limited less than `nmax.lab` (35, by default), for readability. Moreover, observation labels are truncated to maximally `max.strlen` (5) characters.

### References

### See Also

`agnes` and `agnes.object; bannerplot, pltree, and par.`
Examples

```r
### Can also pass 'labels' to pltree() and bannerplot():
data(iris)
cS <- as.character(Sp <- iris$Species)
cS[Sp == "setosa"] <- "S"
cS[Sp == "versicolor"] <- "V"
cS[Sp == "virginica"] <- "g"
ai <- agnes(iris[, 1:4])
plot(ai, labels = cS, nmax = 150)# bannerplot labels are mess
```

Description

Creates plots for visualizing a `diana` object.

Usage

```r
## S3 method for class 'diana':
plot(x, ask = FALSE, which.plots = NULL, main = NULL,
     sub = paste("Divisive Coefficient = ", round(x$dc, digits = 2)),
     adj = 0, nmax.lab = 35, max.strlen = 5, xax.pretty = TRUE, ...)
```

Arguments

- **x**: an object of class "diana", typically created by `diana(.)`.
- **ask**: logical; if true and which.plots is NULL, `plot.diana` operates in interactive mode, via `menu`.
- **which.plots**: integer vector or NULL (default), the latter producing both plots. Otherwise, which.plots must contain integers of 1 for a banner plot or 2 for a dendrogram or "clustering tree".
- **main, sub**: main and sub title for the plot, each with a convenient default. See documentation for these arguments in `plot.default`.
- **adj**: for label adjustment in `bannerplot()`.
- **nmax.lab**: integer indicating the number of labels which is considered too large for single-name labelling the banner plot.
- **max.strlen**: positive integer giving the length to which strings are truncated in banner plot labeling.
- **xax.pretty**: logical or integer indicating if `pretty(*, n = xax.pretty)` should be used for the x axis. `xax.pretty = FALSE` is for back compatibility.
- **...**: graphical parameters (see `par`) may also be supplied and are passed to `bannerplot()` or `pltree()`, respectively.
plot.mona

Details

When ask = TRUE, rather than producing each plot sequentially, plot.diana displays a menu listing all the plots that can be produced. If the menu is not desired but a pause between plots is still wanted one must set `par(ask = TRUE)` before invoking the plot command.

The banner displays the hierarchy of clusters, and is equivalent to a tree. See Rousseeuw (1986) or chapter 6 of Kaufman and Rousseeuw (1990). The banner plots the diameter of each cluster being splitted. The observations are listed in the order found by the `diana` algorithm, and the numbers in the `height` vector are represented as bars between the observations.

The leaves of the clustering tree are the original observations. A branch splits up at the diameter of the cluster being splitted.

Side Effects

An appropriate plot is produced on the current graphics device. This can be one or both of the following choices:
- Banner
- Clustering tree

Note

In the banner plot, observation labels are only printed when the number of observations is limited less than `nmax.lab` (35, by default), for readability. Moreover, observation labels are truncated to maximally `max.strlen` (5) characters.

References

see those in plot.agnes.

See Also

diana, diana.object, twins.object, par.

Examples

e = example(diana)  # -> dv <- diana(....)

plot(dv, which = 1, nmax.lab = 100)

## wider labels :
op <- par(mar = par("mar") + c(0, 2, 0,0))
plot(dv, which = 1, nmax.lab = 100, max.strlen = 12)
par(op)

plot.mona  

Banner of Monothetic Divisive Hierarchical Clusterings

Description

Creates the banner of a `mona` object.
Usage

## S3 method for class 'mona':
plot(x, main = paste("Banner of ", deparse(x$call)),
     sub = NULL, xlab = "Separation step",
     col = c(2,0), axes = TRUE, adj = 0,
     nmax.lab = 35, max.strlen = 5, ...)

Arguments

x  an object of class "mona", typically created by mona(.).
main,sub main and sub titles for the plot, with convenient defaults. See documentation in plot.default.
xlab x axis label, see title.
col,adj graphical parameters passed to bannerplot().
axes logical, indicating if (labeled) axes should be drawn.
nmax.lab integer indicating the number of labels which is considered too large for labeling.
max.strlen positive integer giving the length to which strings are truncated in labeling.
... further graphical arguments are passed to bannerplot() and text.

Details

Plots the separation step at which clusters are splitted. The observations are given in the order found by the mona algorithm, the numbers in the step vector are represented as bars between the observations.

When a long bar is drawn between two observations, those observations have the same value for each variable. See chapter 7 of Kaufman and Rousseeuw (1990).

Side Effects

A banner is plotted on the current graphics device.

Note

In the banner plot, observation labels are only printed when the number of observations is limited less than nmax.lab (35, by default), for readability. Moreover, observation labels are truncated to maximally max.strlen (5) characters.

References

see those in plot.agnes.

mona,mona.object,par.
plot.partition  Plot of a Partition of the Data Set

Description

Creates plots for visualizing a partition object.

Usage

```r
## S3 method for class 'partition':
plot(x, ask = FALSE, which.plots = NULL,
     nmax.lab = 40, max.strlen = 5, data = x$data, dist = NULL,
     cor = TRUE, stand = FALSE, lines = 2,
     shade = FALSE, color = FALSE, labels = 0, plotchar = TRUE,
     span = TRUE, xlim = NULL, ylim = NULL, main = NULL, ...)
```

Arguments

- `x`: an object of class "partition", typically created by the functions `pam`, `clara`, or `fanny`.
- `ask`: logical; if true and `which.plots` is NULL, `plot.partition` operates in interactive mode, via menu.
- `which.plots`: integer vector or NULL (default), the latter producing both plots. Otherwise, `which.plots` must contain integers of 1 for a `clusplot` or 2 for `silhouette`.
- `nmax.lab`: integer indicating the number of labels which is considered too large for single-name labeling the silhouette plot.
- `max.strlen`: positive integer giving the length to which strings are truncated in silhouette plot labeling.
- `data`: numeric matrix with the scaled data; per default taken from the partition object `x`, but can be specified explicitly.
- `dist`: when `x` does not have a `diss` component as for `pam(*, keep.diss=FALSE)`, `dist` must be the dissimilarity if a clusplot is desired.
- `cor, stand, lines, shade, color, labels, plotchar, span, xlim, ylim, main, ...`: All optional arguments available for the `clusplot.default` function (except for the `diss` one) and graphical parameters (see `par`) may also be supplied as arguments to this function.

Details

When `ask = TRUE`, rather than producing each plot sequentially, `plot.partition` displays a menu listing all the plots that can be produced. If the menu is not desired but a pause between plots is still wanted, call `par(ask = TRUE)` before invoking the plot command.

The `clusplot` of a cluster partition consists of a two-dimensional representation of the observations, in which the clusters are indicated by ellipses (see `clusplot.partition` for more details).

The `silhouette plot` of a nonhierarchical clustering is fully described in Rousseeuw (1987) and in chapter 2 of Kaufman and Rousseeuw (1990). For each observation `i`, a bar is drawn, representing its silhouette width `s(i)`, see `silhouette` for details. Observations are grouped per cluster, starting with cluster 1 at the top. Observations with a large `s(i)` (almost 1) are very well clustered, a small `s(i)`
(around 0) means that the observation lies between two clusters, and observations with a negative s(i) are probably placed in the wrong cluster.

A clustering can be performed for several values of k (the number of clusters). Finally, choose the value of k with the largest overall average silhouette width.

Side Effects

An appropriate plot is produced on the current graphics device. This can be one or both of the following choices:

- Clusplot
- Silhouette plot

Note

In the silhouette plot, observation labels are only printed when the number of observations is less than nmax.lab (40, by default), for readability. Moreover, observation labels are truncated to maximally max.strlen (5) characters.

For more flexibility, use `plot(silhouette(x), ...)`, see `plot.silhouette`.

References

Further, the references in `plot.agnes`.

- `clusplot.default`
- `pam`
- `pam.object`
- `clara`
- `clara.object`
- `fanny`
- `fanny.object`
- `par`

Examples

```r
## generate 25 objects, divided into 2 clusters.
x <- rbind(cbind(rnorm(10,0,0.5), rnorm(10,0,0.5)),
           cbind(rnorm(15,5,0.5), rnorm(15,5,0.5)))
plot(pam(x, 2))
```

```r
## Save space not keeping data in clus.object, and still clusplot() it:
data(xclara)
x <- clara(xclara, 3, keep.data = FALSE)
x$data # is NULL
plot(cx, data = xclara)
```

---

**pltree**

*Clustering Trees - Generic Function*

**Description**

Generic function drawing a clustering tree (“dendrogram”) on the current graphics device. There is a `twins` method, see `pltree.twins` for usage and examples.
Usage

```r
pltree(x, ...)```

Arguments

- `x`: an R object (for which a `pltree` method is defined).
- `...`: methods may have additional arguments. Graphical parameters (see `par`) may also be supplied as arguments to this function.

See Also

- `pltree.twins`, `twins.object`.

---

### pltree.twins

**Clustering Tree of a Hierarchical Clustering**

Description

Draws a clustering tree (dendrogram) of a `twins` object, i.e., hierarchical clustering, typically resulting from `agnes()` or `diana()`.

Usage

```r
## S3 method for class 'twins':
pltree(x, main = paste("Dendrogram of ", deparse(x$call)),
labels = NULL, ylab = "Height", ...)
```

Arguments

- `x`: an object of class "twins", typically created by either `agnes()` or `diana()`.
- `main`: main title with a sensible default.
- `labels`: labels to use; the default is constructed from `x`.
- `ylab`: label for y-axis.
- `...`: graphical parameters (see `par`) may also be supplied as arguments to this function.

Details

Creates a plot of a clustering tree given a `twins` object. The leaves of the tree are the original observations. In case of an agglomerative clustering, two branches come together at the distance between the two clusters being merged. For a divisive clustering, a branch splits up at the diameter of the cluster being splitted.

Note that currently the method function simply calls `plot(as.hclust(x), ...)`, which dispatches to `plot.hclust(...)`. If more flexible plots are needed, consider `xx <- as.dendrogram(as.dendrogram(x))` and plotting `xx`, see `plot.dendrogram`.

Value

A NULL value is returned.
pluton

Isotopic Composition Plutonium Batches

Description

The `pluton` data frame has 45 rows and 4 columns, containing percentages of isotopic composition of 45 Plutonium batches.

Usage

data(pluton)

Format

This data frame contains the following columns:

- **Pu238**: the percentages of $^{238}Pu$, always less than 2 percent.
- **Pu239**: the percentages of $^{239}Pu$, typically between 60 and 80 percent (from neutron capture of Uranium, $^{238}U$).
- **Pu240**: percentage of the plutonium 240 isotope.
- **Pu241**: percentage of the plutonium 241 isotope.

Details

Note that the percentage of plutonium 242 can be computed from the other four percentages, see the examples.

In the reference below it is explained why it is very desirable to combine these plutonium patches in three groups of similar size.

Source

References

Examples

data(pluton)

hist(apply(pluton,1,sum), col = "gray") # between 94% and 100%
pu5 <- pluton
pu5$Pu242 <- 100 - apply(pluton,1,sum) # the remaining isotope.
pairs(pu5)

predict.ellipsoid  Predict Method for Ellipsoid Objects

Description

Compute points on the ellipsoid boundary, mostly for drawing.

Usage

predict.ellipsoid(object, n.out=201, ...)
## S3 method for class 'ellipsoid':
predict(object, n.out=201, ...)

ellipsoidPoints(A, d2, loc, n.half = 201)

Arguments

- **object**: an object of class `ellipsoid`, typically from `ellipsoidhull`; alternatively any list-like object with proper components, see details below.
- **n.out, n.half**: half the number of points to create.
- **A, d2, loc**: arguments of the auxiliary `ellipsoidPoints`, see below.
- **...**: passed to and from methods.

Details

Note `ellipsoidPoints` is the workhorse function of `predict.ellipsoid` a standalone function and method for `ellipsoid` objects, see `ellipsoidhull`. The class of `object` is not checked; it must solely have valid components `loc` (length `p`), the `p x p` matrix `cov` (corresponding to `A`) and `d2` for the center, the shape (“covariance”) matrix and the squared average radius (or distance) or `qchisq(*, p)` quantile.

Value

- A numeric matrix of dimension `2*n.out` times `p`.

See Also

- `ellipsoidhull`, `volume.ellipsoid`
Examples

```r
## see also example(ellipsoidhull)

## Robust vs. L.S. covariance matrix
set.seed(143)
x <- rt(200, df=3)
y <- 3*x + rt(200, df=2)
plot(x, y, main="non-normal data (N=200)"
     mtext("with classical and robust cov.matrix ellipsoids")
x <- cbind(x, y)
C.ls <- cov(X); m.ls <- colMeans(X)
d2.99 <- qchisq(0.99, df = 2)
lines(ellipsoidPoints(C.ls, d2.99, loc=m.ls), col="green")
if(require(MASS)) {
    Cxy <- cov.rob(cbind(x, y))
    lines(ellipsoidPoints(Cxy$cov, d2 = d2.99, loc=Cxy$center), col="red")
} # MASS
```

---

print.agnes

**Print Method for AGNES Objects**

**Description**

Prints the call, agglomerative coefficient, ordering of objects and distances between merging clusters ('Height') of an `agnes` object.

This is a method for the generic `print()` function for objects inheriting from class `agnes`, see `agnes.object`.

**Usage**

```r
## S3 method for class 'agnes':
print(x, ...)  
```

**Arguments**

- `x` an `agnes` object.
- `...` potential further arguments (required by generic).

**See Also**

`summary.agnes` producing more output; `agnes`, `agnes.object`, `print`, `print.default`.
print.clara  

Print Method for CLARA Objects

Description

Prints the best sample, medoids, clustering vector and objective function of clara object.
This is a method for the function print() for objects inheriting from class clara.

Usage

```r
## S3 method for class 'clara':
print(x, ..., )
```

Arguments

- `x`  
a clara object.
- `...`  
potential further arguments (require by generic).

See Also

summary.clara producing more output; clara, clara.object, print, print.default.

print.diana  

Print Method for DIANA Objects

Description

Prints the ordering of objects, diameters of splitted clusters, and divisive coefficient of a diana object.
This is a method for the function print() for objects inheriting from class diana.

Usage

```r
## S3 method for class 'diana':
print(x, ...)  
```

Arguments

- `x`  
a diana object.
- `...`  
potential further arguments (require by generic).

See Also

diana,diana.object,print,print.default.
**Print and Summary Methods for Dissimilarity Objects**

**Description**

Print or summarize the distances and the attributes of a dissimilarity object.

These are methods for the functions `print()` and `summary()` for dissimilarity objects. See `print`, `print.default`, or `summary` for the general behavior of these.

**Usage**

```r
## S3 method for class 'dissimilarity':
print(x, diag = NULL, upper = NULL,
      digits = getOption("digits"), justify = "none", right = TRUE, ...)
## S3 method for class 'dissimilarity':
summary(object,
        digits = max(3, getOption("digits") - 2), ...)
## S3 method for class 'summary.dissimilarity':
print(x, ...)  
```

**Arguments**

- `x, object` a dissimilarity object or a summary.dissimilarity one for print.summary.dissimilarity().
- `digits` the number of digits to use, see `print.default`.
- `diag, upper, justify, right` optional arguments specifying how the triangular dissimilarity matrix is printed; see `print.dist`.
- `...` potential further arguments (require by generic).

**See Also**

daisy, dissimilarity.object, print, print.default, print.dist.

**Examples**

```r
## See example(daisy)

sd <- summary(daisy(matrix(rnorm(100), 20, 5)))
sd # -> print.summary.dissimilarity(.)
str(sd)
```
**print.fanny**  
*Print and Summary Methods for FANNY Objects*

Description

Prints the objective function, membership coefficients and clustering vector of fanny object.  
This is a method for the function `print()` for objects inheriting from class `fanny`.

Usage

```r
## S3 method for class 'fanny':
print(x, digits = getOption("digits"), ...)
## S3 method for class 'fanny':
summary(object, ...)
## S3 method for class 'summary.fanny':
print(x, digits = getOption("digits"), ...)
```

Arguments

- `x, object` a `fanny` object.
- `digits` number of significant digits for printing, see `print.default`.
- `...` potential further arguments (required by generic).

See Also

`fanny`, `fanny.object`, `print`, `print.default`.

---

**print.mona**  
*Print Method for MONA Objects*

Description

Prints the ordering of objects, separation steps, and used variables of a mona object.  
This is a method for the function `print()` for objects inheriting from class `mona`.

Usage

```r
## S3 method for class 'mona':
print(x, ...)
```

Arguments

- `x` a `mona` object.
- `...` potential further arguments (require by generic).

See Also

`mona`, `mona.object`, `print`, `print.default`. 

---
print.pam  Print Method for PAM Objects

Description
Prints the medoids, clustering vector and objective function of pam object.
This is a method for the function print() for objects inheriting from class pam.

Usage
## S3 method for class 'pam':
print(x, ...)

Arguments
x  a pam object.
... potential further arguments (require by generic).

See Also
pam, pam.object, print, print.default.

ruspini  Ruspini Data

Description
The Ruspini data set, consisting of 75 points in four groups that is popular for illustrating clustering
techniques.

Usage
data(ruspini)

Format
A data frame with 75 observations on 2 variables giving the x and y coordinates of the points,
respectively.

Source

References
Examples

data(ruspini)

## Plot similar to Figure 4 in Stryuf et al (1996)
## Not run: plot(pam(ruspini, 4), ask = TRUE)

## Plot similar to Figure 6 in Stryuf et al (1996)
plot(fanny(ruspini, 5))

silhouette

Compute or Extract Silhouette Information from Clustering

Description

Compute silhouette information according to a given clustering in \( k \) clusters.

Usage

silhouette(x, ...)

## Default S3 method:
silhouette (x, dist, dmatrix, ...)
## S3 method for class 'partition':
silhouette(x, ...)
## S3 method for class 'clara':
silhouette(x, full = FALSE, ...)

sortSilhouette(object, ...)

## S3 method for class 'silhouette':
summary(object, FUN = mean, ...)
## S3 method for class 'silhouette':
plot(x, nmax.lab = 40, max.strlen = 5,
     main = NULL, sub = NULL, xlab = expression("Silhouette width \[s[i]\]),
     col = "gray", do.col.sort = length(col) > 1, border = 0,
     cex.names = par("cex.axis"), do.n.k = TRUE, do.clus.stat = TRUE, ...)

Arguments

x
  an object of appropriate class; for the default method an integer vector with
  \( k \) different integer cluster codes or a list with such an x$clustering compo-
  nent. Note that silhouette statistics are only defined if \( 2 \leq k \leq n - 1 \).

dist
  a dissimilarity object inheriting from class dist or coercible to one. If not
  specified, dmatrix must be.

dmatrix
  a symmetric dissimilarity matrix \((n \times n)\), specified instead of dist, which can
  be more efficient.

full
  logical specifying if a full silhouette should be computed for clara object.
  Note that this requires \( O(n^2) \) memory, since the full dissimilarity (see daisy)
  is needed internally.

object
  an object of class silhouette.

...t further arguments passed to and from methods.
For each observation \( i \), the **silhouette width** \( s(i) \) is defined as follows: Put \( a(i) = \) average dissimilarity between \( i \) and all other points of the cluster to which \( i \) belongs (if \( i \) is the only observation in its cluster, \( s(i) := 0 \) without further calculations). For all other clusters \( C \), put \( d(i,C) = \) average dissimilarity of \( i \) to all observations of \( C \). The smallest of these \( d(i,C) \) is \( b(i) := \min_C d(i,C) \), and can be seen as the dissimilarity between \( i \) and its “neighbor” cluster, i.e., the nearest one to which it does not belong. Finally,

\[
s(i) := \frac{b(i) - a(i)}{\max(a(i), b(i))}.
\]

**silhouette.default()** is now based on C code donated by Romain Francois (the R version being still available as `cluster:::silhouette.default.R`).

Observations with a large \( s(i) \) (almost 1) are very well clustered, a small \( s(i) \) (around 0) means that the observation lies between two clusters, and observations with a negative \( s(i) \) are probably placed in the wrong cluster.

**Value**

**silhouette()** returns an object, **sil**, of class **silhouette** which is an \([n \times 3]\) matrix with attributes. For each observation \( i \), **sil[i,]** contains the cluster to which \( i \) belongs as well as the neighbor cluster of \( i \) (the cluster, not containing \( i \), for which the average dissimilarity between its observations and \( i \) is minimal), and the silhouette width \( s(i) \) of the observation. The **colnames** correspondingly are **c(“cluster”, “neighbor”, “sil_width”).**

**summary(sil)** returns an object of class **summary.silhouette**, a list with components

- **si.summary** numerical **summary** of the individual silhouette widths \( s(i) \).
- **clus.avg.widths** numeric (rank 1) array of clusterwise **means** of silhouette widths where **mean = FUN** is used.
- **avg.width** the total mean **FUN(s)** where \( s \) are the individual silhouette widths.
silhouette

clus.sizes  table of the \( k \) cluster sizes.
call          if available, the call creating sil.
Ordered        logical identical to attr(sil, "Ordered"), see below.

sortSilhouette(sil) orders the rows of sil as in the silhouette plot, by cluster (increasingly) and decreasing silhouette width \( s(i) \).
attr(sil, "Ordered") is a logical indicating if sil is ordered as by sortSilhouette(). In that case, rownames(sil) will contain case labels or numbers, and
attr(sil, "iOrd") the ordering index vector.

Note

While silhouette() is intrinsic to the partition clusterings, and hence has a (trivial) method for these, it is straightforward to get silhouettes from hierarchical clusterings from silhouette.default() with cutree() and distance as input.

By default, for clara() partitions, the silhouette is just for the best random subset used. Use full = TRUE to compute (and later possibly plot) the full silhouette.

Examples

data(ruspini)
pr4 <- pam(ruspini, 4)
str(si <- silhouette(pr4))
(ssi <- summary(si))
plot(si) # silhouette plot
plot(si, col = c("red", "green", "blue", "purple")) # with cluster-wise coloring

si2 <- silhouette(pr4$clustering, dist(ruspini, "canberra"))
summary(si2) # has small values: "canberra"'s fault
plot(si2, nmax= 80, cex.names=0.6)

op <- par(mfrow= c(3,2), oma= c(0,0, 3, 0),
          mgp= c(1.6,.8,0), mar= .1+c(4,2,2,2))
for(k in 2:6)

plot(silhouette(pam(ruspini, k=k)), main = paste("k = ",k), do.n.k=FALSE)

text("FAM(Ruspini) as in Kaufman & Rousseeuw, p.101",
      outer = TRUE, font = par("font.main"), cex = par("cex.main"))
par(op)

## clara(): standard silhouette is just for the best random subset
data(xclara)
set.seed(?)
str(xclk <- xclara[sample(nrow(xclara), size = 1000) ,])
sizeDiss <- clara(xc1k, 3)
plot(silhouette(sizeDiss))
## only of the "best" subset of 46
## The full silhouette: internally needs large (36 MB) dist object:
sf <- silhouette(sizeDiss, full = TRUE)  ## this is the same as
s.full <- silhouette(sizeDiss$clustering, daisy(xc1k))
if(paste(R.version$major, R.version$minor, sep=".") >= "2.3.0")
  stopifnot(all.equal(sf, s.full, check.attributes = FALSE, tol = 0))
## color dependent on original "3 groups of each 1000":
plot(sf, col = 2 + as.integer(names(sizeDiss$clustering)) %/% 1000,
     main = "plot(silhouette(clara(.), full = TRUE))")

## Silhouette for a hierarchical clustering:
ar <- agnes(ruspini)
si3 <- silhouette(cutree(ar, k = 5), # k = 4 gave the same as pam() above
daisy(ruspini))
plot(si3, nmax = 80, cex.names = 0.5)
## 2 groups: Agnes() wasn’t too good:
si4 <- silhouette(cutree(ar, k = 2), daisy(ruspini))
plot(si4, nmax = 80, cex.names = 0.5)

---

**sizeDiss**

*Sample Size of Dissimilarity Like Object*

**Description**

Returns the number of observations (sample size) corresponding to a dissimilarity like object, or equivalently, the number of rows or columns of a matrix when only the lower or upper triangular part (without diagonal) is given.

It is nothing else but the inverse function of $f(n) = \frac{n(n - 1)}{2}$.

**Usage**

sizeDiss(d)

**Arguments**

d any R object with length (typically) $\frac{n(n - 1)}{2}$.

**Value**

a number; $n$ if length(d) == $n(n-1)/2$, NA otherwise.

**See Also**

dissimilarity.object and also as.dist for class dissimilarity and dist objects which have a Size attribute.

**Examples**

sizeDiss(1:10) # 5, since 10 == 5 * (5 - 1) / 2
sizeDiss(1:9) # NA

n <- 1:100
stopifnot(n == sapply(n*(n-1)/2, function(n) sizeDiss(logical(n))))
**Summary Method for ‘agnes’ Objects**

**Description**

Returns (and prints) a summary list for an `agnes` object. Printing gives more output than the corresponding `print.agnes` method.

**Usage**

```r
## S3 method for class 'agnes':
summary(object, ...)
## S3 method for class 'summary.agnes':
print(x, ...)
```

**Arguments**

- `x, object`  
  a `agnes` object.
- `...`  
  potential further arguments (require by generic).

**See Also**

`agnes`, `agnes.object`.

**Examples**

```r
data(agriculture)
summary(agnes(agriculture))
```

---

**Summary Method for ‘clara’ Objects**

**Description**

Returns (and prints) a summary list for a `clara` object. Printing gives more output than the corresponding `print.clara` method.

**Usage**

```r
## S3 method for class 'clara':
summary(object, ...)
## S3 method for class 'summary.clara':
print(x, ...)
```

**Arguments**

- `x, object`  
  a `clara` object.
- `...`  
  potential further arguments (require by generic).
## generate 2000 objects, divided into 5 clusters.
set.seed(47)
x <- rbind(cbind(rnorm(400, 0, 4), rnorm(400, 0, 4)),  
          cbind(rnorm(400, 10, 8), rnorm(400, 40, 6)),
          cbind(rnorm(400, 30, 4), rnorm(400, 40, 0)),
          cbind(rnorm(400, 40, 4), rnorm(400, 20, 2)),
          cbind(rnorm(400, 50, 4), rnorm(400, 50, 4)))
clx5 <- clara(x, 5)
## Mis`classification' table:
table(rep(1:5, rep(400, 5)), clx5$clust) # -> 1 "error"
summary(clx5)

## Graphically:
par(mfrow = c(3,1), mgp = c(1.5, 0.6, 0), mar = par("mar") - c(0,0,2,0))
plot(x, col = rep(2:6, rep(400, 5)))
plot(clx5)

summary.diana

Summary Method for ‘diana’ Objects

Description

Returns (and prints) a summary list for a diana object.

Usage

## S3 method for class 'diana':
summary(object, ...)
## S3 method for class 'summary.diana':
print(x, ...)

Arguments

x, object a diana object.
...

potential further arguments (require by generic).

See Also
diana, diana.object.
**Summary Method for 'mona' Objects**

**Description**

Returns (and prints) a summary list for a mona object.

**Usage**

```r
## S3 method for class 'mona':
summary(object, ...)
## S3 method for class 'summary.mona':
print(x, ...)
```

**Arguments**

- `x, object` a mona object.
- `...` potential further arguments (require by generic).

**See Also**

mona, mona.object.

---

**Summary Method for PAM Objects**

**Description**

Summarize a pam object and return an object of class summary.pam. There’s a print method for the latter.

**Usage**

```r
## S3 method for class 'pam':
summary(object, ...)
## S3 method for class 'summary.pam':
print(x, ...)
```

**Arguments**

- `x, object` a pam object.
- `...` potential further arguments (require by generic).

**See Also**

pam, pam.object.
twins.object Hierarchical Clustering Object

Description
The objects of class "twins" represent an agglomerative or divisive (polythetic) hierarchical clustering of a dataset.

Value
See agnes.object and diana.object for details.

GENERATION
This class of objects is returned from agnes or diana.

METHODS
The "twins" class has a method for the following generic function: pltree.

INHERITANCE
The following classes inherit from class "twins": "agnes" and "diana".

See Also
agnes, diana.

volume.ellipsoid Compute the Volume of Planar Object

Description
Compute the volume of a planar object. This is a generic function and a method for ellipsoid objects.

Usage
## S3 method for class 'ellipsoid':
volume(object)

Arguments
object an R object the volume of which is wanted; for the ellipsoid method, an object of that class (see ellipsoidhull or the example below).

Value
a number, the volume of the given object.
See Also

ellipsoidhull for spanning ellipsoid computation.

Examples

```r
# which defines 'ellipsoid' object <namefoo>
myEl <- structure(list(cov = rbind(c(3,1),1:2), loc = c(0,0), d2 = 10),
class = "ellipsoid")
volume(myEl)# i.e. "area" here (d = 2)
myEl # also mentions the "volume"
```

votes.repub

Votes for Republican Candidate in Presidential Elections

Description

A data frame with the percents of votes given to the republican candidate in presidential elections from 1856 to 1976. Rows represent the 50 states, and columns the 31 elections.

Usage

data(votes.repub)

Source

Data from 1964 to 1976 is from R. M. Scammon, American Votes 12, Congressional Quarterly.

xclara

Bivariate Data Set with 3 Clusters

Description

An artificial data set consisting of 3000 points in 3 well-separated clusters of size 1000 each.

Usage

data(xclara)

Format

A data frame with 3000 observations on 2 numeric variables giving the x and y coordinates of the points, respectively.

Source

Sample data set accompanying the reference below, obtained from http://www.stat.ucla.edu/journals/jss/v01/i04/data/.
References

Chapter 15

The codetools package

---

**checkUsage**

*Check R Code for Possible Problems*

**Description**

Check R code for possible problems.

**Usage**

```r
checkUsage(fun, name = "<anonymous>", report = cat, all = FALSE, suppressLocal = FALSE, suppressParamAssigns = !all, suppressParamUnused = !all, suppressFundefMismatch = FALSE, suppressLocalUnused = FALSE, suppressNoLocalFun = !all, skipWith = FALSE, suppressUndefined = dfltSuppressUndefined)
checkUsageEnv(env, ...)
checkUsagePackage(pack, ...)
```

**Arguments**

- **fun**: closure.
- **name**: character; name of closure.
- **env**: environment containing closures to check.
- **pack**: character naming package to check.
- **...**: options to be passed to `checkUsage`.
- **report**: function to use to report possible problems.
- **all**: logical; report all possible problems if TRUE.
- **suppressLocal**: suppress all local variable warnings.
- **suppressParamAssigns**: suppress warnings about assignments to formal parameters.
- **suppressParamUnused**: suppress warnings about unused formal parameters.
suppressFundefMismatch
suppress warnings about multiple local function definitions with different formal
argument lists

suppressLocalUnused
suppress warnings about unused local variables

suppressNoLocalFun
suppress warnings about using local variables as functions with no apparent
local function definition

skipWith
logical; if true, do no examine code portion of with expressions.
suppressUndefined
suppress warnings about undefined global functions and variables.

Details

checkUsage checks a single R closure. Options control which possible problems to report. The
default settings are moderately verbose. A first pass might use suppressLocal=TRUE to sup-
press all information related to local variable usage. The suppressXYZ values can either be scalar
logicals or character vectors; then they are character vectors they only suppress problem reports for
the variables with names in the vector.

checkUsageEnv and checkUsagePackage are convenience functions that apply
checkUsage to all closures in an environment or a package. checkUsagePackage re-
quires that the package be loaded. If the package has a name space then the internal name space
frame is checked.

Author(s)
Luke Tierney

Examples

checkUsage(checkUsage)
checkUsagePackage("codetools",all=TRUE)
## Not run: checkUsagePackage("base",suppressLocal=TRUE)

Description

These functions provide an some tools for analysing R code. Mainly indented to support the other
tools in this package and byte code compilation.

Usage

collectLocals(e, collect)
collectUsage(fun, name = "<anonymous>", ...)
constantFold(e, env = NULL, fail = NULL)
findFuncLocals(formals, body)
findLocals(e, envir = .BaseEnv)
findLocalsList(elist, envir = .BaseEnv)
flattenAssignment(e)
getAssignedVar(e)
isConstantValue(v, w)
makeCodeWalker(..., handler, call, leaf)
makeLocalsCollector(..., leaf, handler, isLocal, exit, collect)
makeUsageCollector(fun, ..., name, enterLocal, enterGlobal, enterInternal,
    startCollectLocals, finishCollectLocals, warn, signal)
walkCode(e, w = makeCodeWalker())

Arguments

e R expression.
elist list of R expressions.
v R object.
fun closure.
formals formal arguments of a closure.
body body of a closure.
name character.
env character.
envir environment.
w code walker.
... extra elements for code walker.
collect function.
fail function.
handler function.
call function.
leaf function.
isLocal function.
exit function.
enterLocal function.
enterGlobal function.
enterInternal function.
startCollectLocals function.
finishCollectLocals function.
warn function.
signal function.

Details

Author(s)

Luke Tierney
findGlobals

Find Global Functions and Variables Used by a Closure

Description
Finds global functions and variables used by a closure.

Usage
findGlobals(fun, merge = TRUE)

Arguments
fun   closure.
merge logical

Details
The result is an approximation. R semantics only allow variables that might be local to be identified (and event that assumes no use of `assign` and `rm`).

Value
Character vector if `merge` is `true`; otherwise, a list with `functions` and `variables` components.

Author(s)
Luke Tierney

Examples
findGlobals(findGlobals)
findGlobals(findGlobals, merge = FALSE)
**showTree**  
*Print Lisp-Style Representation of R Expression*

**Description**

Prints a Lisp-style representation of R expression. This can be useful for understanding how some things are parsed.

**Usage**

```r
showTree(e, write = cat)
```

**Arguments**

- `e`  
  R expression.
- `write`  
  function of one argument to write the result.

**Author(s)**

Luke Tierney

**Examples**

```r
showTree(quote(-3))
showTree(quote("x"<-1))
showTree(quote("f"(x)))
```
Chapter 16

The foreign package

lookup.xport  Lookup Information on a SAS XPORT Format Library

Description

Scans a file as a SAS XPORT format library and returns a list containing information about the SAS library.

Usage

lookup.xport(file)

Arguments

file  character variable with the name of the file to read. The file must be in SAS XPORT format.

Value

A list with one component for each dataset in the XPORT format library.

Author(s)

Saikat DebRoy

References

See Also

read.xport
read.arff

Description
Reads data from Weka Attribute-Relation File Format (ARFF) files.

Usage
read.arff(file)

Arguments
file a character string with the name of the ARFF file to read from, or a connection which will be opened if necessary, and if so closed at the end of the function call.

Value
A data frame containing the data from the ARFF file.

References

See Also
write.arff

read.dbf

Description
The function reads a DBF file into a data frame, converting character fields to factors, and trying to respect NULL fields.

Usage
read.dbf(file, as.is = FALSE)

Arguments
file name of input file
as.is should character vectors not be converted to factors?
Details

DBF is the extension used for files written for the ‘XBASE’ family of database languages, covering the dBase, Clipper, FoxPro, and their Windows equivalents Visual dBase, Visual Objects, and Visual FoxPro, plus some older products (http://www.clicketyclick.dk/databases/xbase/format/). Most of these follow the file structure used by Ashton-Tate’s dBase II, III or 4 (later owned by Borland).

read.dbf is based on C code from http://shapelib.maptools.org/ which implements the ‘XBASE’ specification. It can convert fields of type "L" (logical), "N" and "F" (numeric and float) and "D" (dates): all other field types are read as-is as character vectors. A numeric field are read as an R integer vector if it is encoded to have no decimals, otherwise as a numeric vector. However, if the numbers are too large to fit into an integer vector, it is changed to numeric. Note that it is possible to read integers that cannot be represented exactly even as doubles: this sometimes occurs if IDs are incorrectly coded as numeric.

Value

A data frame of data from the DBF file; note that the field names are adjusted to use in R using make.names(unique=TRUE).

There is an attribute "data_type" giving the single-character dBase types for each field.

Author(s)

Nicholas Lewin-Koh and Roger Bivand; shapelib by Frank Warmerdam

References

http://shapelib.maptools.org/.

x <- read.dbf(system.file("files/sids.dbf", package="foreign")[1])
str(x)
summary(x)

read.dta

Read Stata Binary Files

Description

Reads a file in Stata version 5-9 binary format into a data frame.

Usage

read.dta(file, convert.dates = TRUE, tz = NULL,
      convert.factors = TRUE, missing.type = FALSE,
      convert.underscore=TRUE, warn.missing.labels=TRUE)
**Arguments**

- **file**
  a filename as a character string.
- **convert.dates**
  Convert Stata dates to `Date` class?
- **tz**
  Previously used to specify time zone. Now deprecated.
- **convert.factors**
  Use Stata value labels to create factors? (version 6.0 or later).
- **missing.type**
  For version 8.9 only, store information about different types of missing data?
- **convert.underscore**
  Convert "_" in Stata variable names to "." in R names?
- **warn.missing.labels**
  Warn if a variable is specified with value labels and those value labels are not present in the file.

**Details**

The variables in the Stata data set become the columns of the data frame. Missing values are correctly handled. The data label, variable labels, and timestamp are stored as attributes of the data frame. Nothing is done with variable characteristics.

Optionally, Stata dates (%d formats) are converted to R's `Date` class and variables with Stata value labels are converted to factors. Ordinarily, `read.dta` will not convert a variable to a factor unless a label is present for every level. Use `convert.factors=NA` to override this. In any case the value label and format information is stored as attributes on the returned data frame.

Stata 8.0 introduced a system of 27 different missing data values. If `missing.type` is TRUE a separate list is created with the same variable names as the loaded data. For string variables the list value is NULL. For other variables the value is NA where the observation is not missing and 0-26 when the observation is missing. This is attached as the code"missing" attribute of the returned value.

The option to allow underscores in variable names may become the default in future versions now that R supports their use.

**Value**

a data frame

**Author(s)**

Thomas Lumley

**References**

Stata Users Manual (versions 5 & 6), Programming manual (version 7), or online help (version 8,9) describe the format of the files.

**See Also**

`write.dta`, `attributes`, `Date`, `factor`
read.epiinfo

Examples

```r
data(swiss)
write.dta(swiss, swissfile<-tempfile())
read.dta(swissfile)
```

Description

Reads data files in the .REC format used by Epi Info versions 6 and earlier and by EpiData. Epi Info is a public domain database and statistics package produced by the US Centers for Disease Control and EpiData is a freely available data entry and validation system.

Usage

```r
read.epiinfo(file, read.deleted = FALSE, guess.broken.dates = FALSE,
             thisyear = NULL, lower.case.names = FALSE)
```

Arguments

- `file` A filename, URL, or connection.
- `read.deleted` Deleted records are read if TRUE, omitted if FALSE or replaced with NA if NA.
- `guess.broken.dates` Attempt to convert dates with 0 or 2 digit year information (see Details below).
- `thisyear` A 4-digit year to use for dates with no year information. Defaults to the current year.
- `lower.case.names` Convert variable names to lowercase?

Details

Epi Info allows dates to be specified with no year or with a 2 or 4 digits. Dates with four-digit years are always converted to Date class. With the `guess.broken.dates` option the function will attempt to convert two-digit years using the operating system’s default method (see Date) and will use the current year or the `thisyear` argument for dates with no year information.

If `read.deleted` is TRUE the "deleted" attribute of the data frame indicates the deleted records.

Value

A data frame.

Note

Epi Info 2000, the current version, uses the Microsoft Access file format to store data. This may be readable with the RODBC or RDCOM packages.

References

DateTimeClasses

Examples

```r
## Not run:
data<-read.epiinfo("oswego.rec",guess.broken.dates=TRUE,thisyear="1972")
## End(Not run)
```

---

**read.mtp**

*Read a Minitab Portable Worksheet*

**Description**

Return a list with the data stored in a file as a Minitab Portable Worksheet.

**Usage**

```r
read.mtp(file)
```

**Arguments**

- `file` character variable with the name of the file to read. The file must be in Minitab Portable Worksheet format.

**Value**

A list with one component for each column, matrix, or constant stored in the Minitab worksheet.

**Author(s)**

Douglas M. Bates

**References**

http://www.minitab.com/

**Examples**

```r
## Not run:
read.mtp("ex1-10.mtp")
## End(Not run)
```
**read.octave**  
Read Octave Text Data Files

**Description**
Read a file in Octave text data format into a list.

**Usage**
```
read.octave(file)
```

**Arguments**
- `file` a character string with the name of the file to read.

**Details**
This function is used to read in files in Octave text data format, as created by `save -ascii` in Octave. It knows about most of the common types of variables, including the standard atomic (real and complex scalars, matrices, and N-d arrays, strings, ranges, and boolean scalars and matrices) and recursive (structs, cells, and lists) ones, but has no guarantee to read all types. If a type is not recognized, a warning indicating the unknown type is issued, it is attempted to skip the unknown entry, and NULL is used as its value. Note that this will give incorrect results, and maybe even errors, in the case of unknown recursive data types.

As Octave can read MATLAB binary files, one can make the contents of such files available to R by using Octave's load and save (as text) facilities as an intermediary step.

**Value**
A list with one named component for each variable in the file.

**Author(s)**
Stephen Eglen ⟨stephen@gnu.org⟩ and Kurt Hornik

**References**
http://www.octave.org/

---

**read.spss**  
Read an SPSS Data File

**Description**
`read.spss` reads a file stored by the SPSS `save` and `export` commands and returns a list.

**Usage**
```
read.spss(file, use.value.labels=TRUE, to.data.frame=FALSE, max.value.labels=Inf, trim.factor.names=FALSE)
```
Arguments

- **file**: character variable with the name of the file to read.
- **use.value.labels**: Convert variables with value labels into \( \mathbb{R} \) factors with those levels?
- **to.data.frame**: return a data frame?
- **max.value.labels**: Only variables with at most this many unique values will be converted to factors
- **trim.factor.names**: Trim trailing spaces from factor levels?

Details

This uses modified code from the PSPP project for reading the SPSS formats.

Occasionally in SPSS value labels will be added to some values of a continuous variable (e.g., to distinguish different types of missing data), and you will not want these variables converted to factors. By setting `max.val.labels` you can specify that variables with a large number of distinct values are not converted to factors even if they have value labels. In addition, variables will not be converted to factors if there are non-missing values that have no value label. The value labels are then returned in the "value.labels" attribute of the variable.

If SPSS variable labels are present, they are returned as the "variable.labels" attribute of the answer.

Fixed length strings (including value labels) are padded on the right with spaces by SPSS, and so are read that way by \( \mathbb{R} \). See the examples for `sub` for ways to remove trailing spaces in string data.

Value

A list (or data frame) with one component for each variable in the saved data set.

Note

If SPSS value labels are converted to factors the underlying numerical codes will not in general be the same as the SPSS numerical values, since the numerical codes in \( \mathbb{R} \) are always 1,2,3,...

You may see warnings about the file encoding: it is possible such files contain non-ASCII character data which need re-encoding. The most common occurrence is Windows codepage 1252, a superset of Latin-1.

Author(s)

Saikat DebRoy and the \( \mathbb{R} \) Core team

Examples

```r
## Not run:
read.spss("datafile")
## don't convert value labels to factor levels
read.spss("datafile",use.value.labels=FALSE)
## convert value labels to factors for variables with at most
## ten distinct values.
read.spss("datafile",max.value.labels=10)
## End(Not run)
```
Description

Generates a SAS program to convert the ssd contents to SAS transport format and then uses read.xport to obtain a dataframe.

Usage

```r
code(read.ssd(libname, sectionnames,
tmpXport=tempfile(), tmpProgLoc=tempfile(), sascmd="sas"))
```

Arguments

- `libname` character string defining the SAS library (usually a directory reference)
- `sectionnames` character vector giving member names. These are files in the `libname` directory. They will usually have a `.ssd0` or `.sas7bdat` extension, which should be omitted.
- `tmpXport` character string: location where temporary xport format archive should reside – defaults to a randomly named file in the session temporary directory, which will be removed.
- `tmpProgLoc` character string: location where temporary conversion SAS program should reside – defaults to a randomly named file in session temporary directory, which will be removed on successful operation.
- `sascmd` character string giving full path to SAS executable.

Details

Creates a SAS program and runs it.

Error handling is primitive.

Value

A data frame if all goes well, or `NULL` with warnings and some enduring side effects (log file for auditing)

Note

This requires SAS to be available. If you have a SAS dataset without access to SAS you will need another product to convert it to a format such as `.csv`, for example ‘Stat/Transfer’ or ‘DBMS/Copy’ or the ‘SAS System Viewer’ (Windows only).

Examples

```r
## if there were some files on the web we could get a real
## runnable example
## Not run:
R> list.files("trialdata")
[1] "baseline.sas7bdat" "form11.sas7bdat" "form12.sas7bdat"
[4] "form13.sas7bdat" "form22.sas7bdat" "form23.sas7bdat"
[7] "form3.sas7bdat" "form4.sas7bdat" "form48.sas7bdat"
[10] "form50.sas7bdat" "form51.sas7bdat" "form71.sas7bdat"
[13] "form72.sas7bdat" "form8.sas7bdat" "form9.sas7bdat"
[16] "form90.sas7bdat" "form91.sas7bdat"

R> baseline <- read.ssd("trialdata","baseline")
R> form90 <- read.ssd("trialdata","form90")

## Or for a Windows example
sashome <- "/Program Files/SAS/SAS 9.1"
read.ssd(file.path(sashome, "core", "sashelp"), "retail",
          sascmd = file.path(sashome, "sas.exe"))
```

### End(Not run)

**read.systat**

*Obtain a Data Frame from a Systat File*

**Description**

`read.systat` reads a rectangular data file stored by the Systat `SAVE` command as (legacy) `*.sys` or more recently `*.syd` files.

**Usage**

```r
read.systat(file, to.data.frame = TRUE)
```

**Arguments**

- `file` character variable with the name of the file to read
- `to.data.frame` return a data frame (otherwise a list)

**Details**

The function only reads those Systat files that are rectangular data files (`mtype = 1`), and warns when files have non-standard variable name codings. The files tested were produced on MS-DOS and Windows: files for the Mac version of Systat have a completely different format.

The C code was originally written for an add-on module for Systat described in Bivand (1992 paper). Variable names retain the trailing dollar in the list returned when `to.data.frame` is `FALSE`, and in that case character variables are returned as is and filled up to 12 characters with blanks on the right. The original function was limited to reading Systat files with up to 256 variables (a Systat limitation); it will now read up to 8192 variables.

If there is a user comment in the header this is returned as attribute "comment". Such comments are always a multiple of 72 characters (with a maximum of 720 chars returned), normally padded with trailing spaces.
Value

A data frame (or list) with one component for each variable in the saved data set.

Author(s)

Roger Bivand

References

Examples

```r
summary(iris)
iris.s <- read.systat(system.file("files/Iris.syd", package="foreign")[[1]])
str(iris.s)
summary(iris.s)
```

---

**read.xport**  
*Read a SAS XPORT Format Library*

Description

Reads a file as a SAS XPORT format library and returns a list of data.frames.

Usage

```r
read.xport(file)
```

Arguments

- `file` character variable with the name of the file to read. The file must be in SAS XPORT format.

Value

If there is a more than one dataset in the XPORT format library, a named list of data frames, otherwise a data frame. The columns of the data frames will be either numeric (corresponding to numeric in SAS) or factor (corresponding to character in SAS). All SAS numeric missing values (including special missing values represented by ._, .A to .Z by SAS) are mapped to R NA.

Trailing blanks are removed from character columns before conversion to a factor. Some sources claim that character missing values in SAS are represented by ' ' or": these are not treated as R missing values.

S3 read functions  Read an S3 Binary or data.dump File

Description
Reads binary data files or data.dump files that were produced in S version 3.

Usage

```r
data.restore(file, print = FALSE, verbose = FALSE, env = .GlobalEnv)
read.S(file)
```

Arguments

- `file` the filename of the S-PLUS data.dump or binary file.
- `print` whether to print the name of each object as read from the file.
- `verbose` whether to print the name of every subitem within each object.
- `env` environment within which to create the restored object(s).

Details
read.S can read the binary files produced in some older versions of S-PLUS on either Windows (versions 3.x, 4.x, 2000) or Unix (version 3.x with 4 byte integers). It automatically detects whether the file was produced on a big- or little-endian machine and adapts itself accordingly. data.restore can read a similar range of files produced by data.dump and for newer versions of S-PLUS, those from data.dump(....., oldStyle=TRUE).

Not all S3 objects can be handled in the current version. The most frequently encountered exceptions are functions and expressions; you will also have trouble with objects that contain model formulas. In particular, comments will be lost from function bodies, and the argument lists of functions will often be changed.

Value

- for read.S, an R version of the S3 object.
- for data.restore, the name of the file.
write.arff

Author(s)

Duncan Murdoch

Examples

```r
## Not run:
read.S(file.path("_Data", "myobj"))
data.restore("dumpdata", print = TRUE)
## End(Not run)
```

write.arff  Write Data into ARFF Files

Description

Writes data into Weka Attribute-Relation File Format (ARFF) files.

Usage

```r
write.arff(x, file, eol = "\n")
```

Arguments

- `x` the data to be written, preferably a matrix or data frame. If not, coercion to a data frame is attempted.
- `file` either a character string naming a file, or a connection. "" indicates output to the standard output connection.
- `eol` the character(s) to print at the end of each line (row).

References

See Also

- `read.arff`

Examples

```r
write.arff(iris, file = "")
```
**Description**

The function tries to write a data frame to a DBF file.

**Usage**

```r
write.dbf(dataframe, file, factor2char = TRUE, max_nchar = 254)
```

**Arguments**

- `dataframe`: a data frame object.
- `file`: a file name to be written to.
- `factor2char`: logical, default `TRUE`, convert factor columns to character: otherwise they are written as the internal integer codes.
- `max_nchar`: The maximum number of characters allowed in a character field. Strings which exceed this will be truncated with a warning. See Details.

**Details**

Dots in column names are replaced by underlines in the DBF file, and names are truncated to 11 characters.

Only vector columns of classes "logical", "numeric", "integer", "character", "factor" and "Date" can be written. Other columns should be converted to one of these.

Maximum precision (number of digits including minus sign and decimal sign) for numeric is 19 - scale (digits after the decimal sign) which is calculated internally based on the number of digits before the decimal sign.

The original DBASE format limited character fields to 254 bytes. It is said that Clipper and FoxPro can read up to 32K, and it is possible to write a reader that could accept up to 65535 bytes. (The documentation suggests that only ASCII characters can be assumed to be supported.) Readers expecting the older standard (which includes Excel 2003, Access 2003 and OpenOffice 2.0) will truncate the field to the maximum width modulo 256, so increase `max_nchar` only if you are sure the intended reader supports wider character fields.

**Value**

Invisible `NULL`.

**Note**

Other applications have varying abilities to read the data types used here. Microsoft Access reads "numeric", "integer", "character" and "Date" fields, including recognizing missing values, but not "logical" (read as `0,-1`). Microsoft Excel understood all possible types but did not interpret missing values in character fields correctly (showing them as character nuls).

write.dta

Write Files in Stata Binary Format

Description

Writes the data frame to file in the Stata version 6.0 or 7.0 binary format. Does not write matrix variables.

Usage

write.dta(dataframe, file, version = 6,
convert.dates = TRUE, tz = "GMT",
convert.factors = c("labels", "string", "numeric", "codes"))

Arguments

dataframe  a data frame.
file  character string giving filename.
version  Stata version: 6 and 7 are supported.
convert.dates  Convert POSIXt objects to Stata dates?
tz  timezone for date conversion
convert.factors  how to handle factors

Examples

str(warpbreaks)
try1 <- paste(tempfile(), ".dbf", sep = "")
write.dbf(warpbreaks, try1, factor2char = FALSE)
in1 <- read.dbf(try1)
str(in1)
try2 <- paste(tempfile(), ".dbf", sep = "")
write.dbf(warpbreaks, try2, factor2char = TRUE)
in2 <- read.dbf(try2)
str(in2)
unlink(c(try1, try2))
Details

The major differences between Stata versions is that 7.0 allows 32-character variable names. The `abbreviate` function is used to trim long variables to the permitted length. A warning is given if this is needed and it is an error for the abbreviated names not to be unique.

The columns in the data frame become variables in the Stata data set. Missing values are correctly handled. Optionally, R date/time objects (POSIXt classes) are converted into the Stata format. This loses information – Stata dates are in days since 1960-1-1. POSIXct objects can be written without conversion but will not be understood as dates by Stata; POSIXlt objects cannot be written without conversion.

There are four options for handling factors. The default is to use Stata value labels for the factor levels. With `convert.factors="string"`, the factor levels are written as strings. With `convert.factors="numeric"` the numeric values of the levels are written, or NA if they cannot be coerced to numeric. Finally, `convert.factors="codes"` writes the underlying integer codes of the factors. This last used to be the only available method and is provided largely for backwards compatibility.

For Stata 8 or 9 use `version=7` – the only advantage of Stata 8 format is that it can represent multiple different missing value types, and R doesn’t have them.

Value

NULL

Author(s)

Thomas Lumley

References

Stata 6.0 Users Manual, Stata 7.0 Programming manual, Stata 8.0, 9.0 online help describe the file formats.

See Also

`read.dta, attributes, DateTimeClasses, abbreviate`

Examples

```r
write.dta(swiss, swissfile <- tempfile())
read.dta(swissfile)
```

Description

This function exports simple data frames to other statistical packages by writing the data as free-format text and writing a separate file of instructions for the other package to read the data.
Usage

write.foreign(df, datafile, codefile,
    package = c("SPSS", "Stata", "SAS"), ...)

Arguments

df        A data frame
datafile  Name of file for data output
codefile  Name of file for code output
package   Name of package
...       Other arguments for the individual writeForeign functions

Details

The work for this function is done by foreign:::writeForeignStata,
foreign:::writeForeignSAS and foreign:::writeForeignSPSS. To add support
for another package, eg Systat, create a function writeForeignSystat with the same first
three arguments as write.foreign. This will be called from write.foreign when
package="Systat".

Numeric variables and factors are supported for all packages, dates and times (Date, dates,
date, and POSIXt classes) are also supported for SAS and characters are supported for SPSS.

For package="SAS" there are optional arguments dataname="rdata" taking a string that
will be the SAS data set name and validvarname taking either "V6" or "V7".

Value

None

Author(s)

Thomas Lumley and Stephen Weigand

Examples

## Not run:
datafile<-tempfile()
codefile<-tempfile()
write.foreign(esoph,datafile,codefile,package="SPSS")
file.show(datafile)
file.show(codefile)
unlink(datafile)
unlink(codefile)
## End(Not run)
Chapter 17

The lattice package

axis.default  Default axis annotation utilities

Description
Lattice functions provide control over how the plot axes are annotated through a common interface. There are two levels of control. The xscale.components and yscale.components arguments can be functions that determine tick mark locations and labels given a packet. For more direct control, the axis argument can be a function that actually draws the axes. The functions documented here are the defaults for these arguments. They can additionally be used as components of user written replacements.

Usage

xscale.components.default(lim,
                         packet.number = 0,
                         packet.list = NULL,
                         top = TRUE,
                         ...)

yscale.components.default(lim,
                          packet.number = 0,
                          packet.list = NULL,
                          right = TRUE,
                          ...)

axis.default(side = c("top", "bottom", "left", "right"),
              scales, components, as.table,
              labels = c("default", "yes", "no"),
              ticks = c("default", "yes", "no"),
              ...)

Arguments

lim  the range of the data in that packet (data subset corresponding to a combination of levels of the conditioning variable). The range is not necessarily numeric; e.g. for factors, they could be character vectors representing levels, and for the
various date-time representations, they could be vectors of length 2 with the corresponding class.

**packet.number**
which packet (counted according to the packet order, described in `print.trellis`) is being processed. In cases where all panels have the same limits, this function is called only once (rather than once for each packet), in which case this argument will have the value 0.

**packet.list**
list, as long as the number of packets, giving all the actual packets. Specifically, each component is the list of arguments given to the panel function when and if that packet is drawn in a panel. (This has not yet been implemented.)

**top, right**
the value of the top and right components of the result, as appropriate. See below for interpretation.

**side**
on which side the axis is to be drawn. The usual partial matching rules apply.

**scales**
the appropriate component of the scales argument supplied to the high level function, suitably standardized.

**components**
list, similar to those produced by `xscale.components.default` and `yscale.components.default`.

**as.table**
the as.table argument in the high level function.

**labels**
whether labels are to be drawn. By default, the rules determined by scales are used.

**ticks**
whether labels are to be drawn. By default, the rules determined by scales are used.

**...**
many other arguments may be supplied, and are passed on to other internal functions.

**Details**

These functions are part of a new API introduced in lattice 0.14 to provide the user more control over how axis annotation is done. While the API has been designed in anticipation of use that was previously unsupported, the implementation has initially focused on reproducing existing capabilities, rather then test new features. At the time of writing, several features are unimplemented. If you require them, please contact the maintainer.

**Value**

`xscale.components.default` and `yscale.components.default` return lists in a specific format expected by `axis.default`. The exact form will be documented later.

    ans$top$labels$labels <-
      if (require(MASS))
        fractions(2^(ans$top$labels$at))
      else
        2^(ans$top$labels$at)
    ans
  })
```

### Examples

```r
banking(dx, dy)
```

### Description

Calculates banking slope

### Usage

```r
banking(dx, dy)
```

### Arguments

- `dx, dy` vector of consecutive x, y differences.

### Details

`banking` is a crude banking function used when `aspect = "xy"` in high level Trellis functions. It is usually not very meaningful except with `xyplot`. It just considers the absolute slopes (based on `dx` and `dy`) and returns a value which when adjusted by the panel scale limits will make the median of the above absolute slopes correspond to a 45 degree line.

This function was inspired by the discussion of banking in the documentation for Trellis Graphics available at Bell Labs’ website (see `Lattice`), but is most likely identical to an algorithm described previously by Cleveland et al (see below). It is not clear (to the author) whether this is the algorithm used in S-PLUS. Alternative banking rules, implemented as a similar function, can be used as a drop-in replacement by suitably modifying `lattice.options("banking")`.

barchart.table  table methods for barchart and dotplot

Description

Contingency tables are often displayed using barcharts and dotplots. These methods are provided for convenience and operate directly on tables. Arrays and matrices are simply coerced to be a table.

Usage

```r
## S3 method for class 'table':
barchart(x, data, groups = TRUE, 
    origin = 0, stack = TRUE, ...)
```

```r
## S3 method for class 'array':
barchart(x, data, ...)
```

```r
## S3 method for class 'matrix':
barchart(x, data, ...)
```

```r
## S3 method for class 'table':
dotplot(x, data, groups = TRUE, ...)
```

```r
## S3 method for class 'array':
dotplot(x, data, ...)
```

```r
## S3 method for class 'matrix':
dotplot(x, data, ...)
```

Arguments

- `x`  a table, array or matrix object.
- `data`  should not be specified. If specified, will be ignored with a warning.
- `groups`  logical, whether to use the last dimension as the grouping variable in the display.
- `origin, stack`  arguments to panel.barchart controlling the display. The defaults for the table method are different.
- `...`  other arguments, passed to the underlying formula method.
Details

The first dimension is used as the variable on the vertical axis. The last dimension is optionally used as a grouping variable (to produce stacked barcharts by default). All other dimensions are used as conditioning variables. The order of these variables cannot be altered (except by permuting the original argument using \texttt{t} or \texttt{aperm}). For more flexibility, use the formula method after converting the table to a data frame using the relevant \texttt{as.data.frame} method.

Value

An object of class "\texttt{trellis}". The \texttt{update} method can be used to update components of the object and the \texttt{print} method (usually called by default) will plot it on an appropriate plotting device.

\begin{verbatim}
 barley
 Yield data from a Minnesota barley trial
\end{verbatim}

Description

Total yield in bushels per acre for 10 varieties at 6 sites in each of two years.

Usage

\texttt{barley}

Format

A data frame with 120 observations on the following 4 variables.

\begin{verbatim}
 yield  Yield (averaged across three blocks) in bushels/acre.
 variety Factor with levels "Svansota", "No. 462", "Manchuria", "No. 475",
          "Velvet", "Peatland", "Glabron", "No. 457", "Wisconsin No. 38",
          "Trebi".
 year   Factor with levels 1932, 1931
 site   Factor with 6 levels: "Grand Rapids", "Duluth", "University Farm",
          "Morris", "Crookston", "Waseca"
\end{verbatim}
Details

These data are yields in bushels per acre, of 10 varieties of barley grown in 1/40 acre plots at University Farm, St. Paul, and at the five branch experiment stations located at Waseca, Morris, Crookston, Grand Rapids, and Duluth (all in Minnesota). The varieties were grown in three randomized blocks at each of the six stations during 1931 and 1932, different land being used each year of the test.

Immer et al. (1934) present the data for each Year*Site*Variety*Block. The data here is the average yield across the three blocks.

Immer et al. (1934) refer (once) to the experiment as being conducted in 1930 and 1931, then later refer to it (repeatedly) as being conducted in 1931 and 1932. Later authors have continued the confusion.

Cleveland (1993) suggests that the data for the Morris site may have had the years switched.

Author(s)

Documentation contributed by Kevin Wright.

## S3 method for class 'formula':
wireframe(x,
data,
panel = lattice.getOption("panel.wireframe"),
...)

## S3 method for class 'matrix':
cloud(x, data = NULL, type = "h",
zlab = deparse(substitute(x)), ...)
## S3 method for class 'matrix':
wireframe(x, data = NULL, zlab = deparse(substitute(x)), ...)
Arguments

x
The object on which method dispatch is carried out.

For the "formula" methods, a formula of the form \( z \sim x \times y \mid g_1 \times g_2 \times \ldots \), where \( z \) is a numeric response, and \( x, y \) are numeric values. \( g_1, g_2, \ldots \), if present, are conditioning variables used for conditioning, and must be either factors or shingles. In the case of wireframe, calculations are based on the assumption that the \( x \) and \( y \) values are evaluated on a rectangular grid defined by their unique values. The grid points need not be equally spaced.

For wireframe, \( x, y \) and \( z \) may also be matrices (of the same dimension), in which case they are taken to represent a 3-D surface parametrized on a 2-D grid (e.g., a sphere). Conditioning is not possible with this feature. See details below.

Missing values are allowed, either as NA values in the \( z \) vector, or missing rows in the data frame (note however that in that case the X and Y grids will be determined only by the available values). For a grouped display (producing multiple surfaces), missing rows are not allowed, but NA-s in \( z \) are.

Both wireframe and cloud have methods for matrix objects, in which case \( x \) provides the \( z \) vector described above, while its rows and columns are interpreted as the \( x \) and \( y \) vectors respectively. This is similar to the form used in persp.

data
for the "formula" methods, an optional data frame in which variables in the formula (as well as groups and subset, if any) are to be evaluated. data should not be specified except when using the "formula" method.

allow.multiple, outer, auto.key, prepanel, strip, groups, xlab, xlim, ylab, ylim, drop.unused.levels, lattice.options, default.scales, subset
These arguments are documented in the help page for xyplot.

type
type of display in cloud (see panel.3dscatter for details). Defaults to "h" for the matrix method.

aspect
vector of length 2, giving the relative aspects of the y-size/x-size and z-size/x-size of the enclosing cube.

panel
panel function used to create the display. See panel.cloud for (non-trivial) details.

scales
a list describing the scales. As with other high level functions (see xyplot for details), this list can contain parameters in name=value form. It can also contain components with the special names x, y and z, which can be similar lists with axis-specific values overriding the ones specified in scales.

The most common use for this argument is to set arrows=FALSE, which causes tick marks and labels to be used instead of arrows being drawn (the default). Both can be suppressed by draw=FALSE. Another special component is distance, which specifies the relative distance of the axis label from the bounding box. If specified as a component of scales (as opposed to one of scales$z etc), this can be (and is recycled if not) a vector of length 3, specifying distances for the x, y and z labels respectively.

Other components that work in the scales argument of xyplot etc. should also work here (as long as they make sense), including explicit specification of tick mark locations and labels. (Not everything is implemented yet, but if you find something that should work but does not, feel free to bug the maintainer.)

Note, however, that for these functions scales cannot contain information that is specific to particular panels. If you really need that, consider using the scales.3d argument of panel.cloud.
Unlike 2-D display functions, `cloud` does not expand the bounding box to slightly beyond the range of the data, even though it should. This is primarily because this is the natural behaviour in `wireframe`, which uses the same code. `axs.default` is intended to provide a different default for `cloud`. However, this feature has not yet been implemented.

`zlab` specifies a label describing the z variable in ways similar to `xlab` and `ylab` (i.e., “grob”, character string, expression or list) in other high level functions. Additionally, if `zlab` (and `xlab` and `ylab`) is a list, it can contain a component called `rot`, controlling the rotation for the label.

`zlim` limits for the z-axis. Similar to `xlim` and `ylim` in other high level functions.

`drape` logical, whether the wireframe is to be draped in color. If `TRUE`, the height of a facet is used to determine its color in a manner similar to the coloring scheme used in `levelplot`. Otherwise, the background color is used to color the facets. This argument is ignored if `shade = TRUE` (see `panel.3dwire`).

`at`, `col.regions`, `alpha.regions` these arguments are analogous to those in `levelplot`. if `drape=TRUE`, `at` gives the vector of cutpoints where the colors change, and `col.regions` the vector of colors to be used in that case. `alpha.regions` determines the alpha-transparency on supporting devices. These are passed down to the panel function, and also used in the colorkey if appropriate. The default for `col.regions` and `alpha.regions` is derived from the Trellis setting "regions"

`cuts` if `at` is unspecified, the approximate number of cutpoints if `drape=TRUE`

`pretty` whether automatic choice of cutpoints should be prettified

`colorkey` logical indicating whether a color key should be drawn alongside, or a list describing such a key. See `levelplot` for details.

... Any number of other arguments can be specified, and are passed to the panel function. In particular, the arguments `distance`, `perspective`, `screen` and `R.mat` are very important in determining the 3-D display. The argument `shade` can be useful for `wireframe` calls, and controls shading of the rendered surface. These arguments are described in detail in the help page for `panel.cloud`.

Additionally, an argument called `zoom` may be specified, which should be a numeric scalar to be interpreted as a scale factor by which the projection is magnified. This can be useful to get the variable names into the plot. This argument is actually only used by the default `prepanel` function.

**Details**

These functions produce three dimensional plots in each panel (as long as the default panel functions are used). The orientation is obtained as follows: the data are scaled to fall within a bounding box that is contained in the [-0.5, 0.5] cube (even smaller for non-default values of `aspect`). The viewing direction is given by a sequence of rotations specified by the `screen` argument, starting from the positive Z-axis. The viewing point (camera) is located at a distance of `1/distance` from the origin. If `perspective=FALSE`, `distance` is set to 0 (i.e., the viewing point is at an infinite distance).

`cloud` draws a 3-D Scatter Plot, while `wireframe` draws a 3-D surface (usually evaluated on a grid). Multiple surfaces can be drawn by `wireframe` using the `groups` argument (although this is of limited use because the display is incorrect when the surfaces intersect). Specifying `groups` with `cloud` results in a `panel.superpose`-like effect (via `panel.3dscatter`).
wireframe can optionally render the surface as being illuminated by a light source (no shadows though). Details can be found in the help page for `panel.3wire`. Note that although arguments controlling these are actually arguments for the panel function, they can be supplied to `cloud` and `wireframe` directly.

For single panel plots, `wireframe` can also plot parametrized 3-D surfaces (i.e., functions of the form \( f(u,v) = (x(u,v), y(u,v), z(u,v)) \), where values of \((u,v)\) lie on a rectangle. The simplest example of this sort of surface is a sphere parametrized by latitude and longitude. This can be achieved by calling `wireframe` with a formula \( x \) of the form \( z \approx x \ast y \), where \( x, y \) and \( z \) are all matrices of the same dimension, representing the values of \( x(u,v) \), \( y(u,v) \) and \( z(u,v) \) evaluated on a discrete rectangular grid (the actual values of \((u,v)\) are irrelevant).

When this feature is used, the heights used to calculate drape colors or shading colors are no longer the \( z \) values, but the distances of \((x, y, z)\) from the origin.

Note that this feature does not work with `groups`, `subscripts`, `subset`, etc. Conditioning variables are also not supported in this case.

The algorithm for identifying which edges of the bounding box are ‘behind’ the points doesn’t work in some extreme situations. Also, `panel.cloud` tries to figure out the optimal location of the arrows and axis labels automatically, but can fail on occasion (especially when the view is from ‘below’ the data). This can be manually controlled by the `scpos` argument in `panel.cloud`

These and all other high level Trellis functions have several other arguments in common. These are extensively documented only in the help page for `xyplot`, which should be consulted to learn more detailed usage.

**Value**

An object of class "trellis". The `update` method can be used to update components of the object and the `print` method (usually called by default) will plot it on an appropriate plotting device.

**Note**

There is a known problem with grouped `wireframe` displays when the \((x, y)\) coordinates represented in the data do not represent the full evaluation grid. The problem occurs whether the grouping is specified through the `groups` argument or through the formula interface, and currently causes memory access violations. Depending on the circumstances, this is manifested either as a meaningless plot or a crash. To work around the problem, it should be enough to have a row in the data frame for each grid point, with an `NA` response \((z)\) in rows that were previously missing.

## volcano ## 87 x 61 matrix
wireframe(volcano, shade = TRUE,
          aspect = c(61/87, 0.4),
          light.source = c(10,0,10))
```
draw.colorkey

Produce a Colorkey for levelplot

Description

Produces (and possibly draws) a Grid frame grob which is a colorkey that can be placed in other Grid plots. Used in levelplot.

Usage

draw.colorkey(key, draw=FALSE, vp=NULL)

Arguments

key A list determining the key. See documentation for levelplot, in particular the section describing the colorkey argument, for details.
draw logical, whether the grob is to be drawn.vp

viewport

Value

A Grid frame object (that inherits from "grob")

Author(s)

Deepayan Sarkar (Deepayan.Sarkar@R-project.org)
draw.key  Produce a Legend or Key

Description

Produces (and possibly draws) a Grid frame grob which is a legend (aka key) that can be placed in other Grid plots.

Usage

draw.key(key, draw=FALSE, vp=NULL)

Arguments

key  A list determining the key. See documentation for xyplot, in particular the section describing the key argument, for details.
draw  logical, whether the grob is to be drawn.
vp  viewport

Value

A Grid frame object (that inherits from ‘grob’).

## S3 method for class 'numeric':
densityplot(x, data = NULL, xlab, ...)

do.breaks(endpoints, nint)

Arguments

x
The object on which method dispatch is carried out.

For the formula method, a formula of the form ~ x | g1 * g2 * ... indicates that histograms or Kernel Density estimates of x should be produced conditioned on the levels of the (optional) variables g1, g2, ... x can be numeric (or factor for histogram), and each of g1, g2, ... must be either factors or shingles.

As a special case, the right hand side of the formula can contain more than one variable separated by a + sign. What happens in this case is described in details in the documentation for xyplot. Note that in either form, all the variables involved in the formula have to have same length.

For the numeric and factor methods, x replaces the x vector described above. Conditioning is not allowed in these cases.

data
For the formula method, an optional data frame in which variables are to be evaluated. Ignored with a warning in other cases.

type
Character string indicating type of histogram to be drawn. "percent" and "count," give relative frequency and frequency histograms, and can be misleading when breakpoints are not equally spaced. "density" produces a density scale histogram.

type defaults to "percent", except when the breakpoints are unequally spaced or breaks = NULL, when it defaults to "density".

nint
Number of bins. Applies only when breaks is unspecified or NULL in the call. Not applicable when the variable being plotted is a factor.

endpoints
vector of length 2 indicating the range of x-values that is to be covered by the histogram. This applies only when breaks is unspecified and the variable being plotted is not a factor. In do.breaks, this specifies the interval that is to be divided up.
breaks usually a numeric vector of length (number of bins + 1) defining the breakpoints of the bins. Note that when breakpoints are not equally spaced, the only value of type that makes sense is density. When unspecified, the default is to use

$$\text{breaks} = \text{seq}\_\text{len}(1 + \text{nlevels}(x)) - 0.5$$

when \(x\) is a factor, and

$$\text{breaks} = \text{do\_breaks}(\text{endpoints}, \text{nint})$$

otherwise. Breakpoints calculated in such a manner are used in all panels.

Other values of breaks are possible, in which case they affect the display in each panel differently. A special value of breaks is NULL, in which case the number of bins is determined by \(\text{nint}\) and then breakpoints are chosen according to the value of \text{equal.widths}. Other valid values of \text{breaks} are those of the \text{breaks} argument in \text{hist}. This allows specification of \text{breaks} as an integer giving the number of bins (similar to \text{nint}), as a character string denoting a method, and as a function.

\text{equal.widths} logical, relevant only when breaks=\text{NULL}. If \text{TRUE}, equally spaced bins will be selected, otherwise, approximately equal area bins will be selected (this would mean that the breakpoints will not be equally spaced).

\(n\) number of points at which density is to be evaluated

\text{panel} The function that uses the packet (subset of display variables) corresponding to a panel to create a display. Default panel functions are documented separately, and often have arguments that can be used to customize its display in various ways. Such arguments can usually be directly supplied to the high level function.

\text{allow.multiple}, \text{outer}, \text{auto.key}, \text{aspect}, \text{prepanel}, \text{scales}, \text{strip}, \text{groups}, \text{xlab}, \text{ylab}, \text{xlim}, \text{ylim}, \text{drop.unused.levels}, \text{lattice.options}, \text{default.scales}, \text{subscripts}, \text{subset}

\text{See xyplot}

\text{bw}, \text{adjust}, \text{kernel}, \text{window}, \text{width}, \text{give.Rkern}, \text{from}, \text{to}, \text{cut}, \text{na.rm}

arguments to \text{density}, passed on as appropriate

... Further arguments. See corresponding entry in \text{xyplot} for non-trivial details.

**Details**

\text{histogram} draws Conditional Histograms, while \text{densityplot} draws Conditional Kernel Density Plots. The density estimate in \text{densityplot} is actually calculated using the function \text{density}, and all arguments accepted by it can be passed (as ...) in the call to \text{densityplot} to control the output. See documentation of \text{density} for details. (Note: The default value of the argument \text{n} of \text{density} is changed to 50.)

These and all other high level Trellis functions have several arguments in common. These are extensively documented only in the help page for \text{xyplot}, which should be consulted to learn more detailed usage.

\text{do.breaks} is an utility function that calculates breakpoints given an interval and the number of pieces to break it into.

**Value**

An object of class "trellis". The \text{update} method can be used to update components of the object and the \text{print} method (usually called by default) will plot it on an appropriate plotting device.
Note

The form of the arguments accepted by the default panel function panel.histogram is different from that in S-PLUS. Whereas S-PLUS calculates the heights inside histogram and passes only the breakpoints and the heights to the panel function, here the original variable x is passed along with the breakpoints. This allows plots as in the second example below.

**interaction**  
*Functions to Interact with Lattice Plots*

**Description**

The classic Trellis paradigm is to plot the whole object at once, without the possibility of interacting with it afterwards. However, by keeping track of the grid viewports where the panels and strips are drawn, it is possible to go back to them afterwards and enhance them one panel at a time. These functions provide convenient interfaces to help in this. Note that these are still experimental and the exact details may change in future.

**Usage**

```r
panel.identify(x, y = NULL,
  subscripts = seq_along(x),
  labels = subscripts,
  n = length(x), offset = 0.5,
  threshold = 18, ## in points, roughly 0.25 inches
  panel.args = trellis.panelArgs(),
```
interaction 1837

...)

trellis.vpname(name = c("position", "split", "split.location", "toplevel", "panel", "strip", "strip.left", "legend", "main", "sub", "xlab", "ylab", "page"),
    column, row,
    side = c("left", "top", "right", "bottom", "inside"),
    clip.off = FALSE, prefix)
trellis.grobname(name, prefix)
trellis.focus(name, column, row, side, clip.off,
    highlight = interactive(), ...)
trellis.switchFocus(name, side, clip.off, highlight, ...)
trellis.unfocus()
trellis.panelArgs(x, packet.number)

Arguments

x, y  variables defining the contents of the panel. In the case of
trellis.panelArgs, a "trellis" object.

n  the number of points to identify by default (overridden by a right click)

subscripts an optional vector of integer indices associated with each point. See details
below.

labels an optional vector of labels associated with each point. Defaults to
subscripts

offset the labels are printed either below, above, to the left or to the right of the identi-
fified point, depending on the relative location of the mouse click. The offset
specifies (in "char" units) how far from the identified point the labels should be
printed.

threshold threshold in grid's "points" units. Points further than these from the mouse
click position are not considered

panel.args list that contains components names x (and usually y), to be used if x is missing.
Typically, when called after trellis.focus, this would appropriately be the
arguments passed to that panel.

name character string indicating which viewport or grob we are looking for. Although
these do not necessarily provide access to all viewports and grobs created by a
lattice plot, they cover most that users might find interesting.
trellis.vpname and trellis.focus deal with viewport names only,
and only accept the values explicitly listed above. trellis.grobname is
meant to create names for grobs, and can currently accept any value.

column, row integers, indicating position of the panel or strip that should be assigned focus
in the Trellis layout. Rows are usually calculated from the bottom up, unless the
plot was created with as.table=TRUE

side character string, relevant only for legends (i.e. when name="legend"), indicat-
ing their position. Partial specification is allowed, as long as it is unambigu-
ous.

clip.off logical, whether clipping should be off, relevant when name is "panel" or
"strip". This is necessary if axes are to be drawn outside the panel or strip.
Note that setting clip.off=FALSE does not necessarily mean that clipping
is on; that is determined by conditions in effect during printing.
prefix
character string acting as a prefix, meant to distinguish otherwise equivalent viewports in different plots. This only becomes relevant when a particular page is occupied by more than one plot. Defaults to the value appropriate for the last "trellis" object printed, as determined by the prefix argument in print.trellis. Users should not usually need to supply a value for this argument (see note below), however, if supplied explicitly, this has to be a valid R symbol name (briefly, it must start with a letter or a period followed by a letter) and must not contain the grid path separator (currently ":::")

highlight
logical, whether the viewport being assigned focus should be highlighted. For trellis.focus, the default is TRUE in interactive mode, and trellis.switchFocus by default preserves the setting currently active.

packet.number
integer, which panel to get data from. See packet.number for details on how this is calculated

... graphical parameters. For panel.identify these are used for labelling. For trellis.focus and trellis.switchFocus, these are used (in combination with lattice.options) for highlighting the chosen viewport if so requested.

Details

panel.identify is similar to identify. When called, it waits for the user to identify points (in the panel being drawn) via mouse clicks. Clicks other than left-clicks terminate the procedure. Although it is possible to call it as part of the panel function, it is more typical to use it to identify points after plotting the whole object, in which case a call to trellis.focus first is necessary.

One way in which panel.identify is different from identify is in how it uses the subscripts argument. In general, when one identifies points in a panel, one wants to identify the origin in the data frame used to produce the plot, and not within that particular panel. This information is available to the panel function, but only in certain situations. One way to ensure that subscripts is available is to specify subscripts = TRUE in the high level call such as xyplot. If subscripts is not explicitly specified in the call to panel.identify, but is available in panel.args, then those values will be used. Otherwise, they default to seq_along(x). In either case, the final return value will be the subscripts that were marked.

The process of printing (plotting) a Trellis object builds up a grid layout with named viewports which can then be accessed to modify the plot further. While full flexibility can only be obtained by using grid functions directly, a few lattice functions are available for the more common tasks.

trellis.focus can be used to move to a particular panel or strip, identified by its position in the array of panels. It can also be used to focus on the viewport corresponding to one of the labels or a legend, though such usage would be less useful. The exact viewport is determined by the name along with the other arguments, not all of which are relevant for all names. Note that when more than one object is plotted on a page, trellis.focus will always go to the plot that was created last. For more flexibility, use grid functions directly (see note below).

After a successful call to trellis.focus, the desired viewport (typically panel or strip area) will be made the ‘current’ viewport (plotting area), which can then be enhanced by calls to standard lattice panel functions as well as grid functions.

It is quite common to have the layout of panels chosen when a "trellis" object is drawn, and not before then. Information on the layout (specifically, how many rows and columns, and which packet belongs in which position in this layout) is retained for the last "trellis" object plotted, and is available through trellis.currentLayout.

trellis.unfocus unsets the focus, and makes the top level viewport the current viewport.
interaction

\texttt{trellis.switchFocus} is a convenience function to switch from one viewport to another, while preserving the current row and column. Although the rows and columns only make sense for panels and strips, they would be preserved even when the user switches to some other viewport (where row/column is irrelevant) and then switches back.

Once a panel or strip is in focus, \texttt{trellis.panelArgs} can be used to retrieve the arguments that were available to the panel function at that position. In this case, it can be called without arguments as

\begin{verbatim}
    trellis.panelArgs()
\end{verbatim}

This usage is also allowed when a "trellis" object is being printed, e.g. inside the panel functions or the axis function (but not inside the prepanel function). \texttt{trellis.panelArgs} can also retrieve the panel arguments from any "trellis" object. Note that for this usage, one needs to specify the packet.number (as described under the panel entry in \texttt{xyplot}) and not the position in the layout, because a layout determines the panel only after the object has been printed.

It is usually not necessary to call \texttt{trellis.vpname} and \texttt{trellis.grobname} directly. However, they can be useful in generating appropriate names in a portable way when using grid functions to interact with the plots directly, as described in the note below.

\textbf{Value}

\texttt{panel.identify} returns an integer vector containing the subscripts of the identified points (see details above). The equivalent of \texttt{identify} with \texttt{pos=TRUE} is not yet implemented, but can be considered for addition if requested.

\texttt{trellis.panelArgs} returns a named list of arguments that were available to the panel function for the chosen panel.

\texttt{trellis.vpname} and \texttt{trellis.grobname} return character strings.

\textbf{Note}

The viewports created by lattice is accessible to the user only up to a certain extent, as described above. In particular, \texttt{trellis.focus} can only be used to manipulate the last plot drawn. For full flexibility, use appropriate functions from the grid package directly. For example, \texttt{current.vpTree} can be used to inspect the current viewport tree and \texttt{seekViewport} or \texttt{downViewport} can be used to navigate to these viewports. For such usage, \texttt{trellis.vpname} and \texttt{trellis.grobname} (with a non-default prefix argument) provides a portable way to access the appropriate viewports and grobs by name.

Lattice Graphics

Description

Implementation of Trellis Graphics in R

Details

Trellis Graphics is a framework for data visualization developed at the Bell Labs by Rick Becker, Bill Cleveland et al, extending ideas presented in Bill Cleveland’s 1993 book Visualizing Data. Lattice is best thought of as an implementation of Trellis Graphics for R. Its interface is based on the implementation in S-PLUS, but there are several differences. To the extent possible, care has been taken to ensure that existing Trellis code written for S-PLUS works unchanged (or with minimal change) in Lattice. If you are having problems porting S-PLUS code, read the entry for panel in the documentation for xyplot. Most high level Trellis functions in S-PLUS are implemented, with the exception of piechart.

Lattice is built upon the Grid Graphics engine for R being developed by Paul Murrell and requires the grid add-on package.

Type help(package = lattice) to see a list of (public) Lattice graphics functions for which further documentation is available. The ‘See Also’ section below has list of specific areas of possible interest and pointers to the help pages with respective details. Apart from the documentation accompanying this package, several documents outlining the use of Trellis graphics is available from Bell Lab’s website that might provide a holistic introduction to the Trellis paradigm. The example section shows how to bring up a brief history of changes to the lattice package, which provides a summary of new features.

Note

High level Lattice functions (like xyplot) are different from conventional R graphics functions because they don’t actually draw anything. Instead, they return an object of class "trellis" which has to be then printed or plotted to create the actual plot. This is normally done automatically, but not when the high level functions are called inside another function (most often source) or other contexts where automatic printing is suppressed (e.g. for or while loops). In such situations, an explicit call to print or plot is required.

Lattice plots are highly customizable via user-modifiable settings. However, these are completely unrelated to base graphics settings; in particular, changing par() settings usually have no effect on lattice plots.

See Also

The Lattice user interface primarily consists of several ‘high level’ generic functions (listed below), each designed to create a particular type of statistical display by default. While each function does different things, they share several common features, reflected in several common arguments that affect the resulting displays in similar ways. These arguments are extensively (sometimes only) documented in the help page for `xyplot`. This includes a discussion of conditioning and control of the Trellis layout.

Lattice employs an extensive system of user-controllable parameters to determine the look and feel of the displays it produces. To learn how to use and customise the Graphical parameters used by the Lattice functions, see `trellis.par.set`. For other settings, see `lattice.options`. The default graphical settings are different for different graphical devices. To learn how to initialise new devices with the desired settings or change the settings of the current device, see `trellis.device`.

To learn about sophisticated (non-default) printing capabilities, see `print.trellis`. See `update.trellis` to learn about manipulating a "trellis" object. Tools to augment lattice plots after they are drawn (including locator-like functionality) is described in the `interaction` help page.

The following is a list of ‘high level’ functions in the Lattice package with a brief description of what they do. In all cases, the actual display is produced by the so-called panel function, which has a suitable default, but can be substituted by an user defined function to create custom displays. The user will most often be interested in the default panel functions, which have a separate help page, linked to from the help pages of the corresponding high level function. Although documented separately, arguments to these panel functions can be supplied directly to the high level functions, which will forward the arguments as appropriate.

**Univariate:**

*barchart* bar plots

*bwplot* box and whisker plots

*densityplot* kernel density plots

*dotplot* dot plots

*histogram* histograms

*qqmath* quantile plots against mathematical distributions

*stripplot* 1-dimensional scatterplot

**Bivariate:**

*qq* q-q plot for comparing two distributions

*xyplot* scatter plot (and possibly a lot more)

**Trivariate:**

*levelplot* level plots (similar to image plots in R)

*contourplot* contour plots
cloud 3-D scatter plots
wireframe 3-D surfaces (similar to persp plots in R)

Hypervariate:
splom scatterplot matrix
parallel parallel coordinate plots

Miscellaneous:
rfs residual and fitted value plot (also see oneway)
tmd Tukey Mean-Difference plot

Additionally, there are several panel functions that do little by themselves, but can be useful components of custom panel functions. These are documented in panel.functions. Lattice also has a collection of convenience functions that correspond to the base graphics primitives lines, points, etc. They are implemented using Grid graphics, but try to be as close to the base versions as possible in terms of their argument list. These functions have imaginative names like llines or panel.lines and are often useful when writing (or porting from S-PLUS code) nontrivial panel functions.

Examples

```r
## Not run:
## brief history of changes
file.show(system.file("Changes", package = "lattice"))
## End(Not run)
```

lattice.options  

### Low-level Options Controlling Behaviour of Lattice

**Description**

Functions to handle settings used by lattice. Their main purpose is to make code maintenance easier, and users normally should not need to use these functions. However, fine control at this level maybe useful in certain cases.

**Usage**

```
lattice.options("")
lattice.getOption(name)
```

**Arguments**

- `name` character giving the name of a setting
- `...` new options can be defined, or existing ones modified, using one or more arguments of the form `name = value` or by passing a list of such tagged values. Existing values can be retrieved by supplying the names (as character strings) of the components as unnamed arguments.

**Details**

These functions are modeled on options andgetOption, and behave similarly for the most part. The components currently used are not documented here, but are fairly self-explanatory.
latticeParseFormula

Value

lattice.getOption returns the value of a single component, whereas lattice.options always returns a list with one or more named components. When changing the values of components, the old values of the modified components are returned by lattice.options. If called without any arguments, the full list is returned.

lattice.getOption("save.object")

---

latticeParseFormula

_Parse Trellis formula_

Description

this function is used by high level Lattice functions like xyplot to parse the formula argument and evaluate various components of the data.

Usage

latticeParseFormula(model, data, dimension = 2,
                     subset = TRUE, groups = NULL,
                     multiple, outer,
                     subscripts,
                     drop)

Arguments

model
  the model/formula to be parsed. This can be in either of two possible forms, one
  for 2d and one for 3d formulas, determined by the dimension argument. The
  2d formulas are of the form y ~ x | g1 * ... * gn, and the 3d formulas
  are of the form z ~ x * y | g1 * ... * gn. In the first form, y may
  be omitted. The conditioning variables g1, ..., gn can be omitted in either
  case.

data
  the environment/dataset where the variables in the formula are evaluated.

dimension
  dimension of the model, see above

subset
  index for choosing a subset of the data frame

groups
  the grouping variable, if present
levelplot

multiple, outer
logicals, determining how a ‘+’ in the y and x components of the formula are
processed. See xyplot for details

subscripts
logical, whether subscripts are to be calculated
drop
logical or list, similar to the drop.unused.levels argument in xyplot,
indicating whether unused levels of conditioning factors and data variables that
are factors are to be dropped.

Value
returns a list with several components, including left, right, left.name,
right.name, condition for 2-D, and left, right.x, right.y, left.name,
right.x.name, right.y.name, condition for 3-D. Other possible components are
groups, subscr

levelplot  Level Plots

Description
Draw Level Plots and Contour plots.

Usage
levelplot(x, data, ...)
contourplot(x, data, ...)

# S3 method for class 'formula':
levelplot(x,
data,
allow.multiple = is.null(groups) || outer,
outer = TRUE,
aspect = "fill",
panel = lattice.getOption("panel.levelplot"),
prepanel = NULL,
scales = list(),
strip = TRUE,
groups = NULL,
xlab,
xlim,
ylab,
ylim,
at,
## S3 method for class 'formula':
contourplot(x,
data,
panel = lattice.getOption("panel.contourplot"),
cuts = 7,
labels = TRUE,
contour = TRUE,
pretty = TRUE,
region = FALSE,
...)

## S3 method for class 'matrix':
levelplot(x, data = NULL, aspect = "iso", ...)
## S3 method for class 'matrix':
contourplot(x, data = NULL, aspect = "iso", ...)
col.regions color vector to be used if regions is TRUE. The general idea is that this should be a color vector of moderately large length (longer than the number of regions. By default this is 100). It is expected that this vector would be gradually varying in color (so that nearby colors would be similar). When the colors are actually chosen, they are chosen to be equally spaced along this vector. When there are more regions than col.regions, the colors are recycled.

alpha.regions numeric, specifying alpha transparency (works only on some devices)

colorkey logical specifying whether a color key is to be drawn alongside the plot, or a list describing the color key. The list may contain the following components:

  space: location of the colorkey, can be one of "left", "right", "top" and "bottom". Defaults to "right".

  x, y: location, currently unused

  col: vector of colors

  at: numeric vector specifying where the colors change. must be of length 1 more than the col vector.

  labels: a character vector for labelling the at values, or more commonly, a list of components labels, at, cex, col, font describing label positions.

  tick.number: approximate number of ticks.

  corner: interacts with x, y; unimplemented

  width: width of the key

  height: length of key w.r.t side of plot.

contour logical, whether to draw contour lines.

cuts number of levels the range of z would be divided into

labels logical specifying whether contour lines should be labelled, or character vector of labels for contour lines. The type of labelling can be controlled by the label.style argument, which is passed on to panel.levelplot

pretty logical, whether to use pretty cut locations and labels

region logical, whether regions between contour lines should be filled

allow.multiple, outer, prepanel, scales, strip, groups, xlab, xlim, ylab, ylim, these arguments are described in the help page for xyplot.

... other arguments

Details

These and all other high level Trellis functions have several arguments in common. These are extensively documented only in the help page for xyplot, which should be consulted to learn more detailed usage.

Other useful arguments are mentioned in the help page for the default panel function panel.levelplot (these are formally arguments to the panel function, but can be specified in the high level calls directly).

Value

An object of class "trellis". The update method can be used to update components of the object and the print method (usually called by default) will plot it on an appropriate plotting device.

detach()
```

llines

Replacements of traditional graphics functions

Description

These functions are intended to replace common low level traditional graphics functions, primarily for use in panel functions. The originals can not be used (at least not easily) because lattice panel functions need to use grid graphics. Low level drawing functions in grid can be used directly as well, and is often more flexible. These functions are provided for convenience and portability.

Usage

```r
llines(xy, type, pch, lty, col, cex, lwd, font, fontfamily, face, col.line, alpha, fill, origin = 0, ...)
```
lines(x, ...)  
lpoints(x, ...)  
ltext(x, ...)  

## Default S3 method:  
lines(x, y = NULL, type = "l",  
   col, alpha, lty, lwd, ...)  
## Default S3 method:  
lpoints(x, y = NULL, type = "p", col, pch, alpha, fill,  
   font, fontfamily, fontface, cex, ...)  
## Default S3 method:  
ltext(x, y = NULL, labels = seq_along(x),  
   col, alpha, cex, srt = 0,  
   lineheight, font, fontfamily, fontface,  
   adj = c(0.5, 0.5), pos = NULL, offset = 0.5, ...)  

lsegments(x0, y0, x1, y1, x2, y2,  
   col, alpha, lty, lwd, ...)  
lrect(xleft, ybottom, xright, ytop,  
   x = (xleft + xright) / 2,  
   y = (ybottom + ytop) / 2,  
   width = xright - xleft,  
   height = ytop - ybottom,  
   col = "transparent",  
   border = "black",  
   lty = 1, lwd = 1, alpha = 1,  
   just = "center",  
   hjjust = NULL, vjust = NULL,  
   ...)  
larrows(x0 = NULL, y0 = NULL, x1, y1, x2 = NULL, y2 = NULL,  
   angle = 30, code = 2, length = 0.25, unit = "inches",  
   ends = switch(code, "first", "last", "both"),  
   type = "open",  
   col = add.line$col,  
   alpha = add.line$alpha,  
   lty = add.line$lty,  
   lwd = add.line$lwd,  
   fill = NULL, ...)  
lpolygon(x, y = NULL,  
   border = "black", col = "transparent", ...)  

panel.lines(...)  
panel.points(...)  
panel.segments(...)  
panel.text(...)  
panel.rect(...)  
panel.arrows(...)  
panel.polygon(...)
Arguments

`x, y, x0, y0, x1, y1, x2, y2, xy`
locations. `x2` and `y2` are available for for S compatibility.

`length, unit` determines extent of arrow head. `length` specifies the length in terms of `unit`, which can be any valid grid unit as long as it doesn’t need a `data` argument. `unit` defaults to inches, which is the only option in the base version of the function, `arrows`.

`angle, code, type, labels, srt, adj, pos, offset`
arguments controlling behaviour. See respective base functions for details. For `larray` and `panel.larray`, `type` is either "open" or "closed", indicating the type of arrowhead.

`ends` serves the same function as `code`, using descriptive names rather than integer codes. If specified, this overrides `code`.

`col, alpha, lty, lwd, fill, pch, cex, lineheight, font, fontfamily, fontface, col.line, border`
graphical parameters. `fill` applies to points when `pch` is in 21:25 and specifies the fill color, similar to the `bg` argument in the base graphics function `points`. For devices that support alpha-transparency, a numeric argument `alpha` between 0 and 1 can controls transparency. Be careful with this, since for devices that do not support alpha-transparency, nothing will be drawn at all if this is set to anything other than 0.

`origin` for `type="h"` or `type="H"`, the value to which lines drop down.

`xleft, ybottom, xright, ytop`
see `rect`

`width, height, just, hjust, vjust`
finer control over rectangles, see `grid.rect`

`...`
extra arguments, passed on to lower level functions as appropriate.

Details

These functions are meant to be grid replacements of the corresponding base R graphics functions, to allow existing Trellis code to be used with minimal modification. The functions `panel.*` are essentially identical to the `l*` versions, are recommended for use in new code (as opposed to ported code) as they have more readable names.

See the documentation of the base functions for usage. Not all arguments are always supported. All these correspond to the default methods only.

Note

There is a new `type="H"` option wherever appropriate, which is similar to `type="h"`, but with horizontal lines.

**lset**

*Interface to modify Trellis Settings - Deprecated*

**Description**

A (hopefully) simpler alternative to `trellis.par.get/set`. This is deprecated, and the same functionality is now available with `trellis.par.set`.

**Usage**

```r
lset(theme = col.whitebg())
```

**Arguments**

- `theme` a list describing how to change the settings of the current active device. Valid components are those in the list returned by `trellis.par.get()`. Each component must itself be a list, with one or more of the appropriate components (need not have all components). Changes are made to the settings for the currently active device only.

**Author(s)**

Deepayan Sarkar (Deepayan.Sarkar@R-project.org)

**make.groups**

*Grouped data from multiple vectors*

**Description**

Combines two or more vectors, possibly of different lengths, producing a data frame with a second column indicating which of these vectors that row came from. This is mostly useful for getting data into a form suitable for use in high level Lattice functions.

**Usage**

```r
make.groups(...)```

**Arguments**

- `...` one or more vectors of the same type (coercion is attempted if not), or one or more data frames with similar columns, with possibly differing number of rows.

**Value**

When all the input arguments are vectors, a data frame with two columns

- `this-is-escaped-codenormal-bracket9bracket-normal` all the vectors supplied, concatenated

- `this-is-escaped-codenormal-bracket12bracket-normal` factor indicating which vector the corresponding data value came from

When all the input arguments are data frames, the result of `cbind` applied to them, along with an additional which column as described above.

qqmath(~ data | which, sim.dat, scales=list(y="free"))

Description
These data from the Connecticut Tumor Registry present age-adjusted numbers of melanoma skin-cancer incidences per 100,000 people in Connecticut for the years from 1936 to 1972.

Usage
melanoma

Format
A data frame with 37 observations on the following 2 variables.

year  Years 1936 to 1972.
incidence Rate of melanoma cancer per 100,000 population.

Note
This dataset is not related to the melanoma dataset in the boot package with the same name. The S-PLUS 6.2 help for the melanoma data says that the incidence rate is per million, but this is not consistent with data found at the National Cancer Institute (http://www.nci.nih.gov).

    panel = function(x, y)
        panel.xyplot(x, y, type="o", pch = 16),
ylim = c(0, 6),
xlab = "Year",
ylab = "Incidence")

## Fit One-way Model

Description

Fits a One-way model to univariate data grouped by a factor, the result often being displayed using rfs

Usage

oneway(formula, data, location=mean, spread=function(x) sqrt(var(x)))

Arguments

formula
  formula of the form y ~ x where y is the numeric response and x is the grouping factor
data
  data frame in which the model is to be evaluated
location
  function or numeric giving the location statistic to be used for centering the observations, e.g. median, 0 (to avoid centering).
spread
  function or numeric giving the spread statistic to be used for scaling the observations, e.g. sd, 1 (to avoid scaling).

Value

A list with components

location
  vector of locations for each group.
spread
  vector of spreads for each group.
fitted.values
  vector of locations for each observation.
residuals
  residuals(y ~ fitted.values).
scaled.residuals
  residuals scaled by spread for their group

packet.panel.default

ASSOCIATING PACKETS WITH PANELS

Description

When a "trellis" object is plotted, panels are always drawn in an order such that columns vary the fastest, then rows and then pages. An optional function can be specified that determines, given the column, row and page and other relevant information, the packet (if any) which should be used in that panel. The function documented here implements the default behaviour, which is to match panel order with packet order, determined by varying the first conditioning variable the fastest, then the second, and so on. This matching is performed after any reordering and/or permutation of the conditioning variables.

Usage

packet.panel.default(layout, condlevels, page, row, column,
skip, all.pages.skip = TRUE)

Arguments

layout the layout argument in high level functions, suitably standardized.
condlevels a list of levels of conditioning variables, after relevant permutations and/or re-ordering of levels
page, row, column the location of the panel in the coordinate system of pages, rows and columns.
skip the skip argument in high level functions
all.pages.skip whether skip should be replicated over all pages. If FALSE, skip will be replicated to be only as long as the number of positions on a page, and that template will be used for all pages.

Value

A suitable combination of levels of the conditioning variables in the form of a numeric vector as long as the number of conditioning variables, with each element an integer indexing the levels of the corresponding variable. Specifically, if the return value is \( p \), then the \( i \)-th conditioning variable will have level \( \text{condlevels}[i][p[i]] \).

panel.axis

Panel Function for Drawing Axis Ticks and Labels

Description

panel.axis is the function used by lattice to draw axes. It is typically not used by users, except those wishing to create advanced annotation. Keep in mind issues of clipping when trying to use it as part of the panel function. current.panel.limits can be used to retrieve a panel's x and y limits.

Usage

panel.axis(side = c("bottom", "left", "top", "right"),
          at,
          labels = TRUE,
          draw.labels = TRUE,
          check.overlap = FALSE,
          outside = FALSE,
          ticks = TRUE,
          half = !outside,
          which.half,
          tck = as.numeric(ticks),
          rot = if (is.logical(labels)) 0 else c(90, 0),
          text.col, text.alpha, text.cex, text.font,
          text.fontfamily, text.fontface,
          line.col, line.lty, line.lwd, line.alpha)

current.panel.limits(unit = "native")

Arguments

side character string indicating which side axes are to be drawn on. Partial specification is allowed.
at location of labels
labels the labels to go along with at. The labels can be a character vector or a vector of expressions. Alternatively, this can be a logical. If TRUE, the labels are derived from at, otherwise, labels are empty.
draw.labels logical indicating whether labels are to be drawn
check.overlap logical, whether to check for overlapping of labels. This also has the effect of removing at values that are 'too close' to the limits.
outside logical, whether to the labels draw outside the panel or inside. Note that outside=TRUE will only have a visible effect if clipping is disabled for the viewport (panel).
ticks logical, whether to draw the tickmarks
half logical, whether only half of scales will be drawn for each side
which.half character string, one of "lower" and "upper". Indicates which half is to be used for tick locations if half=TRUE. Defaults to whatever is suitable for splom
panel.barchart

tck numeric scalar, multiplier for tick length. Can be negative.

rot rotation angles for labels in degrees. Can be a vector of length 2 for x- and y-axes respectively

text.col, text.alpha, text.cex, text.font, text.fontfamily, text.fontface, line.

unit which grid unit the values should be in

Details

panel.axis can draw axis tick marks inside or outside a panel (more precisely, a grid viewport). It honours the (native) axis scales. Used in panel.pairs for splom, as well as for all the usual axis drawing by the print method for "trellis" objects. It can also be used to enhance plots 'after the fact' by adding axes.

Value

current.panel.limits returns a list with components xlim and ylim, which are both numeric vectors of length 2, giving the scales of the current panel (viewport). The values correspond to the unit system specified by unit, by default "native".

panel.barchart Default Panel Function for barchart

Description

Default panel function for barchart.

Usage

panel.barchart(x, y, box.ratio = 1,
    horizontal = TRUE,
    origin = NULL, reference = TRUE,
    stack = FALSE,
    groups = NULL,
    col = if (is.null(groups)) plot.polygon$col else superpose.polygon$col,
    border = if (is.null(groups)) plot.polygon$border else superpose.polygon$border,
    lty = if (is.null(groups)) plot.polygon$lty else superpose.polygon$lty,
    lwd = if (is.null(groups)) plot.polygon$lwd else superpose.polygon$lwd,
    ...)
Arguments

x  Extent of Bars. By default, bars start at left of panel, unless origin is specified, in which case they start there
y  Horizontal location of bars, possibly factor
box.ratio  ratio of bar width to inter-bar space
horizontal  logical. If FALSE, the plot is ‘transposed’ in the sense that the behaviours of x and y are switched. x is now the ‘factor’. Interpretation of other arguments change accordingly. See documentation of bwplot for a fuller explanation.
origin  the origin for the bars. For grouped displays with stack = TRUE, this argument is ignored and the origin set to 0. Otherwise, defaults to NULL, in which case bars start at the left (or bottom) end of a panel. This choice is somewhat unfortunate, as it can be misleading, but is the default for historical reasons. For tabular (or similar) data, origin = 0 is usually more appropriate; if not, one should reconsider the use of a bar chart in the first place (dot plots are often a good alternative).
reference  logical, whether a reference line is to be drawn at the origin
stack  logical, relevant when groups is non-null. If FALSE (the default), bars for different values of the grouping variable are drawn side by side, otherwise they are stacked.
groups  optional grouping variable
col, border, lty, lwd

...  extra arguments will be accepted but ignored

Details

A barchart is drawn in the panel. Note that most arguments controlling the display can be supplied to the high-level barchart call directly.

panel.bwplot  Default Panel Function for bwplot

Description

This is the default panel function for bwplot.
panel.bwplot

Usage

panel.bwplot(x, y, box.ratio = 1,
              horizontal = TRUE,
              pch, col, cex,
              font, fontfamily, fontface,
              fill, varwidth = FALSE,
              ...,
              levels.fos,
              stats = boxplot.stats,
              coef = 1.5,
              do.out = TRUE)

Arguments

x, y          numeric vector or factor. Boxplots drawn for each unique value of y (x) if horizontal is TRUE (FALSE)
box.ratio     ratio of box height to inter box space
horizontal    logical. If FALSE, the plot is 'transposed' in the sense that the behaviours of x and y are switched. x is now the 'factor'. Interpretation of other arguments change accordingly. See documentation of bwplot for a fuller explanation.
pch, col, cex, font, fontfamily, fontface
              graphical parameters controlling the dot. pch="|" is treated specially, by replacing the dot with a line (similar to boxplot)
fill          color to fill the boxplot
varwidth      logical. If TRUE, widths of boxplots are proportional to the number of points used in creating it.
stats         a function, defaulting to boxplot.stats, that accepts a numeric vector and returns a list similar to the return value of boxplot.stats. The function must accept arguments coef and do.out even if they do not use them (a ... argument is good enough). This function is used to determine the box and whisker plot.
coef, do.out  passed to stats
levels.fos    numeric values corresponding to positions of the factor or shingle variable. For internal use.
...           further arguments, ignored.

Details

Creates Box and Whisker plot of x for every level of y (or the reverse if horizontal=FALSE). By default, the actual boxplot statistics are calculated using boxplot.stats. Note that most arguments controlling the display can be supplied to the high-level bwplot call directly. Unlike the traditional analog boxplot, notches are not implemented.

Although the graphical parameters for the dot representing the median can be controlled by optional arguments, many others can not. These parameters are obtained from the relevant settings parameters ("box.rectangle" for the box, "box.umbrella" for the whiskers and "plot.symbol" for the outliers).

panel.cloud

Default Panel Function for cloud

Description

These are default panel functions controlling cloud and wireframe displays.

Usage

panel.cloud(x, y, subscripts, z,
   groups = NULL,
   perspective = TRUE,
   distance = if (perspective) 0.2 else 0,
   xlim, ylim, zlim,
   panel.3d.cloud = "panel.3dscatter",
   panel.3d.wireframe = "panel.3dwire",
   screen = list(z = 40, x = -60),
   R.mat = diag(4), aspect = c(1, 1),
   par.box = NULL,
   xlab, ylab, zlab,
   xlab.default, ylab.default, zlab.default,
   scales.3d,
   proportion = 0.6,
   wireframe = FALSE,
   scpos,
   ..., at)
panel.wireframe(...)
panel.3dscatter(x, y, z, rot.mat, distance,
   groups, type = "p",
   xlim.scaled, ylim.scaled, zlim.scaled,
   zero.scaled,
   col, col.point, col.line,
   lty, lwd, cex, pch,
   cross, ..., subscripts)
panel.3dwire(x, y, z, rot.mat = diag(4), distance,
   shade = FALSE,
shade.colors.palette = trellis.par.get("shade.colors")$palette,
light.source = c(0, 0, 1000),
xlim.scaled,
ylim.scaled,
zlim.scaled,
col = if (shade) "transparent" else "black",
lty = 1, lwd = 1,
alpha,
col.groups = superpose.polygons$col,
polynum = 100,
...
drape = FALSE,
at,
col.regions = regions$col,
alpha.regions = regions$alpha)

Arguments

x, y, z numeric (or possibly factors) vectors representing the data to be displayed. The interpretation depends on the context. For panel.cloud these are essentially the same as the data passed to the high level plot (except if formula was a matrix, the appropriate x and y vectors are generated). By the time they are passed to panel.3dscatter and panel.3dwire, they have been scaled (to lie inside a bounding box, usually the [-0.5, 0.5] cube).

Further, for panel.3dwire, x and y are shorter than z and represent the sorted locations defining a rectangular grid. Also in this case, z may be a matrix if the display is grouped, with each column representing one surface.

In panel.cloud (called from wireframe) and panel.3dwire, x, y and z could also be matrices (of the same dimension) when they represent a 3-D surface parametrized on a 2-D grid.

subscripts index specifying which points to draw. The same x, y and z values (representing the whole data) are passed to panel.cloud for each panel. subscripts specifies the subset of rows to be used for the particular panel.

groups specification of a grouping variable, passed down from the high level functions.

perspective logical, whether to plot a perspective view. Setting this to FALSE is equivalent to setting distance to 0

distance numeric, between 0 and 1, controls amount of perspective. The distance of the viewing point from the origin (in the transformed coordinate system) is 1 / distance. This is described in a little more detail in the documentation for cloud

screen A list determining the sequence of rotations to be applied to the data before being plotted. The initial position starts with the viewing point along the positive z-axis, and the x and y axes in the usual position. Each component of the list should be named one of "x", "y" or "z" (repetitions are allowed), with their values indicating the amount of rotation about that axis in degrees.

R.mat initial rotation matrix in homogeneous coordinates, to be applied to the data before screen rotates the view further.

par.box graphical parameters for box, namely, col, lty and lwd. By default obtained from the parameter box.3d
xlim, ylim, zlim
limits for the respective axes. As with other lattice functions, these could each
be a numeric 2-vector or a character vector indicating levels of a factor.

panel.3d.cloud, panel.3d.wireframe
functions that draw the data-driven part of the plot (as opposed to the bounding
box and scales) in cloud and wireframe. This function is called after the
‘back’ of the bounding box is drawn, but before the ‘front’ is drawn.

Any user-defined custom display would probably want to change these func-
tions. The intention is to pass as much information to this function as might
be useful (not all of which are used by the defaults). In particular, these func-
tions can expect arguments called xlim, ylim, zlim which give the bound-
ing box ranges in the original data scale and xlim.scaled, ylim.scaled,
zlim.scaled which give the bounding box ranges in the transformed scale.
More arguments can be considered on request.

aspect
aspect as in cloud

xlab, ylab, zlab
Labels, have to be lists. Typically the user will not manipulate these, but instead
control this via arguments to cloud directly.

xlab.default for internal use

ylab.default for internal use

zlab.default for internal use

scales.3d list defining the scales

proportion numeric scalar, gives the length of arrows as a proportion of the sides

scpos A list with three components x, y and z (each a scalar integer), describing which
of the 12 sides of the cube the scales should be drawn. The defaults should be
OK. Valid values are x: 1, 3, 9, 11; y: 8, 5, 7, 6 and z: 4, 2, 10, 12. (See
comments in the source code of panel.cloud to see the details of this enu-
meration.)

wireframe logical, indicating whether this is a wireframe plot

drape logical, whether the facets will be colored by height, in a manner similar to
levelplot. This is ignored if shade=TRUE.

at, col.regions, alpha.regions
deals with specification of colors when drape = TRUE in wireframe.
at can be a numeric vector, col.regions a vector of colors, and
alpha.regions a numeric scalar controlling transparency. The resulting be-

haviour is similar to levelplot, at giving the breakpoints along the z-axis
where colors change, and the other two determining the colors of the facets that
fall in between.

rot.mat 4x4 transformation matrix in homogeneous coordinates. This gives the rotation
matrix combining the screen and R.mat arguments to panel.cloud

type character vector, specifying type of cloud plot. Can include one or more of
"p", "l", "h" or "b". "p" and "l" mean ‘points’ and ‘lines’ respectively,
and "b" means ‘both’. "h" stands for ‘histogram’, and causes a line to be
drawn from each point to the X-Y plane (i.e., the plane representing z = 0), or
the lower (or upper) bounding box face, whichever is closer.

xlim.scaled, ylim.scaled, zlim.scaled
axis limits (after being scaled to the bounding box)
zero.scaled  z-axis location (after being scaled to the bounding box) of the X-Y plane in the original data scale, to which lines will be dropped (if within range) from each point when type = "h"

cross  logical, defaults to TRUE if pch = "+". panel.3dscatter can represent each point by a 3d 'cross' of sorts (it’s much easier to understand looking at an example than from a description). This is different from the usual pch argument, and reflects the depth of the points and the orientation of the axes. This argument indicates whether this feature will be used.

This is useful for two reasons. It can be set to FALSE to use "+" as the plotting character in the regular sense. It can also be used to force this feature in grouped displays.

shade  logical, indicating whether the surface is to be colored using an illumination model with a single light source.

shade.colors.palette  a function (or the name of one) that is supposed to calculate the color of a facet when shading is being used. Three pieces of information is available to the function: first, the cosine of the angle between the incident light ray and the normal to the surface (representing foreshortening); second, the cosine of half the angle between the reflected ray and the viewing direction (useful for non-lambertian surfaces); and third, the scaled (average) height of that particular facet with respect to the total plot z-axis limits.

All three numbers should be between 0 and 1. The shade.colors.palette function should return a valid color. The default function is obtained from the trellis settings.

light.source  a 3-vector representing (in cartesian coordinates) the light source. This is relative to the viewing point being (0, 0, 1/distance) (along the positive z-axis), keeping in mind that all observations are bounded within the [-0.5, 0.5] cube.

polynum  quadrilateral faces are drawn in batches of polynum at a time. Drawing too few at a time increases the total number of calls to the underlying grid.polygon function, which affects speed. Trying to draw too many at once may be unnecessarily memory intensive. This argument controls the trade-off.

col.groups  colors for different groups

col, col.point, col.line, lty, lwd, cex, pch, alpha  graphical parameters

...  other parameters, passed down when appropriate

Details

These functions together are responsible for the content drawn inside each panel in cloud and wireframe. panel.wireframe is a wrapper to panel.cloud, which does the actual work.

panel.cloud is responsible for drawing the content that does not depend on the data, namely, the bounding box, the arrows/scales, etc. At some point, depending on whether wireframe is TRUE, it calls either panel.3d.wireframe or panel.3d.cloud, which draws the data-driven part of the plot.

The arguments accepted by these two functions are different, since they have essentially different purposes. For cloud, the data is unstructured, and x, y and z are all passed to the panel.3d.cloud function. For wireframe, on the other hand, x and y are increasing vectors with unique values, defining a rectangular grid. z must be a matrix with length(x) * length(y) rows, and as many columns as the number of groups.
panel.densityplot is the default panel.3d.cloud function. It has a type argument similar to panel.xyplot, and supports grouped displays. It tries to honour depth ordering, i.e., points and lines closer to the camera are drawn later, overplotting more distant ones. (Of course there is no absolute ordering for line segments, so an ad hoc ordering is used. There is no hidden point removal.)

panel.3d.wire is the default panel.3d.wireframe function. It calculates polygons corresponding to the facets one by one, but waits till it has collected information about polynum facets, and draws them all at once. This avoids the overhead of drawing grid.polygon repeatedly, speeding up the rendering considerably. If shade = TRUE, these attempt to color the surface as being illuminated from a light source at light.source. palette.shade is a simple function that provides the default shading colors.

Multiple surfaces are drawn if groups is non-null in the call to wireframe, however, the algorithm is not sophisticated enough to render intersecting surfaces correctly.

cloud, utilities.3d

Description

This is the default panel function for densityplot.

Usage

panel.densityplot(x, darg, plot.points = "jitter", ref = FALSE, groups = NULL,
    jitter.amount, type, ...)

Arguments

x data points for which density is to be estimated
darg list of arguments to be passed to the density function. Typically, this should be a list with zero or more of the following components: bw, adjust, kernel, window, width, give.Rkern, n, from, to, cut, na.rm (see density for details)
plot.points logical specifying whether or not the data points should be plotted along with the estimated density. Alternatively, a character string specifying how the points should be plotted. Meaningful values are "rug", in which case panel.rug is used to plot a ‘rug’, and "jitter", in which case the points are jittered vertically to better distinguish overlapping points.
ref logical, whether to draw x-axis
groups an optional grouping variable. If present, panel.superpose will be used instead to display each subgroup
jitter.amount

when plot.points="jitter", the value to use as the amount argument to jitter.

type
type argument used to plot points, if requested. This is not expected to be useful, it is available mostly to protect a type argument, if specified, from affecting the density curve.

...
extra graphical parameters

densityplot.jitter Default Panel Function for dotplot

panel.dotplot

Description
Default panel function for dotplot.

Usage
panel.dotplot(x, y, horizontal = TRUE,
pch, col, lty, lwd,
col.line, levels.fos,
groups = NULL,
...)

Arguments
x, y variables to be plotted in the panel. Typically y is the ‘factor’
horizontal logical. If FALSE, the plot is ‘transposed’ in the sense that the behaviours of x and y are switched. x is now the ‘factor’. Interpretation of other arguments change accordingly. See documentation of bwplot for a fuller explanation.
pch, col, lty, lwd, col.line graphical parameters
levels.fos locations where reference lines will be drawn
groups grouping variable (affects graphical parameters)
... extra parameters, passed to panel.xyplot which is responsible for drawing the foreground points (panel.dotplot only draws the background reference lines).

Details
Creates (possibly grouped) Dotplot of x against y or vice versa
These are predefined panel functions available in lattice for use in constructing new panel functions (usually on-the-fly).

Usage

panel.abline(a = NULL, b = 0,
             h = NULL, v = NULL,
             reg = NULL, coef = NULL,
             col, col.line, lty, lwd, type,
             ...)  
panel.curve(expr, from, to, n = 101,
            curve.type = "l",
            col, lty, lwd, type,
            ...)  
panel.rug(x = NULL, y = NULL,
          regular = TRUE,
          start = if (regular) 0 else 0.97,
          end = if (regular) 0.03 else 1,
          x.units = rep("npc", 2),
          y.units = rep("npc", 2),
          col, lty, lwd, alpha,
          ...)  
panel.linejoin(x, y, fun = mean, horizontal = TRUE,
               lwd, lty, col, col.line, type,
               ...)  
panel.fill(col, border, ...)  
panel.grid(h=3, v=3, col, col.line, lty, lwd, ...)  
panel.lmline(x, y, ...)  
panel.loess(x, y, span = 2/3, degree = 1,
            family = c("symmetric", "gaussian"),
            evaluation = 50,
            lwd, lty, col, col.line, type,
            ...)  
panel.mathdensity(dmath = dnorm, args = list(mean=0, sd=1),
                  n = 50, col, col.line, lwd, lty, type,
                  ...)
Arguments

x, y  variables defining the contents of the panel

a, b  Coefficients of the line to be added by `panel.abline`. `a` can be a vector of length 2, representing the coefficients of the line to be added, in which case `b` should be missing. `a` can also be an appropriate ‘regression’ object, i.e., an object which has a `coef` method that returns a length 2 numeric vector. The corresponding line will be plotted. The `reg` argument will override `a` if specified.

coeff  Coefficients of the line to be added as a length 2 vector

reg  A regression object. The corresponding fitted line will be drawn

h, v  For `panel.abline`, these are numeric vectors giving locations respectively of horizontal and vertical lines to be added to the plot, in native coordinates. For `panel.grid`, these usually specify the number of horizontal and vertical reference lines to be added to the plot. Alternatively, they can be negative numbers. `h=-1` and `v=-1` are intended to make the grids aligned with the axis labels. This doesn’t always work; all that actually happens is that the locations are chosen using `pretty`, which is also how the label positions are chosen in the most common cases (but not for factor or date-time variables, for instance). `h` and `v` can be negative numbers other than `-1`, in which case `h` and `-h` (or appropriate) is supplied as the `n` argument to `pretty`.

expr  expression as a function of `x` or a function to plot as a curve

n  the number of points to use for drawing the curve

regular  logical indicating whether the 'rug' is to be drawn on the regular side (left / bottom) or not (right / top)

start, end  endpoints of rug segments, in normalized parent coordinates (between 0 and 1). Defaults depend on value of regular, and cover 3% of the panel width and height

x.units, y.units  character vector, replicated to be of length two. Specifies the (grid) units associated with `start` and `end` above. `x.units` and `y.units` are for the rug on the x-axis and y-axis respectively (and thus are associated with `start` and `end` values on the y and x scales respectively).

from, to  optional lower and upper x-limits of curve. If missing, limits of current panel are used

curve.type  type of curve ("p" for points, etc), passed to `lines`

col, col.line, lty, lwd, alpha, border  graphical parameters

type  usually ignored. This is present only to make sure an explicitly specified `type` argument (perhaps meant for another function) doesn’t affect the display.

span, degree, family, evaluation  arguments to `loess.smooth`, for which `panel.loess` is essentially a wrapper

fun  the function that will be applied to the subset of x(y) determined by the unique values of y(x)

horizontal  logical. If FALSE, the plot is ‘transposed’ in the sense that the behaviours of x and y are switched. x is now the ‘factor’. Interpretation of other arguments change accordingly. See documentation of `bwplot` for a fuller explanation.

dmath  A vectorized function that produces density values given a numeric vector named x, e.g., `dnorm`
Details

panel.abline adds a line of the form $y = a + bx$ or vertical and/or horizontal lines. Graphical parameters are obtained from reference.line for panel.grid, and add.line for the others (can be set using trellis.par.set).

panel.curve adds a curve, similar to what curve does with add = TRUE. Graphical parameters for the line are obtained from the add.line setting.

panel.linejoin treats one of x and y as a factor (according to the value of horizontal), calculates fun applied to the subsets of the other variable determined by each unique value of the factor, and joins them by a line. Can be used in conjunction with panel.xyplot and more commonly with panel.superpose to produce interaction plots. See xyplot documentation for an example.

panel.mathdensity plots a (usually theoretical) probability density function. This can be useful in conjunction with histogram and densityplot to visually estimate goodness of fit (note, however, that qqmath is more suitable for this).

panel.rug adds a rug representation of the (marginal) data to the panel, much like rug.

panel.lmline(x, y) is equivalent to panel.abline(lm(y~x)).

Deepayan Sarkar (Deepayan.Sarkar@R-project.org)

See Also

loess.smooth, panel.axis, panel.identify, identify, trellis.par.get

Description

This is the default panel function for histogram.

Usage

panel.histogram(x, 
    breaks, 
    equal.widths = TRUE, 
    type = "density", 
    nint = round(log2(length(x)) + 1), 
    alpha, col, border, lty, lwd, 
    ...)
Arguments

- **x**: The data points for which the histogram is to be drawn
- **breaks**: The breakpoints for the histogram
- **equal.widths**: logical used when `breaks==NULL`
- **type**: Type of histogram, possible values being "percent", "density" and "count"
- **nint**: Number of bins for the histogram
- **alpha, col, border, lty, lwd**: graphical parameters for bars; defaults are obtained from the `plotpolygon` settings.
- **...**: other arguments, passed to `hist` when deemed appropriate

`histogram`

panel.levelplot  
**Default Panel Function for levelplot**

Description

This is the default panel function for `levelplot`.

Usage

```r
panel.levelplot(x, y, z, subscripts, at = pretty(z), shrink, labels = NULL, label.style = c("mixed", "flat", "align"), contour = FALSE, region = TRUE, col = add.line$col, lty = add.line$lty, lwd = add.line$lwd, cex = add.text$cex, font = add.text$font, fontfamily = add.text$fontfamily, fontface = add.text$fontface, col.text = add.text$col, ..., col.regions = regions$col, alpha.regions = regions$alpha)
panel.contourplot(...)
```
panel.levelplot

Arguments

- **x, y, z** variables defining the plot
- **subscripts** integer vector indicating what subset of x, y and z to draw
- **at** numeric vector specifying breakpoints for change in colors
- **shrink** either a numeric vector of length 2 (meant to work as both x and y components), or a list with components x and y which are numeric vectors of length 2. This allows the rectangles to be scaled proportional to the z-value. The specification can be made separately for widths (x) and heights (y). The elements of the length 2 numeric vector gives the minimum and maximum proportion of shrinkage (corresponding to min and max of z).
- **labels** contour labels
- **label.style** controls choice of how label positions are determined.
- **contour** logical, specifying whether contour lines should be drawn
- **region** logical, specifying whether inter-contour regions should be filled with the appropriate color
- **col, lty, lwd** graphical parameters for contour lines
- **cex, col.text, font, fontfamily, fontface** graphical parameters for contour labels
- **...** extra parameters
- **col.regions** a vector of colors used if region=TRUE. Usually a subset of the colors are used, the exact number being one more than the length of at. These are chosen to be roughly equally spaced along col.regions. In the unusual case when col.regions is not longer than at, it is repeated to be as long as necessary.
- **alpha.regions** numeric scalar controlling transparency of facets

Details

The same function is used for both levelplot and contourplot (which differ only in default values of some arguments). panel.contourplot is a simple wrapper to panel.levelplot.

When contour=TRUE, the contourLines function is used to calculate the contour lines.

levelplot, contourLines
Accessing Auxiliary Information During Plotting

Description

Control over lattice plots are provided through a collection of user specifiable functions that perform various tasks during the plotting. Not all information is available to all functions. The functions documented here attempt to provide a consistent interface to access relevant information from within these user specified functions, namely those specified as the `panel`, `strip` and `axis` functions.

Usage

```r
current.row()
current.column()
panel.number()
packet.number()
which.packet()

trellis.currentLayout(which = c("packet", "panel"))
```

Arguments

- **which**: whether return value (a matrix) should contain panel numbers or packet numbers, which are usually, but not necessarily, the same (see below for details).

Value

- `trellis.currentLayout` returns a matrix with as many rows and columns as in the layout of panels in the current plot. Entries in the matrix are integer indices indicating which packet (or panel; see below) occupies that position, with 0 indicating the absence of a panel. `current.row` and `current.column` return integer indices specifying which row and column in the layout are currently active. `panel.number` returns an integer counting which panel is being drawn (starting from 1 for the first panel, a.k.a. the panel order). `packet.number` gives the packet number according to the packet order, which is determined by varying the first conditioning variable the fastest, then the second, and so on. `which.packet` returns the combination of levels of the conditioning variables in the form of a numeric vector as long as the number of conditioning variables, with each element an integer indexing the levels of the corresponding variable.

Note

The availability of these functions make redundant some features available in earlier versions of lattice, namely optional arguments called `panel.number` and `packet.number` that were made available to `panel` and `strip`. If you have written such functions, it should be enough to replace instances of `panel.number` and `packet.number` by the corresponding function calls. You should also remove `panel.number` and `packet.number` from the argument list of your function to avoid a warning.

If these accessor functions are not enough for your needs, feel free to contact the maintainer and ask for more.

Default Superpanel Function for splom

Description

This is the default superpanel function for splom.

Usage

panel.pairs(z, panel = lattice.getOption("panel.splom"), lower.panel = panel, upper.panel = panel, diag.panel = "diag.panel.splom", as.matrix = FALSE, groups = NULL, panel.subscripts, subscripts, pscales = 5, prepanel.limits = function(x) if (is.factor(x)) levels(x) else extend.limits(range(as.numeric(x), finite = TRUE)),

varname.col, varname.cex, varname.font, varname.fontfamily, varname.fontface, axis.text.col, axis.text.cex, axis.text.font, axis.text.fontfamily, axis.text.fontface, axis.line.col, axis.line.lty, axis.line.lwd, axis.line.alpha, axis.line.tck, ...

diag.panel.splom(x = NULL, varname = NULL, limits, at = NULL, lab = NULL, draw = TRUE, varname.col, varname.cex, varname.lineheight, varname.font, varname.fontfamily, varname.fontface, axis.text.col, axis.text.alpha, axis.text.cex, axis.text.font, axis.text.fontfamily, axis.text.fontface, axis.line.col, axis.line.alpha, axis.line.lty, axis.line.lwd, axis.line.tck, ...)
Arguments

z
The data frame used for the plot.

panel, lower.panel, upper.panel
The panel function used to display each pair of variables. If specified, lower.panel and upper.panel are used for panels below and above the diagonal respectively.

diag.panel
The panel function used for the diagonals. See arguments to diag.panel.splom to know what arguments this function is passed when called.

as.matrix
logical. If TRUE, the layout of the panels will have origin on the top left instead of bottom left (similar to pairs). This is in essence the same functionality as provided by as.table for the panel layout

groups
Grouping variable, if any

panel.subscripts
logical specifying whether the panel function accepts an argument named subscripts.

subscripts
The indices of the rows of z that are to be displayed in this (super)panel.

pscales
Controls axis labels, passed down from splom. If pscales is a single number, it indicates the approximate number of equally-spaced ticks that should appear on each axis. If pscales is a list, it should have one component for each column in z, each of which itself a list with the following valid components:

at: a numeric vector specifying tick locations

labels: character vector labels to go with at

limits: numeric 2-vector specifying axis limits (should be made more flexible at some point to handle factors)

These are specifications on a per-variable basis, and used on all four sides in the diagonal cells used for labelling. Factor variables are labelled with the factor names. Use pscales=0 to suppress the axes entirely.

prepanel.limits
The ‘regular’ high level lattice plots such as xyplot use the prepanel function for deciding on axis limits from data. This function serves a similar function, and works on a per-variable basis, by calculating the limits, which can be overridden by the corresponding limits component in the pscales list.

x
data vector corresponding to that row / column (which will be the same for diagonal ‘panels’).

varname
(scalar) character string or expression that is to be written centred within the panel

limits
numeric of length 2, or, vector of characters, specifying the scale for that panel (used to calculate tick locations when missing)

at
locations of tick marks

lab
optional labels for tick marks

draw
logical, specifying whether to draw the tick marks and labels. If FALSE, only variable names are written

varname.col, varname.cex, varname.lineheight, varname.font, varname.fontfamily, varname.fontface, varname.textalpha, varname.linealpha
graphical parameters for the variable name in each diagonal panel

axis.text.col, axis.text.cex, axis.text.font, axis.text.fontfamily, axis.text.fontface, axis.text.linecol, axis.text.linecol, axis.text.linecolor, axis.text.linealpha
graphical parameters for axis tick marks and labels
panel.parallel

axis.line.tck
length of tick marks in diagonal panels

... extra arguments passed on to panel, lower.panel, upper.panel and diag.panel from panel.pairs. Currently ignored by diag.panel.splom.

Details

panel.pairs is the function that is actually passed in as the panel function in a trellis object produced by splom (taking the panel function as its argument).

panel.parallel Default Panel Function for parallel

Description

This is the default panel function for parallel.

Usage

panel.parallel(x, y, z, subscripts,
   groups = NULL,
col, lwd, lty, alpha,
   common.scale = FALSE,
   lower,
   upper,
   ...)
common.scale  logical, whether a common scale should be used columns of z. Defaults to FALSE, in which case the horizontal range for each column is different (as determined by lower and upper).

lower, upper  numeric vectors replicated to be as long as the number of columns in z. Determines the lower and upper bounds to be used for scaling the corresponding columns of z after coercing them to numeric. Defaults to the minimum and maximum of each column. Alternatively, these could be functions (to be applied on each column) that return a scalar.

... other arguments (ignored)

Details

Difficult to describe. See example for parallel

parallel

panel.qqmath  Default Panel and Prepanel Function for qqmath

Description

This is the default panel function for qqmath.

Usage

panel.qqmath(x, f.value = NULL,
             distribution = qnorm,
             qtype = 7,
             groups = NULL, ...)

Arguments

x  vector (typically numeric, coerced if not) of data values to be used in the panel.
f.value, distribution
   Defines how quantiles are calculated. See qqmath for details.
qtype
   The type argument to be used in quantile
groups
   An optional grouping variable. Within each panel, one Q-Q plot is produced for every level of this grouping variable, differentiated by different graphical parameters.
...
   further arguments, often graphical parameters.

Details

Creates a Q-Q plot of the data and the theoretical distribution given by distribution. Note that most of the arguments controlling the display can be supplied directly to the high-level qqmath call.
Useful panel function with `qqmath`. Draws a line passing through the points (usually) determined by the .25 and .75 quantiles of the sample and the theoretical distribution.

**Usage**

```r
panel.qqmathline(x, y = x, 
distribution = qnorm, 
p = c(0.25, 0.75), 
qtype = 7, 
groups = NULL, 
...)```

**Arguments**

- **x**: The original sample, possibly reduced to a fewer number of quantiles, as determined by the `f.value` argument to `qqmath`
- **y**: an alias for `x` for backwards compatibility
- **distribution**: quantile function for reference theoretical distribution.
- **p**: numeric vector of length two, representing probabilities. Corresponding quantile pairs define the line drawn.
- **qtype**: the type of quantile computation used in `quantile`
- **groups**: optional grouping variable. If non-null, a line will be drawn for each group.
- **...**: other arguments.

**Author(s)**

Deepayan Sarkar  ⟨Deepayan.Sarkar@R-project.org⟩

**See Also**

`prepanel.qqmathline`, `qqmath`, `quantile`
Description

This is the default panel function for `stripplot`. Also see `panel.superpose`.

Usage

```r
panel.stripplot(x, y, jitter.data = FALSE, 
    factor = 0.5, amount = NULL, 
    horizontal = TRUE, groups = NULL, 
    ...)```

Arguments

- `x, y` coordinates of points to be plotted
- `jitter.data` whether points should be jittered to avoid overplotting.
- `factor, amount` amount of jittering. See `jitter`.
- `horizontal` logical. If FALSE, the plot is ‘transposed’ in the sense that the behaviours of `x` and `y` are switched. `x` is now the ‘factor’. Interpretation of other arguments change accordingly. See documentation of `bwplot` for a fuller explanation.
- `groups` optional grouping variable
- `...` graphical parameters etc can be supplied, passed to `panel.xyplot` or `panel.superpose`, depending on whether `groups` is present

Details

Creates stripplot (one dimensional scatterplot) of `x` for each level of `y`.

Author(s)

Deepayan Sarkar (Deepayan.Sarkar@R-project.org)

- `stripplot`, `jitter`
panel.superpose  
Panel Function for Display Marked by groups

Description

These are panel functions for Trellis displays useful when a grouping variable is specified for use within panels. The \( x \) (and \( y \) where appropriate) variables are plotted with different graphical parameters for each distinct value of the grouping variable.

Usage

```r
panel.superpose(x, y = NULL, subscripts, groups,
    panel.groups = "panel.xyplot",
    col, col.line, col.symbol,
    pch, cex, fill, font,
    fontface, fontfamily,
    lty, lwd, alpha,
    type = "p",
    ..., 
    distribute.type = FALSE)
```

```r
panel.superpose.2(..., distribute.type = TRUE)
```

Arguments

- `x,y`  coordinates of the points to be displayed
- `panel.groups` the panel function to be used for each group of points. Defaults to `panel.xyplot` (behaviour in S).
  To be able to distinguish between different levels of the originating group inside `panel.groups`, it will be supplied a special argument called `group.number` which will hold the numeric code corresponding to the current level of `groups`. No special care needs to be taken when writing a `panel.groups` function if this feature is not used.
- `subscripts` subscripts giving indices in original data frame
- `groups` a grouping variable. Different graphical parameters will be used to plot the subsets of observations given by each distinct value of `groups`. The default graphical parameters are obtained from `superpose.symbol` and `superpose.line` using `trellis.par.get` wherever appropriate
- `type` usually a character vector specifying what should be drawn for each group, passed on to the `panel.groups` function, which must know what to do with it. By default, this is `panel.xyplot`, whose help page describes the admissible values.

The functions `panel.superpose` and `panel.superpose.2` differ only in the default value of `distribute.type`, which controls the way the `type` argument is interpreted. If `distribute.type = FALSE`, then the interpretation is the same as for `panel.xyplot` for each of the unique groups. In other words, if `type` is a vector, all the individual components are honoured concurrently. If `distribute.type = TRUE`, `type` is replicated to be as long as the number of unique values in `groups`, and one component used for the points corresponding to the each different group. Even in this case, it is
possible to request multiple types per group, specifying type as a list, each component being the desired type vector for the corresponding group. If distribute.type = FALSE, any occurrence of "g" in type causes a grid to be drawn, and all such occurrences are removed before type is passed on to panel.groups.

col, col.line, col.symbol, pch, cex, fill, font, fontface, fontfamily, lty, lwd, graphical parameters, replicated to be as long as the number of groups. These are eventually passed down to panel.groups, but as scalars rather than vectors. When panel.groups is called for the i-th level of groups, the corresponding element of each graphical parameter is passed to it.

... Extra arguments. Passed down to panel.superpose from panel.superpose.2, and to panel.groups from panel.superpose.

distribute.type
logical controlling interpretation of the type argument.

Details

panel.superpose and panel.superpose.2 differ essentially in how type is interpreted by default. The default behaviour in panel.superpose is the opposite of that in S, which is the same as that of panel.superpose.2.

Author(s)

Deepayan Sarkar (Deepayan.Sarkar@R-project.org) (panel.superpose.2 originally contributed by Neil Klepeis)

See Also

Different functions when used as panel.groups gives different types of plots, for example panel.xyplot, panel.dotplot and panel.linejoin (This can be used to produce interaction plots).

See Lattice for an overview of the package.

panel.violin

Panel Function to create Violin Plots

Description

This is a panel function that can create a violin plot. It is typically used in a high-level call to bwplot.

Usage

panel.violin(x, y, box.ratio = 1, horizontal = TRUE,
alpha, border, lty, lwd, col,
varwidth = FALSE,
bw, adjust, kernel, window,
width, n = 50, from, to, cut,
na.rm, ...)
Arguments

\(x, y\) numeric vector or factor. Violin plots are drawn for each unique value of \(y(x)\) if horizontal is TRUE (FALSE).

box.ratio ratio of height of a violin and inter violin space

horizontal logical. If FALSE, the plot is ‘transposed’ in the sense that the behaviours of \(x\) and \(y\) are switched. \(x\) is now the ‘factor’. See documentation of \(bwplot\) for a fuller explanation.

alpha, border, lty, lwd, col graphical parameters controlling the violin. Defaults are taken from the "plot.polygon" settings.

varwidth logical. If FALSE, the densities are scaled separately for each group, so that the maximum value of the density reaches the limit of the allocated space for each violin (as determined by box.ratio). If TRUE, densities across violins will have comparable scale.

bw, adjust, kernel, window, width, n, from, to, cut, na.rm arguments to \(density\), passed on as appropriate

\(\ldots\) arguments passed on to \(density\).

Details

Creates Violin plot of \(x\) for every level of \(y\). Note that most arguments controlling the display can be supplied to the high-level (typically \(bwplot\)) call directly.

Author(s)

Deepayan Sarkar \(\langle\)Deepayan.Sarkar@R-project.org\(\rangle\)

See Also

\(bwplot, density\)

Examples

\[\begin{align*}
&bwplot(voice.part ~ height, singer, 
&\quad \text{panel = function}(\ldots, \text{box.ratio}) \{ 
&\quad \text{panel.violin}(\ldots, \text{col = "transparent"}, 
&\quad \quad \text{varwidth = FALSE, box.ratio = box.ratio}) 
&\quad \text{panel.bwplot}(\ldots, \text{fill = NULL, box.ratio = .1}) 
&\} \)
\end{align*}\]
panel.xyplot

Usage

panel.xyplot(x, y, type = "p",
             groups = NULL,
             pch, col, col.line, col.symbol,
             font, fontfamily, fontface,
             lty, cex, fill, lwd,
             horizontal = FALSE, ...)

panel.splom(...)  
panel.qq(...)

Arguments

x, y  variables to be plotted in the scatterplot

type  character vector consisting of one or more of the following: "p", "l", "h", "b", "o", "s", "S", "r", "a", "g", "smooth". If type has more than one element, an attempt is made to combine the effect of each of the components. The behaviour if any of the first six are included in type is similar to the effect of type in plot (type "b" is actually the same as "o"). "r" adds a regression line (same as panel.lmline, except for default graphical parameters), and "smooth" adds a lowess fit (same as panel.loess). "g" adds a reference grid using panel.grid in the background. "a" has the effect of calling panel.linejoin, which can be useful for creating interaction plots. The effect of several of these specifications depend on the value of horizontal. See example(xyplot) and demo(lattice) for examples.

groups  an optional grouping variable. If present, panel.superpose will be used instead to display each subgroup

col, col.line, col.symbol   default colours are obtained from plot.symbol and plot.line using trellis.par.get.

font, fontface, fontfamily  font used when pch is a character

pch, lty, cex, lwd, fill  other graphical parameters. fill serves the purpose of bg in points for certain values of pch

...  extra arguments, if any, for panel.xyplot. In most cases panel.xyplot ignores these. For types "r" and "smooth", these are passed on to panel.lmline and panel.loess respectively.

horizontal  logical. Controls orientation for certain type's, e.g. one of "h", "s" or "S"

Details

Creates scatterplot of x and y, with various modifications possible via the type argument. panel.qq draws a 45 degree line before calling panel.xyplot.

Note that most of the arguments controlling the display can be supplied directly to the high-level (e.g. xyplot) call.

prepanel.default  Default Prepanel Functions

Description

These prepanel functions are used as fallback defaults in various high level plot functions in Lattice. These are rarely useful to normal users but may be helpful in developing new displays.

Usage

prepanel.default.bwplot(x, y, horizontal, nlevels, origin, stack, ...)
prepanel.default.histogram(x, breaks, equal.widths, type, nint, ...)
prepanel.default.qq(x, y, ...)
prepanel.default.xyplot(x, y, type, subscripts, groups, ...)
prepanel.default.cloud(perspective, distance, xlim, ylim, zlim,
                       screen = list(z = 40, x = -60),
                       R.mat = diag(4),
                       aspect = c(1, 1), ..., zoom = 0.8)
prepanel.default.levelplot(x, y, subscripts, ...)
prepanel.default.qqmath(x, f.value, distribution, qtype,
                        groups, subscripts, ...)
prepanel.default.densityplot(x, darg, groups, subscripts, ...)
prepanel.default.parallel(x, y, z, ...)
prepanel.default.splom(z, ...)

Arguments

x, y  x and y values, numeric or factor
horizontal  logical, applicable when one of the variables is to be treated as categorical (factor or shingle)
nlevels  number of levels of such a categorical variable.
origin, stack  for barcharts or the type="h" plot type
breaks, equal.widths, type, nint  details of histogram calculations. type has a different meaning in
prepanel.default.xyplot (see panel.xyplot)
groups, subscripts  See xyplot. Whenever appropriate, calculations are done separately for each
group and then combined.
perspective, distance, xlim, ylim, zlim, screen, R.mat, aspect, zoom  see panel.cloud
f.value, distribution  see panel.qqmath
darg  list of arguments passed to density
prepanel.functions

Usage

prepanel.lmline(x, y, ...)  
prepanel.loess(x, y, span, degree, family, evaluation, ...)  
prepanel.qqmathline(x, y = x, distribution = qnorm,  
          p = c(0.25, 0.75), qtype = 7,  
          groups, subscripts,  
          ...)  

Arguments

x, y  
x and y values, numeric or factor  
distribution  
quantile function for theoretical distribution. This is automatically passed in when this is used as a prepanel function in qqmath.  
qtype  
type of quantile  
p  
umeric vector of length two, representing probabilities. If used with aspect="xy", the aspect ratio will be chosen to make the line passing through the corresponding quantile pairs as close to 45 degrees as possible.  
span, degree, family, evaluation  
arguments controlling the underlying loess smooth  
groups, subscripts  
See xyplot. Whenever appropriate, calculations are done separately for each group and then combined.  
...  
other arguments

Value

A list with components xlim, ylim, dx and dy, and possibly xat and yat, the first two being used to calculate panel axes limits, the last two for banking computations. The form of these components are described in the help page for xyplot.

Author(s)

Deepayan Sarkar (Deepayan.Sarkar@R-project.org)

See Also

xyplot, banking, Lattice. See documentation of corresponding panel functions for more details about the arguments.
Value

usually a list with components xlim, ylim, dx and dy, the first two being used to calculate panel axes limits, the last two for banking computations. The form of these components are described under xyplot. There are also several prepanel functions that serve as the default for high level functions, see prepanel.default.xyplot

print.trellis  Plot and Summarize Trellis Objects

Description

The print and plot methods produce a graph from a "trellis" object. The print method is necessary for automatic plotting. plot method is essentially an alias, provided for convenience. The summary method gives a textual summary of the object. dim and dimnames describe the cross-tabulation induced by conditioning.

Usage

## S3 method for class 'trellis':
print(x, position, split,
     more = FALSE, newpage = TRUE,
     packet.panel = packet.panel.default,
     draw.in = NULL,
     panel.height = lattice.getOption("layout.heights")$panel,
     panel.width = lattice.getOption("layout.widths")$panel,
     save.object = lattice.getOption("save.object"),
     prefix,
     ...
)## S3 method for class 'trellis':
plot(x, ...

## S3 method for class 'trellis':
summary(object, ...

## S3 method for class 'trellis':
dim(x)

## S3 method for class 'trellis':
dimnames(x)
Arguments

- **x, object** an object of class "trellis"
- **position** a vector of 4 numbers, typically c(xmin, ymin, xmax, ymax) that give the lower-left and upper-right corners of a rectangle in which the Trellis plot of x is to be positioned. The coordinate system for this rectangle is [0-1] in both the x and y directions.
- **split** a vector of 4 integers, c(x,y,nx,ny) , that says to position the current plot at the x,y position in a regular array of nx by ny plots. (Note: this has origin at top left)
- **more** A logical specifying whether more plots will follow on this page.
- **newpage** A logical specifying whether the plot should be on a new page. This option is specific to lattice, and is useful for including lattice plots in an arbitrary grid viewport (see the details section).
- **packet.panel** a function that determines which packet (data subset) is plotted in which panel. Panels are always drawn in an order such that columns vary the fastest, then rows and then pages. This function determines, given the column, row and page and other relevant information, the packet (if any) which should be used in that panel. By default, the association is determined by matching panel order with packet order, which is determined by varying the first conditioning variable the fastest, then the second, and so on. This association rule is encoded in the default, namely the function `packet.panel.default`, whose help page details the arguments supplied to whichever function is specified as the `packet.panel` argument.
- **draw.in** An optional (grid) viewport (used as the name argument in `downViewport`) in which the plot is to be drawn. If specified, the `newpage` argument is ignored. This feature is not well-tested.
- **panel.width, panel.height** lists with 2 components, that should be valid x and units arguments to `unit()` (the data argument cannot be specified currently, but can be considered for addition if needed). The resulting unit object will be the width/height of each panel in the Lattice plot. These arguments can be used to explicitly control the dimensions of the panel, rather than letting them expand to maximize available space. Vector widths are allowed, and can specify unequal lengths across rows or columns.
  Note that this option should not be used in conjunction with non-default values of the aspect argument in the original high level call (no error will be produced, but the resulting behaviour is undefined).
- **save.object** logical, specifying whether the object being printed is to be saved. The last object thus saved can be subsequently retrieved. This is an experimental feature that should allow access to a panel’s data after the plot is done, making it possible to enhance the plot after the fact. This also allows the user to invoke the `update` method on the current plot, even if it was not assigned to a variable explicitly. For more details, see `trellis.focus`.
- **prefix** character string used as a prefix in viewport and grob names, used to distinguish similar viewports if a page contains multiple plots. The default is based on the serial number of the current plot on the current page (which is one more than the number of plots that have been drawn on the page before the current plot). If supplied explicitly, this has to be a valid R symbol name (briefly, it must start with a letter or a period followed by a letter) and must not contain the grid path separator (currently ":\:").
extra arguments, ignored by the print method. All arguments to the plot method are passed on to the print method.

Details

This is the default print method for objects of class "trellis", produced by calls to functions like xyplot, bwplot etc. It is usually called automatically when a trellis object is produced. It can also be called explicitly to control plot positioning by means of the arguments split and position.

When newpage = FALSE, the current grid viewport is treated as the plotting area, making it possible to embed a Lattice plot inside an arbitrary grid viewport. The draw.in argument provides an alternative mechanism that may be simpler to use.

The print method uses the information in x (the object to be printed) to produce a display using the Grid graphics engine. At the heart of the plot is a grid layout, of which the entries of most interest to the user are the ones containing the display panels.

Unlike in older versions of Lattice (and Grid), the grid display tree is retained after the plot is produced, making it possible to access individual viewport locations and make additions to the plot. For more details and a lattice level interface to these viewports, see trellis.focus.

Note

Unlike S-PLUS, trying to position a multipage display (using position and/or split) will mess things up.

Quantile-Quantile Plots of Two Samples

Description

Quantile-Quantile plots for comparing two Distributions

Usage

qq(x, data, ...)  

## S3 method for class 'formula':  
qq(x, data, aspect = "fill",  
panel = lattice.getOption("panel.qq"),  
prepanel, scales, strip,  
groups, xlab, xlim, ylab, ylim, f.value = NULL,  
drop.unused.levels = lattice.getOption("drop.unused.levels"),  
...,

lattice.options = NULL,  
qtype = 7,

default.scales = list(),

subscripts,

subset)
Arguments

**x**
The object on which method dispatch is carried out.
For the formula method, a formula of the form \( y \sim x \mid g1 \ast g2 \ast \ldots \),
where \( x \) must be a numeric, and \( y \) can be a factor, shingle, character or numeric
vector, with the restriction that there must be exactly two levels of \( y \), which
divide the values of \( x \) into two groups. Quantiles for these groups will be plotted
along the two axes.

**data**
For the formula methods, an optional data frame in which variables in the
formula (as well as groups and subset, if any) are to be evaluated.

**f.value**
optional numeric vector of probabilities, quantiles corresponding to which
should be plotted. Can also be a function of a single integer (representing sam-
ple size) that returns such a numeric vector. The typical value for this argument
is the function `ppoints`, which is also the S-PLUS default. If specified, the
probabilities generated by this function is used for the plotted quantiles, using
the `quantile` function.

`f.value` defaults to `NULL`, which is equivalent to using `function(n)`
`ppoints(n, a = 1)`. This has the effect of including the minimum and
maximum data values in the computed quantiles. This is similar to what hap-
pens for `qqplot` but different from the default `qq` behaviour in S-PLUS.
For large data, this argument can be useful in plotting a smaller set of quantiles,
which is usually enough to capture the pattern.

**panel**
The function that uses the packet (subset of display variables) corresponding to a
panel to create a display. Default panel functions are documented separately, and
often have arguments that can be used to customize its display in various ways.
Such arguments can usually be directly supplied to the high level function.

**qtype**
type argument for the `quantile`

Details

`qq` produces a Q-Q plot of two samples. The default behaviour of `qq` is different from the corre-
sponding S-PLUS function. See the entry for `f.value` for specifics.
This and all other high level Trellis functions have several arguments in common. These are ex-
tensively documented only in the help page for `xyplot`, which should be consulted to learn more
detailed usage.

Value

An object of class "trellis". The `update` method can be used to update components of the
object and the `print` method (usually called by default) will plot it on an appropriate plotting
device.

Examples

```r
qq(voice.part ~ height, aspect = 1, data = singer,
   subset = (voice.part == "Bass 2" | voice.part == "Tenor 1"))
```

**Description**

Quantile-Quantile plot of a sample and a theoretical distribution

**Usage**

```r
qqmath(x, data, 
## S3 method for class 'formula':
qqmath(x,
   data,
   allow.multiple = is.null(groups) || outer,
   outer = !is.null(groups),
   distribution = qnorm,
   f.value = NULL,
   auto.key = FALSE,
   aspect = "fill",
   panel = lattice.getOption("panel.qqmath"),
   prepanel = NULL,
   scales, strip, groups,
   xlab, xlim, ylab, ylim,
   drop.unused.levels = lattice.getOption("drop.unused.levels"),
   ...
   lattice.options = NULL,
   default.scales = list(),
   subscripts,
   subset)
## S3 method for class 'numeric':
qqmath(x, data = NULL, ylab, ...)
```

**Arguments**

- `x` The object on which method dispatch is carried out.
- `data` For the "formula" method, a formula of the form `~ x | g1 * g2 * ....` where `x` must be a numeric. For the "numeric" method, a numeric vector.
- `distribution` a quantile function that takes a vector of probabilities as argument and produces the corresponding quantiles. Possible values are `qnorm`, `qunif` etc. Distributions with other required arguments need to be passed in as user defined functions.
Optional numeric vector of probabilities, quantiles corresponding to which should be plotted. Can also be a function of a single integer (representing sample size) that returns such a numeric vector. The typical value for this argument is the function `ppoints`, which is also the S-PLUS default. If specified, the probabilities generated by this function is used for the plotted quantiles, using the `quantile` function for the sample, and the function specified as the `distribution` argument for the theoretical distribution. `f.value` defaults to `NULL`, which has the effect of using `ppoints` for the quantiles of the theoretical distribution, but the exact data values for the sample. This is similar to what happens for `qqnorm`, but different from the S-PLUS default of `f.value=ppoints`. For large \( x \), this argument can be useful in plotting a smaller set of quantiles, which is usually enough to capture the pattern.

The panel function to be used. Unlike in older versions, the default panel function does most of the actual computations and has support for grouping. See `panel.qqmath` for details.

Further arguments. See corresponding entry in `xyplot` for non-trivial details.

Details

`qqmath` produces a Q-Q plot of the given sample and a theoretical distribution. The default behaviour of `qqmath` is different from the corresponding S-PLUS function, but is similar to `qqnorm`. See the entry for `f.value` for specifics.

The implementation details are also different from S-PLUS. In particular, all the important calculations are done by the panel (and prepanel function) and not `qqmath` itself. In fact, both the arguments `distribution` and `f.value` are passed unchanged to the panel and prepanel function. This allows, among other things, display of grouped Q-Q plots, which are often useful. See the help page for `panel.qqmath` for further details.

This and all other high level Trellis functions have several arguments in common. These are extensively documented only in the help page for `xyplot`, which should be consulted to learn more detailed usage.

Value

An object of class "trellis". The `update` method can be used to update components of the object and the `print` method (usually called by default) will plot it on an appropriate plotting device.

**rfs**

**Residual and Fit Spread Plots**

Description

Plots fitted values and residuals (via qqmath) on a common scale for any object that has methods for fitted values and residuals.

Usage

```r
rfs(model, layout=c(2, 1), xlab="f-value", ylab=NULL,
   distribution = qunif,
   panel, prepanel, strip, ...)
```

Arguments

- **model**: a fitted model object with methods `fitted.values` and `residuals`. Can be the value returned by `oneway`
- **layout**: default layout is `c(2,1)`
- **xlab**: defaults to "f.value"
- **distribution**: the distribution function to be used for `qqmath`
- **ylab, panel, prepanel, strip**
  - See `xyplot`
- **...**: other arguments, passed on to `qqmath`
An object of class "trellis". The `update` method can be used to update components of the object and the `print` method (usually called by default) will plot it on an appropriate plotting device.

shingles

Description

Functions to handle shingles

Usage

shingle(x, intervals=sort(unique(x))
equal.count(x, ...)
as.shingle(x)
is.shingle(x)

## S3 method for class 'shingle':
plot(x, panel, xlab, ylab, ...)

## S3 method for class 'shingle':
print(x, showValues = TRUE, ...)

## S3 method for class 'shingleLevel':
as.character(x, ...)

## S3 method for class 'shingleLevel':
print(x, ...)

## S3 method for class 'shingle':
summary(object, showValues = FALSE, ...)

## S3 method for class 'shingle':
x[subset, drop = FALSE]
as.factorOrShingle(x, subset, drop)

Arguments

x numeric variable or R object, shingle in plot.shingle and x[]. An object (list of intervals) of class "shingleLevel" in print.shingleLevel
object shingle object to be summarized
showValues logical, whether to print the numeric part. If FALSE, only the intervals are printed
intervals numeric vector or matrix with 2 columns
subset logical vector
drop whether redundant shingle levels are to be dropped
panel, xlab, ylab standard Trellis arguments (see xyplot)
... other arguments, passed down as appropriate. For example, extra arguments to equal.count are passed on to co.intervals. graphical parameters can be passed as arguments to the plot method.
simpleKey

Details

A shingle is a data structure used in Trellis, and is a generalization of factors to ‘continuous’ variables. It consists of a numeric vector along with some possibly overlapping intervals. These intervals are the ‘levels’ of the shingle. The levels and nlevels functions, usually applicable to factors, also work on shingles. The implementation of shingles is slightly different from S.

There are print methods for shingles, as well as for printing the result of levels() applied to a shingle. For use in labelling, the as.character method can be used to convert levels of a shingle to character strings.

equal.count converts x to a shingle using the equal count algorithm. This is essentially a wrapper around co.intervals. All arguments are passed to co.intervals.

shingle creates a shingle using the given intervals. If intervals is a vector, these are used to form 0 length intervals.

as.shingle returns shingle(x) if x is not a shingle.

is.shingle tests whether x is a shingle.

plot.shingle displays the ranges of shingles via rectangles. print.shingle and summary.shingle describe the shingle object.

Value

x$intervals for levels.shingle(x), logical for is.shingle, an object of class "trellis" for plot (printed by default by print.trellis), and an object of class "shingle" for the others.

Author(s)

Deepayan Sarkar (Deepayan.Sarkar@R-project.org)

See Also

xyplot, co.intervals, Lattice

Examples

z <- equal.count(rnorm(50))
plot(z)
print(z)
print(levels(z))

simpleKey

Function to generate a simple key

Description

Simple interface to generate a list appropriate for draw.key
Usage

simpleKey(text, points = TRUE,
          rectangles = FALSE,
          lines = FALSE,
          col, cex, alpha, font,
          fontface, fontfamily,
          lineheight, ...)

Arguments

text character or expression vector, to be used as labels for levels of the grouping variable
points logical
rectangles logical
lines logical
col, cex, alpha, font, fontface, fontfamily, lineheight
  Used as top-level components of the list produced, to be used for the text labels. Defaults to the values in trellis.par.get("add.text")
... further arguments added to the list, eventually passed to draw.key

Details

A lattice plot can include a legend (key) if an appropriate list is specified as the key argument to a high level Lattice function such as xyplot. This key can be very flexible, but that flexibility comes at the cost of this list being very complicated even in simple situations. The simpleKey function is a shortcut, which assumes that the key is being drawn in conjunction with the groups argument, and that the default Trellis settings are being used. At most one each of points, rectangles and lines can be drawn.

See also the auto.key argument for high level plots.

Value

A list that would work as the key argument to xyplot etc.

Heights of New York Choral Society singers

Description

Heights in inches of the singers in the New York Choral Society in 1979. The data are grouped according to voice part. The vocal range for each voice part increases in pitch according to the following order: Bass 2, Bass 1, Tenor 2, Tenor 1, Alto 2, Alto 1, Soprano 2, Soprano 1.

Usage

singer

Format

A data frame with 235 observations on the following 2 variables.

height Height in inches of the singers.

**splot**

**Scatter Plot Matrices**

**Description**

Draw Conditional Scatter Plot Matrices and Parallel Coordinate Plots

**Usage**

```r
splot(x, data, ...)
parallel(x, data, ...)
```

```r
## S3 method for class 'formula':
splot(x,
data,
auto.key = FALSE,
aspect = 1,
between = list(x = 0.5, y = 0.5),
panel = lattice.getOption("panel.splot"),
prepanel,
scales,
strip,
groups,
xlab,
xlim,
ylab = NULL,
ylim,
superpanel = lattice.getOption("panel.pairs"),
pscales = 5,
varnames,
drop.unused.levels,
...,
lattice.options = NULL,
default.scales,
subset = TRUE)
```

```r
## S3 method for class 'formula':
parallel(x,
data,
aspect = "fill",
between = list(x = 0.5, y = 0.5),
panel = lattice.getOption("panel.parallel"),
prepanel,
scales,
strip,
groups,
xlab = NULL,
```
The object on which method dispatch is carried out. For the "formula" method, a formula describing the structure of the plot, which should be of the form ~ x | g1 * g2 * ..., where x is a data frame or matrix. Each of g1, g2, ... must be either factors or shingles. The conditioning variables g1, g2, ... may be omitted. For the data.frame methods, a data frame.

data

For the formula methods, an optional data frame in which variables in the formula (as well as groups and subset, if any) are to be evaluated.

aspect

aspect ratio of each panel (and subpanel), square by default for splom.

between

to avoid confusion between panels and subpanels, the default is to show the panels of a splom plot with space between them.

panel

Usual interpretation for parallel, namely the function that creates the display within each panel.

For splom, the terminology is slightly complicated. The role played by the panel function in most other high-level functions is played here by the superpanel function, which is responsible for the display for each conditional data subset. panel is simply an argument to the default superpanel function panel.pairs, and is passed on to it unchanged. It is used there to create each pairwise display. See panel.pairs for more useful options.

superpanel

function that sets up the splom display, by default as a scatterplot matrix.

pscales

a numeric value or a list, meant to be a less functional substitute for the scales argument in xyplot etc. This argument is passed to the superpanel function, and is handled by the default superpanel function panel.pairs. The help page for the latter documents this argument in more detail.

varnames

character vector giving the names of the p variables in x. By default, the column names of x.

auto.key, prepanel, scales, strip, groups, xlab, xlim, ylab, ylim, drop.unused.levels, ...  

Further arguments. See corresponding entry in xyplot for non-trivial details.
Details

`splom` produces Scatter Plot Matrices. The role usually played by `panel` is taken over by `superpanel`, which determines how the columns of `x` are to be arranged for pairwise plots. The only available option currently is `panel.pairs`.

Many of the finer customizations usually done via arguments to high level function like `xyplot` are instead done by `panel.pairs` for `splom`. These include control of axis limits, tick locations and prepanel calculations. If you are trying to fine-tune your `splom` plot, definitely look at the `panel.pairs` help page. The `scales` argument is usually not very useful in `splom`, and trying to change it may have undesired effects.

`parallel` draws Parallel Coordinate Plots. (Difficult to describe, see example.)

These and all other high level Trellis functions have several arguments in common. These are extensively documented only in the help page for `xyplot`, which should be consulted to learn more detailed usage.

Value

An object of class "trellis". The `update` method can be used to update components of the object and the `print` method (usually called by default) will plot it on an appropriate plotting device.

`xyplot`, `Lattice`, `panel.pairs`

Examples

```r
super.sym <- trellis.par.get("superpose.symbol")
splom(~iris[1:4], groups = Species, data = iris,
    panel = panel.superpose,
    key = list(title = "Three Varieties of Iris",
               columns = 3,
               points = list(pch = super.sym$pch[1:3],
                              col = super.sym$col[1:3]),
               text = list(c("Setosa", "Versicolor", "Virginica"))))
splom(~iris[1:3]|Species, data = iris,
    layout=c(2,2), pscales = 0,
    varnames = c("Sepal\nLength", "Sepal\nWidth", "Petal\nLength"),
    page = function(...) {
        ltext(x = seq(.6, .8, len = 4),
              y = seq(.9, .6, len = 4),
              lab = c("Three", "Varieties", "of", "Iris"),
              cex = 2)
    })
parallel(~iris[1:4] | Species, iris)
```
Strips in Trellis plots are often customized using the `strip.default` function. This function is the default for drawing strip elements in Trellis plots and can be extended with user-defined functions. The `strip.default` function is used to draw strips by default, and users can write their own strip functions, typically by calling `strip.default` with slightly different arguments.

### Usage

```r
strip.default(which.given,  
    which.panel,  
    var.name,  
    factor.levels,  
    shingle.intervals,  
    strip.names = c(FALSE, TRUE),  
    strip.levels = c(TRUE, FALSE),  
    sep = " : ",  
    style = 1,  
    horizontal = TRUE,  
    bg = trellis.par.get("strip.background")$col[which.given],  
    fg = trellis.par.get("strip.shingle")$col[which.given],  
    par.strip.text = trellis.par.get("add.text"))
```

### Arguments

- **which.given**: integer index specifying which of the conditioning variables this strip corresponds to.
- **which.panel**: vector of integers as long as the number of conditioning variables. The contents are indices specifying the current levels of each of the conditioning variables (thus, this would be unique for each distinct packet). This is identical to the return value of `which.packet`, which is a more accurate name.
- **var.name**: vector of character strings or expressions as long as the number of conditioning variables. The contents are interpreted as names for the conditioning variables. Whether they are shown on the strip depends on the values of `strip.names` and `style` (see below). By default, the names are shown for shingles, but not for factors.
- **factor.levels**: vector of character strings or expressions giving the levels of the conditioning variable currently being drawn. For more than one conditioning variable, this will vary with `which.given`. Whether these levels are shown on the strip depends on the values of `strip.levels` and `style` (see below). `factor.levels` may be specified for both factors and shingles (despite the name), but by default they are shown only for factors. If shown, the labels may optionally be abbreviated by specifying suitable components in `par.strip.text` (see `xyplot`).
strip.default

shingle.intervals
if the current strip corresponds to a shingle, this should be a 2-column matrix
giving the levels of the shingle. (of the form that would be produced by printing
levels(shingle)). Otherwise, it should be NULL

strip.names
a logical vector of length 2, indicating whether or not the name of the condi-
tioning variable that corresponds to the strip being drawn is to be written on the
strip. The two components give the values for factors and shingles respectively.
This argument is ignored for a factor when style is not one of 1 and 3.

strip.levels
a logical vector of length 2, indicating whether or not the level of the condi-
tioning variable that corresponds to the strip being drawn is to be written on the
strip. The two components give the values for factors and shingles respectively.

sep
character or expression, serving as a separator if the name and level are both to
be shown.

style
integer, with values 1, 2, 3, 4 and 5 currently supported, controlling how
the current level of a factor is encoded. Ignored for shingles (actually, when
shingle.intervals is non-null.
The best way to find out what effect the value of style has is to try them
out. Here is a short description: for a style value of 1, the strip is colored in the
background color with the strip text (as determined by other arguments) centered
on it. A value of 3 is the same, except that a part of the strip is colored in the
foreground color, indicating the current level of the factor. For styles 2 and 4, the
part corresponding to the current level remains colored in the foreground color,
however, for style = 2, the remaining part is not colored at all, whereas for 4, it
is colored with the background color. For both these, the names of all the levels
of the factor are placed on the strip from left to right. Styles 5 and 6 produce
the same effect (they are subtly different in S, this implementation corresponds
to 5), they are similar to style 1, except that the strip text is not centered, it is
instead positioned according to the current level.
Note that unlike S-PLUS, the default value of style is 1. strip.names and
strip.levels have no effect if style is not 1 or 3.

horizontal
logical, specifying whether the labels etc should be horizontal.
horizontal=FALSE is useful for strips on the left of panels using
strip.left=TRUE

par.strip.text
list with parameters controlling the text on each strip, with components col,
cex, font, etc.

bg
strip background color.

fg
strip foreground color.

... arguments to be passed on to strip.default, overriding whatever value it
would have normally assumed

Details
default strip function for trellis functions. Useful mostly because of the style argu-
ment — non-default styles are often more informative, especially when the names of
the levels of the factor x are small. Traditional use is as strip = function(...)
strip.default(style=2,...), though this can be simplified by the use of
strip.custom.
**Value**

`strip.default` is called for its side-effect, which is to draw a strip appropriate for multi-panel Trellis conditioning plots. `strip.custom` returns a function that is similar to `strip.default`, but with different defaults for the arguments specified in the call.

**Author(s)**

Deepayan Sarkar (Deepayan.Sarkar@R-project.org)

**See Also**

`xyplot`, Lattice

**Examples**

```r
## Traditional use
xyplot(Petal.Length ~ Petal.Width | Species, iris,
     strip = function(..., style) strip.default(..., style = 4))

## equivalent call using strip.custom
xyplot(Petal.Length ~ Petal.Width | Species, iris,
     strip = strip.custom(style = 4))

xyplot(Petal.Length ~ Petal.Width | Species, iris,
     strip = FALSE,
     strip.left = strip.custom(style = 4, horizontal = FALSE))
```

---

**Tmd**

*Tukey Mean-Difference Plot*

**Description**

`tmd` Creates Tukey Mean-Difference Plots from a trellis object returned by `xyplot`, `qq` or `qqmath`. The prepanel and panel functions are used as appropriate. The formula method for `tmd` is provided for convenience, and simply calls `tmd` on the object created by calling `xyplot` on that formula.

**Usage**

`tmd(object, ...)`

```r
## S3 method for class 'trellis':
tmd(object,
     xlab = "mean",
     ylab = "difference",
     panel,
     prepanel,
     ...)

prepanel.tmd.qqmath(x,
                     f.value = NULL,
                     distribution = qnorm,
                     ...)
```

---

```r
tmd
```
tmd

qttype = 7,
groups = NULL,
subscripts, ...
panel.tmd.qqmath(x,
f.value = NULL,
distribution = qnorm,
qttype = 7,
groups = NULL,
subscripts, ...)
panel.tmd.default(x, y, groups = NULL, ...)
prepanel.tmd.default(x, y, ...)

Arguments

object An object of class "trellis" returned by xyplot, qq or qqmath.
xlab x label
ylab y label
panel panel function to be used. See details below.
prepanel prepanel function. See details below.
f.value, distribution, qttype see panel.qqmath.
groups, subscripts see xyplot.
x, y data as passed to panel functions in original call.
... other arguments

Details

The Tukey Mean-difference plot is produced by modifying the (x,y) values of each panel as follows: the new coordinates are given by \( x = (x + y)/2 \) and \( y = y - x \), which are then plotted. The default panel function(s) add a reference line at \( y = 0 \) as well.

tmd acts on the a "trellis" object, not on the actual plot this object would have produced. As such, it only uses the arguments supplied to the panel function in the original call, and completely ignores what the original panel function might have done with this data. tmd uses these panel arguments to set up its own scales (using its prepanel argument) and display (using panel). It is thus important to provide suitable prepanel and panel functions to tmd depending on the original call.

Such functions currently exist for xyplot, qq (the ones with default in their name) and qqmath, as listed in the usage section above. These assume the default displays for the corresponding high-level call. If unspecified, the codprepanel and panel arguments default to suitable choices.

tmd uses the update method for "trellis" objects, which processes all extra arguments supplied to tmd.

Value

An object of class "trellis". The update method can be used to update components of the object and the print method (usually called by default) will plot it on an appropriate plotting device.

Deepayan Sarkar ⟨Deepayan.Sarkar@R-project.org⟩

See Also

qq, qqmath, xyplot, Lattice

Examples

tmd(qqmath(~height | voice.part, data = singer))

Description

Initialization of a display device with appropriate graphical parameters.

Usage

trellis.device(device = getOption("device"),
  color = !(dev.name == "postscript"),
  theme = lattice.getOption("default.theme"),
  new = TRUE,
  retain = FALSE,
  ...
)

canonical.theme(name, color)
col.whitebg()

Arguments

device function (or the name of one as a character string) that starts a device. Admissible values depend on the platform and how R was compiled (see Devices), but usually "pdf", "postscript", "png", "jpeg" and at least one of "X11", "windows" and "quartz" will be available.

color logical, whether the initial settings should be color or black and white. Defaults to FALSE for postscript devices, TRUE otherwise. Note that this only applies to the initial choice of colors, which can be overridden using theme or subsequent calls to trellis.par.set (and by arguments supplied directly in high level calls for some settings).

theme list of components that changes the settings of the device opened, or, a function that when called produces such a list. The function name can be supplied as a quoted string. These settings are only used to modify the default settings (determined by other arguments), and need not contain all possible parameters. A possible use of this argument is to change the default settings by specifying lattice.options(default.theme = "col.whitebg"). For back-compatibility, this is initially (when lattice is loaded) set to options(lattice.theme).

If theme is a function, it will not be supplied any arguments, however, it is guaranteed that a device will already be open when it is called, so one may use .Device inside the function to ascertain what device has been opened.
**new**

logical flag indicating whether a new device should be started. If `FALSE`, the options for the current device are changed to the defaults determined by the other arguments.

**retain**

logical. If `TRUE` and a setting for this device already exists, then that is used instead of the defaults for this device. By default, pre-existing settings are overwritten (and lost).

**name**

name of the device for which the setting is required, as returned by `.Device`

... additional parameters to be passed to the `device` function, most commonly `file` for non-screen devices, as well as `height,width`, etc. See the help file for individual devices for admissible arguments.

---

**Details**

Trellis Graphics functions obtain the default values of various graphical parameters (colors, line types, fonts, etc.) from a customizable “settings” list. This functionality is analogous to `par` for standard R graphics and, together with `lattice.options`, mostly supplants it (`par` settings are mostly ignored by Lattice). Unlike `par`, Trellis settings can be controlled separately for each different device type (but not concurrently for different instances of the same device). `canonical.theme` and `col.whitebg` produce predefined settings (a.k.a. themes), while `trellis.device` provides a high level interface to control which “theme” will be in effect when a new device is opened. `trellis.device` is called automatically when a "trellis" object is plotted, and the defaults can be used to provide sufficient control, so in a properly configured system it is rarely necessary for the user to call `trellis.device` explicitly.

The `canonical.theme` function is intended to provide device specific settings (e.g. light colors on a grey background for screen devices, dark colors or black and white for print devices) which were used as defaults prior to R 2.3.0. However, these defaults are not always appropriate, due to the variety of platforms and hardware settings on which R is used, as well as the fact that a plot created on a particular device may be subsequently used in many different ways. For this reason, a “safe” default is used for all devices from R 2.3.0 onwards. The old behaviour can be reinstated by setting `canonical.theme` as the default `theme` argument, e.g. by putting `options(lattice.theme = "canonical.theme")` in a startup script (see the entry for `theme` above for details).

**Value**

`canonical.theme` returns a list of components defining graphical parameter settings for Lattice displays. It is used internally in `trellis.device`, and can also be used as the `theme` argument to `trellis.par.set`, or even as `theme` in `trellis.device` to use the defaults for another device.

`col.whitebg` returns a similar (but smaller) list that is suitable as the `theme` argument to `trellis.device` and `trellis.par.set`. It contains settings values which provide colors suitable for plotting on a white background. Note that the name `col.whitebg` is somewhat a misnomer, since it actually sets the background to transparent rather than white.

**Note**

Earlier versions of `trellis.device` had a `bg` argument to set the background color, but this is no longer supported. If supplied, the `bg` argument will be passed on to the device function; however, this will have no effect on the Trellis settings. It is rarely meaningful to change the background alone; if you feel the need to change the background, consider using the `theme` argument instead.
**trellis.object**

- [Lattice](#) for an overview of the lattice package.
- [Devices](#) for valid choices of device on your platform.
- `trellis.par.get` and `trellis.par.set` can be used to query and modify the settings after a device has been initialized. The `par.settings` argument to high level functions, described in `xyplot`, can be used to attach transient settings to a "trellis" object.

---

**Description**

This class of objects is returned by high level lattice functions, and is usually plotted by default by its print method.

**Details**

A trellis object, as returned by high level lattice functions like `xyplot`, is a list with the "class" attribute set to "trellis". Many of the components of this list are simply the arguments to the high level function that produced the object. Among them are: `as.table`, `layout`, `page`, `panel`, `prepanel`, `main`, `sub`, `par.strip.text`, `strip`, `skip`, `xlab`, `ylab`, `par.settings`, `lattice.options` and `plot.args`. Some other typical components are:

- **formula** the Trellis formula used in the call
- **index.cond** list with index for each of the conditioning variables
- **perm.cond** permutation of the order of the conditioning variables
- **aspect.fill** logical, whether aspect is "fill"
- **aspect.ratio** numeric, aspect ratio to be used if `aspect.fill` is FALSE
- **call** call that generated the object.
- **condlevels** list with levels of the conditioning variables
- **legend** list describing the legend(s) to be drawn
- **panel.args** a list as long as the number of panels, each element being a list itself, containing the arguments in named form to be passed to the panel function in that panel.
- **panel.args.common** a list containing the arguments common to all the panel functions in name=value form
- **x.scales** list describing x-scale, can consist of several other lists, paralleling panel.args, if x-relation is not "same"
- **y.scales** list describing y-scale, similar to `x.scales`
- **x.between** numeric vector of interpanel x-space
- **y.between** numeric vector of interpanel y-space
- **x.limits** numeric vector of length 2 or list, giving x-axis limits
- **y.limits** similar to `x.limits`
- **packet.sizes** array recording the number of observations in each packet
trellis.par.get

Graphical Parameters for Trellis Displays

Description

Functions used to query, display and modify graphical parameters for fine control of Trellis displays. Modifications are made to the settings for the currently active device only.

Usage

trellis.par.set(name, value, ..., theme, warn = TRUE, strict = FALSE)
trellis.par.get(name = NULL)
show.settings(x = NULL)

Arguments

name character giving the name of a component. If unspecified, names(trellis.par.get()) returns a list containing all the current settings (this can be used to get the valid values for name)

value a list giving the desired value of the component. Components that are already defined as part of the current settings but are not mentioned in value will remain unchanged.

theme a list describing how to change the settings, similar to what is returned by trellis.par.get(). This is purely for convenience, allowing multiple calls to trellis.par.set to be condensed into one. The name of each component must be a valid name as described above, with the corresponding value a valid value as described above. As in trellis.device, theme can also be a function that produces such a list when called. The function name can be supplied as a quoted string.

... Multiple settings can be specified in name = value form. Equivalent to calling with theme = list(...) 

warn logical, indicating whether a warning should be issued when trellis.par.get is called when no graphics device is open

strict logical, indicating whether the value should be interpreted strictly. Usually, assignment of value to the corresponding named component is fuzzy in the sense that sub-components that are absent from value but not currently NULL are retained. By specifying strict = TRUE, the assignment will be exact.

x optional list of components that change the settings (any valid value of theme). These are used to modify the current settings (obtained by trellis.par.get) before they are displayed.
Details

The various graphical parameters (color, line type, background etc) that control the look and feel of Trellis displays are highly customizable. Also, R can produce graphics on a number of devices, and it is expected that a different set of parameters would be more suited to different devices. These parameters are stored internally in a variable named `lattice.theme`, which is a list whose components define settings for particular devices. The components are identified by the name of the device they represent (as obtained by `.Device`), and are created as and when new devices are opened for the first time using `trellis.device` (or Lattice plots are drawn on a device for the first time in that session).

The initial settings for each device defaults to values appropriate for that device. In practice, this boils down to three distinct settings, one for screen devices like `x11` and `windows`, one for black and white plots (mostly useful for `postscript`) and one for color printers (color `postscript`, `pdf`).

Once a device is open, its settings can be modified. When another instance of the same device is opened later using `trellis.device`, the settings for that device are reset to its defaults, unless otherwise specified in the call to `trellis.device`. But settings for different devices are treated separately, i.e., opening a postscript device will not alter the x11 settings, which will remain in effect whenever an x11 device is active.

The functions `trellis.par.*` are meant to be interfaces to the global settings. They always apply on the settings for the currently ACTIVE device.

`trellis.par.get`, called without any arguments, returns the full list of settings for the active device. With the `name` argument present, it returns that component only. `trellis.par.get` sets the value of the `name` component of the current active device settings to `value`.

`trellis.par.get` is usually used inside `trellis` functions to get graphical parameters before plotting. Modifications by users via `trellis.par.set` is traditionally done as follows:

```r
add.line <- trellis.par.get("add.line")
add.line$col <- "red"
trellis.par.set("add.line", add.line)
```

More convenient (but not S compatible) ways to do this are

```r
trellis.par.set(list(add.line = list(col = "red")))
```

and

```r
trellis.par.set(add.line = list(col = "red"))
```

The actual list of the components in `trellis.settings` has not been finalized, so I’m not attempting to list them here. The current value can be obtained by `print(trellis.par.get())`. Most names should be self-explanatory.

`show.settings` provides a graphical display summarizing some of the values in the current settings.

Value

`trellis.par.get` returns a list giving parameters for that component. If `name` is missing, it returns the full list.

Note

In some ways, `trellis.par.get` and `trellis.par.set` together are a replacement for the `par` function used in traditional R graphics. In particular, changing `par` settings has little (if any) effect on lattice output. Since lattice plots are implemented using Grid graphics, its parameter
system does have an effect unless overridden by a suitable lattice parameter setting. Such parameters can be specified as part of a lattice theme by including them in the `grid.pars` component (see `gpar` for a list of valid parameter names).

One of the uses of `par` is to set `par(ask = TRUE)` making `R` wait for user input before starting a new graphics page. For Grid graphics, this is done using `grid.prompt`. Lattice has no separate interface for this, and the user must call `grid.prompt` directly. If the grid package is not attached (lattice itself only loads the grid namespace), this may be done using `grid::grid.prompt(TRUE).

**update.trellis**  
*Retrieve and Update Trellis Object*

**Description**

Update method for objects of class "trellis", and a way to retrieve the last printed trellis object (that was saved).

**Usage**

```r
## S3 method for class 'trellis':
update(object,  
panel,  
aspect,  
as.table,  
between,  
key,  
auto.key,  
legend,  
layout,  
main,  
page,  
par.strip.text,  
prepanel,  
scales,  
skip,  
strip,  
strip.left,  
sub,  
xlab,
```
Arguments

- `object, x`: The object to be updated, of class "trellis".
- `i, j`: indices to be used. Names are not currently allowed.
- `drop`: logical, whether dimensions with only one level are to be dropped. Currently ignored, behaves as if it were FALSE.
- `warn`: logical, whether to warn when no plot is saved.
- `...`: arguments that will be used to update `object`. See details below.

Details

All high level lattice functions such as `xyplot` produce an object of (S3) class "trellis", which is usually displayed by its `print` method. However, the object itself can be manipulated and modified to a large extent using the `update` method, and then re-displayed as needed.

Most arguments to high level functions can also be supplied to the `update` method as well, with some exceptions. Generally speaking, anything that would needs to change the data within each panel is a no-no (this includes the formula, data, groups, subscripts and subset). Everything else is technically game, though might not be implemented yet. If you find something missing that you wish to have, feel free to make a request.

Not all arguments accepted by a Lattice function are processed by `update`, but the ones listed above should work. The purpose of these arguments are described in the help page for `xyplot`. Any other argument is added to the list of arguments to be passed to the `panel` function. Because of their somewhat special nature, updates to objects produced by `cloud` and `wireframe` do not work very well yet.

The "[" method is a convenient shortcut for updating `index.cond`. The `t` method is a convenient shortcut for updating `perm.cond` in the special (but frequent) case where there are exactly two conditioning variables, when it has the effect of switching ('transposing') their order.

The print method for "trellis" objects optionally saves the object after printing it. If this feature is enabled, `trellis.last.object` can retrieve it. Note that at most one object can be saved at a time. If `trellis.last.object` is called with arguments, these are used to update the retrieved object before returning it.
1910

utilities.3d

Value
An object of class trellis,
by default plotted by
trellis.last.object returns NULL is no saved object is available.

utilities.3d

Utility functions for 3-D plots

Description
These are (related to) the default panel functions for cloud and wireframe.
Usage
ltransform3dMatrix(screen, R.mat)
ltransform3dto3d(x, R.mat, dist)

Arguments
x

x can be a numeric matrix with 3 rows for ltransform3dto3d

screen

list, as described in panel.cloud

R.mat

4x4 transformation matrix in homogeneous coordinates

dist

controls transformation to account for perspective viewing


Details

ltransform3dMatrix and ltransform3dto3d are utility functions to help in computation of projections. These functions are used inside the panel functions for cloud and wireframe. They may be useful in user-defined panel functions as well.

The first function takes a list of the form of the screen argument in cloud and wireframe and a R.mat, a 4x4 transformation matrix in homogeneous coordinates, to return a new 4x4 transformation matrix that is the result of applying R.mat followed by the rotations in screen. The second function applies a 4x4 transformation matrix in homogeneous coordinates to a 3xn matrix representing points in 3-D space, and optionally does some perspective computations. (There has been no testing with non-trivial transformation matrices, and my knowledge of the homogeneous coordinate system is very limited, so there may be bugs here.)

cloud, panel.cloud

Description

These are the most commonly used high level Trellis functions to plot pairs of variables. By far the most common is xyplot, designed mainly for two continuous variates (though factors can be supplied as well, in which case they will simply be coerced to numeric), which produces Conditional Scatter plots. The others are useful when one of the variates is a factor or a shingle. Most of these arguments are also applicable to other high level functions in the lattice package, but are only documented here.

Usage

xyplot(x, data, ...)
dotplot(x, data, ...)
barchart(x, data, ...)
stripplot(x, data, ...)
bwplot(x, data, ...)

Arguments

\texttt{x}

The object on which method dispatch is carried out.

For the "formula" methods, a formula describing the form of conditioning plot. The formula is generally of the form \( y \sim x | g_1 \times g_2 \times \ldots \), indicating that plots of \( y \) (on the y axis) versus \( x \) (on the x axis) should be produced conditional on the variables \( g_1, g_2, \ldots \). However, the conditioning variables \( g_1, g_2, \ldots \) may be omitted. The formula can also be supplied as \( y \sim x | g_1 + g_2 + \ldots \).

For all of these functions, with the exception of \texttt{xyplot}, a formula of the form \( \sim x | g_1 \times g_2 \times \ldots \) is also allowed. In that case, \( y \) defaults to \texttt{names(x)} if \( x \) is named, and a factor with a single level otherwise.

Other usage of the form \texttt{dotplot(x)} is handled by method dispatch as appropriate. The \texttt{numeric} method is equivalent to a call with no left hand side and no conditioning variables in the formula. For \texttt{barchart} and \texttt{dotplot}, non-trivial methods exist for tables and arrays, documented under \texttt{barchart.table}.

The conditioning variables \( g_1, g_2, \ldots \) must be either factors or shingles. Shingles are a way of processing numeric variables for use in conditioning. See documentation of \texttt{shingle} for details. Like factors, they have a "levels" attribute, which is used in producing the conditional plots.

Numeric conditioning variables are converted to shingles by the function \texttt{shingle} (however, using \texttt{equal.count} might be more appropriate in many cases) and character vectors are coerced to factors.

The formula can involve expressions, e.g. \texttt{sqrt()}, \texttt{log}().

A special case is when the left and/or right sides of the formula (before the conditioning variables) contain a '+' sign, e.g., \texttt{y1+y2} \( \sim x | a*b \). This formula would be taken to mean that the user wants to plot both \( y_{1-x} | a*b \) and \( y_{2-x} | a*b \), but with the \( y_{1-x} \) and \( y_{2-x} \) superposed in each panel (this is slightly more complicated in \texttt{barchart}). The two parts would be distinguished by different graphical parameters. This is essentially what the \texttt{groups} argument would produce, if \( y_1 \) and \( y_2 \) were concatenated to produce a longer vector, with the \texttt{groups} argument being an indicator of which rows come from which variable. In fact, this is exactly what is done internally using the \texttt{reshape} function. This feature cannot be used in conjunction with the \texttt{groups} argument.

To interpret \( y_1 + y_2 \) as a sum, one can either set \texttt{allow.multiple=FALSE} or use \texttt{I(y1+y2)}.

A variation on this feature is when the \texttt{outer} argument is set to \texttt{TRUE} as well as \texttt{allow.multiple}. In that case, the plots are not superposed in each panel, but instead separated into different panels (as if a new conditioning variable had been added).

The \texttt{x} and \texttt{y} variables should both be numeric in \texttt{xyplot}, and an attempt is made to coerce them if not. However, if either is a factor, the levels of that factor are used as axis labels. In the other four functions documented here,
exactly one of \( x \) and \( y \) should be numeric, and the other a factor or shingle. Which of these will happen is determined by the horizontal argument — if horizontal=TRUE, then \( y \) will be coerced to be a factor or shingle, otherwise \( x \). The default value of horizontal is FALSE if \( x \) is a factor or shingle, TRUE otherwise. (The functionality provided by horizontal=FALSE is not S-compatible.)

Note that this argument used to be called formula in earlier versions (when the high level functions were not generic and the formula method was essentially the only method). This is no longer allowed. It is recommended that this argument not be named in any case, but rather be the first (unnamed) argument.

data

For the formula method, a data frame containing values (or more precisely, anything that is a valid envir argument in eval, e.g. a list or an environment) for any variables in the formula, as well as groups and subset if applicable. If not found in data, or if data is unspecified, the variables are looked for in the environment of the formula. For other methods (where \( x \) is not a formula), data is usually ignored, often with a warning.

allow.multiple, outer

logical flags to control what happens with formulas like \( y_1 + y_2 \sim x \). See the entry for \( x \) for details. allow.multiple defaults to TRUE whenever it makes sense, and outer defaults to FALSE except when groups is explicitly specified or grouping doesn’t make sense for the default panel function

box.ratio

applicable to bwplot, barchart and stripplot, specifies the ratio of the width of the rectangles to the inter rectangle space.

horizontal

logical, applicable to bwplot, dotplot, barchart and stripplot. Determines which of \( x \) and \( y \) is to be a factor or shingle (\( y \) if TRUE, \( x \) otherwise). Defaults to FALSE if \( x \) is a factor or shingle, TRUE otherwise. This argument is used to process the arguments to these high level functions, but more importantly, it is passed as an argument to the panel function, which is supposed to use it as appropriate.

A potentially useful component of scales in this case might be abbreviate = TRUE, in which case long labels which would usually overlap will be abbreviated. scales could also contain a minlength argument in this case, which would be passed to the abbreviate function.

panel

Once the subset of rows defined by each unique combination of the levels of the grouping variables are obtained (see details), the corresponding \( x \) and \( y \) variables (or other variables, as appropriate, in the case of other high level functions) are passed on to be plotted in each panel. The actual plotting is done by the function specified by the panel argument. Each high level function has its own default panel function, which could depend on whether the groups argument was supplied.

The panel function can be a function object or a character string giving the name of a predefined function.

Much of the power of Trellis Graphics comes from the ability to define customized panel functions. A panel function appropriate for the functions described here would usually expect arguments named \( x \) and \( y \), which would be provided by the conditioning process. It can also have other arguments. It might be useful to know in this context that all arguments passed to a high level Trellis function (such as xyplot) that are not recognized by it are passed through to the panel function. It is thus generally good practice when defining panel functions to allow a . . . argument. Such extra arguments typically control graphical
parameters, but other uses are also common. See documentation for individual panel functions for specifics.

Note that unlike in S-PLUS, it is not guaranteed that panel functions will be supplied only numeric vectors for the \textit{x} and \textit{y} arguments; they can be factors as well (but not shingles). Panel functions need to handle this case, which in most cases can be done by simply coercing them to numeric.

Technically speaking, panel functions must be written using Grid graphics functions. However, knowledge of Grid is usually not necessary to construct new custom panel functions, there are several predefined panel functions which can help; for example, \texttt{panel.grid}, \texttt{panel.loess}, etc. There are also some grid-compatible replacements of commonly used base R graphics functions useful for this purpose. For example, \texttt{lines} can be replaced by \texttt{linese} (or equivalently, \texttt{panel.lines}). Note that base R graphics functions like \texttt{lines} will not work in a lattice panel function.

One case where a bit more is required of the panel function is when the \texttt{groups} argument is not null. In that case, the panel function should also accept arguments named \texttt{groups} and \texttt{subscripts} (see below for details). A useful panel function predefined for use in such cases is \texttt{panel.superpose}, which can be combined with different \texttt{panel.groups} functions determining what is plotted for each group. See the examples section for an interaction plot constructed in this way. Several other panel functions can also handle the \texttt{groups} argument, including the default ones for \texttt{barchart}, \texttt{dotplot} and \texttt{stripplot}.

Even when \texttt{groups} is not present, the panel function can have \texttt{subscripts} as a formal argument. In either case, the \texttt{subscripts} argument passed to the panel function are the indices of the \textit{x} and \textit{y} data for that panel in the original \texttt{data}, BEFORE taking into account the effect of the \texttt{subset} argument. Note that \texttt{groups} remains unaffected by any subsetting operations, so \texttt{groups[subscripts]} gives the values of \texttt{groups} that correspond to the data in that panel. The value of \texttt{subscripts} becomes slightly more complicated when \texttt{allow.multiple} is in effect. Details can be found in the source code of the function \texttt{latticeParseFormula}.

A panel function can have two other optional arguments for convenience, namely \texttt{panel.number} and \texttt{packet.number}, representing panel order and packet order respectively. Both provide a simple integer index indicating which panel is currently being drawn, but differ in how the count is calculated. \texttt{panel.number} is a simple incremental counter that starts with 1 and is incremented each time a panel is drawn. \texttt{packet.number} on the other hand indexes the combination of levels of the conditioning variables that is represented by that panel. The two indices coincide unless the order of conditioning variables is permuted and/or the plotting order of levels within one or more conditioning variables is altered (using \texttt{perm.cond} and \texttt{index.cond} respectively), in which case \texttt{packet.number} gives the index corresponding to the ‘natural’ ordering of that combination of levels of the conditioning variables. \texttt{panel.xyplot} has an argument called \texttt{type} which is worth mentioning here because it is quite frequently used (and as mentioned above, can be passed to \texttt{xyplot} directly). Panel functions for \texttt{bwplot} and friends should have an argument called \texttt{horizontal} to account for the cases when \textit{x} is the factor or shingle.

\texttt{aspect} controls physical aspect ratio of the panels (same for all the panels). It can be specified as a ratio (vertical size/horizontal size) or as a character string. Legitimate values are "fill" (the default) which tries to make the panels as
big as possible to fill the available space; "xy", which tries to compute the aspect based on the 45 degree banking rule (see Visualizing Data by William S. Cleveland for details); and "iso" for isometric scales, where the relation between physical distance on the device and distance in the data scale are forced to be the same for both axes.

If a prepanel function is specified and it returns components dx and dy, these are used for banking calculations. Otherwise, values from the default prepanel function are used. Currently, only the default prepanel function for xyplot can be expected to produce sensible banking calculations. See banking for details on the implementation of banking.

groups
a variable or expression to be evaluated in the data frame specified by data, expected to act as a grouping variable within each panel, typically used to distinguish different groups by varying graphical parameters like color and line type. Formally, if groups is specified, then groups along with subscripts is passed to the panel function, which is expected to handle these arguments. Not all pre-defined panel functions know how to, but for high level functions where grouping is appropriate, the default panel functions are chosen so that they do.

It is very common to use a key (legend) when a grouping variable is specified. See entries for key, auto.key and simpleKey for how to draw a key.

auto.key
A logical (indicating whether a key is to be drawn automatically when a grouping variable is present in the plot), or a list of parameters that would be valid arguments to simpleKey (in effect, most valid components of key can be specified in this manner). If auto.key is not FALSE, groups is non-null and there is no key or legend argument specified in the call, a key is created with simpleKey with levels(groups) as the first argument. (Note: this may not work in all high level functions, but it does work for the ones where grouping makes sense with the default panel function)

simpleKey uses the trellis settings to determine the graphical parameters in the key, so this will be meaningful only if the settings are used in the plot as well.

One disadvantage to using key (or even simpleKey) directly is that the graphical parameters used in the key are absolutely determined at the time when the "trellis" object is created. Consequently, if a plot once created is reprinted with different settings, the parameter settings for the original device will be used. However, with auto.key, the key is actually created at printing time, so the key settings will match the device settings.

prepanel
function that takes the same arguments as the panel function and returns a list, possibly containing components named xlim, ylim, dx and dy (and less frequently, xat and yat).

The xlim and ylim components are similar to the high level xlim and ylim arguments (i.e., they are usually a numeric vector of length 2 defining a range of values, or a character vector representing levels of a factor). If the xlim and ylim arguments are not explicitly specified (possibly as components in scales), then the actual limits of the panels are guaranteed to include the limits returned by the prepanel function. This happens globally if the relation component of scales is "same", and on a panel by panel basis otherwise. See xlim to see what forms of the components xlim and ylim are allowed.

The dx and dy components are used for banking computations in case aspect is specified as "xy". See documentation for the function banking for details regarding how this is done.
The return value of the prepanel function need not have all the components named above; in case some are missing, they are replaced by the usual component-wise defaults.

If xlim or ylim is a character vector (which is appropriate when the corresponding variable is a factor), this implicitly indicates that the scale should include the first n integers, where n is the length of xlim or ylim, as the case may be. The elements of the character vector are used as the default labels for these n integers. Thus, to make this information consistent between panels, the xlim or ylim values should represent all the levels of the corresponding factor, even if some are not used within that particular panel.

In such cases, an additional component xat or yat may be returned by the prepanel function, which should be a subset of 1:n, indicating which of the n values (levels) are actually represented in the panel. This is useful when calculating the limits with relation="free" or relation="sliced" in scales.

The prepanel function is responsible for providing a meaningful return value when the x, y (etc.) variables are zero-length vectors. When nothing is appropriate, values of NA should be returned for the xlim and ylim components.

strip
logical flag or function. If FALSE, strips are not drawn. Otherwise, strips are drawn using the strip function, which defaults to strip.default. See documentation of strip.default to see the arguments that are available to the strip function. This description also applies to the strip.left argument (see ... below), which can be used to draw strips on the left of each panel, which can be useful for wide short panels, e.g. in time series plots.

xlab
character string or expression (or a "grob") giving label for the x-axis. Defaults to the expression for x in formula. Can be specified as NULL to omit the label altogether. Finer control is possible, see entries for main and xlab.

ylab
character string or expression (or "grob") giving label for the y-axis. Defaults to the expression for y in formula. Fine control is possible, see entries for main and xlab.

scales
list determining how the x- and y-axes (tick marks and labels) are drawn. The list contains parameters in name=value form, and may also contain two other lists called x and y of the same form (described below). Components of x and y affect the respective axes only, while those in scales affect both. When parameters are specified in both lists, the values in x or y are used. Note that certain high-level functions have defaults that are specific to a particular axis (e.g., bwplot has alternating=FALSE for the y-axis only); these can be overridden only by an entry in the corresponding component of scales.

The possible components are:

relation character string that determines how axis limits are calculated for each panel. Possible values are "same" (default), "free" and "sliced". For relation="same", the same limits, usually large enough to encompass all the data, are used for all the panels. For relation="free", limits for each panel is determined by just the points in that panel. Behavior for relation="sliced" is similar, except that the length (max - min) of the scales are constrained to remain the same across panels.

The determination of what axis limits are suitable for each panel can be controlled by the prepanel function, which can be overridden by xlim,
ylim or scales$limits. If relation is not "same", the value of xlim etc is normally ignored, except when it is a list, in which case it is treated as if its components were the limit values obtained from the prepanel calculations for each panel.

**tick.number** Suggested number of ticks (ignored for a factor, shingle or character vector, in which case there is no natural rule for leaving out some of the labels. But see xlim).

draw logical, defaults to TRUE, whether to draw the axis at all.

alternating logical specifying whether axis labels should alternate from one side of the group of panels to the other. For finer control, alternating can be a vector (replicated to be as long as the number of rows or columns per page) consisting of the following numbers

- 0: do not draw tick labels
- 1: bottom/left
- 2: top/right
- 3: both.

alternating applies only when relation="same". The default is TRUE, or equivalently, c(1, 2)

**limits** same as xlim and ylim.

at location of tick marks along the axis (in native coordinates), or a list as long as the number of panels describing tick locations for each panel.

labels Labels (strings or expressions) to go along with at. Can be a list like at as well.

cex numeric multiplier to control character sizes for axis labels. Can be a vector of length 2, to control left/bottom and right/top separately.

font, fontface, fontfamily specifies font for axis labels.

tck numeric to control length of tick marks. Can be a vector of length 2, to control left/bottom and right/top separately.

col color of ticks and labels.

rot Angle by which the axis labels are to be rotated. Can be a vector of length 2, to control left/bottom and right/top separately.

abbreviate logical, whether to abbreviate the labels using abbreviate. Can be useful for long labels (e.g., in factors), especially on the x-axis.

minlength argument passed to abbreviate if abbreviate=TRUE.

log whether to use a log scale. Defaults to FALSE, other possible values are any number that works as a base for taking logarithm, TRUE, equivalent to 10, and "e" (for natural logarithm). Note that in this case the values passed to the panel function are already transformed, so all computations done inside the panel function will be affected accordingly. For example, panel.lmline will fit a line to the transformed values.

format the format to use for POSIXct variables. See strftime for description of valid values.

axs character, "r" or "i". In the latter case, the axis limits are calculated as the exact data range, instead of being padded on either side. (May not always work as expected.)

Note that much of the function of scales is accomplished by pscales in splom.

subscripts logical specifying whether or not a vector named subscripts should be passed to the panel function. Defaults to FALSE, unless groups is specified,
or if the panel function accepts an argument named `subscripts`. (One should be careful when defining the panel function on-the-fly.)

- **subset**: logical or integer indexing vector (can be specified in terms of variables in `data`). Only these rows of `data` will be used for the plot. If `subscripts` is `TRUE`, the subscripts will provide indices to the rows of data before the subsetting is done. Whether levels of factors in the data frame that are unused after the subsetting will be dropped depends on the `drop.unused.levels` argument.

- **xlim**: Normally a numeric vector of length 2 (possibly a DateTime object) giving minimum and maximum for the x-axis, or, a character vector, expected to denote the levels of `x`. The latter form is interpreted as a range containing `c(1, length(xlim))`, with the character vector determining labels at tick positions `1:length(xlim)`.

  - `xlim` could also be a list, with as many components as the number of panels (recycled if necessary), with each component as described above. This is meaningful only when `scales$x$relation` is "free" or "sliced", in which case these are treated as if they were the corresponding limit components returned by prepanel calculations.

- **ylim**: similar to `xlim`, applied to the y-axis.

- **drop.unused.levels**: logical indicating whether the unused levels of factors will be dropped, usually relevant with a subsetting operation is performed or an interaction is created. Unused levels are usually dropped, but it is sometimes appropriate to suppress dropping to preserve a useful layout. For finer control, this argument could also be list containing components `cond` and `data`, both logical, indicating desired behavior for conditioning variables and data variables respectively. The default is given by `lattice.getOption("drop.unused.levels")`, which is initially set to `TRUE` for both components. Note that this argument does not control dropping of levels of the `groups` argument.

- **default.scales**: list giving the default values of `scales` for a particular high level function. This should not be of any interest to the normal user, but may be helpful when defining other functions that act as a wrapper to one of the high level lattice functions.

- **lattice.options**: a list that could be supplied to `lattice.options`. These options are temporarily in effect for the duration of the call, after which the settings revert back to whatever they were before. The settings are also retained along with the object and reused during plotting. This enables the user to attach options settings to the trellis object itself rather than change the settings globally. See also the `par.settings` argument described below for a similar treatment of graphical settings.

- **...**: further arguments, usually not directly processed by the high level functions documented here, but rather passed on to other functions. Such arguments can be broadly categorized into two types: those that affect all high level Trellis functions in a similar manner, and those that are meant for the specific panel function used, which may differ across high level functions.

  - The first group of arguments are processed by a common, unexported function called `trellis.skeleton`. These arguments affect all high level functions, but are only documented here, except to override the behaviour described here. All other arguments specified in a high level call, specifically those neither described here nor in the help page of the relevant high level function, are passed
unchanged to the panel function used. By convention, the default panel function used for any high level function is named as "panel." followed by the name of the high level function; for example, the default panel function for bwplot is panel.bwplot. In practical terms, this means that in addition to the help page of the high level function being used, the user should also consult the help page of the corresponding panel function for arguments that may be specified in the high level call.

The effect of the first group of common arguments are as follows:

**as.table:** logical that controls the order in which panels should be plotted: if FALSE (the default), panels are drawn left to right, bottom to top (as in a graph); if TRUE, left to right, top to bottom.

**between:** a list with components x and y (both usually 0 by default), numeric vectors specifying the space between the panels (units are character heights). x and y are repeated to account for all panels in a page and any extra components are ignored. The result is used for all pages in a multi page display. (In other words, it is not possible to use different between values for different pages).

**key:** A list of arguments that define a legend to be drawn on the plot. This list is used as an argument to the draw.key function, which produces a grid object eventually plotted by the print method for "trellis" objects.

There is also a less flexible but usually sufficient shortcut function simpleKey that can generate such a list, as well as the argument auto.key that can be convenient in the most common situation where legends are used, namely when there is a grouping variable. To use more than one legend, or to have arbitrary legends not constrained by the structure imposed by key, use the legend argument.

The position of the key can be controlled in either of two possible ways. If a component called space is present, the key is positioned outside the plot region, in one of the four sides, determined by the value of space, which can be one of "top", "bottom", "left" and "right". Alternatively, the key can be positioned inside the plot region by specifying components x, y and corner. x and y determine the location of the corner of the key given by corner, which can be one of c(0,0), c(1,0), c(1,1) and c(0,1), which denote the corners of the unit square. x and y must be numbers between 0 and 1, giving coordinates with respect to the whole display area.

The key essentially consists of a number of columns, possibly divided into blocks, each containing some rows. The contents of the key are determined by (possibly repeated) components named "rectangles", "lines", "points" or "text". Each of these must be lists with relevant graphical parameters (see later) controlling their appearance. The key list itself can contain graphical parameters, these would be used if relevant graphical components are omitted from the other components.

The length (number of rows) of each such column (except "text")s is taken to be the largest of the lengths of the graphical components, including the ones specified outside (see the entry for rep below for details on this). The "text" component has to have a character or expression vector as its first component, and the length of this vector determines the number of rows.

The graphical components that can be included in key (and also in the components named "text", "lines", "points" and "rectangles" as appropriate) are:
• `cex=1`
• `col="black"
• `alpha=1`
• `lty=1`
• `lwd=1`
• `font=1`
• `fontface`
• `fontfamily`
• `pch=8`
• `adj=0`
• `type=1"`
• `size=5`
• `angle=0`
• `density=-1`

`angle` and `density` are currently unimplemented. `size` determines the width of columns of rectangles and lines in character widths. `type` is relevant for lines; "l" denotes a line, "p" denotes a point, and "b" and "o" both denote both together.

Other possible components of `key` are:

`reverse.rows` logical, defaulting to `FALSE`. If `TRUE`, all components are reversed after being replicated (the details of which may depend on the value of `rep`). This is useful in certain situations, e.g. with a grouped `barchart` with `stack = FALSE` with the categorical variable on the vertical axis, where the bars in the plot will usually be ordered from bottom to top, but the corresponding legend will have the levels from top to bottom (unless, of course, `reverse.rows = TRUE`). Note that in this case, unless all columns have the same number or rows, they will no longer be aligned.

`between` numeric vector giving the amount of space (character widths) surrounding each column (split equally on both sides)

`title` string or expression giving a title for the key

`rep` logical, defaults to `TRUE`. By default, it’s assumed that all columns in the key (except the "text"s) will have the same number of rows, and all components are replicated to be as long as the longest. This can be suppressed by specifying `rep=FALSE`, in which case the length of each column will be determined by components of that column alone.

`cex.title` `cex` for the title

`lines.title` how many lines the title should occupy (in multiples of itself). Defaults to 2.

`padding.text` how much space (padding) should be used above and below each row containing text, in multiples of the default, which is currently `0.2 * "lines"`. This padding is in addition to the normal height of any row that contains text, which is the minimum amount necessary to contain all the text entries.

`background` background color, defaults to default background

`alpha.background` An alpha transparency value between 0 and 1

`border` either a color for the border, or a logical. In the latter case, the border color is black if `border` is `TRUE`, and no border is drawn if it is `FALSE` (the default)
transparent=FALSE  logical, whether key area should have a transparent background

columns  the number of columns column-blocks the key is to be divided into, which are drawn side by side.

between.columns  Space between column blocks, in addition to between.

divide  Number of point symbols to divide each line when type is "b" or "c" in lines.

legend:  the legend argument can be useful if one wants to place more than one key. It also allows one to use arbitrary "grob"s (grid objects) as legends.

If used, legend must be a list, with an arbitrary number of components. Each component must be named one of "left", "right", "top", "bottom" or "inside". The name "inside" can be repeated, but not the others. This name will be used to determine the location for that component, and is similar to the space component of key. If key (or colorkey for levelplot and wireframe) is specified, their space component must not conflict with the name of any component of legend. Each component of legend must have a component called fun. This can be a "grob", or a function or the name of a function that produces a "grob" when called. If this function expects any arguments, they must be supplied as a list in another component called args. For components named "inside", there can be additional components called x, y and corner, which work in the same way as it does for key.

page:  a function of one argument (page number) to be called after drawing each page. The function must be 'grid-compliant', and is called with the whole display area as the default viewport.

main:  typically a character string or expression or list describing the main title to be placed on top of each page. Defaults to NULL. Can be a character string or expression, or a list with components label, cex, col, alpha and font. The label tag can be omitted if it is the first element of the list. Expressions are treated as specification of LaTeX-like markup as in plotmath.

main can also be an arbitrary "grob" (grid graphical object).

sub:  character string or expression (or a "grob") for a subtitle to be placed at the bottom of each page. See entry for main for finer control options.

par.strip.text:  list of parameters to control the appearance of strip text.

Notable components are col, cex, font and lines. The first three control graphical parameters while the last is a means of altering the height of the strips. This can be useful, for example, if the strip labels (derived from factor levels, say) are double height (i.e., contain "\n"-s) or if the default height seems too small or too large. The lineheight component can control the space between multiple lines. Also, the labels can be abbreviated when shown by specifying abbreviate = TRUE, in which case the components minlength and dot (passed along to the abbreviate function) can be specified to control the details of how this is done.

layout:  In general, a Trellis conditioning plot consists of several panels arranged in a rectangular array, possibly spanning multiple pages. layout determines this arrangement.

layout is a numeric vector giving the number of columns, rows and pages in a multi panel display. By default, the number of columns is the number...
of levels of the first conditioning variable and the number of rows is the number of levels of the second conditioning variable. If there is only one conditioning variable, the default layout vector is \( c(0, n) \), where \( n \) is the number of levels of the given vector. Any time the first value in the layout vector is 0, the second value is used as the desired number of panels per page and the actual layout is computed from this, taking into account the aspect ratio of the panels and the device dimensions (via \( \text{par("din"}) \). The number of pages is by default set to as many as is required to plot all the panels. In general, giving a high value of layout[3] is not wasteful because blank pages are never created.

**skip:** logical vector (default \text{FALSE}), replicated to be as long as the number of panels (spanning all pages). For elements that are \text{TRUE}, the corresponding panel position is skipped; i.e., nothing is plotted in that position. The panel that was supposed to be drawn there is now drawn in the next available panel position, and the positions of all the subsequent panels are bumped up accordingly. This is often useful for arranging plots in an informative manner.

**strip.left:** \text{strip.left} can be used to draw strips on the left of each panel, which can be useful for wide short panels, as in time series (or similar) plots. It is a function similar to \text{strip}.

**xlab.default, ylab.default:** fallback default for \text{xlab} and \text{ylab} when they are not specified. If \text{NULL}, the defaults are parsed from the Trellis formula. This is rarely useful for the end-user, but can be helpful when developing new Trellis functions.

**xscale.components, yscale.components:** functions that determine axis annotation for the x and y axes respectively. See documentation for \text{xscale.components.default}, the default values of these arguments, to learn more.

**axis:** function that draws axis annotation. See documentation for \text{axis.default}, the default value of this argument, to learn more.

**perm.cond:** numeric vector, a permutation of \( 1:n \), where \( n \) is the number of conditioning variables. By default, the order in which panels are drawn depends on the order of the conditioning variables specified in the formula. \text{perm.cond} can modify this order. If the trellis display is thought of as an \( n \)-dimensional array, then during printing, its dimensions are permuted using \text{perm.cond} as the \text{perm} argument to \text{aperm}.

**index.cond:** While \text{perm.cond} permutes the dimensions of the multidimensional array of panels, \text{index.cond} can be used to subset (or reorder) margins of that array. \text{index.cond} can be a list or a function, with behavior in each case described below.

The panel display order within each conditioning variable depends on the order of their levels. \text{index.cond} can be used to choose a ‘subset’ (in the R sense) of these levels, which is then used as the display order for that variable. If \text{index.cond} is a list, it has to be as long as the number of conditioning variables, and the \( i \)-th component has to be a valid indexing vector for the integer vector \( 1:\text{nlevels}(q_i) \) (which can, among other things, repeat some of the levels or drop some altogether). The result of this indexing determines the order of panels within that conditioning variable.

To keep the order of a particular variable unchanged, the corresponding component must be set to \text{TRUE}.

Note that the components of \text{index.cond} are in the order of the conditioning variables in the original call, and is not affected by \text{perm.cond}.
Another possibility is to specify index.cond as a function. In this case, this function is called once for each panel, potentially with all arguments that are passed to the panel function for that panel. (More specifically, if this function has a ... argument, then all panel arguments are passed, otherwise, only named arguments that match are passed.) For a single conditioning variable, the levels of that variable are then sorted so that these values are in ascending order. For multiple conditioning variables, the order for each variable is determined by first taking the average over all other conditioning variables.

Although they can be supplied in high level function calls directly, it is more typical to use perm.cond and index.cond to update an existing "trellis" object, thus allowing it to be displayed in a different arrangement without re-calculating the data subsets that go into each panel. In the update method, both can be set to NULL, which reverts these back to their defaults.

par.settings: a list that could be supplied to trellis.par.set. This enables the user to attach some display settings to the trellis object itself rather than change the settings globally. When the object is plotted, these settings are temporarily in effect for the duration of the plot, after which the settings revert back to whatever they were before.

plot.args: a list of possible arguments to plot.trellis, which will be used by the plot or print methods when drawing the object, unless overridden explicitly. This enables the user to attach such arguments to the trellis object itself. Partial matching is not performed.

Details

All the functions documented here are generic, with the formula method usually doing the actual work. The structure of the plot that is produced is mostly controlled by the formula. For each unique combination of the levels of the conditioning variables g1, g2, ..., a separate panel is produced using the points (x,y) for the subset of the data (also called packet) defined by that combination. The display can be thought of as a 3-dimensional array of panels, consisting of one 2-dimensional matrix per page. The dimensions of this array are determined by the layout argument. If there are no conditioning variables, the plot produced consists of a single panel.

The coordinate system used by lattice by default is like a graph, with the origin at the bottom left, with axes increasing to left and up. In particular, panels are by default drawn starting from the bottom left corner, going right and then up; unless as.table = TRUE, in which case panels are drawn from the top left corner, going right and then down. One might wish to set a global preference for a table-like arrangement by changing the default to as.table=TRUE; this can be done by setting lattice.options(default.args = list(as.table = TRUE)). In fact, default values can be set in this manner for the following arguments: as.table, aspect, between, page, main, sub, par.strip.text, layout, skip and strip. Note that these global defaults are sometimes overridden by individual functions.

The order of the panels depends on the order in which the conditioning variables are specified, with g1 varying fastest. Within a conditioning variable, the order depends on the order of the levels (which for factors is usually in alphabetical order). Both of these orders can be modified using the index.cond and perm.cond arguments, possibly using the update (and other related) method(s).
Value

An object of class "trellis". The update method can be used to update components of the object and the print method (usually called by default) will plot it on an appropriate plotting device.

Note

Most of the arguments documented here are also applicable for the other high level functions in the lattice package. These are not described in any detail elsewhere unless relevant, and this should be considered the canonical documentation for such arguments.

Any arguments passed to these functions and not recognized by them will be passed to the panel function. Most predefined panel functions have arguments that customize its output. These arguments are described only in the help pages for these panel functions, but can usually be supplied as arguments to the high level plot.

Chapter 18

The mgcv package

Description

mgcv provides functions for generalized additive modelling and generalized additive mixed modelling. Particular features of the package are facilities for automatic smoothness selection, and the provision of a variety of smooths of more than one variable. User defined smooths are also supported. A Bayesian approach to confidence/credible interval calculation is provided. Lower level routines for generalized ridge regression and penalized linearly constrained least squares are also provided.

Details

mgcv provides generalized additive modelling functions gam, predict.gam and plot.gam, which are very similar in use to the S functions of the same name designed by Trevor Hastie. However the underlying representation and estimation of the models is based on a penalized regression spline approach, with automatic smoothness selection. A number of other functions such as summary.gam and anova.gam are also provided, for extracting information from a fitted gamObject.

Use of gam is much like use of glm, except that within a gam model formula, isotropic smooths of any number of predictors can be specified using s terms, while scale invariant smooths of any number of predictors can be specified using te terms. Estimation is by penalized likelihood or quasi-likelihood maximization, with smoothness selection by GCV or gAIC/UBRE. See gam, gam.models and gam.selection for some discussion of model specification and selection. For detailed control of fitting see gam.convergence, gam.method and gam.control. For checking and visualization see gam.check, choose.k, vis.gam and plot.gam. While a number of types of smoother are built into the package, it is also extendable with user defined smooths, see p.spline, for example.

A Bayesian approach to smooth modelling is used to derive standard errors on predictions, and hence credible intervals. The Bayesian covariance matrix for the model coefficients is returned in Vp of the gamObject. See predict.gam for examples of how this can be used to obtain credible regions for any quantity derived from the fitted model, either directly, or by direct simulation from the posterior distribution of the model coefficients. Frequentist approximations can be used for hypothesis testing: see anova.gam and summary.gam, but note that the underlying approximations are not always good in this case.
The package also provides a generalized additive mixed modelling function, \texttt{gamm}, based on \texttt{glmmPQL} from the \texttt{MASS} library and \texttt{lme} from the \texttt{nlme} library. \texttt{gamm} is particularly useful for modelling correlated data (i.e. where a simple independence model for the residual variation is inappropriate). In addition, low level routine \texttt{magic} can fit models to data with a known correlation structure.

Some of the underlying GAM fitting methods are available as low level fitting functions: see \texttt{magic} and \texttt{mgcv}. Penalized weighted least squares with linear equality and inequality constraints is provided by \texttt{pcls}.

For a complete list of functions type \texttt{library(help=mgcv)}.

\texttt{## see examples for gam and gamm}

\texttt{anova.gam} \hspace{1cm} Hypothesis tests related to GAM fits

Description

Performs hypothesis tests relating to one or more fitted \texttt{gam} objects. For a single fitted \texttt{gam} object, Wald tests of the significance of each parametric and smooth term are performed. Otherwise the fitted models are compared using an analysis of deviance table. The tests are usually approximate, unless the models are un-penalized.

Usage

\texttt{## S3 method for class 'gam':}
\texttt{anova(object, \ldots, dispersion = NULL, test = NULL)}
\texttt{## S3 method for class 'anova.gam':}
\texttt{print(x, digits = max(3, getOption("digits") - 3), \ldots)}

Arguments

- \texttt{object,\ldots} fitted model objects of class \texttt{gam} as produced by \texttt{gam()}.
- \texttt{x} an \texttt{anova.gam} object produced by a single model call to \texttt{anova.gam()}.
- \texttt{dispersion} a value for the dispersion parameter: not normally used.
- \texttt{test} what sort of test to perform for a multi-model call. One of "Chisq", "F" or "Cp".
- \texttt{digits} number of digits to use when printing output.
Details

If more than one fitted model is provided than \texttt{anova.glm} is used. If only one model is provided then the significance of each model term is assessed using Wald tests: see \texttt{summary.gam} for details of the actual computations. In the latter case \texttt{print.anova.gam} is used as the printing method.

P-values are usually reliable if the smoothing parameters are known, or the model is unpenalized. If smoothing parameters have been estimated then the p-values are typically somewhat too low under the null. This occurs because the uncertainty associated with the smoothing parameters is neglected in the calculations of the distributions under the null, which tends to lead to underdispersion in these distributions, and in turn to p-value estimates that are too low. (In simulations where the null is correct, I have seen p-values that are as low as half of what they should be.) Note however that tests can have low power if the estimated rank of the test statistic is much higher than the EDF, so that p-values can also be too low in some cases.

If it is important to have p-values that are as accurate as possible, then, at least in the single model case, it is probably advisable to perform tests using unpenalized smooths (i.e. \texttt{s(...,fx=TRUE)}) with the basis dimension, \(k\), left at what would have been used with penalization. Such tests are not as powerful, of course, but the p-values are more accurate under the null. Whether or not extra accuracy is required will usually depend on whether or not hypothesis testing is a key objective of the analysis.

Value

In the multi-model case \texttt{anova.gam} produces output identical to \texttt{anova.glm}, which it in fact uses.

In the single model case an object of class \texttt{anova.gam} is produced, which is in fact an object returned from \texttt{summary.gam}.

\texttt{print.anova.gam} simply produces tabulated output.

WARNING

P-values are only approximate, particularly as a result of ignoring smoothing parameter uncertainty.

x3 <- runif(n, 0, 1)
y <- 2 * x0 + exp(2 * x1)
y <- y + 0.2 * x2^11 * (10 * (1 - x2))^6 + 10 * (10 * x2)^3 * (1 - x2)^10
```
choose.k

Basis dimension choice for smooths

Description

Choosing the basis dimension, and checking the choice, when using penalized regression smooths.

Penalized regression smoothers gain computational efficiency by virtue of being defined using a basis of relatively modest size, \( k \). When setting up models in the mgcv package, using \( s \) or \( te \) terms in a model formula, \( k \) must be chosen.

In practice \( k-1 \) sets the upper limit on the degrees of freedom associated with an \( s \) smooth (1 degree of freedom is lost to the identifiability constraint on the smooth). For \( te \) smooths the upper limit of the degrees of freedom is given by the product of the \( k \) values provided for each marginal smooth less one, for the constraint. However the actual effective degrees of freedom are controlled by the degree of penalization selected during fitting, by GCV, AIC or whatever is specified. The exception to this is if a smooth is specified using the \( fx=FALSE \) option, in which case it is unpenalized.

So, exact choice of \( k \) is not generally critical: it should be chosen to be large enough that you are reasonably sure of having enough degrees of freedom to represent the underlying ‘truth’ reasonably well, but small enough to maintain reasonable computational efficiency. Clearly ‘large’ and ‘small’ are dependent on the particular problem being addressed.

As with all model assumptions, it is useful to be able to check the choice of \( k \) informally. If the effective degrees of freedom for a model term are estimated to be much less than \( k-1 \) then this is unlikely to be very worthwhile, but as the EDF approach \( k-1 \), checking can be important. A useful general purpose approach goes as follows: (i) fit your model and extract the deviance residuals; (ii) for each smooth term in your model, fit an equivalent, single, smooth to the residuals, using a substantially increased \( k \) to see if there is pattern in the residuals that could potentially be explained by increasing \( k \). Examples are provided below.

More sophisticated approaches based on partial residuals are also possible.

One scenario that can cause confusion is this: a model is fitted with \( k=10 \) for a smooth term, and the EDF for the term is estimated as 7.6, some way below the maximum of 9. The model is then refitted with \( k=20 \) and the EDF increases to 8.7 - what is happening - how come the EDF was not 8.7 the first time around? The explanation is that the function space with \( k=20 \) contains a larger subspace of functions with EDF 8.7 than did the function space with \( k=10 \): one of the functions in this larger subspace fits the data a little better than did any function in the smaller subspace. These subtleties seldom have much impact on the statistical conclusions to be drawn from a model fit, however.

rsd <- residuals(bp)
gam(rsd~s(x0,k=40,bs="cs"), gamma=1.4) ## fine
## original `k' too low
```
exclude.too.far  

Exclude prediction grid points too far from data

Description
Takes two arrays defining the nodes of a grid over a 2D covariate space and two arrays defining the location of data in that space, and returns a logical vector with elements TRUE if the corresponding node is too far from data and FALSE otherwise. Basically a service routine for vis.gam and plot.gam.

Usage
exclude.too.far(g1,g2,d1,d2,dist)

Arguments
- g1  co-ordinates of grid relative to first axis.
- g2  co-ordinates of grid relative to second axis.
- d1  co-ordinates of data relative to first axis.
- d2  co-ordinates of data relative to second axis.
- dist how far away counts as too far. Grid and data are first scaled so that the grid lies exactly in the unit square, and dist is a distance within this unit square.

Details
Linear scalings of the axes are first determined so that the grid defined by the nodes in g1 and g2 lies exactly in the unit square (i.e. on [0,1] by [0,1]). These scalings are applied to g1, g2, d1 and d2. The minimum Euclidean distance from each node to a datum is then determined and if it is greater than dist the corresponding entry in the returned array is set to TRUE (otherwise to FALSE). The distance calculations are performed in compiled code for speed without storage overheads.

Value
A logical array with TRUE indicating a node in the grid defined by g1, g2 that is 'too far' from any datum.

--

`extract.lme.cov`  
`Extract the data covariance matrix from an lme object`

Description

This is a service routine for `gamm`. Extracts the estimated covariance matrix of the data from an `lme` object, allowing the user control about which levels of random effects to include in this calculation.  
`extract.lme.cov` forms the full matrix explicitly: `extract.lme.cov2` tries to be more economical than this.

Usage

```r
extract.lme.cov(b,data,start.level=1)
extract.lme.cov2(b,data,start.level=1)
```

Arguments

- **b**  
  A fitted model object returned by a call to `lme`

- **data**  
  The data frame/ model frame that was supplied to `lme`.

- **start.level**  
  The level of nesting at which to start including random effects in the calculation. This is used to allow smooth terms to be estimated as random effects, but treated like fixed effects for variance calculations.

Details

The random effects, correlation structure and variance structure used for a linear mixed model combine to imply a covariance matrix for the response data being modelled. These routines extracts that covariance matrix. The process is slightly complicated, because different components of the fitted model object are stored in different orders (see function code for details!). The `extract.lme.cov` calculation is not optimally efficient, since it forms the full matrix, which may in fact be sparse. `extract.lme.cov2` is more efficient. If the covariance matrix is diagonal, then only the leading diagonal is returned; if it can be written as a block diagonal matrix (under some permutation of the original data) then a list of matrices defining the non-zero blocks is returned along with an index indicating which row of the original data each row/column of the block diagonal matrix relates to. The block sizes are defined by the coarsest level of grouping in the random effect structure.  
`gamm` uses `extract.lme.cov2`.  
`extract.lme.cov` does not currently deal with the situation in which the grouping factors for a correlation structure are finer than those for the random effects. `extract.lme.cov2` does deal with this situation.
Value

For `extract.lme.cov` an estimated covariance matrix.
For `extract.lme.cov2` a list containing the estimated covariance matrix and an indexing array.
The covariance matrix is stored as the elements on the leading diagonal, a list of the matrices defining a block diagonal matrix, or a full matrix if the previous two options are not possible.

`gamm`, `formXtViX`

Examples

```r
library(nlme)
data(Rail)
b <- lme(travel~1,Rail,~1|Rail)
e <- lme(travel~1,Rail,~1|Rail)
e %>% extract.lme.cov()
e %>% extract.lme.cov2()
```

Description

Generalized Additive Model fitting by ‘outer’ iteration, requires extra derivatives of the variance and link functions to be added to family objects. The functions add what is needed.

Usage

```r
fix.family.link(fam)
fix.family.var(fam)
```

Arguments

fam  
A family.
Details

Outer iteration GAM estimation requires derivatives of the GCV/UBRE score, which are obtained by differentiating the P-IRLS GAM fitting iteration w.r.t. the model smoothing parameters. The expressions for the derivatives require the second derivative of the link w.r.t. the mean, and the first derivative of the variance function w.r.t. the mean. These functions add functions evaluating these quantities to a family.

If the family already has functions dvar and d2link then these functions simply return the family unmodified: this allows non-standard links to be used with gam when using outer iteration (performance iteration operates with unmodified families).

The dvar function is a function of a mean vector, mu, and returns a vector of corresponding first derivatives of the family variance function. The d2link function is also a function of a vector of mean values, mu: it returns a vector of second derivatives of the link, evaluated at mu.

If modifying your own family, note that you can often get away with supplying only a dvar function if your family only requires links that occur in one of the standard families.

Value

A family object with extra component functions dvar and d2link.

Author(s)

Simon N. Wood ⟨simon.wood@r-project.org⟩

fixDependence

Detect linear dependencies of one matrix on another

Description

Identifies columns of a matrix X2 which are linearly dependent on columns of a matrix X1. Primarily of use in setting up identifiability constraints for nested GAMs.

Usage

fixDependence(X1,X2,tol=.Machine$double.eps^.5)

Arguments

X1 A matrix.
X2 A matrix, the columns of which may be partially linearly dependent on the columns of X1.
tol The tolerance to use when assessing linear dependence.

Details

The algorithm uses a simple approach based on QR decomposition: see code for details.

Value

An array of the columns of X2 which are linearly dependent on columns of X1. NULL if the two matrices are independent.
Author(s)
Simon N. Wood ⟨simon.wood@r-project.org⟩

Examples

```r
n<-20;c1<-4;c2<-7
X1<-matrix(runif(n*c1),n,c1)
X2<-matrix(runif(n*c2),n,c2)
X2[,3]<-X1[,2]+X2[,4]*.1
X2[,5]<-X1[,1]*.2+X1[,2]*.04
fixDependence(X1,X2)
```

Description
Extracts the formula from a fitted gam object.

Usage
```
## S3 method for class 'gam':
formula(x,...)
```

Arguments
- `x` fitted model objects of class `gam` (see `gamObject`) as produced by `gam()`.
- `...` un-used in this case

Details
Returns `x$formula`. Provided so that `anova` methods print an appropriate description of the model.

Value
A model formula.

gam
**formXtViX**  
*Form component of GAMM covariance matrix*

**Description**
This is a service routine for \texttt{gamm}. Given, $V$, an estimated covariance matrix obtained using \texttt{extract.lme.cov2} this routine forms $X^TV^{-1}X$ as efficiently as possible, given the structure of $V$ (usually sparse).

**Usage**

\begin{verbatim}
formXtViX(V,X)
\end{verbatim}

**Arguments**

- $V$ A data covariance matrix list returned from \texttt{extract.lme.cov2}
- $X$ A model matrix.

**Details**

The covariance matrix returned by \texttt{extract.lme.cov2} may be in a packed and re-ordered format, since it is usually sparse. Hence a special service routine is required to form the required products involving this matrix.

**Value**
A matrix.

**Author(s)**
Simon N. Wood (simon.wood@r-project.org)

**References**
For \texttt{lme} see:

For details of how GAMMs are set up here for estimation using \texttt{lme} see:
\url{http://www.maths.bath.ac.uk/~sw283/}

**See Also**

- \texttt{gamm, extract.lme.cov2}
full.score  

**GCV/UBRE score for use within nlm**

**Description**

Evaluates GCV/UBRE score for a GAM, given smoothing parameters. The routine calls `gam.fit` to fit the model, and is usually called by `nlm` to optimize the smoothing parameters. This is basically a service routine for `gam`, and is not usually called directly by users. It is only used in this context for GAMs fitted by outer iteration (see `gam.outer`) when the outer method is "nlm.fd" (see `gam.method`).

**Usage**

```r
full.score(sp,G,family,control,gamma,pearson,...)
```

**Arguments**

- **sp**  
The logs of the smoothing parameters
- **G**  
a list returned by `gam.setup`
- **family**  
The family object for the GAM.
- **control**  
a list returned by `gam.control`
- **gamma**  
the degrees of freedom inflation factor (usually 1).
- **pearson**  
whether the GCV/UBRE score should be based on the Pearson statistic or the deviance. The deviance is usually preferable.
- **...**  
other arguments, typically for passing on to `gam.fit`.

**Value**

The value of the GCV/UBRE score, with attribute "full.gam.object" which is the full object returned by `gam.fit`.

**Author(s)**

Simon N. Wood (simon.wood@r-project.org)

---

**gam**  

*Generalized additive models with integrated smoothness estimation*

**Description**

Fits a generalized additive model (GAM) to data. The degree of smoothness of model terms is estimated as part of fitting; isotropic or scale invariant smooths of any number of variables are available as model terms; confidence/credible intervals are readily available for any quantity predicted using a fitted model; `gam` is extendable: i.e. users can add smooths. Smooth terms are represented using penalized regression splines (or similar smoothers) with smoothing parameters selected by GCV/UBRE or by regression splines with fixed degrees of freedom (mixtures of the two are permitted). Multi-dimensional smooths are available using penalized
thin plate regression splines (isotropic) or tensor product splines (when an isotropic smooth is inappropriate). For more on specifying models see `gam.models`. For more on model selection see `gam.selection`. For faster fits use the "cr" bases for smooth terms, `te` smooths for smooths of several variables, and performance iteration for smoothing parameter estimation (see `gam.method`). For large datasets see warnings.

`gam()` is not a clone of what S-PLUS provides: the major differences are (i) that by default estimation of the degree of smoothness of model terms is part of model fitting, (ii) a Bayesian approach to variance estimation is employed that makes for easier confidence interval calculation (with good coverage probabilities) and (iii) the facilities for incorporating smooths of more than one variable are different: specifically there are no lo smooths, but instead (a) s terms can have more than one argument, implying an isotropic smooth and (b) te smooths are provided as an effective means for modelling smooth interactions of any number of variables via scale invariant tensor product smooths. If you want a clone of what S-PLUS provides use `gam` from package `gam`.

Usage

```r
gam(formula,family=gaussian(),data=list(),weights=NULL,subset=NULL, na.action,offset=NULL,control=gam.control(),method=gam.method(), scale=0,knots=NULL,sp=NULL,min.sp=NULL,H=NULL,gamma=1, fit=TRUE,G=NULL,in.out,...)
```

Arguments

- **formula**: A GAM formula (see also `gam.models`). This is exactly like the formula for a GLM except that smooth terms can be added to the right hand side of the formula (and a formula of the form `y ~ .` is not allowed). Smooth terms are specified by expressions of the form:

  ```r
  s(var1,var2,...,k=12,fx=FALSE,bs="tp",by=a.var) where
  var1, var2, etc. are the covariates which the smooth is a function of and
  k is the dimension of the basis used to represent the smooth term. If k is not
  specified then \( k = 10 \times 3^{(d-1)} \) is used where \( d \) is the number of covariates
  for this term. \( f(x) \) is used to indicate whether or not this term has a fixed number
  of degrees of freedom (\( f(x) = FALSE \) to select d.f. by GCV/UBRE). bs indicates
  the basis to use for the smooth: for a full list see `s`, but note that the default
  "tp", while it possesses nice optimality properties is slow and memory hungry
  for very large datasets (but see examples for how to get around this). by can
  be used to specify a variable by which the smooth should be multiplied. For example
  `gam(y~z+s(x,by=z))` would specify a model \( E(y) = f(x)z \) where \( f(x) \) is a smooth function (the formula is `y~x+s(x,by=z)` rather than
  \( y-s(x,by=z) \) because the smooths are always set up to sum to zero over
  the covariate values). The by option is particularly useful for models in which
  different functions of the same variable are required for each level of a factor
  and for ‘variable parameter models’: see `s`.

  An alternative for specifying smooths of more than one covariate is e.g.
  `te(x,z,bs=c("tp","tp"),k=c(5,10))` which would specify a tensor product smooth of the two covariates \( x \) and \( z \) constructed from
  marginal t.p.r.s. bases of dimension 5 and 10 with marginal penalties of order 2
  and 3. Any combination of basis types is possible, as is any number of covariates.

  Formulae can involve nested or "overlapping" terms such as
  \( y-s(x)+s(z)+s(x,z) \) or \( y-s(x,z)+s(z,v) \): see `gam.side` for further details and examples.
```
family
This is a family object specifying the distribution and link to use in fitting etc.
See `glm` and `family` for more details. The negative binomial families provided
by the MASS library can be used, with or without known $\theta$ parameter: see
`gam.neg.bin` for details.

data
A data frame containing the model response variable and covariates re-
quired by the formula. By default the variables are taken from
`environment(formula)`: typically the environment from which `gam` is
called.

weights
prior weights on the data.

subset
an optional vector specifying a subset of observations to be used in the fitting
process.

na.action
a function which indicates what should happen when the data contain ‘NA’s.
The default is set by the ‘na.action’ setting of ‘options’, and is ‘na.fail’ if that is
unset. The “factory-fresh” default is ‘na.omit’.

offset
Can be used to supply a model offset for use in fitting. Note that this offset
will always be completely ignored when predicting, unlike an offset included in
formula: this conforms to the behaviour of `lm` and `glm`.

control
A list of fit control parameters returned by `gam.control`.

method
A list controlling the fitting methods used. This can make a big difference
to computational speed, and, in some cases, reliability of convergence: see
`gam.method` for details.

scale
If this is zero then GCV is used for all distributions except Poisson and binomial
where UBRE is used with scale parameter assumed to be 1. If this is greater
than 1 it is assumed to be the scale parameter/variance and UBRE is used: to
use the negative binomial in this case $\theta$ must be known. If scale is negative
GCV is always used, which means that the scale parameter will be estimated by
GCV and the Pearson estimator, or in the case of the negative binomial $\theta$ will
be estimated in order to force the GCV/Pearson scale estimate to unity (if this
is possible). For binomial models in particular, it is probably worth comparing
UBRE and GCV results; for “over-dispersed Poisson” GCV is probably more
appropriate than UBRE.

knots
this is an optional list containing user specified knot values to be used for basis
construction. For the `cr` and `cc` bases the user simply supplies the knots to
be used, and there must be the same number as the basis dimension, $k$, for the
smooth concerned. For the `tp` basis knots has two uses. Firstly, for large
datasets the calculation of the `tp` basis can be time-consuming. The user can
retain most of the advantages of the t.p.r.s. approach by supplying a reduced
set of covariate values from which to obtain the basis - typically the number
of covariate values used will be substantially smaller than the number of data,
and substantially larger than the basis dimension, $k$. The second possibility is
to avoid the eigen-decomposition used to find the t.p.r.s. basis altogether and
simply use the basis implied by the chosen knots: this will happen if the number
of knots supplied matches the basis dimension, $k$. For a given basis dimension
the second option is faster, but gives poorer results (and the user must be quite
careful in choosing knot locations). Different terms can use different numbers
of knots, unless they share a covariate.

sp
A vector of smoothing parameters for each term can be provided here. Smooth-
ing parameters must be supplied in the order that the smooth terms appear in
the model formula. With fit method "magic" (see `gam.control` and `magic`)
then negative elements indicate that the parameter should be estimated, and
hence a mixture of fixed and estimated parameters is possible. With fit method "mgcv", if sp is supplied then all its elements must be positive. Note that fx=TRUE in a smooth term over-rides what is supplied here effectively setting the smoothing parameter to zero.

**min.sp** for fit method "magic" only, lower bounds can be supplied for the smoothing parameters. Note that if this option is used then the smoothing parameters sp, in the returned object, will need to be added to what is supplied here to get the actual smoothing parameters. Lower bounds on the smoothing parameters can sometimes help stabilize otherwise divergent P-IRLS iterations.

**gamma** It is sometimes useful to inflate the model degrees of freedom in the GCV or UBRE score by a constant multiplier. This allows such a multiplier to be supplied if fit method is "magic".

**fit** If this argument is TRUE then gam sets up the model and fits it, but if it is FALSE then the model is set up and an object G is returned which is the output from gam.setup plus some extra items required to complete the GAM fitting process.

**G** Usually NULL, but may contain the object returned by a previous call to gam with fit=FALSE, in which case all other arguments are ignored except for gamma, in.out, control, method and fit.

**in.out** optional list for initializing outer iteration. If supplied then this must contain two elements: sp should be an array of initialization values for all smoothing parameters (there must be a value for all smoothing parameters, whether fixed or to be estimated, but those for fixed s.p.s are not used); scale is the typical scale of the GCV/UBRE function, for passing to the outer optimizer.

... further arguments for passing on e.g. to gam.fit (such as mustart).

**Details**

A generalized additive model (GAM) is a generalized linear model (GLM) in which the linear predictor is given by a user specified sum of smooth functions of the covariates plus a conventional parametric component of the linear predictor. A simple example is:

\[
\log(E(y_i)) = f_1(x_{1i}) + f_2(x_{2i})
\]

where the (independent) response variables \(y_i \sim \text{Poi}\), and \(f_1\) and \(f_2\) are smooth functions of covariates \(x_1\) and \(x_2\). The log is an example of a link function.

If absolutely any smooth functions were allowed in model fitting then maximum likelihood estimation of such models would invariably result in complex overfitting estimates of \(f_1\) and \(f_2\). For this reason the models are usually fit by penalized likelihood maximization, in which the model (negative log) likelihood is modified by the addition of a penalty for each smooth function, penalizing its 'wiggliness'. To control the tradeoff between penalizing wigginess and penalizing badness of fit each penalty is multiplied by an associated smoothing parameter: how to estimate these parameters, and how to practically represent the smooth functions are the main statistical questions introduced by moving from GLMs to GAMs.
The mgcv implementation of gam represents the smooth functions using penalized regression splines, and by default uses basis functions for these splines that are designed to be optimal, given the number basis functions used. The smooth terms can be functions of any number of covariates and the user has some control over how smoothness of the functions is measured.

Gam in mgcv solves the smoothing parameter estimation problem by using the Generalized Cross Validation (GCV) criterion

$$nD/(n - DoF)^2$$

or an Un-Biased Risk Estimator (UBRE) criterion

$$D/n + 2sDoF/n - s$$

where $D$ is the deviance, $n$ the number of data, $s$ the scale parameter and $DoF$ the effective degrees of freedom of the model. Notice that UBRE is effectively just AIC rescaled, but is only used when $s$ is known. It is also possible to replace $D$ by the Pearson statistic (see gam.method), but this can lead to over smoothing. Smoothing parameters are chosen to minimize the GCV or UBRE score for the model, and the main computational challenge solved by the mgcv package is to do this efficiently and reliably. Various alternative numerical methods are provided: see gam.method.

Broadly gam works by first constructing basis functions and one or more quadratic penalty coefficient matrices for each smooth term in the model formula, obtaining a model matrix for the strictly parametric part of the model formula, and combining these to obtain a complete model matrix (design matrix) and a set of penalty matrices for the smooth terms. Some linear identifiability constraints are also obtained at this point. The model is fit using gam.fit, a modification of glm.fit. The GAM penalized likelihood maximization problem is solved by penalized Iteratively Reweighted Least Squares (IRLS) (see e.g. Wood 2000). At each iteration a penalized weighted least squares problem is solved, and the smoothing parameters of that problem are estimated by GCV or UBRE. Eventually both model parameter estimates and smoothing parameter estimates converge. Alternatively the P-IRLS scheme is iterated to convergence for each trial set of smoothing parameters, and GCV or UBRE scores are only evaluated on convergence - optimization is then ‘outer’ to the P-IRLS loop: in this case extra derivatives have to be carried along with the P-IRLS iteration, to facilitate optimization, and gam.fit2 is used.

Five alternative basis-penalty types are built in for representing model smooths, but alternatives can easily be added (see smooth.construct which uses p-splines to illustrate how to add new smooths). The built in alternatives for univariate smooths terms are: a conventional penalized cubic regression spline basis, parameterized in terms of the function values at the knots; a cyclic cubic spline with a similar parameterization and thin plate regression splines. The cubic spline bases are computationally very efficient, but require ‘knot’ locations to be chosen (automatically by default). The thin plate regression splines are optimal low rank smooths which do not have knots, but are more computationally costly to set up. Smooths of several variables can be represented using thin plate regression splines, or tensor products of any available basis including user defined bases (tensor product penalties are obtained automatically form the marginal basis penalties). The t.p.r.s. basis is isotropic, so if this is not appropriate tensor product terms should be used. Tensor product smooths have one penalty and smoothing parameter per marginal basis, which means that the relative scaling of covariates is essentially determined automatically by GCV/UBRE. The t.p.r.s. basis and cubic regression spline bases are both available with either conventional ‘wigginess penalties’ or penalties augmented with a shrinkage component: the conventional penalties treat some space of functions as ‘completely smooth’ and do not penalize such functions at all; the penalties with extra shrinkage will zero a term altogether for high enough smoothing parameters: gam.selection has an example of the use of such terms.

For any basis the user specifies the dimension of the basis for each smooth term. The dimension of the basis is one more than the maximum degrees of freedom that the term can have, but usually the term will be fitted by penalized maximum likelihood estimation and the actual degrees of freedom
will be chosen by GCV. However, the user can choose to fix the degrees of freedom of a term, in which case the actual degrees of freedom will be one less than the basis dimension.

Thin plate regression splines are constructed by starting with the basis for a full thin plate spline and then truncating this basis in an optimal manner, to obtain a low rank smoother. Details are given in Wood (2003). One key advantage of the approach is that it avoids the knot placement problems of conventional regression spline modelling, but it also has the advantage that smooths of lower rank are nested within smooths of higher rank, so that it is legitimate to use conventional hypothesis testing methods to compare models based on pure regression splines. The t.p.r.s. basis can become expensive to calculate for large datasets. In this case the user can supply a reduced set of knots to use in basis construction (see knots, in the argument list), or use tensor products of cheaper bases.

In the case of the cubic regression spline basis, knots of the spline are placed evenly throughout the covariate values to which the term refers: For example, if fitting 101 data with an 11 knot spline of \( x \) then there would be a knot at every 10th (ordered) \( x \) value. The parameterization used represents the spline in terms of its values at the knots. The values at neighbouring knots are connected by sections of cubic polynomial constrained to be continuous up to and including second derivative at the knots. The resulting curve is a natural cubic spline through the values at the knots (given two extra conditions specifying that the second derivative of the curve should be zero at the two end knots). This parameterization gives the parameters a nice interpretability.

Details of the underlying fitting methods are given in Wood (2000, 2004a, 2006b).

Value

- If `fit == FALSE` the function returns a list \( G \) of items needed to fit a GAM, but doesn’t actually fit it.
- Otherwise the function returns an object of class "gam" as described in `gamObject`.

WARNINGS

- If fit method "mgcv" is selected, the code does not check for rank deficiency of the model matrix that may result from lack of identifiability between the parametric and smooth components of the model.
- You must have more unique combinations of covariates than the model has total parameters. (Total parameters is sum of basis dimensions plus sum of non-spline terms less the number of spline terms).
- Automatic smoothing parameter selection is not likely to work well when fitting models to very few response data.
- With large datasets (more than a few thousand data) the "tp" basis gets very slow to use: use the knots argument as discussed above and shown in the examples. Alternatively, for 1-d smooths you can use the "cr" basis and for multi-dimensional smooths use te smooths.
- For data with many zeroes clustered together in the covariate space it is quite easy to set up GAMs which suffer from identifiability problems, particularly when using Poisson or binomial families. The problem is that with e.g. log or logit links, mean value zero corresponds to an infinite range on the linear predictor scale. Some regularization is possible in such cases: see `gam.control` for details.

gam.check

Some diagnostics for a fitted gam model

Description

Takes a fitted gam object produced by gam() and produces some diagnostic information about the fitting procedure and results.

Usage

gam.check(b)

Arguments

b a fitted gam object as produced by gam().

Details

This function plots 4 standard diagnostic plots, and some other convergence diagnostics. Output differs depending on whether the underlying fitting method was mgcv or another method (see gam.method).
For \textit{mgcv} based fits, the first plot shows the GCV or UBRE score against model degrees of freedom, given the final estimates of the relative smoothing parameters for the model. This is a slice through the GCV/UBRE score function that passes through the minimum found during fitting. Although not conclusive (except in the single smoothing parameter case), a lack of multiple local minima on this plot is suggestive of a lack of multiple local minima in the GCV/UBRE function and is therefore a good thing. Multiple local minima on this plot indicates that the GCV/UBRE function may have multiple local minima, but in a multiple smoothing parameter case this is not conclusive - multiple local minima on one slice through a function do not necessarily imply that the function has multiple local minima. A ‘good’ plot here is a smooth curve with only one local minimum (which is therefore its global minimum).

The location of the minimum used for the fitted model is also marked on the first plot. Sometimes this location may be a local minimum that is not the global minimum on the plot. There is a legitimate reason for this to happen, and it does not always indicate problems. Smoothing parameter selection is based on applying GCV/UBRE to the approximating linear model produced by the GLM IRLS fitting method employed in \textit{gam.fit()}. It is sometimes possible for these approximating models to develop ‘phantom’ minima in their GCV/UBRE scores. These minima usually imply a big change in model parameters, and have the characteristic that the minima will not be present in the GCV/UBRE score of the approximating model that would result from actually applying this parameter change. In other words, these are spurious minima in regions of parameter space well beyond those for which the weighted least squares problem can be expected to represent the real underlying likelihood well. Such minima can lead to convergence problems. To help ensure convergence even in the presence of phantom minima, \textit{gam.fit} switches to a cautious optimization mode after a user controlled number of iterations of the IRLS algorithm (see \textit{gam.control}). In the presence of local minima in the GCV/UBRE score, this method selects the minimum that leads to the smallest change in model estimated degrees of freedom. This approach is usually sufficient to deal with phantom minima. Setting \texttt{trace} to \texttt{TRUE} in \textit{gam.control} will allow you to check exactly what is happening.

If the location of the point indicating the minimum is not on the curve showing the GCV/UBRE function then there are numerical problems with the estimation of the effective degrees of freedom: this usually reflects problems with the relative scaling of covariates that are arguments of a single smooth. In this circumstance reported estimated degrees of freedom can not be trusted, although the fitted model and term estimates are likely to be quite acceptable.

If the fit method is based on \textit{magic} or \textit{gam.fit2} then there is no global search and the problems with phantom local minima are much reduced. The first plot in this case will simply be a normal QQ plot of the standardized residuals.

The other 3 plots are two residual plots and plot of fitted values against original data.

The function also prints out information about the convergence of the GCV minimization algorithm, indicating how many iterations were required to minimise the GCV/UBRE score. A message is printed if the minimization terminated by failing to improve the score with a steepest descent step: otherwise minimization terminated by meeting convergence criteria. The mean absolute gradient or RMS gradient of the GCV/UBRE function at the minimum is given. An indication of whether or not the Hessian of the GCV/UBRE function is positive definite is given. If some smoothing parameters are not well defined (effectively zero, or infinite) then it may not be, although this is not usually a problem. If the fit method is \textit{mgcv}, a message is printed if the second guess smoothing parameters did not improve on the first guess - this is primarily there for the developer. For other fit methods the estimated rank of the model is printed.

The ideal results from this function have a smooth, single minima GCV/UBRE plot (where appropriate), good residual plots, and convergence to small gradients with a positive definite Hessian. However, failure to meet some of these criteria is often acceptable, and the information provided is primarily of use in diagnosing suspected problems. High gradients at convergence are a clear indication of problems, however.
Fuller data can be extracted from mgcv.conv part of the gam object.

b<-gam(y~s(x0)+s(x1)+s(x2)+s(x3))
plot(b,pages=1)
gam.check(b)

Description
This is an internal function of package mgcv which allows control of the numerical options for fitting a GAM. Typically users will want to modify the defaults if model fitting fails to converge, or if the warnings are generated which suggest a loss of numerical stability during fitting. To change the default choice of fitting method, see gam.method.

Usage
gam.control(irls.reg=0.0,epsilon = 1e-06,maxit = 100,globalit = 20,
mgcvtol=1e-7,mgcv.half=15,nb.theta.mult=10000,trace = FALSE,
rank.tol=.Machine$double.eps^0.5,absorb.cons=TRUE,
max.tprs.knots=5000,nlm=list(),optim=list(),newton=list(),
outerPIsteps=1)
Arguments

**irls.reg**
For most models this should be 0. The iteratively re-weighted least squares method by which GAMs are fitted can fail to converge in some circumstances. For example, data with many zeroes can cause problems in a model with a log link, because a mean of zero corresponds to an infinite range of linear predictor values. Such convergence problems are caused by a fundamental lack of identifiability, but do not show up as lack of identifiability in the penalized linear model problems that have to be solved at each stage of iteration. In such circumstances it is possible to apply a ridge regression penalty to the model to impose identifiability, and *irls.reg* is the size of the penalty. The penalty can not be used if the underlying fitting method is *mgcv* (not the default - see *gam.method* for details).

**epsilon**
This is used for judging conversion of the GLM IRLS loop in *gam.fit* or *gam.fit2*.

**maxit**
Maximum number of IRLS iterations to perform using cautious GCV/UBRE optimization, after *globit* IRLS iterations with normal GCV optimization have been performed. Note that only fitting based on *mgcv* (not default) makes any distinction between cautious and global optimization.

**globit**
Maximum number of IRLS iterations to perform with normal GCV/UBRE optimization. If convergence is not achieved after these iterations then a further *maxit* iterations will be performed using cautious GCV/UBRE optimization.

**mgcv.tol**
The convergence tolerance parameter to use in GCV/UBRE optimization.

**mgcv.half**
If a step of the GCV/UBRE optimization method leads to a worse GCV/UBRE score, then the step length is halved. This is the number of halvings to try before giving up.

**nb.theta.mult**
Controls the limits on theta when negative binomial parameter is to be estimated. Maximum theta is set to the initial value multiplied by *nb.theta.mult*, while the minimum value is set to the initial value divided by *nb.theta.mult*.

**trace**
Set this to TRUE to turn on diagnostic output.

**rank.tol**
The tolerance used to estimate the rank of the fitting problem, for methods which deal with rank deficient cases (basically all except those based on *mgcv*).

**absorb.cons**
If TRUE then the GAM is set up using a parameterization which requires no further constraint. Usually this means that all the smooths are automatically centered (i.e. they sum to zero over the covariate values). If FALSE then the ordinary parameterizations of the smooths are used, which require constraints to be imposed during fitting.

**max.tprs.knots**
This is the default initial maximum number of knots to allow when constructing a t.p.r.s bases (bs="tp"). The set up cost (and storage) for these smooths scales as the square of the number of initial knots, so if it’s too high you can appear to freeze R. Usually one would want to use an alternative smoothing basis (or te terms), or the approach illustrated in the examples in *gam*, rather than simply increasing this default.

**nlm**
list of control parameters to pass to *nlm* if this is used for outer estimation of smoothing parameters. See details.

**optim**
list of control parameters to pass to *optim* if this is used for outer estimation of smoothing parameters. See details.
newton  list of control parameters to pass to default Newton optimizer used for outer estimation of log smoothing parameters. See details.

outerPIsteps  The number of performance iteration steps used to initialize outer iteration. Less than 1 means that only one performance iteration step is taken to get the function scale, but the corresponding smoothing parameter estimates are discarded.

Details

When outer iteration is used for fitting then the control list nlm stores control arguments for calls to routine nlm. The list has the following named elements: (i) ndigit is the number of significant digits in the GCV/UBRE score - by default this is worked out from epsilon; (ii) gradtol is the tolerance used to judge convergence of the gradient of the GCV/UBRE score to zero - by default set to 100*epsilon; (iii) stepmax is the maximum allowable log smoothing parameter step - defaults to 2; (iv) steptol is the minimum allowable step length - defaults to 1e-4; (v) iterlim is the maximum number of optimization steps allowed - defaults to 200; (vi) check.analytical indicates whether the built in exact derivative calculations should be checked numerically - defaults to FALSE. Any of these which are not supplied and named in the list are set to their default values.

Outer iteration using newton is controlled by the list newton with the following elements: conv.tol (default 1e-6) is the relative convergence tolerance; maxNstep is the maximum length allowed for an element of the Newton search direction (default 5); maxSstep is the maximum length allowed for an element of the steepest descent direction (only used if Newton fails - default 2); maxHalf is the maximum number of step halvings to permit before giving up (default 30); use.svd determines whether to use an SVD step or QR step for the part of fitting that determines problem rank, etc. (defaults to FALSE).

Outer iteration using optim is controlled using list optim, which currently has one element: factr which takes default value 1e7.

When fitting is been done by calls to routine mgcv, maxit and globit control the maximum iterations of the IRLS algorithm, as follows: the algorithm will first execute up to globit steps in which the GCV/UBRE algorithm performs a global search for the best overall smoothing parameter at every iteration. If convergence is not achieved within globit iterations, then a further maxit steps are taken, in which the overall smoothing parameter estimate is taken as the one locally minimising the GCV/UBRE score and resulting in the lowest EDF change. The difference between the two phases is only significant if the GCV/UBRE function develops more than one minima. The reason for this approach is that the GCV/UBRE score for the IRLS problem can develop ‘phantom’ minimima for some models: these are minima which are not present in the GCV/UBRE score of the IRLS problem resulting from moving the parameters to the minimum! Such minima can lead to convergence failures, which are usually fixed by the second phase.

gam.convergence GAM convergence and performance issues

Description

When fitting GAMs there is a tradeoff between speed of fitting and probability of fit convergence. The default fitting options specified by \texttt{gam.method} (as the default for argument \texttt{method} of \texttt{gam}), always opt for certainty of convergence over speed of fit. In the additive modelling contexts this means using fitting routine \texttt{magic} rather than the slightly faster routine \texttt{mgcv}. In the Generalized Additive Model case it means using ‘outer’ iteration in preference to ‘performance iteration’: see \texttt{gam.outer} for details.

It is possible for the default ‘outer’ iteration to fail when finding intial smoothing parameters using a few steps of outer iteration (if you get a convergence failure message from \texttt{magic} when outer iterating, then this is what has happened): lower \texttt{outerPIsteps} in \texttt{gam.control} to fix this.

There are two things that you can do to speed up GAM fitting. (i) Change the \texttt{method} argument to \texttt{gam} so that ‘performance iteration’ is used in place of the default outer iteration. See the \texttt{perf.magic} option under \texttt{gam.method}, for example. Usually performance iteration converges well and is quick. (ii) For large datasets it may be worth changing the smoothing basis to use \texttt{bs="cr"} (see \texttt{s} for details) for 1-d smooths, and to use \texttt{te} smooths in place of \texttt{s} smooths for smooths of more than one variable. This is because the default thin plate regression spline basis "tp" is costly to set up for large datasets (much over 1000 data, say). Alternatively see the last few examples for \texttt{gam}.

If the GAM estimation process fails to converge when using performance iteration, then switch to outer iteration via the \texttt{method} argument of \texttt{gam} (see \texttt{gam.method}). If it still fails, try increasing the number of IRLS iterations (see \texttt{gam.control}) or perhaps experiment with the convergence tolerance.

If you still have problems, it’s worth noting that a GAM is just a (penalized) GLM and the IRLS scheme used to estimate GLMs is not guaranteed to converge. Hence non convergence of a GAM may relate to a lack of stability in the basic IRLS scheme. Therefore it is worth trying to establish whether the IRLS iterations are capable of converging. To do this fit the problematic GAM with all smooth terms specified with \texttt{fx=TRUE} so that the smoothing parameters are all fixed at zero. If this ‘largest’ model can converge then, then the maintainer would quite like to know about your problem! If it doesn’t converge, then its likely that your model is just too flexible for the IRLS process itself. Having tried increasing \texttt{maxit} in \texttt{gam.control}, there are several other possibilities for stabilizing the iteration. It is possible to try (i) setting lower bounds on the smoothing parameters using the \texttt{min.sp} argument of \texttt{gam}: this may or may not change the model being fitted; (ii) reducing the flexibility of the model by reducing the basis dimensions \texttt{k} in the specification of \texttt{s} and \texttt{te} model terms: this obviously changes the model being fitted somewhat; (iii) introduce a small regularization term into the fitting via the \texttt{irls.reg} argument of \texttt{gam.control}: this option obviously changes the nature of the fit somewhat, since parameter estimates are pulled towards zero by doing this.

Usually, a major contributer to fitting difficulties is that the model is a very poor description of the data.
gam.fit2

GAM P-IRLS estimation with GCV/UBRE smoothness estimation

Description

This is an internal function of package mgcv. It is a modification of the function glm.fit, designed to be called from gam. The major modification is that rather than solving a weighted least squares problem at each IRLS step, a weighted, penalized least squares problem is solved at each IRLS step with smoothing parameters associated with each penalty chosen by GCV or UBRE, using routine mgcv or magic. For further information on usage see code for gam. Some regularization of the IRLS weights is also permitted as a way of addressing identifiability related problems (see gam.control). Negative binomial parameter estimation is supported.

The basic idea of estimating smoothing parameters at each step of the P-IRLS is due to Gu (1992), and is termed ‘performance iteration’ or ‘performance oriented iteration’.

gam.fit2, gam, mgcv, magic
Description

Estimation of GAM smoothing parameters is most stable if optimization of the UBRE or GCV score is outer to the penalized iteratively re-weighted least squares scheme used to estimate the model given smoothing parameters.

These routines estimates a GAM given log smoothing parameters, and evaluate derivatives of the GCV and UBRE scores of the model with respect to the log smoothing parameters. Calculation of exact derivatives is generally faster than approximating them by finite differencing, as well as generally improving the reliability of GCV/UBRE score minimization.

gam.fit2 evaluates first derivatives, by accumulating them as P-IRLS progresses. gam.fit3 uses a more efficient approach in which the P-IRLS is first run to convergence, and only then are the derivatives evaluated by a separate iteration. gam.fit3 can evaluate second as well as first derivatives.

Not normally called directly, but rather service routines for gam.

Usage

```r
gam.fit2(x, y, sp, S=list(), rS=list(), off, H=NULL, weights = rep(1, nobs), start = NULL, etastart = NULL, mustart = NULL, offset = rep(0, nobs), family = gaussian(), control = gam.control(), intercept = TRUE, deriv=TRUE, gamma=1, scale=1, pearson=FALSE, printWarn=TRUE, ...)
gam.fit3(x, y, sp, S=list(), rS=list(), off, H=NULL, weights = rep(1, nobs), start = NULL, etastart = NULL, mustart = NULL, offset = rep(0, nobs), family = gaussian(), control = gam.control(), intercept = TRUE, deriv=2, use.svd=TRUE, gamma=1, scale=1, printWarn=TRUE, ...)
```

Arguments

- **x**: The model matrix for the GAM.
- **y**: The response variable.
- **sp**: The log smoothing parameters.
- **S**: A list of penalty matrices. Typically penalty matrices contain only a smallish square sub-matrix which is non-zero: this is what is actually stored. `off[i]` indicates which parameter is the first one penalized by `S[[i]]`.
- **rS**: List of square roots of penalty matrices, each having as few columns as possible, but as many rows as there are parameters.
- **off**: `off[i]` indicates which parameter `S[[i]][1,1]` relates to.
- **H**: The fixed penalty matrix for the model.
- **weights**: prior weights for fitting.
- **start**: optional starting parameter guesses.
- **etastart**: optional starting values for the linear predictor.
- **mustart**: optional starting values for the mean.
- **offset**: the model offset
- **family**: the family - actually this routine would never be called with `gaussian()`
- **control**: control list as returned from `glm.control`
- **intercept**: does the model have and intercept, TRUE or FALSE
Should derivatives of the GCV and UBRE scores be calculated? TRUE or FALSE for `gam.fit2`, but 0, 1 or 2, indicating the maximum order of differentiation to apply, for `gam.fit3`.

Should the algorithm use SVD (TRUE) or the cheaper QR (FALSE) as the second matrix decomposition of the final derivative/coefficient evaluation method? Only used by `gam.fit3`.

The weight given to each degree of freedom in the GCV and UBRE scores can be varied (usually increased) using this parameter.

The scale parameter - needed for the UBRE score.

The GCV/UBRE score can be based either on the Pearson statistic or the deviance. The latter is generally to be preferred, as it is less prone to severe under-smoothing. Only used by `gam.fit2`.

Set to FALSE to suppress some warnings. Useful in order to ensure that some warnings are only printed if they apply to the final fitted model, rather than an intermediate used in optimization.

Other arguments: ignored.

This routine is basically `glm.fit` with some modifications to allow (i) for quadratic penalties on the log likelihood; (ii) derivatives of the model coefficients with respect to log smoothing parameters to be obtained (by updating alongside the P-IRLS iteration) and (iii) derivatives of the GAM GCV and UBRE scores to be evaluated at convergence.

In addition the routine applies step halving to any step that increases the penalized deviance substantially.

The most costly parts of the calculation are performed by calls to compiled C code (which in turn calls LAPACK routines) in place of the compiled code that would usually perform least squares estimation on the working model in the IRLS iteration.

Estimation of smoothing parameters by optimizing GCV scores obtained at convergence of the P-IRLS iteration was proposed by O’Sullivan et al. (1986), and is here termed ‘outer’ iteration.

Note that use of non-standard families with this routine requires modification of the families as described in `fix.family.link`.

Simon N. Wood (simon.wood@r-project.org)

The routine has been modified from `glm.fit` in R 2.0.1, written by the R core (see `glm.fit` for further credits).

`gam.fit`, `gam`, `mgcv`, `magic`
Setting GAM fitting method

Description

This is a function of package mgcv which allows selection of the numerical method used to optimize the smoothing parameter estimation criterion for a gam.

It is used to set argument method of gam.

Usage

```r
gam.method(am="magic",gam="outer",outer="newton",gcv="deviance", family=NULL)
```

Arguments

- **am**: Which method to use for a pure additive model (i.e. identity link, gaussian errors). Either "magic" if the Wood (2004) method (magic) is to be used, or "mgcv" if the faster, but less stable and general Wood (2000) method (mgcv) should be used.

- **gam**: Which method to use in the generalized case (i.e. all case other than gaussian with identity link). "perf.magic" for the performance iteration (see details) with magic as the basic estimation engine. "perf.mgcv" for performance iteration with mgcv as the underlying estimation engine. "perf.outer" for magic based performance iteration followed by outer iteration (see details). "outer" for pure outer iteration.

- **outer**: The optimization approach to use to optimize log smoothing parameters by outer iteration."newton" for modified Newton method backed up by steepest descent, based on exact first and second derivatives. "nlm" to use nlm with exact first derivatives to optimize the smoothness selection criterion. "nlm.fd" to use nlm with finite differenced first derivatives (slower and less reliable). "optim" to use the "L-BFGS-B" quasi-Newton method option of routine optim, with exact first derivatives.

- **gcv**: One of "deviance", "GACV" or "pearson", specifying the flavour of GCV to use with outer iteration. "deviance" simply replaces the residual sum of squares term in a GCV score with the deviance, following Hastie and Tibshirani (1990, section 6.9). "GACV" (only available with outer method "newton") uses a variant of Gu and Xiang’s (2001) generalized approximate cross validation, modified to deal with arbitrary link-error combinations. "pearson" uses a suggestion from the literature of replacing the RSS in a GCV score with the Pearson statistic: this is a very poor choise (see Wood, 2006, section 4.5.4). This latter option is not available with outer methods "newton" and "nlm".

- **family**: The routine is called by gam to check the supplied method argument. In this circumstance the family argument is passed, to check that it works with the specified method. Negative binomial families only work with performance iteration, and the method is reset to this if necessary.
Details

The performance iteration was suggested by Gu (and is rather similar to the PQL method in generalized linear mixed modelling). At each step of the P-IRLS (penalized iteratively reweighted least squares) iteration, by which a gam is fitted, the smoothing parameters are estimated by GCV or UBRE applied to the working penalized linear modelling problem. In most cases, this process converges and gives smoothness estimates that perform well. It is usually very fast, since smoothing parameters are estimated alongside other model coefficients in a single P-IRLS process.

The performance iteration has two disadvantages. (i) in the presence of co-linearity or concurvity (a frequent problem when spatial smoothers are included in a model with other covariates) then the process can fail to converge. Suppose we start with some coefficient and smoothing parameter estimates, implying a working penalized linear model: the optimal smoothing parameters and coefficients for this working model may in turn imply a working model for which the original estimates are better than the most recent estimates. This sort of effect can prevent convergence.

Secondly it is often possible to find a set of smoothing parameters that result in a lower GCV or UBRE score, for the final working model, than the final score that results from the performance iterations. This is because the performance iteration is only approximately optimizing this score (since optimization is only performed on the working model). The disadvantage here is not that the model with lower score would perform better (it usually doesn’t), but rather that it makes model comparison on the basis of GCV/UBRE score rather difficult.

Both disadvantages of performance iteration are surmountable by using what is basically O’Sullivan’s (1986) suggestion. Here the P-IRLS scheme is iterated to convergence for a fixed set of smoothing parameters, with an appropriate GCV/UBRE score evaluated at convergence. This score at convergence is optimized in some way. This is termed "outer" optimization, since the optimization is outer to the P-IRLS loop. Outer iteration is slower than performance iteration.

The ‘appropriate GCV/UBRE’ score in the previous paragraph can be defined in one of two ways either (i) the deviance, or (ii) the Pearson statistic can be used in place of the residual sum of squares in the GCV/UBRE score. (ii) makes the GCV/UBRE score correspond to the score for the working linear model at convergence of the P-IRLS, but in practice tends to result in oversmoothing, particularly with low n binomial data, or low mean counts. Hence the default is to use (i).

Several alternative optimisation methods can be used for outer optimization. Usually the fastest and most reliable approach is to use a modified Newton optimizer with exact first and second derivatives, and this is the default. nlm can be used with finite differenced first derivatives. This is not ideal theoretically, since it is possible for the finite difference estimates of derivatives to be very badly in error on rare occasions when the P-IRLS convergence tolerance is close to being matched exactly, so that two components of a finite differenced derivative require different numbers of iterations of P-IRLS in their evaluation. An alternative is provided in which nlm uses numerically exact first derivatives, this is faster and less problematic than the other scheme. An further alternative is to use a quasi-Newton scheme with exact derivatives, based on optim. In practice this usually seems to be slower than the nlm method.

In summary: performance iteration is fast, but can fail to converge. Outer iteration is a little slower, but more reliable. At present only performance iteration is available for negative binomial families.

**gam.models**

**Specifying generalized additive models**

**Description**

This page is intended to provide some more information on how to specify GAMs. Assume that in general we are interested in modelling some response variable \(y_i\) with an exponential family distribution (e.g. Normal, Poisson, binomial, etc.) using predictor variables \(x_{1i}, x_{2i}, \ldots\), and let \(\mu_i \equiv E(y_i)\). A typical GAM might be:

\[
g(\mu_i) = \beta_0 + \beta_1 x_{1i} + \beta_2 x_{2i} + f_1(x_{3i}) + f_2(x_{4i}, x_{5i})
\]

where \(g\) is a smooth monotonic ‘link’ function, and \(f_1\) and \(f_2\) are smooth functions. The key idea here is that the dependence of the response on the predictors can be represented as a parametric sub-model plus the sum of some smooth functions of one or more of the predictor variables. Thus the model is quite flexible relative to strictly parametric linear or generalized linear models, but still has much more structure than the completely general model that says that the response is just some smooth function of all the covariates.

Note one important point. In order for the model to be identifiable the smooth functions have to be constrained to have zero mean (usually taken over the set of covariate values). Such constraints are always applied by `gam`.

Specification of the distribution and link function is done using the `family` argument to `gam` and works in the same way as for `glm`. This page hence assumes the default identity link normal error family, since the generalizations are easy.

Starting with the model given above then, the `gam` formula would be:

\[
y \sim x_1 + x_2 + s(x_3) + s(x_4, x_5)
\]

This would use the default basis for the smooths (a thin plate regression spline basis for each), with automatic selection of the effective degrees of freedom for both smooths. The dimension of the smoothing basis is given a default value as well (the dimension of the basis sets an upper limit on the maximum possible degrees of freedom for the basis - the limit is typically one less than basis dimension). Full details of how to control smooths are given in `s` and `te`, and further discussion of basis dimension choice can be found in `choose.k`. For the moment suppose that we would like to change the basis of the first smooth to a cubic regression spline basis with a dimension of 20, while fixing the second term at 25 degrees of freedom. The appropriate formula would be:

\[
y \sim x_1 + x_2 + s(x_3, bs="cr", k=20) + s(x_4, x_5, k=26, fx=T)
\]

Now consider some more unusual models. Consider a model in which \(y\) is a smooth function of \(x\) except at a point \(x^*\) where the function jumps discontinuously. This model can be written as:

\[
E(y_i) = \beta_0 + \beta_1 h(x^*, x_i) + f_1(x_i)
\]
where $h$ is a step function jumping from 0 to 1 at $x^*$. The way to fit this model is to create a variable $h$ which is zero for all $x$ less than $x^*$ and one otherwise. Then the model formula is:

$$y - h + s(x).$$

Another situation that occurs quite often is the one in which we would like to find out if the model:

$$E(y_i) = f(x_i, z_i)$$

is really necessary or whether:

$$E(y_i) = f_1(x_i) + f_2(z_i)$$

wouldn’t do just as well. One way to do this is to look at the results of fitting:

$$y - s(x) + s(z) + s(x, z).$$

gam automatically generates side conditions to make this model identifiable. You can also estimate ‘overlapping’ models like:

$$y - s(x, z) + s(z, v).$$

Sometimes models of the form:

$$E(y_i) = \beta_0 + f(x_i)z_i$$

need to be estimated (where $f$ is a smooth function, as usual.) The appropriate formula is:

$$y - z + s(x, by=z)$$

- the by argument ensures that the smooth function gets multiplied by covariate $z$, but GAM smooths are centred (average value zero), so the $z+$ term is needed as well ($f$ is being represented by a constant plus a centred smooth). If we’d wanted:

$$E(y_i) = f(x_i)z_i$$

then the appropriate formula would be:

$$y - z + s(x, by=z) - 1.$$

The by mechanism also allows models to be estimated in which the form of a smooth depends on the level of a factor, but to do this the user must generate the dummy variables for each level of the factor. Suppose for example that fac is a factor with 3 levels 1, 2, 3, and at each level of this factor ther response depends smoothly on a variable $x$ in a manner that is level dependent. Three dummy variables fac.1, fac.2, fac.3, can be generated for the factor (e.g. fac.1<-as.numeric(fac==1)). Then the model formula would be:

$$y = fac + s(x, by=fac.1) + s(x, by=fac.2) + s(x, by=fac.3).$$

In the above examples the smooths of more than one covariate have all employed single penalty thin plate regression splines. These isotropic smooths are not always appropriate: if variables are not naturally ‘well scaled’ relative to each other then it is often preferable to use tensor product smooths, with a wiggliness penalty for each covariate of the term. See te for examples.

**WARNING**

There are no identifiability checks made between the smooth and parametric parts of a gam formula, and any such lack of identifiability will cause problems if the underlying fitting routine is mgcv (not the default).

```

Description

The `gam` modelling function is designed to be able to use the `negative.binomial` and `neg.bin` families from the MASS library, with or without a known \( \theta \) parameter. A value for \( \text{theta} \) must always be passed to these families, but if \( \theta \) is to be estimated then the passed value is treated as a starting value for estimation.

If the `scale` argument passed to `gam` is positive, then it is used as the scale parameter \( \text{theta} \) treated as a fixed known parameter and any smoothing parameters are chosen by UBRE. If `scale` is not positive then \( \theta \) is estimated. The method of estimation is to choose \( \hat{\theta} \) so that the GCV (Pearson) estimate of the scale parameter is one (since the scale parameter is one for the negative binomial).

\( \theta \) estimation is nested within the IRLS loop used for GAM fitting. After each call to fit an iteratively weighted additive model to the IRLS pseudodata, the \( \theta \) estimate is updated. This is done by conditioning on all components of the current GCV/Pearson estimator of the scale parameter except \( \theta \) and then searching for the \( \hat{\theta} \) which equates this conditional estimator to one. The search is a simple bisection search after an initial crude line search to bracket one. The search will terminate at the upper boundary of the search region is a Poisson fit would have yielded an estimated scale parameter <1. Search limits can be set in `gam.control`.

Note that `neg.bin` only allows a log link, while `negative.binomial` also allows "sqrt" and "identity". In addition the `negative.binomial` family results in a more informative `gam` summary.

The negative binomial families can not yet be used with ‘outer’ estimation of smoothing parameters (see `gam.method`).
Examples

```
library(MASS) # required for negative binomial families
set.seed(3)
n<-400
x0 <- runif(n, 0, 1)
x1 <- runif(n, 0, 1)
x2 <- runif(n, 0, 1)
x3 <- runif(n, 0, 1)
pi <- asin(1) * 2
f <- 2 * sin(pi * x0)
f <- f + exp(2 * x1) - 3.75887
f <- f + 0.2 * x2^11 * (10 * (1 - x2))^6 + 10 * (10 * x2)^3 * (1 - x2)^10 - 1.396
g<-exp(f/5)
# negative binomial data
y<-rnbinom(g,size=3,mu=g)
# unknown theta ...
b<-gam(y~s(x0)+s(x1)+s(x2)+s(x3),family=negative.binomial(1))
plot(b,pages=1)
print(b)
b<-gam(y~s(x0)+s(x1)+s(x2)+s(x3),family=neg.bin(1)) # unknown theta
plot(b,pages=1)
print(b)
# known theta example ...
b<-gam(y~s(x0)+s(x1)+s(x2)+s(x3),family=negative.binomial(3),scale=1)
plot(b,pages=1)
print(b)
# Now use "sqrt" link available in negative.binomial (but not neg.bin)
set.seed(1)
f<-f-min(f);g<-f^2
y<-rnbinom(g,size=3,mu=g)
b<-gam(y~s(x0)+s(x1)+s(x2)+s(x3),family=negative.binomial(1,link="sqrt"))
plot(b,pages=1)
print(b)
```
Not normally called directly, but rather a service routine for `gam`.

**Usage**

```r
gam.outer(lsp, fscale, family, control, method, gamma, G, ...)
```

**Arguments**

- `lsp`: The log smoothing parameters.
- `fscale`: Typical scale of the GCV or UBRE score.
- `family`: the model family.
- `control`: control argument to pass to `gam.fit` if pure finite differencing is being used.
- `method`: method list returned from `gam.method`. This defines the optimization method to use.
- `gamma`: The degree of freedom inflation factor for the GCV/UBRE score.
- `G`: List produced by `gam.setup`, containing most of what’s needed to actually fit GAM.
- `...`: other arguments, typically for passing on to `gam.fit2` (ultimately).

**Details**

Estimation of smoothing parameters by optimizing GCV scores obtained at convergence of the P-IRLS iteration was proposed by O’Sullivan et al. (1986), and is here termed ‘outer’ iteration.

`gam.fit2, gam, mgcv, magic`
Description

This page is intended to provide some more information on how to select GAMs. Given a model structure specified by a gam model formula, `gam()` attempts to find the appropriate smoothness for each applicable model term using Generalized Cross Validation (GCV) or an Un-Biased Risk Estimator (UBRE), the latter being used in cases in which the scale parameter is assumed known. GCV and UBRE are covered in Craven and Wahba (1979) and Wahba (1990), see `gam.method` for more detail about the numerical optimization approaches available.

Automatic smoothness selection is unlikely to be successful with few data, particularly with multiple terms to be selected. In addition GCV and UBRE score can occasionally display local minima that can trap the minimisation algorithms. GCV/UBRE scores become constant with changing smoothing parameters at very low or very high smoothing parameters, and on occasion these ‘flat’ regions can be separated from regions of lower score by a small ‘lip’. This seems to be the most common form of local minimum, but is usually avoidable by avoiding extreme smoothing parameters as starting values in optimization, and by avoiding big jumps in smoothing parameters while optimizing. Never the less, if you are suspicious of smoothing parameter estimates, try changing fit method (see `gam.method`) and see if the estimates change, or try changing some or all of the smoothing parameters ‘manually’ (argument `sp` of `gam`).

In general the most logically consistent method to use for deciding which terms to include in the model is to compare GCV/UBRE scores for models with and without the term. More generally the score for the model with a smooth term can be compared to the score for the model with the smooth term replaced by appropriate parametric terms. Candidates for removal can be identified by reference to the approximate p-values provided by `summary.gam`. Candidates for replacement by parametric terms are smooth terms with estimated degrees of freedom close to their minimum possible.

One appealing approach to model selection is via shrinkage. Smooth classes `cs.smooth` and `tprs.smooth` (specified by "cs" and "ts" respectively) have smoothness penalties which include a small shrinkage component, so that for large enough smoothing parameters the smooth becomes identically zero. This allows automatic smoothing parameter selection methods to effectively remove the term from the model altogether. The shrinkage component of the penalty is set at a level that usually makes negligible contribution to the penalization of the model, only becoming effective when the term is effectively ‘completely smooth’ according to the conventional penalty.

gam, gamm, magic, mgcv
Description

GAM formulae with repeated variables only correspond to identifiable models given some side conditions. This routine works out appropriate side conditions, based on zeroing redundant parameters. It is called from gam.setup and is not intended to be called by users.

The method identifies nested and repeated variables by their names, but evaluates what constraints to impose, numerically. Constraints are always applied to smooths of more variables in preference to smooths of fewer variables. The numerical approach allows appropriate constraints to be applied to models constructed using any smooths, including user defined smooths.

Usage

gam.side(sm,tol=.Machine$double.eps^.5)

Arguments

sm A list of smooth objects as returned by smooth.construct.
tol The tolerance to use when assessing linear dependence of smooths.

Details

Models such as \( y \sim s(x) + s(z) + s(x,z) \) can be estimated by gam, but require identifiability constraints to be applied, to make them identifiable. This routine does this, effectively setting redundant parameters to zero. When the redundancy is between smooths of lower and higher numbers of variables, the constraint is always applied to the smooth of the higher number of variables.

Dependent smooths are identified symbolically, but which constraints are needed to ensure identifiability of these smooths is determined numerically, using fixDependence. This makes the routine rather general, and not dependent on any particular basis.

Value

A list of smooths, with model matrices and penalty matrices adjusted to automatically impose the required constraints. Any smooth that has been modified will have an attribute "del.index", listing the columns of its model matrix that were deleted. This index is used in the creation of prediction matrices for the term.

**gam2objective**

*Objective functions for GAM smoothing parameter estimation*

**Description**

Estimation of GAM smoothing parameters is most stable if optimization of the UBRE or GCV score is outer to the penalized iteratively re-weighted least squares scheme used to estimate the model given smoothing parameters. These functions evaluate the GCV/UBRE score of a GAM model, given smoothing parameters, in a manner suitable for use by `optim` or `nlm`. Not normally called directly, but rather service routines for `gam.outer`.

**Usage**

```r
gam2objective(lsp, args, printWarn = FALSE, ...)
gam2derivative(lsp, args, ...)
gam3objective(lsp, args, ...)
```

**Arguments**

- **lsp**
  - The log smoothing parameters.

- **args**
  - List of arguments required to call `gam.fit2`.

- **printWarn**
  - Should `gam.fit2` print some warnings? Used to suppress warnings that are only of interest for the final fitted model, until that model is reached.

- **...**
  - Other arguments for passing to `gam.fit2`.
gamm

Details

gam2objective and gam2derivative are functions suitable for calling by optim, to evaluate the GCV/UBRE score and it's derivatives w.r.t. log smoothing parameters.
gam3objective is an equivalent to gam2objective, suitable for optimization by nlm - derivatives of the GCV/UBRE function are calculated and returned as attributes.

The basic idea of optimizing smoothing parameters 'outer' to the P-IRLS loop was first proposed in O’Sullivan et al. (1986).

gamm

Generalized Additive Mixed Models

Description

Fits the specified generalized additive mixed model (GAMM) to data, by a call to lme in the normal errors identity link case, or by a call to glmmPQL from the MASS library otherwise. In the latter case estimates are only approximately MLEs. The routine is typically slower than gam, and not quite as numerically robust.

Smooths are specified as in a call to gam as part of the fixed effects model formula, but the wiggly components of the smooth are treated as random effects. The random effects structures and correlation structures available for lme are used to specify other random effects and correlations.

It is assumed that the random effects and correlation structures are employed primarily to model residual correlation in the data and that the prime interest is in inference about the terms in the fixed effects model formula including the smooths. For this reason the routine calculates a posterior covariance matrix for the coefficients of all the terms in the fixed effects formula, including the smooths.

To use this function effectively it helps to be quite familiar with the use of gam and lme.

Usage

gamm(formula, random=NULL, correlation=NULL, family=gaussian(), data=list(), weights=NULL, subset=NULL, na.action, knots=NULL, control=nlme::lmeControl(niterEM=0, optimMethod="L-BFGS-B"), niterPQL=20, verbosePQL=TRUE, method="ML",...)

See Also

gam.fit2, gam, mgcv, magic
Arguments

**formula**
A GAM formula (see also `gam.models`). This is exactly like the formula for a glm except that smooth terms can be added to the right hand side of the formula (and a formula of the form `y ~ .` is not allowed). Smooth terms are specified by expressions of the form:

```r
s(var1, var2, ..., k=12, fx=FALSE, bs="tp", by=a.var)
```

where `var1, var2, etc.` are the covariates which the smooth is a function of and `k` is the dimension of the basis used to represent the smooth term. If `k` is not specified then `k=10*3^(d-1)` is used where `d` is the number of covariates for this term. `fx` is used to indicate whether or not this term has a fixed number of degrees of freedom (`fx=FALSE` to select d.f. by GCV/UBRE). `bs` indicates the basis to use: see `s` for full details, but note that the default "tp" can be slow with large data sets. Tensor product smooths are specified using `te` terms.

**random**
The (optional) random effects structure as specified in a call to `lme`: only the list form is allowed, to facilitate manipulation of the random effects structure within `gamm` in order to deal with smooth terms. See example below.

**correlation**
An optional `corStruct` object (see `corClasses`) as used to define correlation structures in `lme`. Any grouping factors in the formula for this object are assumed to be nested within any random effect grouping factors, without the need to make this explicit in the formula (this is slightly different to the behaviour of `lme`). See examples below.

**family**
A `family` as used in a call to `glm` or `gam`. The default gaussian with identity link causes `gamm` to fit by a direct call to `lme` provided there is no offset term, otherwise `glmmPQL` from the `MASS` library is used.

**data**
A data frame containing the model response variable and covariates required by the formula. By default the variables are taken from `environment(formula)`, typically the environment from which `gamm` is called.

**weights**
In the generalized case, weights with the same meaning as `glm` weights. An `lme` type weights argument may only be used in the identity link gaussian case, with no offset (see documentation for `lme` for details of how to use such an argument).

**subset**
an optional vector specifying a subset of observations to be used in the fitting process.

**na.action**
a function which indicates what should happen when the data contain 'NA's. The default is set by the `na.action` setting of `options`, and is `na.fail` if that is unset. The "factory-fresh" default is `na.omit`.

**knots**
this is an optional list containing user specified knot values to be used for basis construction. For the `cr` basis the user simply supplies the knots to be used, and there must be the same number as the basis dimension, `k`, for the smooth concerned. For the `tp` basis `knots` has two uses. Firstly, for large datasets the calculation of the `tp` basis can be time-consuming. The user can retain most of the advantages of the `tprs` approach by supplying a reduced set of covariate values from which to obtain the basis - typically the number of covariate values used will be substantially smaller than the number of data, and substantially larger than the basis dimension, `k`. The second possibility is to avoid the eigen-decomposition used to find the `tprs` basis altogether and simply use the basis implied by the chosen knots: this will happen if the number of knots supplied matches the basis dimension, `k`. For a given basis dimension the second option is faster, but gives poorer results (and the user must be quite careful in choosing
knot locations). Different terms can use different numbers of knots, unless they share a covariate.

control A list of fit control parameters for lme returned by lmeControl. Note the default setting for the number of EM iterations used by lme: smooths are set up using custom pdMat classes, which are currently not supported by the EM iteration code. Only increase this number if you want to perturb the starting values used in model fitting (usually to worse values!). The optimMethod option is only used if your version of R does not have the nlminb optimizer function.

niterPQL Maximum number of PQL iterations (if any).

verbosePQL Should PQL report its progress as it goes along?

method Which of "ML" or "REML" to use in the Gaussian additive mixed model case when lme is called directly. Ignored in the generalized case (or if the model has an offset), in which case glmmPQL is used.

... further arguments for passing on e.g. to lme

Details

The Bayesian model of spline smoothing introduced by Wahba (1983) and Silverman (1985) opens up the possibility of estimating the degree of smoothness of terms in a generalized additive model as variances of the wiggly components of the smooth terms treated as random effects. Several authors have recognised this (see Wang 1998; Ruppert, Wand and Carroll, 2003) and in the normal errors, identity link case estimation can be performed using general linear mixed effects modelling software such as lme. In the generalized case only approximate inference is so far available, for example using the Penalized Quasi-Likelihood approach of Breslow and Clayton (1993) as implemented in glmmPQL by Venables and Ripley (2002). One advantage of this approach is that it allows correlated errors to be dealt with via random effects or the correlation structures available in the nlme library.

Some brief details of how GAMs are represented as mixed models and estimated using lme or glmmPQL in gamm can be found in Wood (2004a,b). In addition gamm obtains a posterior covariance matrix for the parameters of all the fixed effects and the smooth terms. The approach is similar to that described in (Lin & Zhang, 1999) - the covariance matrix of the data (or pseudodata in the generalized case) implied by the weights, correlation and random effects structure is obtained, based on the estimates of the parameters of these terms and this is used to obtain the posterior covariance matrix of the fixed and smooth effects.

The bases used to represent smooth terms are the same as those used in gam.

In the event of lme convergence failures, consider modifying option(mgcv.vc.logrange): reducing it helps to remove indefiniteness in the likelihood, if that is the problem, but too large a reduction can force over or undersmoothing. See notExp2 for more information on this option. Failing that, you can try increasing the niterEM option in control: this will perturb the starting values used in fitting, but usually to values with lower likelihood! Note that this version of gamm works best with R 2.2.0 or above and nlme, 3.1-62 and above, since these use an improved optimizer.

Value

Returns a list with two items:

gam an object of class gam, less information relating to GCV/UBRE model selection. At present this contains enough information to use predict, summary and print methods and vis.gam, but not to use e.g. the anova method function to compare models.
the fitted model object returned by \texttt{lme} or \texttt{glmmPQL}. Note that the model formulae and grouping structures may appear to be rather bizarre, because of the manner in which the GAMM is split up and the calls to \texttt{lme} and \texttt{glmmPQL} are constructed.

\section*{WARNINGS}

This version of \texttt{gamm} works best with \texttt{nlme} 3.1-62 and above and R 2.2.0 and above. This is because it is designed to work with the optimizers used from these versions onwards, rather than the earlier default optimizers.

The routine will be very slow and memory intensive if correlation structures are used for the very large groups of data. e.g. attempting to run the spatial example in the examples section with many 1000’s of data is definitely not recommended: often the correlations should only apply within clusters that can be defined by a grouping factor, and provided these clusters do not get too huge then fitting is usually possible.

Models must contain at least one random effect: either a smooth with non-zero smoothing parameter, or a random effect specified in argument \texttt{random}.

Models like \texttt{s(x)+s(x)+s(x,z)} are not currently supported.

\texttt{gamm} is not as numerically stable as \texttt{gam}: an \texttt{lme} call will occasionally fail. See details section for suggestions.

\texttt{gamm} is usually much slower than \texttt{gam}, and on some platforms you may need to increase the memory available to R in order to use it with large data sets (see \texttt{mem.limits}).

Note that the weights returned in the fitted GAM object are dummy, and not those used by the PQL iteration: this makes partial residual plots look odd.

Note that the \texttt{gam} object part of the returned object is not complete in the sense of having all the elements defined in \texttt{gamObject} and does not inherit from \texttt{glm}; hence e.g. multi-model \texttt{anova} calls will not work.

The parameterization used for the smoothing parameters in \texttt{gamm}, bounds them above and below by an effective infinity and effective zero. See \texttt{notExp2} for details of how to change this.

**Description**

This is an internal function of package mgcv. It is called by gamm to set up a generalized additive mixed model in a form suitable for fitting by calls to glmmPQL from the MASS library or lme from the nlme library. The main task is the representation of the smooth terms as random effects.

gamm
Description

A fitted GAM object returned by function `gam` and of class "gam" inheriting from classes "glm" and "lm". Method functions `anova`, `logLik`, `influence`, `plot`, `predict`, `print`, `residuals` and `summary` exist for this class.

All compulsory elements of "glm" and "lm" objects are present, but the fitting method for a GAM is different to a linear model or GLM, so that the elements relating to the QR decomposition of the model matrix are absent.

Value

A `gam` object has the following elements:

- **aic**: AIC of the fitted model: bear in mind that the degrees of freedom used to calculate this are the effective degrees of freedom of the model, and the likelihood is evaluated at the maximum of the penalized likelihood in most cases, not at the MLE.
- **assign**: Array whose elements indicate which model term (listed in `pterms`) each parameter relates to: applies only to non-smooth terms.
- **boundary**: did parameters end up at boundary of parameter space?
- **call**: the matched call (allows `update` to be used with `gam` objects, for example).
- **coefficients**: the coefficients of the fitted model. Parametric coefficients are first, followed by coefficients for each spline term in turn.
- **control**: the `gam` control list used in the fit.
- **converged**: indicates whether or not the iterative fitting method converged.
- **data**: the original supplied data argument (for class "glm" compatibility).
- **deviance**: model deviance (not penalized deviance).
- **df.null**: null degrees of freedom.
- **df.residual**: effective residual degrees of freedom of the model.
- **edf**: estimated degrees of freedom for each model parameter. Penalization means that many of these are less than 1.
- **family**: family object specifying distribution and link used.
- **fit.method**: Character string describing the multiple GCV/UBRE smoothing parameter estimation method used.
- **fitted.values**: fitted model predictions of expected value for each datum.
- **formula**: the model formula.
- **full.formula**: the model formula with each smooth term fully expanded and with option arguments given explicitly (i.e. not with reference to other variables) - useful for later prediction from the model.
- **gcv.ubre**: The minimized GCV or UBRE score.
- **hat**: array of elements from the leading diagonal of the ‘hat’ (or ‘influence’) matrix. Same length as response data vector.
iter  number of iterations of P-IRLS taken to get convergence.
linear.predictors  fitted model prediction of link function of expected value for each datum.
method  One of "GCV" or "UBRE", depending on the fitting criterion used.
mgcv.conv  A list of convergence diagnostics relating to the "mgcv" or "magic" parts of smoothing parameter estimation - this will not be very meaningful for pure "outer" estimation of smoothing parameters. mgcv.conv differs for method "magic" and "mgcv". Here is the "mgcv" version:
score  corresponding to edf, an array of GCV or UBRE scores for the model given the final estimated relative smoothing parameters.
g  the gradient of the GCV/UBRE score w.r.t. the relative smoothing parameters at termination.
h  the second derivatives corresponding to \( g \) above - i.e. the leading diagonal of the Hessian.
e  the eigen-values of the Hessian. All non-negative indicates a positive definite Hessian.
iter  the number of iterations taken.
in.ok  TRUE if the second smoothing parameter guess improved the GCV/UBRE score.
step.fail  TRUE if the algorithm terminated by failing to improve the GCV/UBRE score rather than by 'converging'. Not necessarily a problem, but check the above derivative information quite carefully.
In the case of "magic" the items are:
full.rank  The apparent rank of the problem given the model matrix and constraints.
rank  The numerical rank of the problem.
fully.converged  TRUE is multiple GCV/UBRE converged by meeting convergence criteria. FALSE if method stopped with a steepest descent step failure.
hess.pos.def  Was the hessian of the GCV/UBRE score positive definite at smoothing parameter estimation convergence?
iter  How many iterations were required to find the smoothing parameters?
score.calls  and how many times did the GCV/UBRE score have to be evaluated?
rms.grad  root mean square of the gradient of the GCV/UBRE score at convergence.
min.edf  Minimum possible degrees of freedom for whole model.
model  model frame containing all variables needed in original model fit.
na.action  The na.action used in fitting.
nsdf  number of parametric, non-smooth, model terms including the intercept.
null.deviance  deviance for single parameter model.
offset  model offset.
outer.info  If 'outer' iteration has been used to fit the model (see gam.method) then this is present and contains whatever was returned by the optimization routine used (currently nlm or optim).
prior.weights  prior weights on observations.
pters  terms object for strictly parametric part of model.
rank  apparent rank of fitted model.
residuals  the working residuals for the fitted model.
sig2  estimated or supplied variance/scale parameter.
smooth  list of smooth objects, containing the basis information for each term in the model formula in the order in which they appear. These smooth objects are what gets returned by the smooth.construct objects.
sp  smoothing parameter for each smooth.
terms  terms object of model model frame.
Vp  estimated covariance matrix for the parameters. This is a Bayesian posterior covariance matrix that results from adopting a particular Bayesian model of the smoothing process. Particularly useful for creating credible/confidence intervals.
Ve  frequentist estimated covariance matrix for the parameter estimators. Particularly useful for testing whether terms are zero. Not so useful for CI’s as smooths are usually biased.
weights  final weights used in IRLS iteration.
y  response data.

WARNINGS

This model object is different to that described in Chambers and Hastie (1993) in order to allow smoothing parameter estimation etc.

gam
get.var

Get named variable or evaluate expression from list or data.frame

Description
This routine takes a text string and a data frame or list. It first sees if the string is the name of a variable in the data frame/list. If it is then the value of this variable is returned. Otherwise the routine tries to evaluate the expression within the data.frame/list (but nowhere else) and if successful returns the result. If neither step works then NULL is returned. The routine is useful for processing gam formulae.

Usage
get.var(txt, data)

Arguments

- `txt`: a text string which is either the name of a variable in `data` or when parsed is an expression that can be evaluated in `data`. It can also be neither in which case the function returns NULL.
- `data`: A data frame or list.

Value
The evaluated variable, or NULL

y <- 1:4; dat <- data.frame(x=5:10)
ger.get.var("x", dat)
ger.get.var("y", dat)
ger.get.var("x==6", dat)
```
influence.gam

Extract the diagonal of the influence/hat matrix for a GAM

Description

Extracts the leading diagonal of the influence matrix (hat matrix) of a fitted gam object.

Usage

## S3 method for class 'gam':
influence(model,...)

Arguments

model fitted model objects of class gam as produced by gam().
... un-used in this case

Details

Simply extracts hat array from fitted model. (More may follow!)

Value

An array (see above).

gam

initial.sp

Starting values for multiple smoothing parameter estimation

Description

Finds initial smoothing parameter guesses for multiple smoothing parameter estimation. The idea is to find values such that the estimated degrees of freedom per penalized parameter should be well away from 0 and 1 for each penalized parameter, thus ensuring that the values are in a region of parameter space where the smoothing parameter estimation criterion is varying substantially with smoothing parameter value.

Usage

initial.sp(X,S,off,expensive=FALSE)
Arguments

X  
is the model matrix.

S  
is a list of of penalty matrices. $S[[i]]$ is the ith penalty matrix, but note that it
is not stored as a full matrix, but rather as the smallest square matrix including all
the non-zero elements of the penalty matrix. Element 1,1 of $S[[i]]$ occupies
element $off[i], off[i]$ of the ith penalty matrix. Each $S[[i]]$ must be
positive semi-definite.

off  
is an array indicating the first parameter in the parameter vector that is penalized
by the penalty involving $S[[i]]$.

expensive  
if TRUE then the overall amount of smoothing is adjusted so that the average
degrees of freedom per penalized parameter is exactly 0.5: this is numerically
costly.

Details

Basically uses a crude approximation to the estimated degrees of freedom per model coefficient, to
try and find smoothing parameters which bound these e.d.f.'s away from 0 and 1.
Usually only called by magic and gam.

Value

An array of initial smoothing parameter estimates.

Author(s)

magic, gam.outer, gam,

Description

This is an internal function of package mgcv. It is a service routine for gam which splits off the
strictly parametric part of the model formula, returning it as a formula, and interprets the smooth
parts of the model formula.
Not normally called directly.

Usage

interpret.gam(gf)

Arguments

gf  
A GAM formula as supplied to gam or gamm.
**Value**

An object of class `split.gam.formula` with the following items:

- **pf**: A model formula for the strictly parametric part of the model.
- **pfok**: TRUE if there is a pf formula.
- **smooth.spec**: A list of class `xx.smooth.spec` objects where `xx` depends on the basis specified for the term. (These can be passed to smooth constructor method functions to actually set up penalties and bases.)
- **full.formula**: An expanded version of the model formula in which the options are fully expanded, and the options do not depend on variables which might not be available later.
- **fake.formula**: A formula suitable for use in evaluating a model frame.
- **response**: Name of the response variable.

**logLik.gam**

`Extract the log likelihood for a fitted GAM`

**Description**

Function to extract the log-likelihood for a fitted `gam` model (note that the models are usually fitted by penalized likelihood maximization).

**Usage**

```r
## S3 method for class 'gam':
logLik(object, ...)
```

**Arguments**

- **object**: fitted model objects of class `gam` as produced by `gam()`.
- **...**: un-used in this case
Details

Modification of \texttt{logLik.glm} which corrects the degrees of freedom for use with \texttt{gam} objects.

The function is provided so that \texttt{AIC} functions correctly with \texttt{gam} objects, and uses the appropriate degrees of freedom (accounting for penalization). Note, when using \texttt{AIC} for penalized models, that the degrees of freedom are the effective degrees of freedom and not the number of parameters, and the model maximizes the penalized likelihood, not the actual likelihood! This seems to be reasonably well founded for the known scale parameter case (see Hastie and Tibshirani, 1990, section 6.8.3), and in fact in this case the default smoothing parameter estimation criterion is effectively this modified \texttt{AIC}.

Value

Standard \texttt{logLik} object: see \texttt{logLik}.

Author(s)

Simon N. Wood \texttt{(simon.wood@r-project.org)} based directly on \texttt{logLik.glm}

\texttt{AIC}

Usage

\texttt{magic(y,X,sp,S,off,rank=NULL,H=NULL,C=NULL,w=NULL,gamma=1,}
\texttt{scale=1,gcv=TRUE,ridge.parameter=NULL,}
\texttt{control=list(maxit=50,tol=1e-6,step.half=25,}
\texttt{rank.tol=.Machine$double.eps^0.5),extra.rss=0,n.score=length(y))}
Arguments

- **y** is the response data vector.
- **X** is the model matrix.
- **sp** is the array of smoothing parameters multiplying the penalty matrices stored in **S**. Any that are negative are autoinitialized, otherwise they are taken as supplying starting values. A supplied starting value will be reset to a default starting value if the gradient of the GCV/UBRE score is too small at the supplied value.
- **S** is a list of penalty matrices. **S[[i]]** is the ith penalty matrix, but note that it is not stored as a full matrix, but rather as the smallest square matrix including all the non-zero elements of the penalty matrix. Element 1,1 of **S[[i]]** occupies element **off[i]**, **off[i]** of the ith penalty matrix. Each **S[[i]]** must be positive semi-definite.
- **off** is an array indicating the first parameter in the parameter vector that is penalized by the penalty involving **S[[i]]**.
- **rank** is an array specifying the ranks of the penalties. This is useful, but not essential, for forming square roots of the penalty matrices.
- **H** is the optional offset penalty - i.e. a penalty with a smoothing parameter fixed at 1. This is useful for allowing regularization of the estimation process, fixed smoothing penalties etc.
- **C** is the optional matrix specifying any linear equality constraints on the fitting problem. If **b** is the parameter vector then the parameters are forced to satisfy **Cb = 0**.
- **w** is the regression weights. If this is a matrix then it is taken as being the square root of the inverse of the covariance matrix of **y**, specifically **V w⁻¹ = w'w**. If **w** is an array then it is taken as the diagonal of this matrix, or simply the weight for each element of **y**. See below for an example using this.
- **gamma** is an inflation factor for the model degrees of freedom in the GCV or UBRE score.
- **scale** is the scale parameter for use with UBRE.
- **gcv** should be set to **TRUE** if GCV is to be used, **FALSE** for UBRE.
- **ridge.parameter** It is sometimes useful to apply a ridge penalty to the fitting problem, penalizing the parameters in the constrained space directly. Setting this parameter to a value greater than zero will cause such a penalty to be used, with the magnitude given by the parameter value.
- **control** is a list of iteration control constants with the following elements:
  - **maxit** The maximum number of iterations of the magic algorithm to allow.
  - **tol** The tolerance to use in judging convergence.
  - **step.half** If a trial step fails then the method tries halving it up to a maximum of **step.half** times.
  - **rank.tol** is a constant used to test for numerical rank deficiency of the problem. Basically any singular value less than **rank_tol** multiplied by the largest singular value of the problem is set to zero.
  - **extra.rss** is a constant to be added to the residual sum of squares (squared norm) term in the calculation of the GCV, UBRE and scale parameter estimate. In conjuction with **n.score**, this is useful for certain methods for dealing with very large data sets.
n.score  number to use as the number of data in GCV/UBRE score calculation: usually the actual number of data, but there are methods for dealing with very large datasets that change this.

Details

The method is a computationally efficient means of applying GCV or UBRE (often approximately AIC) to the problem of smoothing parameter selection in generalized ridge regression problems of the form:

$$\text{minimise } \|W(Xb - y)\|^2 + b'Hb + \sum_{i=1}^{m} \theta_i b'S_i b$$

possibly subject to constraints $Cb = 0$. $X$ is a design matrix, $b$ a parameter vector, $y$ a data vector, $W$ a weight matrix, $S_i$ a positive semi-definite matrix of coefficients defining the $i$th penalty with associated smoothing parameter $\theta_i$, $H$ is the positive semi-definite offset penalty matrix and $C$ a matrix of coefficients defining any linear equality constraints on the problem. $X$ need not be of full column rank.

The $\theta_i$ are chosen to minimize either the GCV score:

$$V_g = n \frac{\|W(y - Ay)\|^2}{[tr(I - \gamma A)]^2}$$

or the UBRE score:

$$V_u = \|W(y - Ay)\|^2/n - 2\phi tr(I - \gamma A)/n + \phi$$

where $\gamma$ is gamma, the inflation factor for degrees of freedom (usually set to 1) and $\phi$ is scale, the scale parameter. $A$ is the hat matrix (influence matrix) for the fitting problem (i.e the matrix mapping data to fitted values). Dependence of the scores on the smoothing parameters is through $A$.

The method operates by Newton or steepest descent updates of the logs of the $\theta_i$. A key aspect of the method is stable and economical calculation of the first and second derivatives of the scores w.r.t. the log smoothing parameters. Because the GCV/UBRE scores are flat w.r.t. very large or very small $\theta_i$, it's important to get good starting parameters, and to be careful not to step into a flat region of the smoothing parameter space. For this reason the algorithm rescales any Newton step that would result in a $\log(\theta_i)$ change of more than 5. Newton steps are only used if the Hessian of the GCV/UBRE is positive definite, otherwise steepest descent is used. Similarly steepest descent is used if the Newton step has to be contracted too far (indicating that the quadratic model underlying Newton is poor). All initial steepest descent steps are scaled so that their largest component is 1. However a step is calculated, it is never expanded if it is successful (to avoid flat portions of the objective), but steps are successively halved if they do not decrease the GCV/UBRE score, until they do, or the direction is deemed to have failed. (Given the smoothing parameters the optimal $b$ parameters are easily found.)

The method is coded in C with matrix factorizations performed using LINPACK and LAPACK routines.

Value

The function returns a list with the following items:

$b$  The best fit parameters given the estimated smoothing parameters.

scale  the estimated (GCV) or supplied (UBRE) scale parameter.
score is the minimized GCV or U BRE score.
sp is an array of the estimated smoothing parameters.
rV is a factored form of the parameter covariance matrix. The (Bayesian) covariance matrix of the parameters \( \hat{b} \) is given by \( rV \hat{V}^{-1} rV \times \text{scale} \).
gcv.info is a list of information about the performance of the method with the following elements:
full.rank is the apparent rank of the problem: number of parameters less number of equality constraints.
rank is the estimated actual rank of the problem (at the final iteration of the method).
fully.converged is TRUE if the method converged by satisfying the convergence criteria, and FALSE if it converged by failing to decrease the score along the search direction.
hess.pos.def is TRUE if the hessian of the U BRE or GCV score was positive definite at convergence.
iter is the number of Newton/Steepest descent iterations taken.
score.calls is the number of times that the GCV/UBRE score had to be evaluated.
rms.grad is the root mean square of the gradient of the UBRE/GCV score w.r.t. the smoothing parameters.

Note that some further useful quantities can be obtained using magic.post.proc.

**magic.post.proc**

**Auxilliary information from magic fit**

**Description**

Obtains Bayesian parameter covariance matrix, frequentist parameter estimator covariance matrix, estimated degrees of freedom for each parameter and leading diagonal of influence/hat matrix, for a penalized regression estimated by magic.

**Usage**

`magic.post.proc(X,object,w)`

**Arguments**

- **X** is the model matrix.
- **object** is the list returned by magic after fitting the model with model matrix X.
is the weight vector used in fitting, or the weight matrix used in fitting (i.e. supplied to magic, if one was.) \( \times (w)^{-1} \times \) should typically give the inverse of the covariance matrix of the response data supplied to magic.

**Details**

object contains \( rV \) (\( V \), say), and scale (\( \phi \), say) which can be used to obtain the require quantities as follows. The Bayesian covariance matrix of the parameters is \( VV' \phi \). The vector of estimated degrees of freedom for each parameter is the leading diagonal of \( VV'X'W'WX \) where \( W \) is either the weight matrix \( w \) or the matrix \( \text{diag}(w) \). The hat/influence matrix is given by \( WXVV'X'W' \).

The frequentist parameter estimator covariance matrix is \( VV'X'W'WXVV' \phi \): it is useful for testing terms for equality to zero.

**Value**

A list with three items:

- **Vb** the Bayesian covariance matrix of the model parameters.
- **Ve** the frequentist covariance matrix for the parameter estimators.
- **hat** the leading diagonal of the hat (influence) matrix.
- **edf** the array giving the estimated degrees of freedom associated with each parameter.

**Author(s)**

Simon N. Wood \( \langle \text{simon.wood@r-project.org} \rangle \)

**See Also**

magic

---

**Description**

Function to efficiently estimate smoothing parameters in Generalized Ridge Regression Problem with multiple (quadratic) penalties, by GCV or UBRE. The function uses Newton’s method in multi-dimensions, backed up by steepest descent to iteratively adjust a set of relative smoothing parameters for each penalty. To ensure that the overall level of smoothing is optimal, and to guard against trapping by local minima, a highly efficient global minimisation with respect to one overall smoothing parameter is also made at each iteration.

For a listing of all routines in the mgcv package type:

```r
library(help="mgcv")
```

**Usage**

```r
mgcv(y,X,sp,S,off,C=NULL,w=rep(1,length(y)),H=NULL,
scale=1,gcv=TRUE,control=mgcv.control())
```
Arguments

`y`  The response data vector.

`X`  The design matrix for the problem, note that `nrow(X)` must give the number of model parameters, while `ncol(X)` should give the number of data.

`spp`  An array of smoothing parameters. If `control$fixed==TRUE` then these are taken as being the smoothing parameters. Otherwise any positive values are assumed to be initial estimates and negative values to signal auto-initialization.

`S`  A list of penalty matrices. Only the smallest square block containing all non-zero matrix elements is actually stored, and `off[i]` indicates the element of the parameter vector that `S[[i]][1,1]` relates to.

`off`  Offset values indicating where in the overall parameter a particular stored penalty starts operating. For example if `p` is the model parameter vector and `k=nrow(S[[i]])-1`, then the ith penalty is given by `t(p[off[i]:off[i]+k])*%*%S[[i]][1,1]*%*%(p[off[i]:off[i]+k])`.

`C`  Matrix containing any linear equality constraints on the problem (i.e. `C` in `Cp = 0`).

`w`  A vector of weights for the data (often proportional to the reciprocal of the standard deviation of `y`).

`H`  A single fixed penalty matrix to be used in place of the multiple penalty matrices in `S`. `mgcv` cannot mix fixed and estimated penalties.

`scale`  This is the known scale parameter/error variance to use with UBRE. Note that it is assumed that the variance of `y_i` is given by `sigma^2/w_i`.

`gcv`  If `gcv` is TRUE then smoothing parameters are estimated by GCV, otherwise UBRE is used.

`control`  A list of control options returned by `mgcv.control`.

Details

This is documentation for the code implementing the method described in section 4 of Wood (2000). The method is a computationally efficient means of applying GCV to the problem of smoothing parameter selection in generalized ridge regression problems of the form:

\[
\min \|W(Xp - y)\|^2 + \rho + \sum_{i=1}^{m} \lambda_i p' S_i p
\]

possibly subject to constraints `Cp = 0`. `X` is a design matrix, `p` a parameter vector, `y` a data vector, `W` a diagonal weight matrix, `S_i` a positive semi-definite matrix of coefficients defining the ith penalty and `C` a matrix of coefficients defining any linear equality constraints on the problem. The smoothing parameters are the `\lambda_i` but there is an overall smoothing parameter `\rho` as well. Note that `X` must be of full column rank, at least when projected into the null space of any equality constraints.

The method operates by alternating very efficient direct searches for `\rho` with Newton or steepest descent updates of the logs of the `\lambda_i`. Because the GCV/UBRE scores are flat w.r.t. very large or very small `\lambda_i`, it’s important to get good starting parameters, and to be careful not to step into a flat region of the smoothing parameter space. For this reason the algorithm rescales any Newton step that would result in a `log(\lambda_i)` change of more than 5. Newton steps are only used if the Hessian of the GCV/UBRE is postive definite, otherwise steepest descent is used. Similarly steepest descent is used if the Newton step has to be contracted too far (indicating that the quadratic model underlying Newton is poor). All initial steepest descent steps are scaled so that their largest component is
1. However a step is calculated, it is never expanded if it is successful (to avoid flat portions of the objective), but steps are successively halved if they do not decrease the GCV/UBRE score, until they do, or the direction is deemed to have failed. `M$conv` provides some convergence diagnostics. The method is coded in C and is intended to be portable. It should be noted that seriously ill conditioned problems (i.e. with close to column rank deficiency in the design matrix) may cause problems, especially if weights vary wildly between observations.

Value

An object is returned with the following elements:

- **b**: The best fit parameters given the estimated smoothing parameters.
- **scale**: The estimated or supplied scale parameter/error variance.
- **score**: The UBRE or GCV score.
- **sp**: The estimated (or supplied) smoothing parameters ($\lambda_i/\rho$)
- **Vb**: Estimated covariance matrix of model parameters.
- **hat**: diagonal of the hat/influence matrix.
- **edf**: array of estimated degrees of freedom for each parameter.
- **info**: A list of convergence diagnostics, with the following elements:
  - **score**: Array of ubre/gcv scores at the edfs for the final set of relative smoothing parameters.
  - **g**: the gradient of the GCV/UBRE score w.r.t. the smoothing parameters at termination.
  - **h**: the second derivatives corresponding to $g$ above - i.e. the leading diagonal of the Hessian.
  - **e**: the eigenvalues of the Hessian. These should all be non-negative!
  - **iter**: the number of iterations taken.
  - **in.ok**: TRUE if the second smoothing parameter guess improved the GCV/UBRE score. (Please report examples where this is FALSE)
  - **step.fail**: TRUE if the algorithm terminated by failing to improve the GCV/UBRE score rather than by "converging". Not necessarily a problem, but check the above derivative information quite carefully.

**WARNING**

The method may not behave well with near column rank deficient X especially in contexts where the weights vary wildly.

mgcv.control

Setting mgcv defaults

Description

This is an internal function of package mgcv which allows control of the numerical options for fitting a generalized ridge regression problem using routine mgcv.

Usage

mgcv.control(conv.tol=1e-7,max.half=20,target.edf=NULL,min.edf=-1)

Arguments

conv.tol The convergence tolerance.

max.half successive step halvings are employed if the Newton method and then the steepest descent backup fail to improve the UBRE/GCV score. This is how many to use before giving up.

target.edf If this is non-null it indicates that cautious optimization should be used, which opts for the local minimum closest to the target model edf if there are multiple local minima in the GCV/UBRE score.

min.edf Lower bound on the model edf. Useful for avoiding numerical problems at high smoothing parameter values. Negative for none.

mono.con

Monotonicity constraints for a cubic regression spline

Description

Finds linear constraints sufficient for monotonicity (and optionally upper and/or lower boundedness) of a cubic regression spline. The basis representation assumed is that given by the gam,"cr" basis: that is the spline has a set of knots, which have fixed x values, but the y values of which constitute the parameters of the spline.

Usage

mono.con(x,up=TRUE,lower=NA,upper=NA)

Arguments

x The array of knot locations.
up If TRUE then the constraints imply increase, if FALSE then decrease.
lower This specifies the lower bound on the spline unless it is NA in which case no lower bound is imposed.
upper This specifies the upper bound on the spline unless it is NA in which case no upper bound is imposed.

Details

Consider the natural cubic spline passing through the points: \( \{x_i, p_i : i = 1 \ldots n\} \). Then it is possible to find a relatively small set of linear constraints on \( p \) sufficient to ensure monotonicity (and bounds if required): \( A p \geq b \). Details are given in Wood (1994). This function returns a list containing \( A \) and \( b \).

Value

The function returns a list containing constraint matrix \( A \) and constraint vector \( b \).

mgcv  pcls

Examples

## see ?pcls

\[
\text{mroot} \quad \text{Smallest square root of matrix}
\]

Description

Find a square root of a positive semi-definite matrix, having as few columns as possible. Uses either pivoted choleski decomposition or singular value decomposition to do this.

Usage

\[
mroot(A, \text{rank=NULL, method="chol"})
\]

Arguments

- **A** The positive semi-definite matrix, a square root of which is to be found.
- **rank** if the rank of the matrix \( A \) is known then it should be supplied.
- **method** "chol" to use pivoted choleski decompositon, which is fast but tends to overestimate rank. "svd" to use singular value decomposition, which is slow, but is the most accurate way to estimate rank.

Details

The routine uses an LAPACK SVD routine, or the LINPACK pivoted Choleski routine. It is primarily of use for turning penalized regression problems into ordinary regression problems.

Value

A matrix, \( B \) with as many columns as the rank of \( A \), and such that \( A = BB' \).

Author(s)

Simon N. Wood \( \langle \text{simon.wood@r-project.org} \rangle \)
Examples

```r
set.seed(0)
a <- matrix(runif(24),6,4)
A <- a%*%t(a)  ## A is +ve semi-definite, rank 4
B <- mroot(A)  ## default pivoted choleski method
tol <- 100*.Machine$double.eps
chol.err <- max(abs(A-B%*%t(B)));chol.err
if (chol.err>tol) warning("mroot (chol) suspect")
B <- mroot(A,method="svd")  ## svd method
svd.err <- max(abs(A-B%*%t(B)));svd.err
if (svd.err>tol) warning("mroot (svd) suspect")
```

new.name

Obtain a name for a new variable that is not already in use

Description

gamm works by transforming a GAMM into something that can be estimated by lme, but this involves creating new variables, the names of which should not clash with the names of other variables on which the model depends. This simple service routine checks a suggested name against a list of those in use, and if necessary modifies it so that there is no clash.

Usage

```r
new.name(proposed,old.names)
```

Arguments

- **proposed**: a suggested name
- **old.names**: An array of names that must not be duplicated

Value

A name that is not in old.names.

```
notExp

Functions for better-than-log positive parameterization

Description

It is common practice in statistical optimization to use log-parameterizations when a parameter ought to be positive. i.e. if an optimization parameter \( a \) should be non-negative then we use \( a = \exp(b) \) and optimize with respect to the unconstrained parameter \( b \). This often works well, but it does imply a rather limited working range for \( b \): using 8 byte doubles, for example, if \( b \)’s magnitude gets much above 700 then \( a \) overflows or underflows. This can cause problems for numerical optimization methods.

\( \text{notExp} \) is a monotonic function for mapping the real line into the positive real line with much less extreme underflow and overflow behaviour than \( \exp \). It is a piece-wise function, but is continuous to second derivative: see the source code for the exact definition, and the example below to see what it looks like.

\( \text{notLog} \) is the inverse function of \( \text{notExp} \).

The major use of these functions was originally to provide more robust \( \text{pdMat} \) classes for \( \text{lme} \) for use by \( \text{gamm} \). Currently the \( \text{notExp2} \) and \( \text{notLog2} \) functions are used in their place, as a result of changes to the \( \text{nlme} \) optimization routines.

Usage

\[ \text{notExp}(x) \]
\[ \text{notLog}(x) \]

Arguments

\( x \)                  Argument array of real numbers (\( \text{notExp} \)) or positive real numbers (\( \text{notLog} \)).

Value

An array of function values evaluated at the supplied argument values.

plot(x,notExp(x),type="l")
lines(x,exp(x),col=2)
plot(x,log(notExp(x)),type="l")
lines(x,log(exp(x)),col=2) # redundancy intended
x <- x/4
plot(x,notExp(x),type="l")
lines(x,exp(x),col=2)
plot(x,log(notExp(x)),type="l")
lines(x,log(exp(x)),col=2) # redundancy intended
par(op)
range(notLog(notExp(x))-x) # show that inverse works!
```

notExp2

Alternative to log parameterization for variance components

Description

notLog2 and notExp2 are alternatives to log and exp or notLog and notExp for reparameterization of variance parameters. They are used by the pdTens and pdIdnot classes which in turn implement smooths for gamm.

The functions are typically used to ensure that smoothing parameters are positive, but the notExp2 is not monotonic: rather it cycles between ‘effective zero’ and ‘effective infinity’ as its argument changes. The notLog2 is the inverse function of the notExp2 only over an interval centered on zero.

Parameterizations using these functions ensure that estimated smoothing parameters remain positive, but also help to ensure that the likelihood is never indefinite: once a working parameter pushes a smoothing parameter below ‘effective zero’ or above ‘effective infinity’ the cyclic nature of the notExp2 causes the likelihood to decrease, where otherwise it might simply have flattened.

This parameterization is really just a numerical trick, in order to get lme to fit gamm models, without failing due to indefiniteness. Note in particular that asymptotic results on the likelihood/REML criterion are not invalidated by the trick, unless parameter estimates end up close to the effective zero or effective infinity: but if this is the case then the asymptotics would also have been invalid for a conventional monotonic parameterization.

This reparameterization was made necessary by some modifications to the underlying optimization method in lme introduced in nlme 3.1-62. It is possible that future releases will return to the notExp parameterization.

Note that you can reset ‘effective zero’ and ‘effective infinity’; see below.

Usage

```r
notExp2(x,d=OptionSmgcv.vc.logrange,b=1/d)
notLog2(x,d=OptionSmgcv.vc.logrange,b=1/d)
```
null.space.dimension

Arguments

- **x**: Argument array of real numbers (notExp) or positive real numbers (notLog).
- **d**: the range of notExp runs from \( \exp(-d) \) to \( \exp(d) \). To change the range used by `gamm` reset `mgcv.vc.logrange` using `options`.
- **b**: determines the period of the cycle of notExp.

Value

An array of function values evaluated at the supplied argument values.

null.space.dimension

The basis of the space of un-penalized functions for a TPRS

Description

The thin plate spline penalties give zero penalty to some functions. The space of these functions is spanned by a set of polynomial terms. `null.space.dimension` finds the dimension of this space, \( M \), given the number of covariates that the smoother is a function of, \( d \), and the order of the smoothing penalty, \( m \). If \( m \) does not satisfy \( 2m > d \) then the smallest possible dimension for the null space is found given \( d \) and the requirement that the smooth should be visually smooth.
Usage

null.space.dimension(d,m)

Arguments

d  
is a positive integer - the number of variables of which the t.p.s. is a function.

m  
a non-negative integer giving the order of the penalty functional, or signalling that the default order should be used.

Details

Thin plate splines are only visually smooth if the order of the wigginess penalty, m, satisfies \(2^m > d + 1\). If \(2^m < d + 1\) then this routine finds the smallest \(m\) giving visual smoothness for the given \(d\), otherwise the supplied \(m\) is used. The null space dimension is given by:

\[ M = \frac{(m + d + 1)!}{d!(m - d)!} \]

which is the value returned.

Value

An integer (array), the null space dimension \(M\).

Examples

null.space.dimension(2,0)

pcls

Penalized Constrained Least Squares Fitting

Description

Solves least squares problems with quadratic penalties subject to linear equality and inequality constraints using quadratic programming.

Usage

pcls(M)
Arguments

\( M \) is the single list argument to \texttt{pcls}. It should have the following elements:

- \( y \) The response data vector.
- \( w \) A vector of weights for the data (often proportional to the reciprocal of the variance).
- \( X \) The design matrix for the problem, note that \( ncol(M \cdot X) \) must give the number of model parameters, while \( nrow(M \cdot X) \) should give the number of data.
- \( C \) Matrix containing any linear equality constraints on the problem (e.g. \( C \cdot p = c \)). If you have no equality constraints initialize this to a zero by zero matrix. Note that there is no need to supply the vector \( c \), it is defined implicitly by the initial parameter estimates \( p \).
- \( S \) A list of penalty matrices. \( S[[i]] \) is the smallest contiguous matrix including all the non-zero elements of the \( i \)th penalty matrix. The first parameter it penalizes is given by \( \text{off}[i]+1 \) (starting counting at 1).
- \( \text{off} \) Offset values locating the elements of \( M \cdot S \) in the correct location within each penalty coefficient matrix. (Zero offset implies starting in first location)
- \( sp \) An array of smoothing parameter estimates.
- \( p \) An array of feasible initial parameter estimates - these must satisfy the constraints, but should avoid satisfying the inequality constraints as equality constraints.
- \( \text{Ain} \) Matrix for the inequality constraints \( A_{in} \cdot p > b_{in} \).
- \( \text{bin} \) vector in the inequality constraints.

Details

This solves the problem:

\[
\text{minimise} \quad \| W^{1/2}(X \cdot p - y) \|^2 + \sum_{i=1}^{m} \lambda_i \cdot p'S_i p
\]

subject to constraints \( C \cdot p = c \) and \( A_{in} \cdot p > b_{in} \), w.r.t. \( p \) given the smoothing parameters \( \lambda_i \). \( X \) is a design matrix, \( p \) a parameter vector, \( y \) a data vector, \( W \) a diagonal weight matrix, \( S_i \) a positive semi-definite matrix of coefficients defining the \( i \)th penalty and \( C \) a matrix of coefficients defining the linear equality constraints on the problem. The smoothing parameters are the \( \lambda_i \). Note that \( X \) must be of full column rank, at least when projected into the null space of any equality constraints. \( A_{in} \) is a matrix of coefficients defining the inequality constraints, while \( b_{in} \) is a vector involved in defining the inequality constraints.

Quadratic programming is used to perform the solution. The method used is designed for maximum stability with least squares problems: i.e. \( X'X \) is not formed explicitly. See Gill et al. 1981.

Value

The function returns an array containing the estimated parameter vector.

**pdIdnot**

*Overflow proof pdMat class for multiples of the identity matrix*

### Description

This set of functions is a modification of the `pdMat` class `pdIdent` from library `nlme`. The modification is to replace the log parameterization used in `pdMat` with a `notLog2` parameterization, since the latter avoids indefiniteness in the likelihood and associated convergence problems: the parameters also relate to variances rather than standard deviations, for consistency with the `pdTens` class. The functions are particularly useful for working with Generalized Additive Mixed Models where variance parameters/smoothing parameters can be very large or very small, so that overflow or underflow can be a problem.

These functions would not normally be called directly, although unlike the `pdTens` class it is easy to do so.

### Usage

```r
pdIdnot(value = numeric(0), form = NULL,
         nam = NULL, data = sys.frame(sys.parent()))
```

### Arguments

- **value**: Initialization values for parameters. Not normally used.
- **form**: A one sided formula specifying the random effects structure.
- **nam**: A names argument, not normally used with this class.
- **data**: Data frame in which to evaluate formula.

### Details

Note that while the `pdFactor` and `pdMatrix` functions return the inverse of the scaled random effect covariance matrix or its factor, the `pdConstruct` function is initialised with estimates of the scaled covariance matrix itself.

### Value

A class `pdIdnot` object, or related quantities. See the `nlme` documentation for further details.

### Author(s)

Simon N. Wood (simon.wood@r-project.org)

**pdTens**

*Functions implementing a pdMat class for tensor product smooths*

Description

This set of functions implements an nlme library pdMat class to allow tensor product smooths to be estimated by lme as called by gamm. Tensor product smooths have a penalty matrix made up of a weighted sum of penalty matrices, where the weights are the smoothing parameters. In the mixed model formulation the penalty matrix is the inverse of the covariance matrix for the random effects of a term, and the smoothing parameters (times a half) are variance parameters to be estimated. It’s not possible to transform the problem to make the required random effects covariance matrix look like one of the standard pdMat classes: hence the need for the pdTens class. A notLog2 parameterization ensures that the parameters are positive.

These functions (pdTens, pdConstruct.pdTens, pdFactor.pdTens, pdMatrix.pdTens, coef.pdTens and summary.pdTens) would not normally be called directly.

Usage

```r
pdTens(value = numeric(0), form = NULL,
       nam = NULL, data = sys.frame(sys.parent()))
```

Arguments

- value: Initialization values for parameters. Not normally used.
- form: A one sided formula specifying the random effects structure. The formula should have an attribute S which is a list of the penalty matrices the weighted sum of which gives the inverse of the covariance matrix for these random effects.
- nam: a names argument, not normally used with this class.
- data: data frame in which to evaluate formula.
place.knots

Details

If using this class directly note that it is worthwhile scaling the $S$ matrices to be of ‘moderate size’, for example by dividing each matrix by its largest singular value: this avoids problems with lme defaults (\ref{smooth.construct.tensor.smooth.spec} does this automatically).

This appears to be the minimum set of functions required to implement a new \texttt{pdMat} class.

Note that while the \texttt{pdFactor} and \texttt{pdMatrix} functions return the inverse of the scaled random effect covariance matrix or its factor, the \texttt{pdConstruct} function is sometimes initialised with estimates of the scaled covariance matrix, and sometimes intialized with its inverse.

Value

A class \texttt{pdTens} object, or its coefficients or the matrix it represents or the factor of that matrix. \texttt{pdFactor} returns the factor as a vector (packed column-wise) (\texttt{pdMatrix} always returns a matrix).

place.knots \hspace{1cm} \textit{Automatically place a set of knots evenly through covariate values}

Description

Given a univariate array of covariate values, places a set of knots for a regression spline evenly through the covariate values.

Usage

\texttt{place.knots(x,nk)}

Arguments

\begin{itemize}
  \item \texttt{x} \hspace{1cm} array of covariate values (need not be sorted).
  \item \texttt{nk} \hspace{1cm} integer indicating the required number of knots.
\end{itemize}
plot.gam

Details

Places knots evenly throughout a set of covariates. For example, if you had 11 covariate values and wanted 6 knots then a knot would be placed at the first (sorted) covariate value and every second (sorted) value thereafter. With less convenient numbers of data and knots the knots are placed within intervals between data in order to achieve even coverage, where even means having approximately the same number of data between each pair of knots.

Value

An array of knot locations.

rm(x)

plot.gam

Default GAM plotting

Description

Takes a fitted gam object produced by gam() and plots the component smooth functions that make it up, on the scale of the linear predictor. Optionally produces term plots for parametric model components as well.

Usage

## S3 method for class 'gam':
plot(x,residuals=FALSE,rug=TRUE,se=TRUE,pages=0,select=NULL,scale=-1,
n=100,n2=40,pers=FALSE,theta=30,phi=30,jit=FALSE,xlab=NULL,
ylab=NULL,main=NULL,ylim=NULL,xlim=NULL,too.far=0.1,
all.terms=FALSE,shade=FALSE,shade.col="gray80",
shift=0,trans=I,...)
Arguments

x
a fitted \texttt{gam} object as produced by \texttt{gam()}. 

residuals
If \texttt{TRUE} then partial residuals are added to plots of 1-D smooths. If \texttt{FALSE} then no residuals are added. If this is an array of the correct length then it is used as the array of residuals to be used for producing partial residuals. If \texttt{TRUE} then the residuals are the working residuals from the IRLS iteration weighted by the IRLS weights. Partial residuals for a smooth term are the residuals that would be obtained by dropping the term concerned from the model, while leaving all other estimates fixed (i.e. the estimates for the term plus the residuals).

rug
when \texttt{TRUE} (default) then the covariate to which the plot applies is displayed as a rug plot at the foot of each plot of a 1-d smooth, and the locations of the covariates are plotted as points on the contour plot representing a 2-d smooth.

se
when \texttt{TRUE} (default) upper and lower lines are added to the 1-d plots at 2 standard errors above and below the estimate of the smooth being plotted while for 2-d plots, surfaces at +1 and -1 standard errors are contoured and overlayed on the contour plot for the estimate. If a positive number is supplied then this number is multiplied by the standard errors when calculating standard error curves or surfaces. See also \texttt{shade}, below.

pages
(default 0) the number of pages over which to spread the output. For example, if \texttt{pages=1} then all terms will be plotted on one page with the layout performed automatically. Set to 0 to have the routine leave all graphics settings as they are.

select
Allows the plot for a single model term to be selected for printing. e.g. if you just want the plot for the second smooth term set \texttt{select=2}.

scale
set to -1 (default) to have the same y-axis scale for each plot, and to 0 for a different y axis for each plot. Ignored if \texttt{ylim} supplied.

n
number of points used for each 1-d plot - for a nice smooth plot this needs to be several times the estimated degrees of freedom for the smooth. Default value 100.

n2
Square root of number of points used to grid estimates of 2-d functions for contouring.

pers
Set to \texttt{TRUE} if you want perspective plots for 2-d terms.

theta
One of the perspective plot angles.

phi
The other perspective plot angle.

jit
Set to \texttt{TRUE} if you want rug plots for 1-d terms to be jittered.

xlab
If supplied then this will be used as the x label for all plots.

ylab
If supplied then this will be used as the y label for all plots.

main
Used as title (or z axis label) for plots if supplied.

ylim
If supplied then this pair of numbers are used as the y limits for each plot.

xlim
If supplied then this pair of numbers are used as the x limits for each plot.

too.far
If greater than 0 then this is used to determine when a location is too far from data to be plotted when plotting 2-D smooths. This is useful since smooths tend to go wild away from data. The data are scaled into the unit square before deciding what to exclude, and \texttt{too.far} is a distance within the unit square.

all.terms
if set to \texttt{TRUE} then the partial effects of parametric model components are also plotted, via a call to \texttt{termplot}. Only terms of order 1 can be plotted in this way.
shade
Set to TRUE to produce shaded regions as confidence bands for smooths (not available for parametric terms, which are plotted using \texttt{termplot}).

shade.col
define the color used for shading confidence bands.

shift
constant to add to each smooth (on the scale of the linear predictor) before plotting. Can be useful for some diagnostics, or with \texttt{trans}.

trans
function to apply to each smooth (after any shift), before plotting. \texttt{shift} and \texttt{trans} are occasionally useful as a means for getting plots on the response scale, when the model consists only of a single smooth.

...other graphics parameters to pass on to plotting commands.

Details

Produces default plot showing the smooth components of a fitted GAM, and optionally parametric terms as well, when these can be handled by \texttt{termplot}.

For plots of 1-d smooths, the x axis of each plot is labelled with the covariate name, while the y axis is labelled \(s(\texttt{cov},\texttt{edf})\) where \texttt{cov} is the covariate name, and \texttt{edf} the estimated (or user defined for regression splines) degrees of freedom of the smooth.

Contour plots are produced for 2-d smooths with the x-axes labelled with the first covariate name and the y axis with the second covariate name. The main title of the plot is something like \(s(\texttt{var1},\texttt{var2},\texttt{edf})\), indicating the variables of which the term is a function, and the estimated degrees of freedom for the term. When \texttt{se=TRUE}, estimator variability is shown by overlaying contour plots at plus and minus 1 s.e. relative to the main estimate. If \texttt{se} is a positive number then contour plots are at plus or minus \texttt{se} multiplied by the s.e. Contour levels are chosen to try and ensure reasonable separation of the contours of the different plots, but this is not always easy to achieve. Note that these plots can not be modified to the same extent as the other plot.

Smoothes of more than 2 variables are not currently dealt with, but simply generate a warning, but see \texttt{vis.gam}.

Fine control of plots for parametric terms can be obtained by calling \texttt{termplot} directly, taking care to use its \texttt{terms} argument.

Value

The function simply generates plots.

WARNING

Note that the behaviour of this function is not identical to \texttt{plot.gam()} in S-PLUS.

Plots of 2-D smooths with standard error contours shown can not easily be customized.

The function can not deal with smooths of more than 2 variables!

Author(s)

Simon N. Wood (simon.wood@r-project.org)

Henric Nilsson (henric.nilsson@statisticon.se) donated the code for the \texttt{shade} option.

The design is inspired by the S function of the same name described in Chambers and Hastie (1993) (but is not a clone).

predict.gam          Prediction from fitted GAM model

Description

Takes a fitted `gam` object produced by `gam()` and produces predictions given a new set of values for
the model covariates or the original values used for the model fit. Predictions can be accompanied
by standard errors, based on the posterior distribution of the model coefficients. The routine can
optionally return the matrix by which the model coefficients must be pre-multiplied in order to
yield the values of the linear predictor at the supplied covariate values: this is useful for obtaining
credible regions for quantities derived from the model, and for lookup table prediction outside R
(see example code below).

Usage

## S3 method for class 'gam':
predict(object,newdata,type="link",se.fit=FALSE,terms=NULL,
        block.size=1000,newdata.guaranteed=FALSE,na.action=na.pass,...)

Arguments

object  a fitted `gam` object as produced by `gam()`.
newdata A data frame containing the values of the model covariates at which predictions
         are required. If this is not provided then predictions corresponding to the original
         data are returned. If `newdata` is provided then it should contain all the
         variables needed for prediction: a warning is generated if not.

se.fit  when this is TRUE (not default) standard error estimates are returned for each
         prediction.

Examples

## example with 2-d plots...
b1<-gam(y~x0+s(x1,x2)+s(x3))
opt<-par(mfrow=c(2,2))
plot(b1,all.terms=TRUE)
par(opt)
predict.gam

terms if type=="terms" then only results for the terms given in this array will be returned.

block.size maximum number of predictions to process per call to underlying code: larger is quicker, but more memory intensive. Set to < 1 to use total number of predictions as this.

newdata.guaranteed Set to TRUE to turn off all checking of newdata except for sanity of factor levels: this can speed things up for large prediction tasks, but newdata must be complete, with no NA values for predictors required in the model.

na.action what to do about NA values in newdata. With the default na.pass, any row of newdata containing NA values for required predictors, gives rise to NA predictions (even if the term concerned has no NA predictors). na.exclude or na.omit result in the dropping of newdata rows, if they contain any NA values for required predictors. If newdata is missing then NA handling is determined from object$na.action.

... other arguments.

Details

The standard errors produced by predict.gam are based on the Bayesian posterior covariance matrix of the parameters Vp in the fitted gam object.

To facilitate plotting with termplot, if object possesses an attribute "para.only" and type=="terms" then only parametric terms of order 1 are returned (i.e. those that termplot can handle).

Note that, in common with other prediction functions, any offset supplied to gam as an argument is always ignored when predicting, unlike offsets specified in the gam model formula.

See the examples for how to use the lpmatrix for obtaining credible regions for quantities derived from the model.

Value

If type=="lpmatrix" then a matrix is returned which will give a vector of linear predictor values (minus any offset) at the supplied covariate values, when applied to the model coefficient vector. Otherwise, if se.fit is TRUE then a 2 item list is returned with items (both arrays) fit and se.fit containing predictions and associated standard error estimates, otherwise an array of predictions is returned. The dimensions of the returned arrays depends on whether type is "terms" or not: if it is then the array is 2 dimensional with each term in the linear predictor separate, otherwise the array is 1 dimensional and contains the linear predictor/predicted values (or corresponding s.e.s). The linear predictor returned termwise will not include the offset or the intercept.

newdata can be a data frame, list or model.frame: if it’s a model frame then all variables must be supplied.

WARNING

Note that the behaviour of this function is not identical to predict.gam() in Splus.

type="terms" does not exactly match what predict.lm does for parametric model components.

mean(res); var(res)

## loop is replace-able by following ....
res <- colSums(log(abs(Xp %*% t(br))))

## The following shows how to use use an "lpmatrix" as a lookup
## table for approximate prediction. The idea is to create
## approximate prediction matrix rows by appropriate linear
## interpolation of an existing prediction matrix. The additivity
## of a GAM makes this possible.
## There is no reason to ever do this in R, but the following
## code provides a useful template for predicting from a fitted
## gam *outside* R: all that is needed is the coefficient vector
## and the prediction matrix. Use larger `Xp'/ smaller `dx' and/or
## higher order interpolation for higher accuracy.

xn <- c(.341, .122, .476, .981) ## want prediction at these values
x0 <- 1 ## intercept column
dx <- 1/30 ## covariate spacing in `newd'
for (j in 0:2) { ## loop through smooth terms
   cols <- 1+j*9+1:9 ## relevant cols of Xp
   i <- floor(xn[j+1]*30) ## find relevant rows of Xp
   w1 <- (xn[j+1]-i*dx)/dx ## interpolation weights
   ## find approx. predict matrix row portion, by interpolation
   x0 <- c(x0, Xp[i+2, cols]*w1 + Xp[i+1, cols]*(1-w1))
}
dim(x0)<-c(1,28)
fv <- x0%*%coef(b) + xn[4]; fv  ## evaluate and add offset
se <- sqrt(x0%*%b$Vp%*%t(x0)); se ## get standard error
## compare to normal prediction
predict(b, newdata=data.frame(x0=xn[1], x1=xn[2], x2=xn[3], x3=xn[4]), se=TRUE)

---

Predict.matrix  

Prediction methods for smooth terms in a GAM

Description

Takes smooth objects produced by smooth.construct methods and obtains the matrix mapping the parameters associated with such a smooth to the predicted values of the smooth at a set of new covariate values.

In practice this method is often called via the wrapper function PredictMat.
Usage

`Predict.matrix(object, data)`

Arguments

- `object` is a smooth object produced by a `smooth.construct` method function. The object contains all the information required to specify the basis for a term of its class, and this information is used by the appropriate `Predict.matrix` function to produce a prediction matrix for new covariate values. Further details are given in `smooth.construct`.

- `data` A data frame containing the values of the (named) covariates at which the smooth term is to be evaluated.

Details

Smooth terms in a GAM formula are turned into smooth specification objects of class `xx.smooth.spec` during processing of the formula. Each of these objects is converted to a smooth object using an appropriate `smooth.construct` function. The `Predict.matrix` functions are used to obtain the matrix that will map the parameters associated with a smooth term to the predicted values for the term at new covariate values.

Note that new smooth classes can be added by writing a new `smooth.construct` method function and a corresponding `Predict.matrix` method function: see the example code provided for `smooth.construct` for details.

Value

A matrix which will map the parameters associated with the smooth to the vector of values of the smooth evaluated at the covariate values given in `object`.

print.gam

Generalized Additive Model default print statement

Description

This is the default print statement for a GAM object. If you need a list of everything that is part of a gam object see gam, or use names(). The family (including link), model formula, and estimated degrees of freedom for each model term (plus total) are printed, as well as the minimized GCV or UBRE score, depending on which was used.

residuals.gam

Generalized Additive Model residuals

Description

Returns residuals for a fitted gam model object. Pearson, deviance, working and response residuals are available.

Usage

## S3 method for class 'gam':
residuals(object, type = c("deviance", "pearson", "scaled.pearson", "working", "response"), ...)

Arguments

object  a gam fitted model object.

b       the type of residuals wanted.

...     other arguments.
Details

Response residuals are the raw residuals (data minus fitted values). Scaled Pearson residuals are raw residuals divided by the standard deviation of the data according to the model mean variance relationship and estimated scale parameter. Pearson residuals are the same, but multiplied by the square root of the scale parameter (so they are independent of the scale parameter): \( \frac{(y-\mu)}{\sqrt{V(\mu)}} \), where \( y \) is data \( \mu \) is model fitted value and \( V \) is model mean-variance relationship.). Both are provided since not all texts agree on the definition of Pearson residuals. Deviance residuals simply return the deviance residuals defined by the model family. Working residuals are the residuals returned from model fitting at convergence.

There is a special function for \texttt{gam} objects because of a bug in the calculation of Pearson residuals in some earlier versions of \texttt{residual.glm}.

Value

An array of residuals.

\texttt{gam}

\begin{verbatim}
\texttt{s} \qquad \textit{Defining smooths in GAM formulae}
\end{verbatim}

Description

Function used in definition of smooth terms within \texttt{gam} model formulae. The function does not evaluate a (spline) smooth - it exists purely to help set up a model using spline based smooths.

Usage

\begin{verbatim}
s(..., k=-1, fx=FALSE, bs="tp", m=0, by=NA)
\end{verbatim}

Arguments

\begin{itemize}
  \item \ldots a list of variables that are the covariates that this smooth is a function of.
  \item \texttt{k} the dimension of the basis used to represent the smooth term. The default depends on the number of variables that the smooth is a function of. \texttt{k} should not be less than the dimension of the null space of the penalty for the term (see \texttt{null.space.dimension}), but will be reset if it is. See \texttt{choose.k} for further information.
  \item \texttt{fx} indicates whether the term is a fixed d.f. regression spline (\texttt{TRUE}) or a penalized regression spline (\texttt{FALSE}).
\end{itemize}
bs
this can be "cr" for a cubic regression spline, "cs" for a cubic regression spline with shrinkage, "cc" for a cyclic (periodic) spline, "tp" for a thin plate regression spline, "ts" for a thin plate regression spline with shrinkage or a user defined character string for other user defined smooth classes. Of the built in alternatives, only thin plate regression splines can be used for multidimensional smooths. Note that the "cr" and "cc" bases are faster to set up than the "tp" basis, particularly on large data sets (although the knots argument to gam can be used to get round this).

m
The order of the penalty for this t.p.r.s. term (e.g. 2 for normal cubic spline penalty with 2nd derivatives). 0 signals autoinitialization, which sets the order to the lowest value satisfying 2m>d+1, where d is the number of covariates: this choice ensures visual smoothness. In addition, m must satisfy the technical restriction 2m>d, otherwise it will be autoinitialized.

by
specifies a covariate by which the whole smooth term is to be multiplied. This is particularly useful for creating models in which a smooth interacts with a factor: in this case the by variable would usually be the dummy variable coding one level of the factor. See the examples below. This is the means by which ‘variable coefficient models’ can be specified.

Details
The function does not evaluate the variable arguments. To use this function to specify use of your own smooths, note the relationships between the inputs and the output object and see the example in smooth.construct.

Value
A class xx.smooth.spec object, where xx is a basis identifying code given by the bs argument of s. These smooth.spec objects define smooths and are turned into bases and penalties by smooth.construct method functions.

The returned object contains the following items:

term
An array of text strings giving the names of the covariates that the term is a function of.

bs.dim
The dimension of the basis used to represent the smooth.

fixed
TRUE if the term is to be treated as a pure regression spline (with fixed degrees of freedom); FALSE if it is to be treated as a penalized regression spline.

dim
The dimension of the smoother - i.e. the number of covariates that it is a function of.

p.order
The order of the t.p.r.s. penalty, or 0 for auto-selection of the penalty order.

by
is the name of any by variable as text ("NA" for none).

full.call
Text for pasting into a string to be converted to a gam formula, which has the values of function options given explicitly - this is useful for constructing a fully expanded gam formula which can be used without needing access to any variables that may have been used to define k, fx, bs or m in the original call. i.e. this is text which when parsed and evaluated generates a call to s() with all the options spelled out explicitly.

label
A suitable text label for this smooth term.

Examples

# example utilising 'by' variables
library(mgcv)
set.seed(0)
n<-200; sig2<-4
x1 <- runif(n, 0, 1); x2 <- runif(n, 0, 1); x3 <- runif(n, 0, 1)
fac<-c(rep(1,n/2),rep(2,n/2)) # create factor
fac.1<-rep(0,n)+(fac==1); fac.2<-1-fac.1 # and dummy variables
fac<-as.factor(fac)
f1 <- exp(2 * x1) - 3.75887
f2 <- 0.2 * x1^11 * (10 * (1 - x1))^6 + 10 * (10 * x1)^3 * (1 - x1)^10
f <- f1*fac.1+f2*fac.2+x2
e <- rnorm(n, 0, sqrt(abs(sig2)))
y <- f + e # NOTE: smooths will be centered, so need to include fac in model....
b<-gam(y~fac+s(x1,by=fac.1)+s(x1,by=fac.2)+x2)
plot(b,pages=1)
Arguments

`object` is a smooth specification object, generated by an `s` or `te` term in a GAM formula. Objects generated by `s` terms have class `xx.smooth.spec` where `xx` is given by the `bs` argument of `s` (this convention allows the user to add their own smoothers). If `object` is not class `tensor.smooth.spec` it will have the following elements:

- **term** The names of the covariates for this smooth, in an array.
- **bs.dim** Argument `k` of the `s` term generating the object. This is the dimension of the basis used to represent the term (or, arguably, 1 greater than the basis dimension for `cc` terms).
- **fixed** TRUE if the term is to be unpenalized, otherwise FALSE.
- **dim** the number covariates of which this smooth is a function.
- **p.order** the order of the smoothness penalty or 0 for autoselection of this. This is argument `m` of the `s` term that generated `object`.
- **by** the name of any `by` variable to multiply this term as supplied as an argument to `s`. "NA" if there is no such term.
- **full.call** The full version of the `s` term, with all defaults expanded explicitly.
- **label** A suitable label for use with this term.
- **null.space.dim** The dimension of the null space of the wiggliness penalty.

If `object` is of class `tensor.smooth.spec` then it was generated by a `te` term in the GAM formula, and specifies a smooth of several variables with a basis generated as a tensor product of lower dimensional bases. In this case the object will be different and will have the following elements:

- **margin** is a list of smooth specification objects of the type listed above, defining the bases which have their tensor product formed in order to construct this term.
- **term** is the array of names of the covariates that are arguments of the smooth.
- **by** is the name of any `by` variable, or "NA".
- **fx** is an array, the elements of which indicate whether (TRUE) any of the margins in the tensor product should be unpenalized.
- **full.call** The full version of the `s` term, with all defaults expanded explicitly.
- **label** A suitable label for use with this term.
- **dim** is the number of covariates of which this smooth is a function.
- **mp** TRUE if multiple penalties are to be used.
- **np** TRUE if 1-D marginal smooths are to be re-parameterized in terms of function values.

**Details**

The returned objects for the built-in smooth classes have the following extra elements. `cr.smooth` objects (generated using `bs="cr"`) have an additional array `xp` giving the knot locations used to generate the basis.

`cyclic.smooth` objects (generated using `bs="cc"`) have an array `xp` of knot locations and a matrix `BD` used to define the basis (BD transforms function values at the knots to second derivatives at the knots).

`tprs.smooth` objects require several items to be stored in order to define the basis. These are:
A record of the shift applied to each covariate in order to center it around zero and avoid any co-linearity problems that might otherwise occur in the penalty null space basis of the term.

A matrix of the unique covariate combinations for this smooth (the basis is constructed by first stripping out duplicate locations).

The matrix mapping the t.p.r.s. parameters back to the parameters of a full thin plate spline.

The dimension of the space of functions that have zero wiggliness according to the wiggliness penalty for this term.

Again, these extra elements would be found in the elements of the margin list of tensor.smooth class object.

The classes cs.smooth and ts.smooth are modifications of the classes cr.smooth and tprs.smooth respectively: they differ only in having an extra shrinkage component added to their penalties, so that automatic model selection can effectively remove such terms from a model altogether.

The input argument object, assigned a new class to indicate what type of smooth it is and with at least the following items added:

- **X**: The model matrix from this term.
- **C**: The matrix defining any constraints on the term - usually a one row matrix giving the column sums of the model matrix, which defines the constraint that each term should sum to zero over the covariate values.
- **S**: A list of positive semi-definite penalty matrices that apply to this term. The list will be empty if the term is to be left un-penalized.
- **rank**: an array giving the ranks of the penalties.
- **df**: the degrees of freedom associated with this term (at least when unpenalized).

Usually the returned object will also include extra information required to define the basis, and used by Predict.matrix methods to make predictions using the basis. See the Details section for the information included for the built in smooth classes.

Tensor.smooth returned objects will additionally have each element of the margin list updated in the same way. Tensor.smooths also have a list, XP, containing re-parameterization matrices for any 1-D marginal terms re-parameterized in terms of function values. This list will have NULL entries for marginal smooths that are not re-parameterized, and is only long enough to reach the last re-parameterized marginal in the list.

User defined smooth objects should avoid having attributes names "qrc" or "nCons" as these are used internally to provide constraint free parameterizations.

smoothCon

Prediction/Construction wrapper functions for GAM smooth terms

Description

Wrapper functions for construction of and prediction from smooth terms in a GAM. The purpose of the wrappers is to allow user-transparent re-parameterization of smooth terms, in order to allow identifiability constraints to be absorbed into the parameterization of each term, if required.

Usage

smoothCon(object, data, knots, absorb.cons = FALSE, scale.penalty = TRUE)
PredictMat(object, data)
Arguments

object
is a smooth specification object or a smooth object.
data
A data frame containing the values of the (named) covariates at which the smooth term is to be evaluated.
knots
An optional data frame supplying any knot locations to be supplied for basis construction.
absorb.cons
Set to TRUE in order to have identifiability constraints absorbed into the basis.
scale.penalty
should the penalty coefficient matrix be scaled to have approximately the same 'size' as the inner product of the terms model matrix with itself? This can improve the performance of \texttt{gamm} fitting.

Details

These wrapper functions exist to allow smooths specified using \texttt{smooth.construct} and \texttt{Predict.matrix} method functions to be re-parameterized so that identifiability constraints are no longer required in fitting. This is done in a user transparent manner, but is typically of no importance in use of GAMs.

The parameterization used by \texttt{gam} can be controlled via \texttt{gam.control}.

Value

From \texttt{smoothCon} a \texttt{smooth} object returned by the appropriate \texttt{smooth.construct} method function. If constraints are to be absorbed then the object will have attributes "\texttt{qrc}" and "\texttt{nCons}". the qr decomposition of the constraint matrix (returned by \texttt{qr}) and the number of constraints, respectively: these are used in the re-parameterization.

For \texttt{predictMat} a matrix which will map the parameters associated with the smooth to the vector of values of the smooth evaluated at the covariate values given in \texttt{object}.

\texttt{gam.control, smooth.construct, Predict.matrix}
Alternatives to step.gam

Description

There is no step.gam in package mgcv. The mgcv default for model selection is to use MSE/KL-distance criteria such as GCV or UBRE/AIC. Since the smoothness estimation part of model selection is done in this way it is logically most consistent to perform model selection on the basis of such criteria: i.e. to decide which terms to include or omit by looking at changes in GCV/UBRE score.

To facilitate fully automatic model selection the package includes 2 classes of smoothers ("cs" and "ts": see s) which can be penalized to zero for sufficiently high smoothing parameter estimates: use of such smooths provides an effective alternative to step-wise model selection. The example below shows an example of the application of this approach, where selection is a fully integrated part of model estimation.

Author(s)

Simon N. Wood ⟨simon.wood@r-project.org⟩

Examples

```r
## an example of GCV based model selection as
## an alternative to stepwise selection
library(mgcv)
set.seed(0)
n<-400; sig<-2
x0 <- runif(n, 0, 1); x1 <- runif(n, 0, 1)
x2 <- runif(n, 0, 1); x3 <- runif(n, 0, 1)
x4 <- runif(n, 0, 1); x5 <- runif(n, 0, 1)
f <- 2 + sin(pi * x0)
f <- f + exp(2 * x1) - 3.75887
f <- f + 0.2 * x2^11 * (10 * (1 - x2))^6 + 10 * (10 * x2)^3 * (1 - x2)^10 - 1.396
e <- rnorm(n, 0, sig)
y <- f + e
## Note the increased gamma parameter below to favour
## slightly smoother models...
b<-gam(y~s(x0,bs="ts") + s(x1,bs="ts") + s(x2,bs="ts") +
    s(x3,bs="ts") + s(x4,bs="ts") + s(x5,bs="ts"), gamma=1.4)
summary(b)
plot(b, pages=1)
```

Summary for a GAM fit

Description

Takes a fitted gam object produced by gam() and produces various useful summaries from it.
## Usage

```r
## S3 method for class 'gam':
summary(object, dispersion=NULL, freq=TRUE, ...)
## S3 method for class 'summary.gam':
print(x,digits = max(3, getOption("digits") - 3),
      signif.stars = getOption("show.signif.stars"),...)
```

### Arguments

- `object` a fitted `gam` object as produced by `gam()`.
- `x` a `summary.gam` object produced by `summary.gam()`.
- `dispersion` A known dispersion parameter. NULL to use estimate or default (e.g. 1 for Poisson).
- `freq` By default p-values for individual terms are calculated using the frequentist estimated covariance matrix of the parameter estimators. If this is set to FALSE then the Bayesian covariance matrix of the parameters is used instead. See details.
- `digits` controls number of digits printed in output.
- `signif.stars` Should significance stars be printed alongside output.
- `...` other arguments.

### Details

Model degrees of freedom are taken as the trace of the influence (or hat) matrix $A$ for the model fit. Residual degrees of freedom are taken as number of data minus model degrees of freedom. Let $P_i$ be the matrix giving the parameters of the ith smooth when applied to the data (or pseudodata in the generalized case) and let $X$ be the design matrix of the model. Then $\text{tr}(XP_i)$ is the edf for the ith term. Clearly this definition causes the edf’s to add up properly!

`print.summary.gam` tries to print various bits of summary information useful for term selection in a pretty way.

If freq=FALSE then the Bayesian parameter covariance matrix, `object$Vp`, is used to calculate test statistics for terms, and the degrees of freedom for reference distributions is taken as the estimated degrees of freedom for the term concerned. This is not easy to justify theoretically, and the resulting ‘Bayesian p-values’ are difficult to interpret and often have much worse frequentist performance than the default p-values.

### Value

`summary.gam` produces a list of summary information for a fitted `gam` object.

- `p.coef` is an array of estimates of the strictly parametric model coefficients.
- `p.t` is an array of the `p.coef`’s divided by their standard errors.
- `p.pv` is an array of p-values for the null hypothesis that the corresponding parameter is zero. Calculated with reference to the t distribution with the estimated residual degrees of freedom for the model fit if the dispersion parameter has been estimated, and the standard normal if not.
- `m` The number of smooth terms in the model.
An array of test statistics for assessing the significance of model smooth terms. If \( p_i \) is the parameter vector for the \( i \)th smooth term, and this term has estimated covariance matrix \( V_i \) then the statistic is \( p_i' V_i^{-1} p_i \), where \( V_i^{-1} \) is the rank \( k \) pseudo-inverse of \( V_i \), and \( k \) is estimated rank of \( V_i \).

An array of approximate p-values for the null hypotheses that each smooth term is zero. Be warned, these are only approximate. In the case of known dispersion parameter, they are obtained by comparing the chi.sq statistic given above to the chi-squared distribution with \( k \) degrees of freedom, where \( k \) is the estimated rank of \( V_i \). If the dispersion parameter is unknown (in which case it will have been estimated) the statistic is compared to an F distribution with \( k \) upper d.f. and lower d.f. given by the residual degrees of freedom for the model. Typically the p-values will be somewhat too low, because they are conditional on the smoothing parameters, which are usually uncertain, but note that the statistic can also have low power if the rank, \( k \), is too high relative to the EDF of the term!

Array of standard error estimates for all parameter estimates.

The adjusted r-squared for the model. Defined as the proportion of variance explained, where original variance and residual variance are both estimated using unbiased estimators. This quantity can be negative if your model is worse than a one parameter constant model, and can be higher for the smaller of two nested models! Note that proportion null deviance explained is probably more appropriate for non-normal errors.

The proportion of the null deviance explained by the model.

Array of estimated degrees of freedom for the model terms.

Number of data.

Minimized GCV score for the model, if GCV used.

Minimized UBRE score for the model, if UBRE used.

Estimated (or given) scale parameter.

The original GAM formula.

The scale parameter.

The degrees of freedom associated with each parametric term (excluding the constant).

A Wald statistic for testing the null hypothesis that the each parametric term is zero.

p-values associated with the tests that each term is zero. For penalized fits these are approximate, being conditional on the smoothing parameters. The reference distribution is an appropriate chi-squared when the scale parameter is known, and is based on an F when it is not.

The estimated covariance matrix of the parameters (or estimators if freq=TRUE), divided by scale parameter.

The estimated covariance matrix of the parameters (estimators if freq=TRUE).

Significance table for parameters

Significance table for smooths

Significance table for parametric model terms
WARNING

The supplied p-values will often be underestimates if smoothing parameters have been estimated as part of model fitting.

Define tensor product smooths in GAM formulae

Description

Function used in definition of tensor product smooth terms within gam model formulae. The function does not evaluate a smooth - it exists purely to help set up a model using tensor product based smooths.

Usage

te(..., k=NA, bs="cr", m=0, d=NA, by=NA, fx=FALSE, mp=TRUE, np=TRUE)

Arguments

... a list of variables that are the covariates that this smooth is a function of.

k the dimension(s) of the bases used to represent the smooth term. If not supplied then set to 5^d. If supplied as a single number then this basis dimension is used for each basis. If supplied as an array then the elements are the dimensions of the component (marginal) bases of the tensor product. See choose.k for further information.

bs array (or single character string) specifying the type for each marginal basis. "cr" for cubic regression spline; "cs" for cubic regression spline with shrinkage; "cc" for periodic/cyclic cubic regression spline; "tp" for thin plate regression spline; "ts" for t.p.r.s. with extra shrinkage. User defined bases can also be used here (see smooth.construct for an example). If only one identifier is given then this is used for all bases.

m The order of the penalty for each t.p.r.s. term (e.g. 2 for normal cubic spline penalty with 2nd derivatives). If a single number is given then it is used for all terms. 0 autoinitializes. m is ignored for the "cr" and "cc" bases.

d array of marginal basis dimensions. For example if you want a smooth for 3 covariates made up of a tensor product of a 2 dimensional t.p.r.s. basis and a 1-dimensional basis, then set d=c(2,1).

by specifies a covariate by which the whole smooth term is to be multiplied. This is particularly useful for creating models in which a smooth interacts with a factor: in this case the by variable would usually be the dummy variable coding one level of the factor. See the examples below.

fx indicates whether the term is a fixed d.f. regression spline (TRUE) or a penalized regression spline (FALSE).

mp TRUE to use multiple penalties for the smooth. FALSE to use only a single penalty: single penalties are not recommended - they tend to allow only rather wiggly models.
np  TRUE to use the ‘normal parameterization’ for a tensor product smooth. This parameterization represents any 1-d marginal smooths using a parameterization where the parameters are function values at ‘knots’ spread evenly through the data. The parameterization makes the penalties easily interpretable, however it can reduce numerical stability.

Details

Smooths of several covariates can be constructed from tensor products of the bases used to represent smooths of one (or sometimes more) of the covariates. To do this ‘marginal’ bases are produced with associated model matrices and penalty matrices, and these are then combined in the manner described in tensor.prod.model.matrix and tensor.prod.penalties, to produce a single model matrix for the smooth, but multiple penalties (one for each marginal basis). The basis dimension of the whole smooth is the product of the basis dimensions of the marginal smooths.

An option for operating with a single penalty (The Kronecker product of the marginal penalties) is provided, but it is rarely of practical use: the penalty is typically so rank deficient that even the smoothest resulting model will have rather high estimated degrees of freedom.

Tensor product smooths are especially useful for representing functions of covariates measured in different units, although they are typically not quite as nicely behaved as t.p.r.s. smooths for well scaled covariates.

Note also that GAMs constructed from lower rank tensor product smooths are nested within GAMs constructed from higher rank tensor product smooths if the same marginal bases are used in both cases (the marginal smooths themselves are just special cases of tensor product smooths.)

The ‘normal parameterization’ (np=TRUE) re-parameterizes the marginal smooths of a tensor product smooth so that the parameters are function values at a set of points spread evenly through the range of values of the covariate of the smooth. This means that the penalty of the tensor product associated with any particular covariate direction can be interpreted as the penalty of the appropriate marginal smooth applied in that direction and averaged over the smooth. Currently this is only done for marginals of a single variable. This parameterization can reduce numerical stability for when used with marginal smooths other than "cc", "cr" and "cs": if this causes problems, set np=FALSE.

The function does not evaluate the variable arguments.

Value

A class tensor.smooth.spec object defining a tensor product smooth to be turned into a basis and penalties by the smooth.construct.tensor.smooth.spec function.

The returned object contains the following items:

margin  A list of smooth.spec objects of the type returned by s, defining the basis from which the tensor product smooth is constructed.

term  An array of text strings giving the names of the covariates that the term is a function of.

by  is the name of any by variable as text ("NA" for none).

fx  logical array with element for each penalty of the term (tensor product smooths have multiple penalties). TRUE if the penalty is to be ignored, FALSE, otherwise.

full.call  Text for pasting into a string to be converted to a gam formula, which has the values of function options given explicitly - this is useful for constructing a fully expanded gam formula which can be used without needing access to any
variables that may have been used to define k, fx, bs or m in the original call.

i.e. this is text which when parsed and evaluated generates a call to \texttt{s()} with all
the options spelled out explicitly.

\begin{description}
\item[label] A suitable text label for this smooth term.
\item[dim] The dimension of the smoother - i.e. the number of covariates that it is a function of.
\item[mp] TRUE is multiple penalties are to be used (default).
\item[np] TRUE to re-parameterize 1-D marginal smooths in terms of function values (defualt).
\end{description}

tensor.prod.model.matrix

Utility functions for constructing tensor product smooths

Description

Produce model matrices or penalty matrices for a tensor product smooth from the model matrices or penalty matrices for the marginal bases of the smooth.

Usage

tensor.prod.model.matrix(X)
tensor.prod.penalties(S)

Arguments

X a list of model matrices for the marginal bases of a smooth
S a list of penalties for the marginal bases of a smooth.

Details

If \(X[[1]], X[[2]] \ldots X[[m]]\) are the model matrices of the marginal bases of a tensor product smooth then the \(i\)th row of the model matrix for the whole tensor product smooth is given by

\[ X[[1]][i,] \times X[[2]][i,] \times \ldots \times X[[m]][i,] \]

where \(\times\) is the Kronecker product. Of course the routine operates column-wise, not row-wise!

If \(S[[1]], S[[2]] \ldots S[[m]]\) are the penalty matrices for the marginal bases, and \(I[[1]], I[[2]] \ldots I[[m]]\) are corresponding identity matrices, each of the same dimension as its corresponding penalty, then the tensor product smooth has \(m\) associate penalties of the form:

\[ S[[1]] \times I[[2]] \times \ldots \times I[[m]] \]

\[ I[[1]] \times S[[2]] \times \ldots \times I[[m]] \]

\[ \ldots \]

\[ I[[1]] \times I[[2]] \times \ldots \times S[[m]] \]

Of course it’s important that the model matrices and penalty matrices are presented in the same order when constructing tensor product smooths.
**uniquecombs**

**Value**

Either a single model matrix for a tensor product smooth, or a list of penalty terms for a tensor product smooth.

**Author(s)**

Simon N. Wood ⟨simon.wood@r-project.org⟩

**References**

http://www.maths.bath.ac.uk/~sw283/

**See Also**

tensor.prod.penalties

**Examples**

```r
X <- list(matrix(1:4,2,2),matrix(5:10,2,3))
tensor.prod.model.matrix(X)
S<-list(matrix(c(2,1,1,2),2,2),matrix(c(2,1,0,1,2,1,0,1,2),3,3))
tensor.prod.penalties(S)
```

---

**uniquecombs**

find the unique rows in a matrix

**Description**

This routine returns a matrix containing all the unique rows of the matrix supplied as its argument. That is, all the duplicate rows are stripped out. Note that the ordering of the rows on exit is not the same as on entry.

**Usage**

```r
uniquecombs(x)
```

**Arguments**

- `x` is an R matrix

**Details**

Models with more parameters than unique combinations of covariates are not identifiable. This routine provides a means of evaluating the number of unique combinations of coavariates in a model. The routine calls compiled C code.

**Value**

A matrix consisting of the unique rows of `x` (in arbitrary order).
Author(s)
Simon N. Wood ⟨simon.wood@r-project.org⟩

Examples
X<-matrix(c(1,2,3,1,2,3,4,5,6,1,3,2,4,5,6,1,1,1),6,3,byrow=TRUE)
print(X)
uniquecombs(X)

vcov.gam  Extract parameter (estimator) covariance matrix from GAM fit

Description
Extracts the Bayesian posterior covariance matrix of the parameters or frequentist covariance matrix
of the parameter estimators from a fitted gam object.

Usage
### S3 method for class 'gam':
vcov(object, freq = TRUE, dispersion = NULL, ...)

Arguments
- object  fitted model object of class gam as produced by gam().
- freq  TRUE to return the frequentist covariance matrix of the parameter estimators,
FALSE to return the Bayesian posterior covariance matrix of the parameters.
- dispersion  a value for the dispersion parameter: not normally used.
- ...  other arguments, currently ignored.

Details
Basically, just extracts object$Ve or object$Vp from a gamObject.

Value
A matrix corresponding to the estimated frequentist covariance matrix of the model parameter esti-
mators/coefficients, or the estimated posterior covariance matrix of the parameters, depending on
the argument freq.

Author(s)
Henric Nilsson. Maintained by Simon N. Wood ⟨simon.wood@r-project.org⟩

gam
Examples
n <- 100
x <- runif(n)
y <- sin(x*2*pi) + rnorm(n)*.2
mod <- gam(y-s(x,bs="cc",k=10),knots=list(x=seq(0,1,length=10)))
diag(vcov(mod))

vis.gam
Visualization of GAM objects

Description
Produces perspective or contour plot views of gam model predictions, fixing all but the values in view to the values supplied in cond.

Usage
vis.gam(x,view=NULL,cond=list(),n.grid=30,too.far=0,col=NA,
color="heat",contour.col=NULL,se=-1,type="link",
plot.type="persp",zlim=NULL,nCol=50,...)

Arguments
x
a gam object, produced by gam()

view
an array containing the names of the two main effect terms to be displayed on the x and y dimensions of the plot. If omitted the first two suitable terms will be used. Names must be names from names(x$model). i.e. terms are used, rather than variables.

cond
a named list of the values to use for the other predictor terms (not in view). Terms omitted from this list will have their values set to their mean for continuous variables, or first level for factors. Names must correspond to names(x$model).

n.grid
The number of grid nodes in each direction used for calculating the plotted surface.

too.far
plot grid nodes that are too far from the points defined by the variables given in view can be excluded from the plot. too.far determines what is too far. The grid is scaled into the unit square along with the view variables and then grid nodes more than too.far from the predictor variables are excluded.

col
The colours for the facets of the plot. If this is NA then if se>0 the facets are transparent, otherwise the colour scheme specified in color is used. If col is not NA then it is used as the facet colour.

color
the colour scheme to use for plots when se<=0. One of "topo", "heat", "cm", "terrain", "gray" or "bw". Schemes "gray" and "bw" also modify the colors used when se>0.

contour.col
sets the colour of contours when using plot.type="contour". Default scheme used if NULL.

se
if less than or equal to zero then only the predicted surface is plotted, but if greater than zero, then 3 surfaces are plotted, one at the predicted values minus se standard errors, one at the predicted values and one at the predicted values plus se standard errors.
type  "link" to plot on linear predictor scale and "response" to plot on the response scale.
plot.type  one of "contour" or "persp".
zlim  a two item array giving the lower and upper limits for the z-axis scale. NULL to choose automatically.
nCol  The number of colors to use in color schemes.

...  other options to pass on to persp, image or contour. In particular ticktype="detailed" will add proper axes labelling to the plots.

Details
The x and y limits are determined by the ranges of the terms named in view. If se<=0 then a single (height colour coded, by default) surface is produced, otherwise three (by default see-through) meshes are produced at mean and +/- se standard errors. Parts of the x-y plane too far from data can be excluded by setting too.far.

All options to the underlying graphics functions can be reset by passing them as extra arguments ...: such supplied values will always over-ride the defualt values used by vis.gam.

Value
Simply produces a plot.

The nlme package

<table>
<thead>
<tr>
<th>ACF</th>
<th>Autocorrelation Function</th>
</tr>
</thead>
</table>

Description

This function is generic; method functions can be written to handle specific classes of objects. Classes which already have methods for this function include: gls and lme.

Usage

ACF(object, maxLag, ...)

Arguments

- object: any object from which an autocorrelation function can be obtained. Generally an object resulting from a model fit, from which residuals can be extracted.
- maxLag: maximum lag for which the autocorrelation should be calculated.
- ...: some methods for this generic require additional arguments.

Value

will depend on the method function used; see the appropriate documentation.

Author(s)

Jose Pinheiro (Jose.Pinheiro@pharma.novartis.com) and Douglas Bates (Bates@stat.wisc.edu)

## ACF.gls

### Autocorrelation Function for gls Residuals

**Description**

This method function calculates the empirical autocorrelation function for the residuals from a `gls` fit. If a grouping variable is specified in `form`, the autocorrelation values are calculated using pairs of residuals within the same group; otherwise all possible residual pairs are used. The autocorrelation function is useful for investigating serial correlation models for equally spaced data.

### Usage

```r
## S3 method for class 'gls':
ACF(object, maxLag, resType, form, na.action, ...)
```

### Arguments

- **object**: an object inheriting from class `gls`, representing a generalized least squares fitted model.
- **maxLag**: an optional integer giving the maximum lag for which the autocorrelation should be calculated. Defaults to maximum lag in the residuals.
- **resType**: an optional character string specifying the type of residuals to be used. If "response", the "raw" residuals (observed - fitted) are used; else, if "pearson", the standardized residuals (raw residuals divided by the corresponding standard errors) are used; else, if "normalized", the normalized residuals (standardized residuals pre-multiplied by the inverse square-root factor of the estimated error correlation matrix) are used. Partial matching of arguments is used, so only the first character needs to be provided. Defaults to "pearson".
- **form**: an optional one sided formula of the form \( \sim t \), or \( \sim t \ | g \), specifying a time covariate \( t \) and, optionally, a grouping factor \( g \). The time covariate must be integer valued. When a grouping factor is present in `form`, the autocorrelations are calculated using residual pairs within the same group. Defaults to \( \sim 1 \), which corresponds to using the order of the observations in the data as a covariate, and no groups.
- **na.action**: a function that indicates what should happen when the data contain NAs. The default action (`na.fail`) causes ACF.gls to print an error message and terminate if there are any incomplete observations.
- ... some methods for this generic require additional arguments.

### Value

A data frame with columns `lag` and `ACF` representing, respectively, the lag between residuals within a pair and the corresponding empirical autocorrelation. The returned value inherits from class ACF.
**ACF.lme**

**Autocorrelation Function for lme Residuals**

**Description**

This method function calculates the empirical autocorrelation function for the within-group residuals from an lme fit. The autocorrelation values are calculated using pairs of residuals within the innermost group level. The autocorrelation function is useful for investigating serial correlation models for equally spaced data.

**Usage**

```r
## S3 method for class 'lme':
ACF(object, maxLag, resType, ...)
```

**Arguments**

- **object**: an object inheriting from class lme, representing a fitted linear mixed-effects model.
- **maxLag**: an optional integer giving the maximum lag for which the autocorrelation should be calculated. Defaults to maximum lag in the within-group residuals.

**Examples**

```r
fm1 <- gls(follicles ~ sin(2*pi*Time) + cos(2*pi*Time), Ovary)
ACF(fm1, form = ~ 1 | Mare)

# Pinheiro and Bates, p. 255-257
fm1Dial.gls <- gls(rate ~ (pressure+I(pressure^2)+I(pressure^3)+I(pressure^4))*QB,
                   Dialyzer)

fm2Dial.gls <- update(fm1Dial.gls,
                       weights = varPower(form = ~ pressure))
ACF(fm2Dial.gls, form = ~ 1 | Subject)
```
resType an optional character string specifying the type of residuals to be used. If "response", the "raw" residuals (observed - fitted) are used; else, if "pearson", the standardized residuals (raw residuals divided by the corresponding standard errors) are used; else, if "normalized", the normalized residuals (standardized residuals pre-multiplied by the inverse square-root factor of the estimated error correlation matrix) are used. Partial matching of arguments is used, so only the first character needs to be provided. Defaults to "pearson".

... some methods for this generic require additional arguments – not used.

Value

a data frame with columns lag and ACF representing, respectively, the lag between residuals within a pair and the corresponding empirical autocorrelation. The returned value inherits from class ACF.

plot(ACF.fm1Over, alpha=0.01)

Alfalfa

Split-Plot Experiment on Varieties of Alfalfa

Description

The Alfalfa data frame has 72 rows and 4 columns.
Format

This data frame contains the following columns:

**Variety** a factor with levels Cossack, Ladak, and Ranger

**Date** a factor with levels None S1 S20 O7

**Block** a factor with levels 1 2 3 4 5 6

**Yield** a numeric vector

Details

These data are described in Snedecor and Cochran (1980) as an example of a split-plot design. The treatment structure used in the experiment was a $3 \times 4$ full factorial, with three varieties of alfalfa and four dates of third cutting in 1943. The experimental units were arranged into six blocks, each subdivided into four plots. The varieties of alfalfa (Cossack, Ladak, and Ranger) were assigned randomly to the blocks and the dates of third cutting (None, S1—September 1, S20—September 20, and O7—October 7) were randomly assigned to the plots. All four dates were used on each block.

Source

---

**allCoef**

*Extract Coefficients from a Set of Objects*

**Description**

The extractor function is applied to each object in ..., with the result being converted to a vector. A `map` attribute is included to indicate which pieces of the returned vector correspond to the original objects in `dots`.

**Usage**

`allCoef(..., extract)`

**Arguments**

- `...` objects to which `extract` will be applied. Generally these will be model components, such as `corStruct` and `varFunc` objects.
- `extract` an optional extractor function. Defaults to `coef`.

**Value**

a vector with all elements, generally coefficients, obtained by applying `extract` to the objects in `...`

**Author(s)**

Jose’ Pinheiro and Douglas Bates
See Also

lmeStruct, nlmeStruct

Examples

c1 <- corAR1(0.1)
vf1 <- varPower(0.5)
allCoef(c1, vf1)

Description

When only one fitted model object is present, a data frame with the sums of squares, numerator
degrees of freedom, F-values, and P-values for Wald tests for the terms in the model (when Terms
and L are NULL), a combination of model terms (when Terms in not NULL), or linear combi-
nations of the model coefficients (when L is not NULL). Otherwise, when multiple fitted objects
are being compared, a data frame with the degrees of freedom, the (restricted) log-likelihood, the
Akaike Information Criterion (AIC), and the Bayesian Information Criterion (BIC) of each object
is returned. If test=TRUE, whenever two consecutive objects have different number of degrees
of freedom, a likelihood ratio statistic, with the associated p-value is included in the returned data
frame.

Usage

## S3 method for class 'gls':
anova(object, ..., test, type, adjustSigma, Terms, L, verbose)

Arguments

object

a fitted model object inheriting from class gls, representing a generalized least
squares fit.

... other optional fitted model objects inheriting from classes gls, gnls, lm, lme,
mlm, nlme, nlsList, or nls.

test an optional logical value controlling whether likelihood ratio tests should be
used to compare the fitted models represented by object and the objects in
.... Defaults to TRUE.

type an optional character string specifying the type of sum of squares to be used in
F-tests for the terms in the model. If "sequential", the sequential sum of
squares obtained by including the terms in the order they appear in the model is
used; else, if "marginal", the marginal sum of squares obtained by deleting a
term from the model at a time is used. This argument is only used when a single
fitted object is passed to the function. Partial matching of arguments is used, so
only the first character needs to be provided. Defaults to "sequential".

adjustSigma an optional logical value. If TRUE and the estimation method used to obtain
object was maximum likelihood, the residual standard error is multiplied by
$\sqrt{\frac{n_{obs}}{n_{obs} - n_{par}}}$, converting it to a REML-like estimate. This argument is
only used when a single fitted object is passed to the function. Default is TRUE.
Terms
an optional integer or character vector specifying which terms in the model should be jointly tested to be zero using a Wald F-test. If given as a character vector, its elements must correspond to term names; else, if given as an integer vector, its elements must correspond to the order in which terms are included in the model. This argument is only used when a single fitted object is passed to the function. Default is NULL.

L
an optional numeric vector or array specifying linear combinations of the coefficients in the model that should be tested to be zero. If given as an array, its rows define the linear combinations to be tested. If names are assigned to the vector elements (array columns), they must correspond to coefficients names and will be used to map the linear combination(s) to the coefficients; else, if no names are available, the vector elements (array columns) are assumed in the same order as the coefficients appear in the model. This argument is only used when a single fitted object is passed to the function. Default is NULL.

verbose
an optional logical value. If TRUE, the calling sequences for each fitted model object are printed with the rest of the output, being omitted if verbose = FALSE. Defaults to FALSE.

Value
a data frame inheriting from class anova.lme.

Note
Likelihood comparisons are not meaningful for objects fit using restricted maximum likelihood and with different fixed effects.

anova.lme

### Compare Likelihoods of Fitted Objects

When only one fitted model object is present, a data frame with the sums of squares, numerator degrees of freedom, denominator degrees of freedom, F-values, and P-values for Wald tests for the terms in the model (when Terms and L are NULL), a combination of model terms (when Terms in not NULL), or linear combinations of the model coefficients (when L is not NULL). Otherwise, when multiple fitted objects are being compared, a data frame with the degrees of freedom, the (restricted) log-likelihood, the Akaike Information Criterion (AIC), and the Bayesian Information Criterion (BIC) of each object is returned. If test=TRUE, whenever two consecutive objects have different number of degrees of freedom, a likelihood ratio statistic, with the associated p-value is included in the returned data frame.

#### Usage

```r
## S3 method for class 'lme':
anova(object, ..., test, type, adjustSigma, Terms, L, verbose)
## S3 method for class 'anova.lme':
print(x, verbose, ...)
```
Arguments

object  
a fitted model object inheriting from class lme, representing a mixed-effects model.

...  
other optional fitted model objects inheriting from classes gls, gnls, lm, lme, lmList, nlme, nlsList, or nls.

test  
an optional logical value controlling whether likelihood ratio tests should be used to compare the fitted models represented by object and the objects in ... Defaults to TRUE.

type  
an optional character string specifying the type of sum of squares to be used in F-tests for the terms in the model. If "sequential", the sequential sum of squares obtained by including the terms in the order they appear in the model is used; else, if "marginal", the marginal sum of squares obtained by deleting a term from the model at a time is used. This argument is only used when a single fitted object is passed to the function. Partial matching of arguments is used, so only the first character needs to be provided. Defaults to "sequential".

adjustSigma  
an optional logical value. If TRUE and the estimation method used to obtain object was maximum likelihood, the residual standard error is multiplied by \( \sqrt{\frac{n_{obs}}{n_{obs} - n_{par}}} \), converting it to a REML-like estimate. This argument is only used when a single fitted object is passed to the function. Default is TRUE.

Terms  
an optional integer or character vector specifying which terms in the model should be jointly tested to be zero using a Wald F-test. If given as a character vector, its elements must correspond to term names; else, if given as an integer vector, its elements must correspond to the order in which terms are included in the model. This argument is only used when a single fitted object is passed to the function. Default is NULL.

L  
an optional numeric vector or array specifying linear combinations of the coefficients in the model that should be tested to be zero. If given as an array, its rows define the linear combinations to be tested. If names are assigned to the vector elements (array columns), they must correspond to coefficients names and will be used to map the linear combination(s) to the coefficients; else, if no names are available, the vector elements (array columns) are assumed in the same order as the coefficients appear in the model. This argument is only used when a single fitted object is passed to the function. Default is NULL.

x  
an object inheriting from class anova.lme

verbose  
an optional logical value. If TRUE, the calling sequences for each fitted model object are printed with the rest of the output, being omitted if verbose = FALSE. Defaults to FALSE.

Value

a data frame inheriting from class anova.lme.

Note

Likelihood comparisons are not meaningful for objects fit using restricted maximum likelihood and with different fixed effects.

as.matrix.corStruct

Matrix of a corStruct Object

Description

This method function extracts the correlation matrix, or list of correlation matrices, associated with object.

Usage

```
## S3 method for class 'corStruct':
as.matrix(x, ...)
```

Arguments

- `x`: an object inheriting from class `corStruct`, representing a correlation structure.
- `...`: further arguments passed from other methods.

Value

If the correlation structure includes a grouping factor, the returned value will be a list with components given by the correlation matrices for each group. Otherwise, the returned value will be a matrix representing the correlation structure associated with `object`.

**asOneFormula**

*Combine Formulas of a Set of Objects*

Description

The names of all variables used in the formulas extracted from the objects defined in ... are converted into a single linear formula, with the variables names separated by +.

Usage

```r
asOneFormula(..., omit)
```

Arguments

- **...**: objects, or lists of objects, from which a formula can be extracted.
- **omit**: an optional character vector with the names of variables to be omitted from the returned formula. Defaults to c(".", "pi").

Value

A one-sided linear formula with all variables named in the formulas extracted from the objects in ..., except the ones listed in omit.
Assay

See Also

formula, all.vars

Examples

asOneFormula(y ~ x + z | g, list(~ w, ~ t * sin(2 * pi)))

Description

The Assay data frame has 60 rows and 4 columns.

Format

This data frame contains the following columns:

- **Block** an ordered factor with levels 2 < 1 identifying the block where the wells are measured.
- **sample** a factor with levels a to f identifying the sample corresponding to the well.
- **dilut** a factor with levels 1 to 5 indicating the dilution applied to the well
- **logDens** a numeric vector of the log-optical density

Details

These data, courtesy of Rich Wolfe and David Lansky from Searle, Inc., come from a bioassay run on a 96-well cell culture plate. The assay is performed using a split-block design. The 8 rows on the plate are labeled A–H from top to bottom and the 12 columns on the plate are labeled 1–12 from left to right. Only the central 60 wells of the plate are used for the bioassay (the intersection of rows B–G and columns 2–11). There are two blocks in the design: Block 1 contains columns 2–6 and Block 2 contains columns 7–11. Within each block, six samples are assigned randomly to rows and five (serial) dilutions are assigned randomly to columns. The response variable is the logarithm of the optical density. The cells are treated with a compound that they metabolize to produce the stain. Only live cells can make the stain, so the optical density is a measure of the number of cells that are alive and healthy.

Source

Description

Create a tabular representation of the response in a balanced groupedData object.

Usage

asTable(object)

Arguments

object A balanced groupedData object

Details

A balanced groupedData object can be represented as a matrix or table of response values corresponding to the values of a primary covariate for each level of a grouping factor. This function creates such a matrix representation of the data in object.

Value

A matrix. The data in the matrix are the values of the response. The columns correspond to the distinct values of the primary covariate and are labelled as such. The rows correspond to the distinct levels of the grouping factor and are labelled as such.

Examples

asTable(Orthodont)

# Pinheiro and Bates, p. 109
dergoStool.mat <- asTable(ergoStool)

**augPred**

*Augmented Predictions*

**Description**

Predicted values are obtained at the specified values of primary. If object has a grouping structure (i.e. getGroups(object) is not NULL), predicted values are obtained for each group. If level has more than one element, predictions are obtained for each level of the max(level) grouping factor. If other covariates besides primary are used in the prediction model, their average (numeric covariates) or most frequent value (categorical covariates) are used to obtain the predicted values. The original observations are also included in the returned object.

**Usage**

```r
augPred(object, primary, minimum, maximum, length.out, ...)
```

**Arguments**

- **object**: a fitted model object from which predictions can be extracted, using a predict method.
- **primary**: an optional one-sided formula specifying the primary covariate to be used to generate the augmented predictions. By default, if a covariate can be extracted from the data used to generate object (using getCovariate), it will be used as primary.
- **minimum**: an optional lower limit for the primary covariate. Defaults to min(primary).
- **maximum**: an optional upper limit for the primary covariate. Defaults to max(primary).
- **length.out**: an optional integer with the number of primary covariate values at which to evaluate the predictions. Defaults to 51.
- **...**: some methods for the generic may require additional arguments.

**Value**

A data frame with four columns representing, respectively, the values of the primary covariate, the groups (if object does not have a grouping structure, all elements will be 1), the predicted or observed values, and the type of value in the third column: original for the observed values and predicted (single or no grouping factor) or predict.groupVar (multiple levels of grouping), with groupVar replaced by the actual grouping variable name (fixed is used for population predictions). The returned object inherits from class augPred.

**Note**

This function is generic; method functions can be written to handle specific classes of objects. Classes which already have methods for this function include: gls, lme, and lmList.

**Author(s)**

Jose Pinheiro (Jose.Pinheiro@pharma.novartis.com) and Douglas Bates (bates@stat.wisc.edu)
balancedGrouped  Create a groupedData object from a matrix

Description

Create a groupedData object from a data matrix. This function can be used only with balanced data. The opposite conversion, from a groupedData object to a matrix, is done with asTable.

Usage

balancedGrouped(form, data, labels=NULL, units=NULL)

Arguments

form  A formula of the form y ~ x | g giving the name of the response, the primary covariate, and the grouping factor.

data  A matrix or data frame containing the values of the response grouped according to the levels of the grouping factor (rows) and the distinct levels of the primary covariate (columns). The dimnames of the matrix are used to construct the levels of the grouping factor and the primary covariate.

labels  an optional list of character strings giving labels for the response and the primary covariate. The label for the primary covariate is named x and that for the response is named y. Either label can be omitted.

units  an optional list of character strings giving the units for the response and the primary covariate. The units string for the primary covariate is named x and that for the response is named y. Either units string can be omitted.

Value

A balanced groupedData object.

bdf  

Language scores

Description

The bdf data frame has 2287 rows and 25 columns of language scores from grade 8 pupils in elementary schools in The Netherlands.

Usage

data(bdf)

Format

schoolNR  a factor denoting the school.
pupilNR  a factor denoting the pupil.
IQ.verb  a numeric vector of verbal IQ scores
IQ.perf  a numeric vector of IQ scores.
sex  Sex of the student.
Minority  a factor indicating if the student is a member of a minority group.
repeatgr  an ordered factor indicating if one or more grades have been repeated.
aritPRET  a numeric vector
classNR  a numeric vector
aritPOST  a numeric vector
langPRET  a numeric vector
langPOST  a numeric vector
ses a numeric vector of socioeconomic status indicators.
denomina a factor indicating of the school is a public school, a Protestant private school, a Catholic private school, or a non-denominational private school.
schoolSES a numeric vector
satiprin a numeric vector
natitest a factor with levels 0 and 1
meetings a numeric vector
currmeet a numeric vector
mixedgra a factor indicating if the class is a mixed-grade class.

summary(bdf)

BIC

Bayesian Information Criterion

Description
This generic function calculates the Bayesian information criterion, also known as Schwarz’s Bayesian criterion (SBC), for one or several fitted model objects for which a log-likelihood value can be obtained, according to the formula $-2 \log \text{likelihood} + n_{par} \log (n_{obs})$, where $n_{par}$ represents the number of parameters and $n_{obs}$ the number of observations in the fitted model.

Usage
BIC(object, ...)

Arguments
object a fitted model object, for which there exists a logLik method to extract the corresponding log-likelihood, or an object inheriting from class logLik.
... optional fitted model objects.
Value

if just one object is provided, returns a numeric value with the corresponding BIC; if more than one object are provided, returns a data.frame with rows corresponding to the objects and columns representing the number of parameters in the model (df) and the BIC.

Author(s)

Jose Pinheiro (Jose.Pinheiro@pharma.novartis.com) and Douglas Bates (bates@stat.wisc.edu)

logLik, AIC, BIC.logLik

Examples

fm1 <- lm(distance ~ age, data = Orthodont) # no random effects
BIC(fm1)

fm2 <- lme(distance ~ age, data = Orthodont) # random is ~age
BIC(fm1, fm2)

BIC.logLik

BIC of a logLik Object

Description

This function calculates the Bayesian information criterion, also known as Schwarz’s Bayesian criterion (SBC) for an object inheriting from class logLik, according to the formula 

\[-2 \log\text{-likelihood} + n_{\text{par}} \log(n_{\text{obs}}),\]

where \(n_{\text{par}}\) represents the number of parameters and \(n_{\text{obs}}\) the number of observations in the fitted model. When comparing fitted objects, the smaller the BIC, the better the fit.

Usage

## S3 method for class 'logLik':

BIC(object, ...)

Arguments

object an object inheriting from class logLik, usually resulting from applying a logLik method to a fitted model object.

... some methods for this generic use optional arguments. None are used in this method.

Value

a numeric value with the corresponding BIC.
Author(s)

Jose Pinheiro (Jose.Pinheiro@pharma.novartis.com) and Douglas Bates (bates@stat.wisc.edu)

References

See Also

BIC, logLik, AIC.

Examples

```r
fm1 <- lm(distance ~ age, data = Orthodont)
BIC(logLik(fm1))
```

---

Description

The BodyWeight data frame has 176 rows and 4 columns.

Format

This data frame contains the following columns:

- **weight**: a numeric vector giving the body weight of the rat (grams).
- **Time**: a numeric vector giving the time at which the measurement is made (days).
- **Rat**: an ordered factor with levels 2 < 3 < 4 < 1 < 8 < 5 < 6 < 7 < 11 < 9 < 10 < 12 < 13 < 15 < 14 < 16 identifying the rat whose weight is measured.
- **Diet**: a factor with levels 1 to 3 indicating the diet that the rat receives.

Details

Hand and Crowder (1996) describe data on the body weights of rats measured over 64 days. These data also appear in Table 2.4 of Crowder and Hand (1990). The body weights of the rats (in grams) are measured on day 1 and every seven days thereafter until day 64, with an extra measurement on day 44. The experiment started several weeks before “day 1.” There are three groups of rats, each on a different diet.

Source

Pharmacokinetics of Cefamandole

Cefamandole

Description

The Cefamandole data frame has 84 rows and 3 columns.

Format

This data frame contains the following columns:

- **Subject**: a factor giving the subject from which the sample was drawn.
- **Time**: a numeric vector giving the time at which the sample was drawn (minutes post-injection).
- **conc**: a numeric vector giving the observed plasma concentration of cefamandole (mcg/ml).

Details

Davidian and Giltinan (1995, p. 2) describe data obtained during a pilot study to investigate the pharmacokinetics of the drug cefamandole. Plasma concentrations of the drug were measured on six healthy volunteers at 14 time points following an intravenous dose of 15 mg/kg body weight of cefamandole.

Source

Examples

```r
plot(Cefamandole)
fm1 <- nlsList(SSbiexp, data = Cefamandole)
summary(fm1)
```

Assign Values to Coefficients

Description

This function is generic; method functions can be written to handle specific classes of objects. Classes which already have methods for this function include all **pdMat**, **corStruct**, and **varFunc** classes, **reStruct**, and **modelStruct**.

Usage

```r
coef(object, ...) <- value
```
coef.corStruct

Arguments

object any object representing a fitted model, or, by default, any object with a coef component.

... some methods for this generic function may require additional arguments.

value a value to be assigned to the coefficients associated with object.

Value

will depend on the method function; see the appropriate documentation.

Author(s)

Jose Pinheiro (Jose.Pinheiro@pharma.novartis.com) and Douglas Bates (bates@stat.wisc.edu)

---

c coef.corStruct Coefficients of a corStruct Object

Description

This method function extracts the coefficients associated with the correlation structure represented by object.

Usage

### S3 method for class 'corStruct':
coef(object, unconstrained, ...)

### S3 replacement method for class 'corStruct':
coef(object, ...) <- value

Arguments

object an object inheriting from class corStruct, representing a correlation structure.

unconstrained a logical value. If TRUE the coefficients are returned in unconstrained form (the same used in the optimization algorithm). If FALSE the coefficients are returned in "natural", possibly constrained, form. Defaults to TRUE.

value a vector with the replacement values for the coefficients associated with object. It must be a vector with the same length of coef(object) and must be given in unconstrained form.

... some methods for this generic require additional arguments. None are used in this method.
Value

a vector with the coefficients corresponding to object.

SIDE EFFECTS

On the left side of an assignment, sets the values of the coefficients of object to value. Object must be initialized (using Initialize) before new values can be assigned to its coefficients.

Author(s)

Jose Pinheiro and Douglas Bates

References

coef(cst1)

coef.gnls

Extract gnls Coefficients

Description

The estimated coefficients for the nonlinear model represented by object are extracted.

Usage

## S3 method for class 'gnls':
coef(object, ...)

Arguments

object an object inheriting from class gnls, representing a generalized nonlinear least squares fitted model.

... some methods for this generic require additional arguments. None are used in this method.

Value

a vector with the estimated coefficients for the nonlinear model represented by object.
Author(s)

Jose Pinheiro (Jose.Pinheiro@pharma.novartis.com) and Douglas Bates (bates@stat.wisc.edu)

See Also

gnls

Examples

```r
fm1 <- gnls(weight ~ SSlogis(Time, Asym, xmid, scal), Soybean,
weights = varPower())
coef(fm1)
```

Description

The estimated coefficients at level \( i \) are obtained by adding together the fixed effects estimates and the corresponding random effects estimates at grouping levels less or equal to \( i \). The resulting estimates are returned as a data frame, with rows corresponding to groups and columns to coefficients. Optionally, the returned data frame may be augmented with covariates summarized over groups.

Usage

```r
## S3 method for class 'lme':
coef(object, augFrame, level, data, which, FUN,
omitGroupingFactor, subset, ...)
```

Arguments

- `object`: an object inheriting from class `lme`, representing a fitted linear mixed-effects model.
- `augFrame`: an optional logical value. If TRUE, the returned data frame is augmented with variables defined in `data`; else, if FALSE, only the coefficients are returned. Defaults to FALSE.
- `level`: an optional positive integer giving the level of grouping to be used in extracting the coefficients from an object with multiple nested grouping levels. Defaults to the highest or innermost level of grouping.
- `data`: an optional data frame with the variables to be used for augmenting the returned data frame when `augFrame = TRUE`. Defaults to the data frame used to fit `object`.
- `which`: an optional positive integer or character vector specifying which columns of `data` should be used in the augmentation of the returned data frame. Defaults to all columns in `data`.
- `FUN`: an optional summary function or a list of summary functions to be applied to group-varying variables, when collapsing `data` by groups. Group-invariant variables are always summarized by the unique value that they assume within that group. If `FUN` is a single function it will be applied to each non-invariant variable by group to produce the summary for that variable. If `FUN` is a list of
functions, the names in the list should designate classes of variables in the frame such as ordered, factor, or numeric. The indicated function will be applied to any group-varying variables of that class. The default functions to be used are mean for numeric factors, and Mode for both factor and ordered. The Mode function, defined internally in gsummary, returns the modal or most popular value of the variable. It is different from the mode function that returns the S-language mode of the variable.

omitGroupingFactor
an optional logical value. When TRUE the grouping factor itself will be omitted from the group-wise summary of data but the levels of the grouping factor will continue to be used as the row names for the returned data frame. Defaults to FALSE.

subset
an optional expression specifying a subset

...some methods for this generic require additional arguments. None are used in this method.

Value
a data frame inheriting from class coef.lme with the estimated coefficients at level level and, optionally, other covariates summarized over groups. The returned object also inherits from classes ranef.lme and data.frame.

Author(s)
Jose Pinheiro (Jose.Pinheiro@pharma.novartis.com) and Douglas Bates (bates@stat.wisc.edu)

References

See Also
lme, ranef.lme, plot.ranef.lme, gsummary

Examples
fm1 <- lme(distance ~ age, Orthodont, random = ~ age | Subject)
coef(fm1)
coef(fm1, augFrame = TRUE)

description: coef.lmList

The coefficients of each lm object in the object list are extracted and organized into a data frame, with rows corresponding to the lm components and columns corresponding to the coefficients. Optionally, the returned data frame may be augmented with covariates summarized over the groups associated with the lm components.
Usage

```r
## S3 method for class 'lmList':
coef(object, augFrame, data, which, FUN,
     omitGroupingFactor, ...)
```

Arguments

- `object`: an object inheriting from class `lmList`, representing a list of `lm` objects with a common model.
- `augFrame`: an optional logical value. If `TRUE`, the returned data frame is augmented with variables defined in the data frame used to produce `object`; else, if `FALSE`, only the coefficients are returned. Defaults to `FALSE`.
- `data`: an optional data frame with the variables to be used for augmenting the returned data frame when `augFrame = TRUE`. Defaults to the data frame used to fit `object`.
- `which`: an optional positive integer or character vector specifying which columns of the data frame used to produce `object` should be used in the augmentation of the returned data frame. Defaults to all variables in the data.
- `FUN`: an optional summary function or a list of summary functions to be applied to group-varying variables, when collapsing the data by groups. Group-invariant variables are always summarized by the unique value that they assume within that group. If `FUN` is a single function it will be applied to each non-invariant variable by group to produce the summary for that variable. If `FUN` is a list of functions, the names in the list should designate classes of variables in the frame such as `ordered`, `factor`, or `numeric`. The indicated function will be applied to any group-varying variables of that class. The default functions to be used are `mean` for numeric factors, and `Mode` for both `factor` and `ordered`. The `Mode` function, defined internally in `gsummary`, returns the modal or most popular value of the variable. It is different from the `mode` function that returns the S-language mode of the variable.
- `omitGroupingFactor`: an optional logical value. When `TRUE` the grouping factor itself will be omitted from the group-wise summary of `data` but the levels of the grouping factor will continue to be used as the row names for the returned data frame. Defaults to `FALSE`.
- `...`: some methods for this generic require additional arguments. None are used in this method.

Value

A data frame inheriting from class `coef.lmList` with the estimated coefficients for each `lm` component of `object` and, optionally, other covariates summarized over the groups corresponding to the `lm` components. The returned object also inherits from classes `ranef.lmList` and `data.frame`.

coef.modelStruct

References

See Also

lmList, fixed.effects.lmList, ranef.lmList, plot.ranef.lmList, gsummary

Examples

```r
fm1 <- lmList(distance ~ age|Subject, data = Orthodont)
coef(fm1)
coef(fm1, augFrame = TRUE)
```

Description

This method function extracts the coefficients associated with each component of the `modelStruct` list.

Usage

```r
## S3 method for class 'modelStruct':
coef(object, unconstrained, ...)
## S3 replacement method for class 'modelStruct':
coef(object, ...) <- value
```

Arguments

- `object` an object inheriting from class `modelStruct`, representing a list of model components, such as `corStruct` and `varFunc` objects.
- `unconstrained` a logical value. If `TRUE` the coefficients are returned in unconstrained form (the same used in the optimization algorithm). If `FALSE` the coefficients are returned in "natural", possibly constrained, form. Defaults to `TRUE`.
- `value` a vector with the replacement values for the coefficients associated with `object`. It must be a vector with the same length of `coef(object)` and must be given in unconstrained form.
- `...` some methods for this generic require additional arguments. None are used in this method.

Value

a vector with all coefficients corresponding to the components of `object`.

SIDE EFFECTS

On the left side of an assignment, sets the values of the coefficients of `object` to `value`. Object must be initialized (using `Initialize`) before new values can be assigned to its coefficients.
Description

This method function extracts the coefficients associated with the positive-definite matrix represented by argument object.

Usage

```r
## S3 method for class 'pdMat':
coef(object, unconstrained, ...)
## S3 replacement method for class 'pdMat':
coef(object, ...) <- value
```

Arguments

- `object`: an object inheriting from class `pdMat`, representing a positive-definite matrix.
- `unconstrained`: a logical value. If `TRUE` the coefficients are returned in unconstrained form (the same used in the optimization algorithm). If `FALSE` the upper triangular elements of the positive-definite matrix represented by `object` are returned. Defaults to `TRUE`.
- `value`: a vector with the replacement values for the coefficients associated with `object`. It must be a vector with the same length of `coef(object)` and must be given in unconstrained form.
- `...`: some methods for this generic require additional arguments. None are used in this method.

Value

A vector with the coefficients corresponding to `object`.

SIDE EFFECTS

On the left side of an assignment, sets the values of the coefficients of `object` to `value`.

calc_coef.varFunc <- function(coefVarFunc) {
  # Function to calculate coefficients
}

Description

This method function extracts the coefficients associated with the variance function structure represented by object.

Usage

## S3 method for class 'varFunc':
coef(object, unconstrained, allCoef, ...)
## S3 replacement method for class 'varIdent':
coef(object, ...) <- value

Arguments

object

an object inheriting from class varFunc representing a variance function structure.

unconstrained

a logical value. If TRUE the coefficients are returned in unconstrained form (the same used in the optimization algorithm). If FALSE the coefficients are returned in "natural", generally constrained form. Defaults to TRUE.

allCoef

a logical value. If FALSE only the coefficients which may vary during the optimization are returned. If TRUE all coefficients are returned. Defaults to FALSE.

value

a vector with the replacement values for the coefficients associated with object. It must be the same length of coef(object) and must be given in unconstrained form. Object must be initialized before new values can be assigned to its coefficients.

...some methods for this generic require additional arguments. None are used in this method.
Value

a vector with the coefficients corresponding to `object`.

SIDE EFFECTS

On the left side of an assignment, sets the values of the coefficients of `object` to `value`.

collapse  
*Collapse According to Groups*

Description

This function is generic; method functions can be written to handle specific classes of objects. Currently, only a `groupedData` method is available.

Usage

```r
collapse(object, ...)
```

Arguments

- `object`  
an object to be collapsed, usually a data frame.
- `...`  
some methods for the generic may require additional arguments.

Value

will depend on the method function used; see the appropriate documentation.

Author(s)

Jose Pinheiro (Jose.Pinheiro@pharma.novartis.com) and Douglas Bates (bates@stat.wisc.edu)

`collapse.groupedData`

Examples

```r
## see the method function documentation
```
collapse.groupedData

Collapse a groupedData Object

Description

If object has a single grouping factor, it is returned unchanged. Else, it is summarized by the values of the displayLevel grouping factor (or the combination of its values and the values of the covariate indicated in preserve, if any is present). The collapsed data is used to produce a new groupedData object, with grouping factor given by the displayLevel factor.

Usage

```r
## S3 method for class 'groupedData':
collapse(object, collapseLevel, displayLevel,
          outer, inner, preserve, FUN, subset, ...)
```

Arguments

- **object**: an object inheriting from class groupedData, generally with multiple grouping factors.
- **collapseLevel**: an optional positive integer or character string indicating the grouping level to use when collapsing the data. Level values increase from outermost to innermost grouping. Default is the highest or innermost level of grouping.
- **displayLevel**: an optional positive integer or character string indicating the grouping level to use as the grouping factor for the collapsed data. Default is collapseLevel.
- **outer**: an optional logical value or one-sided formula, indicating covariates that are outer to the displayLevel grouping factor. If equal to TRUE, the displayLevel element attr(object, "outer") is used to indicate the outer covariates. An outer covariate is invariant within the sets of rows defined by the grouping factor. Ordering of the groups is done in such a way as to preserve adjacency of groups with the same value of the outer variables. Defaults to NULL, meaning that no outer covariates are to be used.
- **inner**: an optional logical value or one-sided formula, indicating a covariate that is inner to the displayLevel grouping factor. If equal to TRUE, attr(object, "outer") is used to indicate the inner covariate. An inner covariate can change within the sets of rows defined by the grouping factor. Defaults to NULL, meaning that no inner covariate is present.
- **preserve**: an optional one-sided formula indicating a covariate whose levels should be preserved when collapsing the data according to the collapseLevel grouping factor. The collapsing factor is obtained by pasting together the levels of the collapseLevel grouping factor and the values of the covariate to be preserved. Default is NULL, meaning that no covariates need to be preserved.
- **FUN**: an optional summary function or a list of summary functions to be used for collapsing the data. The function or functions are applied only to variables in object that vary within the groups defined by collapseLevel. Invariant variables are always summarized by group using the unique value that they assume within that group. If FUN is a single function it will be applied to each
non-invariant variable by group to produce the summary for that variable. If 
FUN is a list of functions, the names in the list should designate classes of vari-
ables in the data such as ordered, factor, or numeric. The indicated 
function will be applied to any non-invariant variables of that class. The default 
functions to be used are mean for numeric factors, and Mode for both factor 
and ordered. The Mode function, defined internally in gsummary, returns 
the modal or most popular value of the variable. It is different from the mode 
function that returns the S-language mode of the variable.

subset an optional named list. Names can be either positive integers representing 
grouping levels, or names of grouping factors. Each element in the list is a 
vector indicating the levels of the corresponding grouping factor to be preserved 
in the collapsed data. Default is NULL, meaning that all levels are used.

... some methods for this generic require additional arguments. None are used in 
this method.

Value

a groupedData object with a single grouping factor given by the displayLevel grouping 
factor, resulting from collapsing object over the levels of the collapseLevel grouping factor.

compareFits Compare Fitted Objects

Description

The columns in object1 and object2 are put together in matrices which allow direct compar-
ison of the individual elements for each object. Missing columns in either object are replaced by 
NAs.

Usage

compareFits(object1, object2, which)
### Arguments

- `object1, object2`
  - data frames, or matrices, with the same row names, but possibly different column names. These will usually correspond to coefficients from fitted objects with a grouping structure (e.g. `lme` and `lmList` objects).
- `which`
  - an optional integer or character vector indicating which columns in `object1` and `object2` are to be used in the returned object. Defaults to all columns.

### Value

- a three-dimensional array, with the third dimension given by the number of unique column names in either `object1` or `object2`. To each column name there corresponds a matrix with as many rows as the rows in `object1` and two columns, corresponding to `object1` and `object2`. The returned object inherits from class `compareFits`.

### Author(s)

Jose Pinheiro (Jose.Pinheiro@pharma.novartis.com) and Douglas Bates (bates@stat.wisc.edu)

### See Also

- `plot.compareFits`, `pairs.compareFits`, `comparePred`, `coef`, `random.effects`

### Examples

```r
fm1 <- lmList(Orthodont)
fm2 <- lme(fm1)
compareFits(coef(fm1), coef(fm2))
```

---

### Description

Predicted values are obtained at the specified values of `primary` for each object. If either `object1` or `object2` have a grouping structure (i.e. `getGroups(object)` is not NULL), predicted values are obtained for each group. When both objects determine groups, the group levels must be the same. If other covariates besides `primary` are used in the prediction model, their group-wise averages (numeric covariates) or most frequent values (categorical covariates) are used to obtain the predicted values. The original observations are also included in the returned object.

### Usage

```r
comparePred(object1, object2, primary, minimum, maximum, length.out, level, ...)
```
Arguments

object1, object2
  fitted model objects, from which predictions can be extracted using the predict method.

primary
  an optional one-sided formula specifying the primary covariate to be used to generate the augmented predictions. By default, if a covariate can be extracted from the data used to generate the objects (using getCovariate), it will be used as primary.

minimum
  an optional lower limit for the primary covariate. Defaults to min(primary), after primary is evaluated in the data used in fitting object1.

maximum
  an optional upper limit for the primary covariate. Defaults to max(primary), after primary is evaluated in the data used in fitting object1.

length.out
  an optional integer with the number of primary covariate values at which to evaluate the predictions. Defaults to 51.

level
  an optional integer specifying the desired prediction level. Levels increase from outermost to innermost grouping, with level 0 representing the population (fixed effects) predictions. Only one level can be specified. Defaults to the innermost level.

... some methods for the generic may require additional arguments.

Value

a data frame with four columns representing, respectively, the values of the primary covariate, the groups (if object does not have a grouping structure, all elements will be 1), the predicted or observed values, and the type of value in the third column: the objects’ names are used to classify the predicted values and original is used for the observed values. The returned object inherits from classes comparePred and augPred.

Note

This function is generic; method functions can be written to handle specific classes of objects. Classes which already have methods for this function include: gls, lme, and lmList.

fm2 <- update(fm1, distance ~ age)
comparePred(fm1, fm2, length.out = 2)
**Description**

This function is a constructor for the corAR1 class, representing an autocorrelation structure of order 1. Objects created using this constructor must later be initialized using the appropriate Initialize method.

**Usage**

corAR1(value, form, fixed)

**Arguments**

- **value**: the value of the lag 1 autocorrelation, which must be between -1 and 1. Defaults to 0 (no autocorrelation).
- **form**: a one sided formula of the form ~ t, or ~ t | g, specifying a time covariate t and, optionally, a grouping factor g. A covariate for this correlation structure must be integer valued. When a grouping factor is present in form, the correlation structure is assumed to apply only to observations within the same grouping level; observations with different grouping levels are assumed to be uncorrelated. Defaults to ~ 1, which corresponds to using the order of the observations in the data as a covariate, and no groups.
- **fixed**: an optional logical value indicating whether the coefficients should be allowed to vary in the optimization, or kept fixed at their initial value. Defaults to FALSE, in which case the coefficients are allowed to vary.

**Value**

an object of class corAR1, representing an autocorrelation structure of order 1.

corARMA

### ARMA(p,q) Correlation Structure

**Description**

This function is a constructor for the corARMA class, representing an autocorrelation-moving average correlation structure of order (p, q). Objects created using this constructor must later be initialized using the appropriate Initialize method.

**Usage**

```r
corARMA(value, form, p, q, fixed)
```
Arguments

value

A vector with the values of the autoregressive and moving average parameters, which must have length \( p + q \) and all elements between -1 and 1. Defaults to a vector of zeros, corresponding to uncorrelated observations.

form

A one sided formula of the form \( \sim t \), or \( \sim t \mid g \), specifying a time covariate \( t \) and, optionally, a grouping factor \( g \). A covariate for this correlation structure must be integer valued. When a grouping factor is present in form, the correlation structure is assumed to apply only to observations within the same grouping level; observations with different grouping levels are assumed to be uncorrelated. Defaults to \( \sim 1 \), which corresponds to using the order of the observations in the data as a covariate, and no groups.

\( p, q \)

Non-negative integers specifying respectively the autoregressive order and the moving average order of the ARMA structure. Both default to 0.

fixed

An optional logical value indicating whether the coefficients should be allowed to vary in the optimization, or kept fixed at their initial value. Defaults to FALSE, in which case the coefficients are allowed to vary.

Value

An object of class corARMA, representing an autocorrelation-moving average correlation structure.

# from p. 240 needed on p. 396
```
corCAR1

Continuous AR(1) Correlation Structure

Description

This function is a constructor for the corCAR1 class, representing an autocorrelation structure of order 1, with a continuous time covariate. Objects created using this constructor must be later initialized using the appropriate Initialize method.

Usage

corCAR1(value, form, fixed)

Arguments

- `value`: the correlation between two observations one unit of time apart. Must be between 0 and 1. Defaults to 0.2.
- `form`: a one sided formula of the form ~ t, or ~ t | g, specifying a time covariate t and, optionally, a grouping factor g. Covariates for this correlation structure need not be integer valued. When a grouping factor is present in `form`, the correlation structure is assumed to apply only to observations within the same grouping level; observations with different grouping levels are assumed to be uncorrelated. Defaults to ~ 1, which corresponds to using the order of the observations in the data as a covariate, and no groups.
- `fixed`: an optional logical value indicating whether the coefficients should be allowed to vary in the optimization, or kept fixed at their initial value. Defaults to FALSE, in which case the coefficients are allowed to vary.

Value

an object of class corCAR1, representing an autocorrelation structure of order 1, with a continuous time covariate.

corClasses  

Correlation Structure Classes

Description

Standard classes of correlation structures (corStruct) available in the nlme library.

Value

Available standard classes:

- **corAR1**: autoregressive process of order 1.
- **corARMA**: autoregressive moving average process, with arbitrary orders for the autoregressive and moving average components.
- **corCAR1**: continuous autoregressive process (AR(1) process for a continuous time covariate).
- **corCompSymm**: compound symmetry structure corresponding to a constant correlation.
- **corExp**: exponential spatial correlation.
- **corGaus**: Gaussian spatial correlation.
- **corLin**: linear spatial correlation.
- **corRatio**: Rational quadratics spatial correlation.
- **corSpher**: spherical spatial correlation.
- **corSymm**: general correlation matrix, with no additional structure.
Users may define their own corStruct classes by specifying a constructor function and, at a minimum, methods for the functions corMatrix and coef. For examples of these functions, see the methods for classes corSymm and corAR1.

corAR1, corARMA, corCAR1, corCompSymm, corExp, corGaus, corLin, corRatio, corSpher, corSymm, summary.corStruct

Description

This function is a constructor for the corCompSymm class, representing a compound symmetry structure corresponding to uniform correlation. Objects created using this constructor must later be initialized using the appropriate Initialize method.

Usage

corCompSymm(value, form, fixed)

Arguments

value the correlation between any two correlated observations. Defaults to 0.
form a one sided formula of the form ~ t, or ~ t | g, specifying a time covariate t and, optionally, a grouping factor g. When a grouping factor is present in form, the correlation structure is assumed to apply only to observations within the same grouping level; observations with different grouping levels are assumed to be uncorrelated. Defaults to ~ 1, which corresponds to using the order of the observations in the data as a covariate, and no groups.
fixed an optional logical value indicating whether the coefficients should be allowed to vary in the optimization, or kept fixed at their initial value. Defaults to FALSE, in which case the coefficients are allowed to vary.

Value

an object of class corCompSymm, representing a compound symmetry correlation structure.

cs1CompSymm <- Initialize(cs1CompSymm, data = Orthodont)
corMatrix(cs1CompSymm)

corExp

Exponential Correlation Structure

Description

This function is a constructor for the corExp class, representing an exponential spatial correlation structure. Letting $d$ denote the range and $n$ denote the nugget effect, the correlation between two observations a distance $r$ apart is $\exp(-r/d)$ when no nugget effect is present and $(1-n)\exp(-r/d)$ when a nugget effect is assumed. Objects created using this constructor must later be initialized using the appropriate Initialize method.

Usage

corExp(value, form, nugget, metric, fixed)

Arguments

value an optional vector with the parameter values in constrained form. If nugget is FALSE, value can have only one element, corresponding to the "range" of the exponential correlation structure, which must be greater than zero. If nugget is TRUE, meaning that a nugget effect is present, value can contain one or two elements, the first being the "range" and the second the "nugget effect" (one minus the correlation between two observations taken arbitrarily close together); the first must be greater than zero and the second must be between zero and one.
corExp

Defaults to numeric(0), which results in a range of 90% of the minimum distance and a nugget effect of 0.1 being assigned to the parameters when object is initialized.

form

a one sided formula of the form ~ S1+...+Sp, or ~ S1+...+Sp | g, specifying spatial covariates S1 through Sp and, optionally, a grouping factor g. When a grouping factor is present in form, the correlation structure is assumed to apply only to observations within the same grouping level; observations with different grouping levels are assumed to be uncorrelated. Defaults to ~ 1, which corresponds to using the order of the observations in the data as a covariate, and no groups.

nugget

an optional logical value indicating whether a nugget effect is present. Defaults to FALSE.

metric

an optional character string specifying the distance metric to be used. The currently available options are "euclidean" for the root sum-of-squares of distances; "maximum" for the maximum difference; and "manhattan" for the sum of the absolute differences. Partial matching of arguments is used, so only the first three characters need to be provided. Defaults to "euclidean".

fixed

an optional logical value indicating whether the coefficients should be allowed to vary in the optimization, or kept fixed at their initial value. Defaults to FALSE, in which case the coefficients are allowed to vary.

Value

an object of class corExp, also inheriting from class corSpatial, representing an exponential spatial correlation structure.

corFactor

Factor of a Correlation Matrix

Description
This function is generic; method functions can be written to handle specific classes of objects. Classes which already have methods for this function include all corStruct classes.

Usage

corFactor(object, ...)

Arguments

object

... an object from which a correlation matrix can be extracted.

some methods for this generic function require additional arguments.

Value

will depend on the method function used; see the appropriate documentation.

Author(s)

Jose Pinheiro (Jose.Pinheiro@pharma.novartis.com) and Douglas Bates (bates@stat.wisc.edu)
See Also

corFactor.corStruct, recalc.corStruct

Examples

```r
## see the method function documentation
```

corFactor.corStruct

Factor of a corStruct Object Matrix

Description

This method function extracts a transpose inverse square-root factor, or a series of transpose inverse square-root factors, of the correlation matrix, or list of correlation matrices, represented by object. Letting $\Sigma$ denote a correlation matrix, a square-root factor of $\Sigma$ is any square matrix $L$ such that $\Sigma = L'L$. This method extracts $L^{-t}$.

Usage

```r
## S3 method for class 'corStruct':
corFactor(object, ...)
```

Arguments

- `object` an object inheriting from class corStruct representing a correlation structure, which must have been initialized (using Initialize).
- `...` some methods for this generic require additional arguments. None are used in this method.

Value

If the correlation structure does not include a grouping factor, the returned value will be a vector with a transpose inverse square-root factor of the correlation matrix associated with `object` stacked column-wise. If the correlation structure includes a grouping factor, the returned value will be a vector with transpose inverse square-root factors of the correlation matrices for each group, stacked by group and stacked column-wise within each group.

Note

This method function is used intensively in optimization algorithms and its value is returned as a vector for efficiency reasons. The corMatrix method function can be used to obtain transpose inverse square-root factors in matrix form.

```

---

**corGaus**  
*Gaussian Correlation Structure*

**Description**

This function is a constructor for the `corGaus` class, representing a Gaussian spatial correlation structure. Letting $d$ denote the range and $n$ denote the nugget effect, the correlation between two observations a distance $r$ apart is $\exp\left(-\frac{(r/d)^2}{2}\right)$ when no nugget effect is present and $(1-n)\exp\left(-\frac{(r/d)^2}{2}\right)$ when a nugget effect is assumed. Objects created using this constructor must later be initialized using the appropriate `Initialize` method.

**Usage**

```r
corGaus(value, form, nugget, metric, fixed)
```

**Arguments**

- **value**: an optional vector with the parameter values in constrained form. If `nugget` is `FALSE`, `value` can have only one element, corresponding to the "range" of the Gaussian correlation structure, which must be greater than zero. If `nugget` is `TRUE`, meaning that a nugget effect is present, `value` can contain one or two elements, the first being the "range" and the second the "nugget effect" (one minus the correlation between two observations taken arbitrarily close together); the first must be greater than zero and the second must be between zero and one. Defaults to numeric(0), which results in a range of 90% of the minimum distance and a nugget effect of 0.1 being assigned to the parameters when object is initialized.

- **form**: a one sided formula of the form ~ S1+...+Sp, or ~ S1+...+Sp | g, specifying spatial covariates S1 through Sp and, optionally, a grouping factor g. When a grouping factor is present in `form`, the correlation structure is assumed to apply only to observations within the same grouping level; observations with different grouping levels are assumed to be uncorrelated. Defaults to ~ 1, which corresponds to using the order of the observations in the data as a covariate, and no groups.

- **nugget**: an optional logical value indicating whether a nugget effect is present. Defaults to FALSE.

- **metric**: an optional character string specifying the distance metric to be used. The currently available options are "euclidean" for the root sum-of-squares of distances; "maximum" for the maximum difference; and "manhattan" for the sum of the absolute differences. Partial matching of arguments is used, so only the first three characters need to be provided. Defaults to "euclidean".

- **fixed**: an optional logical value indicating whether the coefficients should be allowed to vary in the optimization, or kept fixed at their initial value. Defaults to FALSE, in which case the coefficients are allowed to vary.
Value

an object of class corGaus, also inheriting from class corSpatial, representing a Gaussian spatial correlation structure.

corLin

Linear Correlation Structure

Description

This function is a constructor for the corLin class, representing a linear spatial correlation structure. Letting \( d \) denote the range and \( n \) denote the nugget effect, the correlation between two observations a distance \( r < d \) apart is \( 1 - (r/d) \) when no nugget effect is present and \( (1-n)(1-(r/d)) \) when a nugget effect is assumed. If \( r \geq d \) the correlation is zero. Objects created using this constructor must later be initialized using the appropriate Initialize method.

Usage

corLin(value, form, nugget, metric, fixed)
**Arguments**

- **value**: an optional vector with the parameter values in constrained form. If `nugget` is `FALSE`, `value` can have only one element, corresponding to the "range" of the linear correlation structure, which must be greater than zero. If `nugget` is `TRUE`, meaning that a nugget effect is present, `value` can contain one or two elements, the first being the "range" and the second the "nugget effect" (one minus the correlation between two observations taken arbitrarily close together); the first must be greater than zero and the second must be between zero and one. Defaults to `numeric(0)`, which results in a range of 90% of the minimum distance and a nugget effect of 0.1 being assigned to the parameters when `object` is initialized.

- **form**: a one sided formula of the form `~ S1+...+Sp`, or `~ S1+...+Sp | g`, specifying spatial covariates `S1` through `Sp` and, optionally, a grouping factor `g`. When a grouping factor is present in `form`, the correlation structure is assumed to apply only to observations within the same grouping level; observations with different grouping levels are assumed to be uncorrelated. Defaults to `~ 1`, which corresponds to using the order of the observations in the data as a covariate, and no groups.

- **nugget**: an optional logical value indicating whether a nugget effect is present. Defaults to `FALSE`.

- **metric**: an optional character string specifying the distance metric to be used. The currently available options are "euclidean" for the root sum-of-squares of distances; "maximum" for the maximum difference; and "manhattan" for the sum of the absolute differences. Partial matching of arguments is used, so only the first three characters need to be provided. Defaults to "euclidean".

- **fixed**: an optional logical value indicating whether the coefficients should be allowed to vary in the optimization, or kept fixed at their initial value. Defaults to `FALSE`, in which case the coefficients are allowed to vary.

**Value**

An object of class `corLin`, also inheriting from class `corSpatial`, representing a linear spatial correlation structure.

corMatrix

**Extract Correlation Matrix**

Description

This function is generic; method functions can be written to handle specific classes of objects. Classes which already have methods for this function include all corStruct classes.

Usage

```
corMatrix(object, ...)
```

Arguments

- `object`:
  - an object for which a correlation matrix can be extracted.
- `...`:
  - some methods for this generic function require additional arguments.

Value

will depend on the method function used; see the appropriate documentation.

Author(s)

Jose Pinheiro (Jose.Pinheiro@pharma.novartis.com) and Douglas Bates (bates@stat.wisc.edu)

See Also

Examples

```
## see the method function documentation
```
corMatrix.corStruct

Matrix of a corStruct Object

Description

This method function extracts the correlation matrix (or its transpose inverse square-root factor),
or list of correlation matrices (or their transpose inverse square-root factors) corresponding to
covariate and object. Letting Σ denote a correlation matrix, a square-root factor of Σ is
any square matrix L such that Σ = L'L. When corr = FALSE, this method extracts L⁻¹.

Usage

## S3 method for class 'corStruct':
corMatrix(object, covariate, corr, ...)

Arguments

object an object inheriting from class corStruct representing a correlation structure.
covariate an optional covariate vector (matrix), or list of covariate vectors (matrices), at
which values the correlation matrix, or list of correlation matrices, are to be
evaluated. Defaults to getCovariate(object).
corr a logical value. If TRUE the function returns the correlation matrix, or list of
correlation matrices, represented by object. If FALSE the function returns
a transpose inverse square-root of the correlation matrix, or a list of transpose
inverse square-root factors of the correlation matrices.
...
some methods for this generic require additional arguments. None are used in
this method.

Value

If covariate is a vector (matrix), the returned value will be an array with the corresponding
correlation matrix (or its transpose inverse square-root factor). If the covariate is a list of
vectors (matrices), the returned value will be a list with the correlation matrices (or their transpose
inverse square-root factors) corresponding to each component of covariate.

corMatrix.pdMat  
Extract Correlation Matrix from a pdMat Object

description

The correlation matrix corresponding to the positive-definite matrix represented by object is obtained.

Usage

## S3 method for class 'pdMat':
corMatrix(object, ...)

Arguments

object  
an object inheriting from class pdMat, representing a positive definite matrix.

...  
some methods for this generic require additional arguments. None are used in this method.

Value

the correlation matrix corresponding to the positive-definite matrix represented by object.
Extract Correlation Matrix from Components of an reStruct Object

Description

This method function extracts the correlation matrices corresponding to the pdMat elements of object.

Usage

## S3 method for class 'reStruct':
corMatrix(object, ...)

Arguments

- **object**: an object inheriting from class reStruct, representing a random effects structure and consisting of a list of pdMat objects.
- **...**: some methods for this generic require additional arguments. None are used in this method.

Value

a list with components given by the correlation matrices corresponding to the elements of object.

Examples

rs1 <- reStruct(pdSymm(diag(3), ~age+Sex, data = Orthodont))
corMatrix(rs1)
corNatural

General correlation in natural parameterization

Description

This function is a constructor for the corNatural class, representing a general correlation structure in the “natural” parameterization, which is described under pdNatural. Objects created using this constructor must later be initialized using the appropriate Initialize method.

Usage

corNatural(value, form, fixed)

Arguments

value  an optional vector with the parameter values. Default is numeric(0), which results in a vector of zeros of appropriate dimension being assigned to the parameters when object is initialized (corresponding to an identity correlation structure).

form   a one sided formula of the form ~ t, or ~ t | g, specifying a time covariate t and, optionally, a grouping factor g. A covariate for this correlation structure must be integer valued. When a grouping factor is present in form, the correlation structure is assumed to apply only to observations within the same grouping level; observations with different grouping levels are assumed to be uncorrelated. Defaults to ~ 1, which corresponds to using the order of the observations in the data as a covariate, and no groups.

fixed  an optional logical value indicating whether the coefficients should be allowed to vary in the optimization, or kept fixed at their initial value. Defaults to FALSE, in which case the coefficients are allowed to vary.

Value

an object of class corNatural representing a general correlation structure.

Examples

## covariate is observation order and grouping factor is Subject
cs1 <- corNatural(form = ~ 1 | Subject)
corRatio

Rational Quadratic Correlation Structure

Description

This function is a constructor for the corRatio class, representing a rational quadratic spatial correlation structure. Letting \( d \) denote the range and \( n \) denote the nugget effect, the correlation between two observations a distance \( r \) apart is \((r/d)^2/(1+(r/d)^2)\) when no nugget effect is present and \((1-n)(r/d)^2/(1+(r/d)^2)\) when a nugget effect is assumed. Objects created using this constructor need to be later initialized using the appropriate Initialize method.

Usage

corRatio(value, form, nugget, metric, fixed)

Arguments

value an optional vector with the parameter values in constrained form. If nugget is FALSE, value can have only one element, corresponding to the "range" of the rational quadratic correlation structure, which must be greater than zero. If nugget is TRUE, meaning that a nugget effect is present, value can contain one or two elements, the first being the "range" and the second the "nugget effect" (one minus the correlation between two observations taken arbitrarily close together); the first must be greater than zero and the second must be between zero and one. Defaults to numeric(0), which results in a range of 90% of the minimum distance and a nugget effect of 0.1 being assigned to the parameters when object is initialized.

form a one sided formula of the form \(~ S_1+...+S_p\) or \(~ S_1+...+S_p \mid g\), specifying spatial covariates \( S_1 \) through \( S_p \) and, optionally, a grouping factor \( g \). When a grouping factor is present in form, the correlation structure is assumed to apply only to observations within the same grouping level; observations with different grouping levels are assumed to be uncorrelated. Defaults to \(~ 1\), which corresponds to using the order of the observations in the data as a covariate, and no groups.

nugget an optional logical value indicating whether a nugget effect is present. Defaults to FALSE.

metric an optional character string specifying the distance metric to be used. The currently available options are "euclidean" for the root sum-of-squares of distances; "maximum" for the maximum difference; and "manhattan" for the sum of the absolute differences. Partial matching of arguments is used, so only the first three characters need to be provided. Defaults to "euclidean".

fixed an optional logical value indicating whether the coefficients should be allowed to vary in the optimization, or kept fixed at their initial value. Defaults to FALSE, in which case the coefficients are allowed to vary.

Value

an object of class corRatio, also inheriting from class corSpatial, representing a rational quadratic spatial correlation structure.
corSpatial

Spatial Correlation Structure

This function is a constructor for the `corSpatial` class, representing a spatial correlation structure. This class is "virtual", having four "real" classes, corresponding to specific spatial correlation structures, associated with it: `corExp`, `corGaus`, `corLin`, `corRatio`, and `corSpher`. The returned object will inherit from one of these "real" classes, determined by the `type` argument, and from the "virtual" `corSpatial` class. Objects created using this constructor must later be initialized using the appropriate `Initialize` method.

Examples

```r
sp1 <- corRatio(form = ~ x + y + z)

# example lme(..., corRatio ...)
# Pinheiro and Bates, pp. 222-249
fm1BW.lme <- lme(weight ~ Time * Diet, BodyWeight,
               random = ~ Time)

# p. 223
fm2BW.lme <- update(fm1BW.lme, weights = varPower())

# p 246
fm3BW.lme <- update(fm2BW.lme,
               correlation = corExp(form = ~ Time))

# p. 249
fm5BW.lme <- update(fm3BW.lme, correlation =
               corRatio(form = ~ Time))

# example gls(..., corRatio ...)
# Pinheiro and Bates, pp. 261, 263
fm1Wheat2 <- gls(yield ~ variety - 1, Wheat2)

# p. 263
fm3Wheat2 <- update(fm1Wheat2, corr =
              corRatio(c(12.5, 0.2),
              form = ~ latitude + longitude,
              nugget = TRUE))
```

References

See Also

`Initialize.corStruct`, `summary.corStruct`, `dist`
corSpatial

Usage

corSpatial(value, form, nugget, type, metric, fixed)

Arguments

value

an optional vector with the parameter values in constrained form. If nugget
is FALSE, value can have only one element, corresponding to the "range" of
the spatial correlation structure, which must be greater than zero. If nugget
is TRUE, meaning that a nugget effect is present, value can contain one or two
elements, the first being the "range" and the second the "nugget effect" (one mi-
nus the correlation between two observations taken arbitrarily close together);
the first must be greater than zero and the second must be between zero and one.
Defaults to numeric(0), which results in a range of 90% of the minimum dis-
tance and a nugget effect of 0.1 being assigned to the parameters when object
is initialized.

form

a one sided formula of the form ~ S1+...+Sp, or ~ S1+...+Sp | g,
specifying spatial covariates S1 through Sp and, optionally, a grouping fac-
tor g. When a grouping factor is present in form, the correlation structure is
assumed to apply only to observations within the same grouping level; observa-
tions with different grouping levels are assumed to be uncorrelated. Defaults to
~ 1, which corresponds to using the order of the observations in the data as a
covariate, and no groups.

nugget

an optional logical value indicating whether a nugget effect is present. Defaults
to FALSE.

type

an optional character string specifying the desired type of correlation structure.
Available types include "spherical", "exponential", "gaussian", "linear", and "rational". See the documentation on the functions
corSpher, corExp, corGaus, corLin, and corRatio for a description
of these correlation structures. Partial matching of arguments is used, so only
the first character needs to be provided. Defaults to "spherical".

metric

an optional character string specifying the distance metric to be used. The cur-
rently available options are "eucledian" for the root sum-of-squares of dis-
tances; "maximum" for the maximum difference; and "manhattan" for the
sum of the absolute differences. Partial matching of arguments is used, so only
the first three characters need to be provided. Defaults to "euclidean".

fixed

an optional logical value indicating whether the coefficients should be allowed to
vary in the optimization, or kept fixed at their initial value. Defaults to FALSE,
in which case the coefficients are allowed to vary.

Value

an object of class determined by the type argument and also inheriting from class corSpatial,
representing a spatial correlation structure.

---

corSpher  Spherical Correlation Structure

Description

This function is a constructor for the corSpher class, representing a spherical spatial correlation structure. Letting \( d \) denote the range and \( n \) denote the nugget effect, the correlation between two observations a distance \( r < d \) apart is \( 1 - 1.5(r/d) + 0.5(r/d)^3 \) when no nugget effect is present and \( (1 - n)(1 - 1.5(r/d) + 0.5(r/d)^3) \) when a nugget effect is assumed. If \( r \geq d \) the correlation is zero. Objects created using this constructor must later be initialized using the appropriate Initialize method.

Usage

```
corSpher(value, form, nugget, metric, fixed)
```

Arguments

- `value`: an optional vector with the parameter values in constrained form. If `nugget` is FALSE, `value` can have only one element, corresponding to the "range" of the spherical correlation structure, which must be greater than zero. If `nugget` is TRUE, meaning that a nugget effect is present, `value` can contain one or two elements, the first being the "range" and the second the "nugget effect" (one minus the correlation between two observations taken arbitrarily close together); the first must be greater than zero and the second must be between zero and one. Defaults to `numeric(0)`, which results in a range of 90% of the minimum distance and a nugget effect of 0.1 being assigned to the parameters when object is initialized.

- `form`: a one sided formula of the form \(~ S1+...+Sp\) or \(~ S1+...+Sp \mid g\), specifying spatial covariates \( S1 \) through \( Sp \) and, optionally, a grouping factor \( g \). When a grouping factor is present in `form`, the correlation structure is assumed to apply only to observations within the same grouping level; observations with different grouping levels are assumed to be uncorrelated. Defaults to \(~ 1\), which corresponds to using the order of the observations in the data as a covariate, and no groups.
nugget an optional logical value indicating whether a nugget effect is present. Defaults to FALSE.

metric an optional character string specifying the distance metric to be used. The currently available options are "euclidean" for the root sum-of-squares of distances; "maximum" for the maximum difference; and "manhattan" for the sum of the absolute differences. Partial matching of arguments is used, so only the first three characters need to be provided. Defaults to "euclidean".

fixed an optional logical value indicating whether the coefficients should be allowed to vary in the optimization, or kept fixed at their initial value. Defaults to FALSE, in which case the coefficients are allowed to vary.

Value

an object of class corSpher, also inheriting from class corSpatial, representing a spherical spatial correlation structure.

corSymm  General Correlation Structure

Description

This function is a constructor for the corSymm class, representing a general correlation structure. The internal representation of this structure, in terms of unconstrained parameters, uses the spherical parametrization defined in Pinheiro and Bates (1996). Objects created using this constructor must later be initialized using the appropriate Initialize method.

Usage

corSymm(value, form, fixed)

Arguments

value  an optional vector with the parameter values. Default is numeric(0), which results in a vector of zeros of appropriate dimension being assigned to the parameters when object is initialized (corresponding to an identity correlation structure).

form  a one sided formula of the form ~ t, or ~ t | g, specifying a time covariate t and, optionally, a grouping factor g. A covariate for this correlation structure must be integer valued. When a grouping factor is present in form, the correlation structure is assumed to apply only to observations within the same grouping level; observations with different grouping levels are assumed to be uncorrelated. Defaults to ~ 1, which corresponds to using the order of the observations in the data as a covariate, and no groups.

fixed  an optional logical value indicating whether the coefficients should be allowed to vary in the optimization, or kept fixed at their initial value. Defaults to FALSE, in which case the coefficients are allowed to vary.

Value

an object of class corSymm representing a general correlation structure.

## Covariate

### Assign Covariate Values

**Description**

This function is generic; method functions can be written to handle specific classes of objects. Classes which already have methods for this function include all varFunc classes.

**Usage**

```r
covariate(object) <- value
```

**Arguments**

- **object**: any object with a covariate component.
- **value**: a value to be assigned to the covariate associated with `object`.

**Value**

will depend on the method function; see the appropriate documentation.
Covariate.varFunc

Assign varFunc Covariate

Description

The covariate(s) used in the calculation of the weights of the variance function represented by object is (are) replaced by value. If object has been initialized, value must have the same dimensions as getCovariate(object).

Usage

## S3 replacement method for class 'varFunc':

covariate(object) <- value

Arguments

object an object inheriting from class varFunc, representing a variance function structure.

value a value to be assigned to the covariate associated with object.

Value

a varFunc object similar to object, but with its covariate attribute replaced by value.

Author(s)

Jose Pinheiro (Jose.Pinheiro@pharma.novartis.com) and Douglas Bates (bates@stat.wisc.edu)

See Also

getcovariate.varFunc

Examples

vf1 <- varPower(1.1, form = ~age)
covariate(vf1) <- Orthodont[["age"]]

## see the method function documentation
Dialyzer

Description

The Dialyzer data frame has 140 rows and 5 columns.

Format

This data frame contains the following columns:

- **Subject**: an ordered factor with levels 10 < 8 < 6 < 5 < 9 < 7 < 1 < 4 < 17 < 20 < 11 < 12 < 16 < 13 < 14 < 18 < 15 < 19 giving the unique identifier for each subject.
- **QB**: a factor with levels 200 and 300 giving the bovine blood flow rate (dL/min).
- **pressure**: a numeric vector giving the transmembrane pressure (dmHg).
- **rate**: the hemodialyzer ultrafiltration rate (mL/hr).
- **index**: index of observation within subject—1 through 7.

Details

Vonesh and Carter (1992) describe data measured on high-flux hemodialyzers to assess their *in vivo* ultrafiltration characteristics. The ultrafiltration rates (in mL/hr) of 20 high-flux dialyzers were measured at seven different transmembrane pressures (in dmHg). The *in vitro* evaluation of the dialyzers used bovine blood at flow rates of either 200 dL/min or 300 dL/min. The data, are also analyzed in Littell, Milliken, Stroup, and Wolfinger (1996).

**Dim**

Extract Dimensions from an Object

Description

This function is generic; method functions can be written to handle specific classes of objects. Classes which already have methods for this function include: corSpatial, corStruct, pdCompSymm, pdDiag, pdIdent, pdMat, and pdSymm.

Usage

Dim(object, ...)
Arguments

object  any object for which dimensions can be extracted.

...  some methods for this generic function require additional arguments.

Value

will depend on the method function used; see the appropriate documentation.

Note

If \texttt{dim}\_allowed more than one argument, there would be no need for this generic function.

Author(s)

Jose Pinheiro (Jose.Pinheiro@pharma.novartis.com) and Douglas Bates (bates@stat.wisc.edu)

See Also

\texttt{Dim.pdMat, Dim.corStruct}

Examples

## see the method function documentation

---

\textbf{Dim.corSpatial} \hspace{1cm} \textit{Dimensions of a corSpatial Object}

Description

if \texttt{groups} is missing, it returns the \texttt{Dim} attribute of \texttt{object}; otherwise, calculates the dimensions associated with the grouping factor.

Usage

## S3 method for class 'corSpatial':
\texttt{Dim(object, groups, ...)}

Arguments

object  an object inheriting from class \texttt{corSpatial}, representing a spatial correlation structure.

groups  an optional factor defining the grouping of the observations; observations within a group are correlated and observations in different groups are uncorrelated.

...  further arguments to be passed to or from methods.
Value

a list with components:

N length of groups
M number of groups
spClass an integer representing the spatial correlation class; 0 = user defined class, 1 = corSpher, 2 = corExp, 3 = corGaus, 4 = corLin
sumLenSq sum of the squares of the number of observations per group
len an integer vector with the number of observations per group
start an integer vector with the starting position for the distance vectors in each group, beginning from zero

Author(s)

Jose Pinheiro (Jose.Pinheiro@pharma.novartis.com) and Douglas Bates (bates@stat.wisc.edu)

See Also

Dim, Dim.corStruct

Examples

Dim(corGaus(), getGroups(Orthodont))
c1ARMA <- corARMA(0.4, form = ~ 1 | Subject, q = 1)
c1ARMA <- Initialize(c1ARMA, data = Orthodont)
Dim(c1ARMA)

Description

if groups is missing, it returns the Dim attribute of object; otherwise, calculates the dimensions associated with the grouping factor.

Usage

## S3 method for class 'corStruct':
Dim(object, groups, ...)

Arguments

object an object inheriting from class corStruct, representing a correlation structure.
groups an optional factor defining the grouping of the observations; observations within a group are correlated and observations in different groups are uncorrelated.
... some methods for this generic require additional arguments. None are used in this method.
Value

a list with components:

- **N**: length of groups
- **M**: number of groups
- **maxLen**: maximum number of observations in a group
- **sumLenSq**: sum of the squares of the number of observations per group
- **len**: an integer vector with the number of observations per group
- **start**: an integer vector with the starting position for the observations in each group, beginning from zero

Author(s)

Jose Pinheiro (Jose.Pinheiro@pharma.novartis.com) and Douglas Bates (bates@stat.wisc.edu)

`Dim`, `Dim.corSpatial`

Examples

```r
Dim(corAR1(), getGroups(Orthodont))
```

---

### Description

This method function returns the dimensions of the matrix represented by `object`.

#### Usage

```r
## S3 method for class 'pdMat':
Dim(object, ...)
```

#### Arguments

- **object**: an object inheriting from class `pdMat`, representing a positive-definite matrix.
- **...**: some methods for this generic require additional arguments. None are used in this method.

#### Value

an integer vector with the number of rows and columns of the matrix represented by `object`.

```

<table>
<thead>
<tr>
<th>Earthquake</th>
<th>Earthquake Intensity</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Description

The Earthquake data frame has 182 rows and 5 columns.

Format

This data frame contains the following columns:

- **Quake** an ordered factor with levels 20 < 16 < 14 < 10 < 3 < 8 < 23 < 22 < 6 < 13 < 7 < 21 < 18 < 15 < 4 < 12 < 19 < 5 < 9 < 1 < 2 < 17 < 11 indicating the earthquake on which the measurements were made.
- **Richter** a numeric vector giving the intensity of the earthquake on the Richter scale.
- **distance** the distance from the seismological measuring station to the epicenter of the earthquake (km).
- **soil** a factor with levels 0 and 1 giving the soil condition at the measuring station, either soil or rock.
- **accel** maximum horizontal acceleration observed (g).

Details

Measurements recorded at available seismometer locations for 23 large earthquakes in western North America between 1940 and 1980. They were originally given in Joyner and Boore (1981); are mentioned in Brillinger (1987); and are analyzed in Davidian and Giltinan (1995).

Source

ergoStool

Ergometrics experiment with stool types

Description

The ergoStool data frame has 36 rows and 3 columns.

Format

This data frame contains the following columns:

- **effort** a numeric vector giving the effort (Borg scale) required to arise from a stool.
- **Type** a factor with levels T1, T2, T3, and T4 giving the stool type.
- **Subject** an ordered factor giving a unique identifier for the subject in the experiment.

Details

Devore (2000) cites data from an article in *Ergometrics* (1993, pp. 519-535) on “The Effects of a Pneumatic Stool and a One-Legged Stool on Lower Limb Joint Load and Muscular Activity.”

Source

Examples

```r
fm1 <-
  lme(effort ~ Type, data = ergoStool, random = ~ 1 | Subject)
anova(fm1)
```

Fatigue

Cracks caused by metal fatigue

Description

The Fatigue data frame has 262 rows and 3 columns.

Format

This data frame contains the following columns:

- **Path** an ordered factor with levels 1 < 2 < 3 < 4 < 5 < 6 < 7 < 8 < 9 < 10 < 11 < 12 < 13 < 14 < 15 < 16 < 17 < 18 < 19 < 20 < 21 giving the test path (or test unit) number. The order is in terms of increasing failure time or decreasing terminal crack length.
- **cycles** number of test cycles at which the measurement is made (millions of cycles).
- **relLength** relative crack length (dimensionless).
These data are given in Lu and Meeker (1993) where they state “We obtained the data in Table 1 visually from figure 4.5.2 on page 242 of Bogdanoff and Kozin (1985).” The data represent the growth of cracks in metal for 21 test units. An initial notch of length 0.90 inches was made on each unit which then was subjected to several thousand test cycles. After every 10,000 test cycles the crack length was measured. Testing was stopped if the crack length exceeded 1.60 inches, defined as a failure, or at 120,000 cycles.

**fdHess**

Finite difference Hessian

**Description**

Evaluate an approximate Hessian and gradient of a scalar function using finite differences.

**Usage**

```r
fdHess(pars, fun, ..., .relStep=(.Machine$double.eps)^(1/3), minAbsPar=0)
```

**Arguments**

- `pars` the numeric values of the parameters at which to evaluate the function `fun` and its derivatives.
- `fun` a function depending on the parameters `pars` that returns a numeric scalar.
- `...` Optional additional arguments to `fun`
- `relStep` The relative step size to use in the finite differences. It defaults to the cube root of `.Machine$double.eps`
- `minAbsPar` The minimum magnitude of a parameter value that is considered non-zero. It defaults to zero meaning that any non-zero value will be considered different from zero.

**Details**

This function uses a second-order response surface design known as a Koschal design to determine the parameter values at which the function is evaluated.

**Value**

A list with components

- `mean` the value of function `fun` evaluated at the parameter values `pars`
- `gradient` an approximate gradient
- `Hessian` a matrix whose upper triangle containst an approximate Hessian.
Author(s)

Jose Pinheiro (jcp@research.bell-labs.com), Douglas Bates (bates@stat.wisc.edu)

Examples

fdHess(c(12.3, 2.34), function(x) x[1]*(1-exp(-0.4*x[2])))

fitted.glsStruct  Calculate glsStruct Fitted Values

Description

The fitted values for the linear model represented by object are extracted.

Usage

## S3 method for class 'glsStruct':
fitted(object, glsFit, ...)

Arguments

object  an object inheriting from class glsStruct, representing a list of linear model components, such as corStruct and varFunc objects.
glsFit  an optional list with components logLik (log-likelihood), beta (coefficients), sigma (standard deviation for error term), varBeta (coefficients’ covariance matrix), fitted (fitted values), and residuals (residuals). Defaults to attr(object, "glsFit").
...  some methods for this generic require additional arguments. None are used in this method.

Value

a vector with the fitted values for the linear model represented by object.

Note

This method function is generally only used inside gls and fitted.gls.

Author(s)

Jose Pinheiro (Jose.Pinheiro@pharma.novartis.com) and Douglas Bates (bates@stat.wisc.edu)

See Also

gls, residuals.glsStruct
fitted.gnlsStruct  

Calculate gnlsStruct Fitted Values

Description
The fitted values for the nonlinear model represented by object are extracted.

Usage
## S3 method for class 'gnlsStruct':
fitted(object, ...)

Arguments
object an object inheriting from class gnlsStruct, representing a list of model components, such as corStruct and varFunc objects, and attributes specifying the underlying nonlinear model and the response variable.

... some methods for this generic require additional arguments. None are used in this method.

Value
a vector with the fitted values for the nonlinear model represented by object.

Note
This method function is generally only used inside gnls and fitted.gnls.

Author(s)
Jose Pinheiro (Jose.Pinheiro@pharma.novartis.com) and Douglas Bates (bates@stat.wisc.edu)

See Also
gnls, residuals.gnlsStruct

fitted.lme  

Extract lme Fitted Values

Description
The fitted values at level i are obtained by adding together the population fitted values (based only on the fixed effects estimates) and the estimated contributions of the random effects to the fitted values at grouping levels less or equal to i. The resulting values estimate the best linear unbiased predictions (BLUPs) at level i.

Usage
## S3 method for class 'lme':
fitted(object, level, asList, ...)

Arguments

object an object inheriting from class lme, representing a fitted linear mixed-effects model.

level an optional integer vector giving the level(s) of grouping to be used in extracting the fitted values from object. Level values increase from outermost to innermost grouping, with level zero corresponding to the population fitted values. Defaults to the highest or innermost level of grouping.

asList an optional logical value. If TRUE and a single value is given in level, the returned object is a list with the fitted values split by groups; else the returned value is either a vector or a data frame, according to the length of level. Defaults to FALSE.

... some methods for this generic require additional arguments. None are used in this method.

Value

If a single level of grouping is specified in level, the returned value is either a list with the fitted values split by groups (asList = TRUE) or a vector with the fitted values (asList = FALSE); else, when multiple grouping levels are specified in level, the returned object is a data frame with columns given by the fitted values at different levels and the grouping factors.

Author(s)

Jose Pinheiro (Jose.Pinheiro@pharma.novartis.com) and Douglas Bates (bates@stat.wisc.edu)

References

See Also

lme, residuals.lme

Examples

fm1 <- lme(distance ~ age + Sex, data = Orthodont, random = ~ 1)
fitted(fm1, level = 0:1)

fitted.lmeStruct

Calculate lmeStruct Fitted Values

Description

The fitted values at level $i$ are obtained by adding together the population fitted values (based only on the fixed effects estimates) and the estimated contributions of the random effects to the fitted values at grouping levels less or equal to $i$. The resulting values estimate the best linear unbiased predictions (BLUPs) at level $i$. 
## Usage

```r
## S3 method for class 'lmeStruct':
fitted(object, level, conLin, lmeFit, ...)
```

### Arguments

- `object`:
  an object inheriting from class `lmeStruct`, representing a list of linear mixed-effects model components, such as `reStruct`, `corStruct`, and `varFunc` objects.

- `level`:
  an optional integer vector giving the level(s) of grouping to be used in extracting the fitted values from `object`. Level values increase from outermost to innermost grouping, with level zero corresponding to the population fitted values. Defaults to the highest or innermost level of grouping.

- `conLin`:
  an optional condensed linear model object, consisting of a list with components "Xy", corresponding to a regression matrix (X) combined with a response vector (y), and "logLik", corresponding to the log-likelihood of the underlying `lme` model. Defaults to `attr(object, "conLin")`.

- `lmeFit`:
  an optional list with components `beta` and `b` containing respectively the fixed effects estimates and the random effects estimates to be used to calculate the fitted values. Defaults to `attr(object, "lmeFit")`.

- `...`:
  some methods for this generic accept other optional arguments.

### Value

if a single level of grouping is specified in `level`, the returned value is a vector with the fitted values at the desired level; else, when multiple grouping levels are specified in `level`, the returned object is a matrix with columns given by the fitted values at different levels.

### Note

This method function is generally only used inside `lme` and `fitted.lme`.

fitted.lmList  

Extract lmList Fitted Values

Description

The fitted values are extracted from each lm component of object and arranged into a list with as many components as object, or combined into a single vector.

Usage

```r
## S3 method for class 'lmList':
fitted(object, subset, asList, ...)
```

Arguments

- `object`: an object inheriting from class lmList, representing a list of lm objects with a common model.
- `subset`: an optional character or integer vector naming the lm components of object from which the fitted values are to be extracted. Default is NULL, in which case all components are used.
- `asList`: an optional logical value. If TRUE, the returned object is a list with the fitted values split by groups; else the returned value is a vector. Defaults to FALSE.
- `...`: some methods for this generic require additional arguments. None are used in this method.

Value

- A list with components given by the fitted values of each lm component of object, or a vector with the fitted values for all lm components of object.

Author(s)

Jose Pinheiro (Jose.Pinheiro@pharma.novartis.com) and Douglas Bates (bates@stat.wisc.edu)

fm1 <- lmList(distance ~ age | Subject, Orthodont)
fitted(fm1)
```
fitted.nlmeStruct  Calculate nlmeStruct Fitted Values

Description

The fitted values at level \( i \) are obtained by adding together the contributions from the estimated fixed effects and the estimated random effects at levels less or equal to \( i \) and evaluating the model function at the resulting estimated parameters. The resulting values estimate the predictions at level \( i \).

Usage

```r
## S3 method for class 'nlmeStruct':
fitted(object, level, conLin, ...)
```

Arguments

- `object`: an object inheriting from class `nlmeStruct`, representing a list of mixed-effects model components, such as `reStruct`, `corStruct`, and `varFunc` objects, plus attributes specifying the underlying nonlinear model and the response variable.
- `level`: an optional integer vector giving the level(s) of grouping to be used in extracting the fitted values from `object`. Level values increase from outermost to innermost grouping, with level zero corresponding to the population fitted values. Defaults to the highest or innermost level of grouping.
- `conLin`: an optional condensed linear model object, consisting of a list with components "Xy", corresponding to a regression matrix \( (X) \) combined with a response vector \( (y) \), and "logLik", corresponding to the log-likelihood of the underlying nlme model. Defaults to `attr(object, "conLin")`.
- `...`: additional arguments that could be given to this method. None are used.

Value

If a single level of grouping is specified in `level`, the returned value is a vector with the fitted values at the desired level; else, when multiple grouping levels are specified in `level`, the returned object is a matrix with columns given by the fitted values at different levels.

Note

This method function is generally only used inside `nlme` and `fitted.nlme`.

fixed.effects

**Extract Fixed Effects**

**Description**

This function is generic; method functions can be written to handle specific classes of objects. Classes which already have methods for this function include `lmList` and `lme`.

**Usage**

```r
fixed.effects(object, 
fixef(object, 

```  

**Arguments**

- `object` any fitted model object from which fixed effects estimates can be extracted.
- `...` some methods for this generic function require additional arguments.

**Value**

will depend on the method function used; see the appropriate documentation.

**References**

**See Also**

**Examples**

```r
## see the method function documentation
```
fixef.lmList

Extract lmList Fixed Effects

Description

The average of the coefficients corresponding to the lm components of object is calculated.

Usage

```r
## S3 method for class 'lmList':
fixef(object, ...)
```

Arguments

- `object`: an object inheriting from class lmList, representing a list of lm objects with a common model.
- `...`: some methods for this generic require additional arguments. None are used in this method.

Value

a vector with the average of the individual lm coefficients in object.

Author(s)

Jose Pinheiro (Jose.Pinheiro@pharma.novartis.com) and Douglas Bates (bates@stat.wisc.edu)

See Also

lmList, random.effects.lmList

Examples

```r
fm1 <- lmList(distance ~ age | Subject, Orthodont)
fixed.effects(fm1)
```

formula.pdBlocked

Extract pdBlocked Formula

Description

The formula attributes of the pdMat elements of x are extracted and returned as a list, in case asList=TRUE, or converted to a single one-sided formula when asList=FALSE. If the pdMat elements do not have a formula attribute, a NULL value is returned.

Usage

```r
## S3 method for class 'pdBlocked':
formula(x, asList, ...)
```
Arguments

x an object inheriting from class `pdBlocked`, representing a positive definite block diagonal matrix.

asList an optional logical value. If `TRUE`, a list with the formulas for the individual block diagonal elements of x is returned; else, if `FALSE`, a one-sided formula combining all individual formulas is returned. Defaults to `FALSE`.

... some methods for this generic require additional arguments. None are used in this method.

Value

a list of one-sided formulas, or a single one-sided formula, or `NULL`.

Author(s)

Jose Pinheiro (Jose.Pinheiro@pharma.novartis.com) and Douglas Bates (bates@stat.wisc.edu)

See Also

`pdBlocked`, `pdMat`

Examples

```r
pd1 <- pdBlocked(list(~ age, ~ Sex - 1))
formula(pd1)
formula(pd1, asList = TRUE)
```

Description

This method function extracts the formula associated with a `pdMat` object, in which the column and row names are specified.

Usage

```r
## S3 method for class 'pdMat':
formula(x, asList, ...)
```

Arguments

x an object inheriting from class `pdMat`, representing a positive definite matrix.

asList logical. Should the asList argument be applied to each of the components? Never used.

... some methods for this generic require additional arguments. None are used in this method.

Value

if x has a formula attribute, its value is returned, else `NULL` is returned.
Note

Because factors may be present in formula(x), the pdMat object needs to have access to a data frame where the variables named in the formula can be evaluated, before it can resolve its row and column names from the formula.

formula.reStruct  Extract reStruct Object Formula

Description

This method function extracts a formula from each of the components of x, returning a list of formulas.

Usage

## S3 method for class 'reStruct':
formula(x, asList, ...)

Arguments

x  
an object inheriting from class reStruct, representing a random effects structure and consisting of a list of pdMat objects.

asList  
logical. Should the asList argument be applied to each of the components?

...  
some methods for this generic require additional arguments. None are used in this method.

Value

a list with the formulas of each component of x.

### gapply

**Apply a Function by Groups**

#### Description

Applies the function to the distinct sets of rows of the data frame defined by `groups`.

#### Usage

```r
gapply(object, which, FUN, form, level, groups, ...)
```

#### Arguments

- `object`: an object to which the function will be applied - usually a `groupedData` object or a `data.frame`. Must inherit from class `data.frame`.
- `which`: an optional character or positive integer vector specifying which columns of `object` should be used with `FUN`. Defaults to all columns in `object`.
- `FUN`: function to apply to the distinct sets of rows of the data frame `object` defined by the values of `groups`.
- `form`: an optional one-sided formula that defines the groups. When this formula is given the right-hand side is evaluated in `object`, converted to a factor if necessary, and the unique levels are used to define the groups. Defaults to `formula(object)`.
- `level`: an optional positive integer giving the level of grouping to be used in an object with multiple nested grouping levels. Defaults to the highest or innermost level of grouping.
- `groups`: an optional factor that will be used to split the rows into groups. Defaults to `getGroups(object, form, level)`. 
- `...`: optional additional arguments to the summary function `FUN`. Often it is helpful to specify `na.rm = TRUE`.

#### Value

Returns a data frame with as many rows as there are levels in the `groups` argument.

#### Author(s)

Jose Pinheiro (Jose.Pinheiro@pharma.novartis.com) and Douglas Bates (bates@stat.wisc.edu)

#### References

Gasoline

Description

The Gasoline data frame has 32 rows and 6 columns.

Format

This data frame contains the following columns:

- **yield** a numeric vector giving the percentage of crude oil converted to gasoline after distillation and fractionation
- **endpoint** a numeric vector giving the temperature (degrees F) at which all the gasoline is vaporized
- **Sample** an ordered factor giving the inferred crude oil sample number
- **API** a numeric vector giving the crude oil gravity (degrees API)
- **vapor** a numeric vector giving the vapor pressure of the crude oil (lbf/in²)
- **ASTM** a numeric vector giving the crude oil 10% point ASTM—the temperature at which 10% of the crude oil has become vapor.

Details

Prater (1955) provides data on crude oil properties and gasoline yields. Atkinson (1985) uses these data to illustrate the use of diagnostics in multiple regression analysis. Three of the covariates—API, vapor, and ASTM—measure characteristics of the crude oil used to produce the gasoline. The other covariate — endpoint—is a characteristic of the refining process. Daniel and Wood (1980) notice that the covariates characterizing the crude oil occur in only ten distinct groups and conclude that the data represent responses measured on ten different crude oil samples.

Source

getCovariate

Extract Covariate from an Object

Description

This function is generic; method functions can be written to handle specific classes of objects. Classes which already have methods for this function include corStruct, corSpatial, data.frame, and varFunc.

Usage

getCovariate(object, form, data)

Arguments

object any object with a covariate component
form an optional one-sided formula specifying the covariate(s) to be extracted. Defaults to formula(object).
data a data frame in which to evaluate the variables defined in form.

Value

will depend on the method function used; see the appropriate documentation.

Author(s)

Jose Pinheiro (Jose.Pinheiro@pharma.novartis.com) and Douglas Bates (bates@stat.wisc.edu)

References

See Also

getcovariate.corStruct, getCovariate.data.frame, getCovariate.varFunc, getCovariateFormula

Examples

## see the method function documentation
getCovariate.corStruct

Extract corStruct Object Covariate

Description

This method function extracts the covariate(s) associated with object.

Usage

```r
## S3 method for class 'corStruct':
getCovariate(object, form, data)
```

Arguments

- `object` an object inheriting from class `corStruct` representing a correlation structure.
- `form` this argument is included to make the method function compatible with the generic. It will be assigned the value of `formula(object)` and should not be modified.
- `data` an optional data frame in which to evaluate the variables defined in `form`, in case `object` is not initialized and the covariate needs to be evaluated.

Value

when the correlation structure does not include a grouping factor, the returned value will be a vector or a matrix with the covariate(s) associated with `object`. If a grouping factor is present, the returned value will be a list of vectors or matrices with the covariate(s) corresponding to each grouping level.

`getCovariate`

Examples

```r
cs1 <- corAR1(form = ~ 1 | Subject)
getCovariate(cs1, data = Orthodont)
```
getCovariate.data.frame

*Extract Data Frame Covariate*

**Description**

The right hand side of form, stripped of any conditioning expression (i.e. an expression following a | operator), is evaluated in object.

**Usage**

```r
## S3 method for class 'data.frame':
getCovariate(object, form, data)
```

**Arguments**

- `object`: an object inheriting from class `data.frame`.
- `form`: an optional formula specifying the covariate to be evaluated in object. Defaults to `formula(object)`.
- `data`: some methods for this generic require a separate data frame. Not used in this method.

**Value**

the value of the right hand side of form, stripped of any conditional expression, evaluated in object.

getCovariate.varFunc

*Extract varFunc Covariate*

**Description**

This method function extracts the covariate(s) associated with the variance function represented by object, if any is present.
## S3 method for class 'varFunc'

getCovariate(object, form, data)

### Arguments

- **object**: an object inheriting from class `varFunc`, representing a variance function structure.
- **form**: an optional formula specifying the covariate to be evaluated in `object`. Defaults to `formula(object)`.
- **data**: some methods for this generic require a `data` object. Not used in this method.

### Value

If `object` has a `covariate` attribute, its value is returned; else `NULL` is returned.

### Author(s)

Jose Pinheiro (Jose.Pinheiro@pharma.novartis.com) and Douglas Bates (bates@stat.wisc.edu)

### See Also

covariate<-.varFunc

getCovariateFormula

evf1 <- varPower(1.1, form = ~age)
covariate(evf1) <- Orthodont[["age"]]
getCovariate(evf1)

---

### Description

The right hand side of `formula(object)`, without any conditioning expressions (i.e. any expressions after a `|` operator) is returned as a one-sided formula.

### Usage

ggetCovariateFormula(object)

### Arguments

- **object**: any object from which a formula can be extracted.

### Value

A one-sided formula describing the covariates associated with `formula(object)`. 
getData

Extract Data from an Object

Description
This function is generic; method functions can be written to handle specific classes of objects. Classes which already have methods for this function include `gls`, `lme`, and `lmList`.

Usage
getData(object)

Arguments

object
an object from which a data.frame can be extracted, generally a fitted model object.

Value
will depend on the method function used; see the appropriate documentation.

Author(s)
Jose Pinheiro (Jose.Pinheiro@pharma.novartis.com) and Douglas Bates (bates@stat.wisc.edu)

See Also

Examples

```R
## see the method function documentation
```
**getData.gls**

*Extract gls Object Data*

**Description**

If present in the calling sequence used to produce *object*, the data frame used to fit the model is obtained.

**Usage**

```r
## S3 method for class 'gls':
getData(object)
```

**Arguments**

- **object**: an object inheriting from class `gls`, representing a generalized least squares fitted linear model.

**Value**

If a `data` argument is present in the calling sequence that produced *object*, the corresponding data frame (with `na.action` and `subset` applied to it, if also present in the call that produced *object*) is returned; else, `NULL` is returned.

**Author(s)**

getData(fm1)
```

---

**getData.lme**

*Extract lme Object Data*

**Description**

If present in the calling sequence used to produce *object*, the data frame used to fit the model is obtained.

**Usage**

```r
## S3 method for class 'lme':
getData(object)
```

---
Arguments

object     an object inheriting from class lme, representing a linear mixed-effects fitted model.

Value

if a data argument is present in the calling sequence that produced object, the corresponding data frame (with na.action and subset applied to it, if also present in the call that produced object) is returned; else, NULL is returned.

getGroups

Extract Grouping Factors from an Object

Description

This function is generic; method functions can be written to handle specific classes of objects. Classes which already have methods for this function include corStruct, data.frame, gls, lme, lmList, and varFunc.

Usage

```
getGroups(object, form, level, data, sep)
```

Arguments

- `object` any object
- `form` an optional formula with a conditioning expression on its right hand side (i.e. an expression involving the `|` operator). Defaults to `formula(object)`.
- `level` a positive integer vector with the level(s) of grouping to be used when multiple nested levels of grouping are present. This argument is optional for most methods of this generic function and defaults to all levels of nesting.
- `data` a data frame in which to interpret the variables named in `form`. Optional for most methods.
- `sep` character, the separator to use between group levels when multiple levels are collapsed. The default is `'/'`.

Value

will depend on the method function used; see the appropriate documentation.

getGroups.corStruct

Extract corStruct Groups

Description

This method function extracts the grouping factor associated with object, if any is present.

Usage

```r
## S3 method for class 'corStruct':
getGroups(object, form, level, data, sep)
```

Arguments

- **object**: an object inheriting from class `corStruct` representing a correlation structure.
- **form**: this argument is included to make the method function compatible with the generic. It will be assigned the value of `formula(object)` and should not be modified.
- **level**: this argument is included to make the method function compatible with the generic and is not used.
- **data**: an optional data frame in which to evaluate the variables defined in `form`, in case `object` is not initialized and the grouping factor needs to be evaluated.
- **sep**: character, the separator to use between group levels when multiple levels are collapsed. The default is `/`.

Value

if a grouping factor is present in the correlation structure represented by `object`, the function returns the corresponding factor vector; else the function returns `NULL`.

Author(s)

Jose Pinheiro (Jose.Pinheiro@pharma.novartis.com) and Douglas Bates (bates@stat.wisc.edu)

getGroups(cs1, data = Orthodont)
```
### getGroups.data.frame

**Extract Groups from a Data Frame**

#### Description

Each variable named in the expression after the | operator on the right hand side of form is evaluated in object. If more than one variable is indicated in level they are combined into a data frame; else the selected variable is returned as a vector. When multiple grouping levels are defined in form and level > 1, the levels of the returned factor are obtained by pasting together the levels of the grouping factors of level greater or equal to level, to ensure their uniqueness.

#### Usage

```r
## S3 method for class 'data.frame':
getGroups(object, form, level, data, sep)
```

#### Arguments

- **object**: an object inheriting from class data.frame.
- **form**: an optional formula with a conditioning expression on its right hand side (i.e. an expression involving the | operator). Defaults to `formula(object)`.
- **level**: a positive integer vector with the level(s) of grouping to be used when multiple nested levels of grouping are present. Defaults to all levels of nesting.
- **data**: unused
- **sep**: character, the separator to use between group levels when multiple levels are collapsed. The default is ‘/’.

#### Value

either a data frame with columns given by the grouping factors indicated in level, from outer to inner, or, when a single level is requested, a factor representing the selected grouping factor.

#### Author(s)

Jose Pinheiro (Jose.Pinheiro@pharma.novartis.com) and Douglas Bates (bates@stat.wisc.edu)

#### References

#### See Also

- `getGroupsFormula`

#### Examples

```r
getGroups(Pixel)
getGroups(Pixel, level = 2)
```
Description

If present, the grouping factor associated to the correlation structure for the linear model represented by object is extracted.

Usage

```r
## S3 method for class 'gls':
getGroups(object, form, level, data, sep)
```

Arguments

- **object**: an object inheriting from class `gls`, representing a generalized least squares fitted linear model.
- **form**: an optional formula with a conditioning expression on its right hand side (i.e. an expression involving the `|` operator). Defaults to `formula(object)`. Not used.
- **level**: a positive integer vector with the level(s) of grouping to be used when multiple nested levels of grouping are present. This argument is optional for most methods of this generic function and defaults to all levels of nesting. Not used.
- **data**: a data frame in which to interpret the variables named in `form`. Optional for most methods. Not used.
- **sep**: character, the separator to use between group levels when multiple levels are collapsed. The default is `'/`. Not used.

Value

if the linear model represented by `object` incorporates a correlation structure and the corresponding `corStruct` object has a grouping factor, a vector with the group values is returned; else, `NULL` is returned.

Author(s)

Jose Pinheiro (Jose.Pinheiro@pharma.novartis.com) and Douglas Bates (bates@stat.wisc.edu)

           correlation = corAR1(form = ~ l | Mare))
getGroups(fm1)
```
**getGroups.lme**

**Extract lme Object Groups**

**Description**

The grouping factors corresponding to the linear mixed-effects model represented by `object` are extracted. If more than one level is indicated in `level`, the corresponding grouping factors are combined into a data frame; else the selected grouping factor is returned as a vector.

**Usage**

```r
## S3 method for class 'lme':
getGroups(object, form, level, data, sep)
```

**Arguments**

- `object`: an object inheriting from class `lme`, representing a fitted linear mixed-effects model.
- `form`: this argument is included to make the method function compatible with the generic and is ignored in this method.
- `level`: an optional integer vector giving the level(s) of grouping to be extracted from `object`. Defaults to the highest or innermost level of grouping.
- `data`: unused
- `sep`: character, the separator to use between group levels when multiple levels are collapsed. The default is `'/'.`

**Value**

either a data frame with columns given by the grouping factors indicated in `level`, or, when a single level is requested, a factor representing the selected grouping factor.

**Author(s)**

Jose Pinheiro (Jose.Pinheiro@pharma.novartis.com) and Douglas Bates (bates@stat.wisc.edu)

    random = list(Dog = ~day, Side = ~1))
getGroups(fm1, level = 1:2)
```
getGroups.lmList  Extract lmList Object Groups

Description

The grouping factor determining the partitioning of the observations used to produce the \texttt{lm} components of \texttt{object} is extracted.

Usage

```r
## S3 method for class 'lmList':
getGroups(object, form, level, data, sep)
```

Arguments

- \texttt{object}: an object inheriting from class \texttt{lmList}, representing a list of \texttt{lm} objects with a common model.
- \texttt{form}: an optional formula with a conditioning expression on its right hand side (i.e. an expression involving the | operator). Defaults to \texttt{formula(object)}. Not used.
- \texttt{level}: a positive integer vector with the level(s) of grouping to be used when multiple nested levels of grouping are present. This argument is optional for most methods of this generic function and defaults to all levels of nesting. Not used.
- \texttt{data}: a data frame in which to interpret the variables named in \texttt{form}. Optional for most methods. Not used.
- \texttt{sep}: character, the separator to use between group levels when multiple levels are collapsed. The default is ‘/’. Not used.

Value

a vector with the grouping factor corresponding to the \texttt{lm} components of \texttt{object}.

Author(s)

Jose Pinheiro (Jose.Pinheiro@pharma.novartis.com) and Douglas Bates (bates@stat.wisc.edu)

**getGroups.varFunc**

**Extract varFunc Groups**

**Description**

This method function extracts the grouping factor associated with the variance function represented by object, if any is present.

**Usage**

```r
## S3 method for class 'varFunc':
getGroups(object, form, level, data, sep)
```

**Arguments**

- `object`: an object inheriting from class `varFunc`, representing a variance function structure.
- `form`: an optional formula with a conditioning expression on its right hand side (i.e. an expression involving the `|` operator). Defaults to `formula(object)`. Not used.
- `level`: a positive integer vector with the level(s) of grouping to be used when multiple nested levels of grouping are present. This argument is optional for most methods of this generic function and defaults to all levels of nesting. Not used.
- `data`: a data frame in which to interpret the variables named in `form`. Optional for most methods. Not used.
- `sep`: character, the separator to use between group levels when multiple levels are collapsed. The default is `/`. Not used.

**Value**

- If `object` has a `groups` attribute, its value is returned; else `NULL` is returned.

**Author(s)**

Jose Pinheiro (Jose.Pinheiro@pharma.novartis.com) and Douglas Bates (bates@stat.wisc.edu)

**Examples**

```r
vf1 <- varPower(form = ~ age | Sex)
vf1 <- Initialize(vf1, Orthodont)
getGroups(vf1)
```
getGroupsFormula  

Extract Grouping Formula

Description

The conditioning expression associated with `formula(object)` (i.e. the expression after the `|` operator) is returned either as a named list of one-sided formulas, or a single one-sided formula, depending on the value of `asList`. The components of the returned list are ordered from outermost to innermost level and are named after the grouping factor expression.

Usage

groupsFormula(object, asList, sep)

Arguments

- **object**: any object from which a formula can be extracted.
- **asList**: an optional logical value. If `TRUE` the returned value will be a list of formulas; else, if `FALSE` the returned value will be a one-sided formula. Defaults to `FALSE`.
- **sep**: character, the separator to use between group levels when multiple levels are collapsed. The default is `'/'`.

Value

A one-sided formula, or a list of one-sided formulas, with the grouping structure associated with `formula(object)`. If no conditioning expression is present in `formula(object)` a `NULL` value is returned.

---

**getDescription**

Extract variance-covariance matrix

**Description**

Extract the variance-covariance matrix from a fitted model, such as a mixed-effects model.

**Usage**

```r
getVarCov(obj, ...)
## S3 method for class 'lme':
getVarCov(obj, individuals,
    type = c("random.effects", "conditional", "marginal"), ...)
## S3 method for class 'gls':
getVarCov(obj, individual = 1, ...)
```

**Arguments**

- `obj` A fitted model. Methods are available for models fit by `lme` and `gls`.
- `individuals` For models fit by `lme` a vector of levels of the grouping factor can be specified for the conditional or marginal variance-covariance matrices.
- `individual` For models fit by `gls` the only type of variance-covariance matrix provided is the marginal variance-covariance of the responses by group. The optional argument `individual` specifies the group of responses.
- `type` For models fit by `lme` the `type` argument specifies the type of variance-covariance matrix, either "random.effects" for the random-effects variance-covariance (the default), or "conditional" for the conditional variance-covariance of the responses or "marginal" for the the marginal variance-covariance of the responses.
- `...` Optional arguments for some methods, as described above

**Value**

A variance-covariance matrix or a list of variance-covariance matrices.

gls

Fit Linear Model Using Generalized Least Squares

Description
This function fits a linear model using generalized least squares. The errors are allowed to be correlated and/or have unequal variances.

Usage

gls(model, data, correlation, weights, subset, method, na.action,
   control, verbose)

## S3 method for class 'gls':
update(object, model., ..., evaluate = TRUE)

Arguments

object
an object inheriting from class gls, representing a generalized least squares fitted linear model.

model
a two-sided linear formula object describing the model, with the response on the left of a ~ operator and the terms, separated by + operators, on the right.

model.
Changes to the model – see update.formula for details.

data
an optional data frame containing the variables named in model, correlation, weights, and subset. By default the variables are taken from the environment from which gls is called.

correlation
an optional corStruct object describing the within-group correlation structure. See the documentation of corClasses for a description of the available corStruct classes. If a grouping variable is to be used, it must be specified in the form argument to the corStruct constructor. Defaults to NULL, corresponding to uncorrelated errors.
weights

An optional varFunc object or one-sided formula describing the within-group heteroscedasticity structure. If given as a formula, it is used as the argument to varFixed, corresponding to fixed variance weights. See the documentation on varClasses for a description of the available varFunc classes. Defaults to NULL, corresponding to homoscedastic errors.

subset

An optional expression indicating which subset of the rows of data should be used in the fit. This can be a logical vector, or a numeric vector indicating which observation numbers are to be included, or a character vector of the row names to be included. All observations are included by default.

method

A character string. If "REML" the model is fit by maximizing the restricted log-likelihood. If "ML" the log-likelihood is maximized. Defaults to "REML".

na.action

A function that indicates what should happen when the data contain NAs. The default action (na.fail) causes gls to print an error message and terminate if there are any incomplete observations.

control

A list of control values for the estimation algorithm to replace the default values returned by the function glsControl. Defaults to an empty list.

verbose

An optional logical value. If TRUE information on the evolution of the iterative algorithm is printed. Default is FALSE.

... some methods for this generic require additional arguments. None are used in this method.

evaluate

If TRUE evaluate the new call else return the call.

Value

An object of class gls representing the linear model fit. Generic functions such as print, plot, and summary have methods to show the results of the fit. See glsObject for the components of the fit. The functions resid, coef, and fitted can be used to extract some of its components.

# variance increases as a power of the absolute fitted values
fm2 <- update(fm1, weights = varPower())

glsControl

Control Values for gls Fit

Description

The values supplied in the function call replace the defaults and a list with all possible arguments is returned. The returned list is used as the control argument to the gls function.

Usage

glsControl(maxIter, msMaxIter, tolerance, msTol, msScale, msVerbose,
            singular.ok, qrTol, returnObject, apVar, .relStep,
            nlmStepMax, opt=c("nlminb", "optim"), optimMethod,
            minAbsParApVar, natural)

Arguments

maxIter maximum number of iterations for the gls optimization algorithm. Default is 50.
msMaxIter maximum number of iterations for the optimization step inside the gls optimization. Default is 50.
tolerance tolerance for the convergence criterion in the gls algorithm. Default is 1e-6.
msTol tolerance for the convergence criterion in ms, passed as the rel.tolerance argument to the function (see documentation on ms). Default is 1e-7.
msScale scale function passed as the scale argument to the ms function (see documentation on that function). Default is lmeScale.
msVerbose a logical value passed as the trace argument to ms (see documentation on that function). Default is FALSE.
singular.ok a logical value indicating whether non-estimable coefficients (resulting from linear dependencies among the columns of the regression matrix) should be allowed. Default is FALSE.
qrTol a tolerance for detecting linear dependencies among the columns of the regression matrix in its QR decomposition. Default is .Machine$single.eps.
**returnObject**
a logical value indicating whether the fitted object should be returned when the maximum number of iterations is reached without convergence of the algorithm. Default is FALSE.

**apVar**
a logical value indicating whether the approximate covariance matrix of the variance-covariance parameters should be calculated. Default is TRUE.

**.relStep**
relative step for numerical derivatives calculations. Default is .Machine$double.eps^(1/3).

**nlmStepMax**
stepmax value to be passed to nlm. See nlm for details. Default is 100.0

**opt**
the optimizer to be used, either nlminb (the default since R 2.2.0) or optim (the previous default).

**optimMethod**
character - the optimization method to be used with the optim optimizer. The default is "BFGS". An alternative is "L-BFGS-B".

**minAbsParApVar**
numeric value - minimum absolute parameter value in the approximate variance calculation. The default is 0.05.

**natural**
logical. Should the natural parameterization be used for the approximate variance calculations? Default is TRUE.

**Value**
a list with components for each of the possible arguments.

**Author(s)**
Jose Pinheiro ⟨Jose.Pinheiro@pharma.novartis.com⟩ and Douglas Bates ⟨bates@stat.wisc.edu⟩

**See Also**
gls, lmeScale

**Examples**

```r
# decrease the maximum number iterations in the optimization call and
# request that information on the evolution of the ms iterations be printed
glsControl(msMaxIter = 20, msVerbose = TRUE)
```

---

**glsObject**

**Fitted gls Object**

**Description**

An object returned by the gls function, inheriting from class gls and representing a generalized least squares fitted linear model. Objects of this class have methods for the generic functions anova, coef, fitted, formula, getGroups, getResponse, intervals, logLik, plot, predict, print, residuals, summary, and update.
Value

The following components must be included in a legitimate gls object.

- **apVar**: An approximate covariance matrix for the variance-covariance coefficients. If `apVar = FALSE` in the list of control values used in the call to `gls`, this component is equal to `NULL`.
- **call**: A list containing an image of the `gls` call that produced the object.
- **coefficients**: A vector with the estimated linear model coefficients.
- **contrasts**: A list with the contrasts used to represent factors in the model formula. This information is important for making predictions from a new data frame in which not all levels of the original factors are observed. If no factors are used in the model, this component will be an empty list.
- **dims**: A list with basic dimensions used in the model fit, including the components `N` - the number of observations in the data and `p` - the number of coefficients in the linear model.
- **fitted**: A vector with the fitted values.
- **glsStruct**: An object inheriting from class `glsStruct`, representing a list of linear model components, such as `corStruct` and `varFunc` objects.
- **groups**: A vector with the correlation structure grouping factor, if any is present.
- **logLik**: The log-likelihood at convergence.
- **method**: The estimation method: either "ML" for maximum likelihood, or "REML" for restricted maximum likelihood.
- **numIter**: The number of iterations used in the iterative algorithm.
- **residuals**: A vector with the residuals.
- **sigma**: The estimated residual standard error.
- **varBeta**: An approximate covariance matrix of the coefficients estimates.

**glsStruct**  
**Generalized Least Squares Structure**

Description

A generalized least squares structure is a list of model components representing different sets of parameters in the linear model. A `glsStruct` may contain `corStruct` and `varFunc` objects. NULL arguments are not included in the `glsStruct` list.

Usage

```r
glsStruct(corStruct, varStruct)
```
Arguments

- **corStruct**: an optional `corStruct` object, representing a correlation structure. Default is `NULL`.
- **varStruct**: an optional `varFunc` object, representing a variance function structure. Default is `NULL`.

Value

A list of model variance-covariance components determining the parameters to be estimated for the associated linear model.

Examples

```r
gls1 <- glsStruct(corAR1(), varPower())
```

```
Glucose  Glucose levels over time
```

Description

The Glucose data frame has 378 rows and 4 columns.

Format

This data frame contains the following columns:

- **Subject**: an ordered factor with levels 6 < 2 < 3 < 5 < 1 < 4
- **Time**: a numeric vector
- **conc**: a numeric vector of glucose levels
- **Meal**: an ordered factor with levels 2am < 6am < 10am < 2pm < 6pm < 10pm

Source

**Glucose**

**Glucose Levels Following Alcohol Ingestion**

**Description**

The Glucose data frame has 196 rows and 4 columns.

**Format**

This data frame contains the following columns:

- **Subject** a factor with levels 1 to 7 identifying the subject whose glucose level is measured.
- **Date** a factor with levels 1 2 indicating the occasion in which the experiment was conducted.
- **Time** a numeric vector giving the time since alcohol ingestion (in min/10).
- **glucose** a numeric vector giving the blood glucose level (in mg/dl).

**Details**

Hand and Crowder (Table A.14, pp. 180-181, 1996) describe data on the blood glucose levels measured at 14 time points over 5 hours for 7 volunteers who took alcohol at time 0. The same experiment was repeated on a second date with the same subjects but with a dietary additive used for all subjects.

**gnls**

*Fit Nonlinear Model Using Generalized Least Squares*

**Description**

This function fits a nonlinear model using generalized least squares. The errors are allowed to be correlated and/or have unequal variances.

**Usage**

gnls(model, data, params, start, correlation, weights, subset, na.action, naPattern, control, verbose)
Arguments

model
da two-sided formula object describing the model, with the response on the left of a ~ operator and a nonlinear expression involving parameters and covariates on the right. If data is given, all names used in the formula should be defined as parameters or variables in the data frame.

data
an optional data frame containing the variables named in model, correlation, weights, subset, and naPattern. By default the variables are taken from the environment from which gnls is called.

params
an optional two-sided linear formula of the form \( p_1 + \ldots + p_n \sim x_1 + \ldots + x_m \), or list of two-sided formulas of the form \( p_1 \sim x_1 + \ldots + x_m \), with possibly different models for each parameter. The \( p_1, \ldots, p_n \) represent parameters included on the right hand side of model and \( x_1 + \ldots + x_m \) define a linear model for the parameters (when the left hand side of the formula contains several parameters, they are all assumed to follow the same linear model described by the right hand side expression). A 1 on the right hand side of the formula(s) indicates a single fixed effects for the corresponding parameter(s). By default, the parameters are obtained from the names of start.

start
an optional named list, or numeric vector, with the initial values for the parameters in model. It can be omitted when a selfStarting function is used in model, in which case the starting estimates will be obtained from a single call to the nls function.

correlation
an optional corStruct object describing the within-group correlation structure. See the documentation of corClasses for a description of the available corStruct classes. If a grouping variable is to be used, it must be specified in the form argument to the corStruct constructor. Defaults to NULL, corresponding to uncorrelated errors.

weights
an optional varFunc object or one-sided formula describing the within-group heteroscedasticity structure. If given as a formula, it is used as the argument to varFixed, corresponding to fixed variance weights. See the documentation on varClasses for a description of the available varFunc classes. Defaults to NULL, corresponding to homoscedastic errors.

subset
an optional expression indicating which subset of the rows of data should be used in the fit. This can be a logical vector, or a numeric vector indicating which observation numbers are to be included, or a character vector of the row names to be included. All observations are included by default.

na.action
a function that indicates what should happen when the data contain NAs. The default action (na.fail) causes gnls to print an error message and terminate if there are any incomplete observations.

naPattern
an expression or formula object, specifying which returned values are to be regarded as missing.

control
a list of control values for the estimation algorithm to replace the default values returned by the function gnlsControl. Defaults to an empty list.

verbose
an optional logical value. If TRUE information on the evolution of the iterative algorithm is printed. Default is FALSE.

... some methods for this generic require additional arguments. None are used in this method.
an object of class\texttt{gnls}, also inheriting from class\texttt{gls}, representing the nonlinear model fit. Generic functions such as \texttt{print}, \texttt{plot} and \texttt{summary} have methods to show the results of the fit. See \texttt{gnlsObject} for the components of the fit. The functions \texttt{resid}, \texttt{coef}, and \texttt{fitted} can be used to extract some of its components.

gnlsControl

\textit{Control Values for gnls Fit}

Description

The values supplied in the function call replace the defaults and a list with all possible arguments is returned. The returned list is used as the \texttt{control} argument to the \texttt{gnls} function.
Usage

gnlsControl(maxIter, nlsMaxIter, msMaxIter, minScale, tolerance, nlsTol, msTol, msScale, returnObject, msVerbose, apVar, .relStep, nlmStepMax, opt = c("nlminb", "optim"), optimMethod, minAbsParApVar)

Arguments

maxIter  maximum number of iterations for the gnls optimization algorithm. Default is 50.
nlsMaxIter  maximum number of iterations for the nls optimization step inside the gnls optimization. Default is 7.
msMaxIter  maximum number of iterations for the ms optimization step inside the gnls optimization. Default is 50.
minScale  minimum factor by which to shrink the default step size in an attempt to decrease the sum of squares in the nls step. Default 0.001.
tolerance  tolerance for the convergence criterion in the gnls algorithm. Default is 1e-6.
nlsTol  tolerance for the convergence criterion in nls step. Default is 1e-3.
msTol  tolerance for the convergence criterion in ms, passed as the rel.tolerance argument to the function (see documentation on ms). Default is 1e-7.
msScale  scale function passed as the scale argument to the ms function (see documentation on that function). Default is lmeScale.
returnObject  a logical value indicating whether the fitted object should be returned when the maximum number of iterations is reached without convergence of the algorithm. Default is FALSE.
msVerbose  a logical value passed as the trace argument to ms (see documentation on that function). Default is FALSE.
apVar  a logical value indicating whether the approximate covariance matrix of the variance-covariance parameters should be calculated. Default is TRUE.
opt  the optimizer to be used, either nlminb (the default since R 2.2.0) or optim (the previous default).
optimMethod  character - the optimization method to be used with the optim optimizer. The default is "BFGS". An alternative is "L-BFGS-B".
nlmStepMax  stepmax value to be passed to nlm. See nlm for details. Default is 100.0
minAbsParApVar  numeric value - minimum absolute parameter value in the approximate variance calculation. The default is 0.05.

Value

a list with components for each of the possible arguments.

gnlsControl(msMaxIter = 20, msVerbose = TRUE)

gnlsObject  Fitted gnls Object

Description

An object returned by the gnls function, inheriting from class gnls and also from class gls, and representing a generalized nonlinear least squares fitted model. Objects of this class have methods for the generic functions anova, coef, fitted, formula, getGroups,getResponse, intervals, logLik, plot, predict, print, residuals, summary, and update.

Value

The following components must be included in a legitimate gnls object.

- **apVar**: an approximate covariance matrix for the variance-covariance coefficients. If apVar = FALSE in the list of control values used in the call to gnls, this component is equal to NULL.
- **call**: a list containing an image of the gnls call that produced the object.
- **coefficients**: a vector with the estimated nonlinear model coefficients.
- **contrasts**: a list with the contrasts used to represent factors in the model formula. This information is important for making predictions from a new data frame in which not all levels of the original factors are observed. If no factors are used in the model, this component will be an empty list.
- **dims**: a list with basic dimensions used in the model fit, including the components $N$ - the number of observations used in the fit and $p$ - the number of coefficients in the nonlinear model.
- **fitted**: a vector with the fitted values.
- **modelStruct**: an object inheriting from class gnlsStruct, representing a list of model components, such as corStruct and varFunc objects.
- **groups**: a vector with the correlation structure grouping factor, if any is present.
- **logLik**: the log-likelihood at convergence.
- **numIter**: the number of iterations used in the iterative algorithm.
- **plist**: a vector with the residuals.
- **pmap**: the estimated residual standard error.
- **varBeta**: an approximate covariance matrix of the coefficients estimates.
Description

A generalized nonlinear least squares structure is a list of model components representing different sets of parameters in the nonlinear model. A `gnlsStruct` may contain `corStruct` and `varFunc` objects. NULL arguments are not included in the `gnlsStruct` list.

Usage

```r
gnlsStruct(corStruct, varStruct)
```

Arguments

- `corStruct`: an optional `corStruct` object, representing a correlation structure. Default is NULL.
- `varStruct`: an optional `varFunc` object, representing a variance function structure. Default is NULL.

Value

a list of model variance-covariance components determining the parameters to be estimated for the associated nonlinear model.

Examples

```r
gnls1 <- gnlsStruct(corAR1(), varPower())
```
groupedData

Construct a groupedData Object

Description

An object of the groupedData class is constructed from the formula and data by attaching the formula as an attribute of the data, along with any of outer, inner, labels, and units that are given. If order.groups is TRUE the grouping factor is converted to an ordered factor with the ordering determined by FUN. Depending on the number of grouping levels and the type of primary covariate, the returned object will be of one of three classes: nfnGroupedData - numeric covariate, single level of nesting; nffGroupedData - factor covariate, single level of nesting; and nmGroupedData - multiple levels of nesting. Several modeling and plotting functions can use the formula stored with a groupedData object to construct default plots and models.

Usage

```r
groupedData(formula, data, order.groups, FUN, outer, inner, labels, units)
```

## S3 method for class 'groupedData':
```r
update(object, formula, data, order.groups, FUN, outer, inner, labels, units, ...)
```

Arguments

- **object**: an object inheriting from class groupedData.
- **formula**: a formula of the form `resp ~ cov | group` where `resp` is the response, `cov` is the primary covariate, and `group` is the grouping factor. The expression `1` can be used for the primary covariate when there is no other suitable candidate. Multiple nested grouping factors can be listed separated by the `/` symbol as in `fact1/fact2`. In an expression like this the `fact2` factor is nested within the `fact1` factor.
- **data**: a data frame in which the expressions in `formula` can be evaluated. The resulting groupedData object will consist of the same data values in the same order but with additional attributes.
- **order.groups**: an optional logical value, or list of logical values, indicating if the grouping factors should be converted to ordered factors according to the function `FUN` applied to the response from each group. If multiple levels of grouping are present, this argument can be either a single logical value (which will be repeated for all grouping levels) or a list of logical values. If no names are assigned to the list elements, they are assumed in the same order as the group levels (outermost to innermost grouping). Ordering within a level of grouping is done within the levels of the grouping factors which are outer to it. Changing the grouping factor to an ordered factor does not affect the ordering of the rows in the data frame but does affect the order of the panels in a trellis display of the data or models fitted to the data. Defaults to TRUE.
- **FUN**: an optional summary function that will be applied to the values of the response for each level of the grouping factor, when `order.groups = TRUE`, to determine the ordering. Defaults to the `max` function.
an optional one-sided formula, or list of one-sided formulas, indicating covariates that are outer to the grouping factor(s). If multiple levels of grouping are present, this argument can be either a single one-sided formula, or a list of one-sided formulas. If no names are assigned to the list elements, they are assumed in the same order as the group levels (outermost to innermost grouping). An outer covariate is invariant within the sets of rows defined by the grouping factor. Ordering of the groups is done in such a way as to preserve adjacency of groups with the same value of the outer variables. When plotting a groupedData object, the argument \texttt{outer} = \texttt{TRUE} causes the panels to be determined by the \texttt{outer} formula. The points within the panels are associated by level of the grouping factor. Defaults to \texttt{NULL}, meaning that no outer covariates are present.

an optional one-sided formula, or list of one-sided formulas, indicating covariates that are inner to the grouping factor(s). If multiple levels of grouping are present, this argument can be either a single one-sided formula, or a list of one-sided formulas. If no names are assigned to the list elements, they are assumed in the same order as the group levels (outermost to innermost grouping). An inner covariate can change within the sets of rows defined by the grouping factor. An inner formula can be used to associate points in a plot of a groupedData object. Defaults to \texttt{NULL}, meaning that no inner covariates are present.

an optional list of character strings giving labels for the response and the primary covariate. The label for the primary covariate is named \texttt{x} and that for the response is named \texttt{y}. Either label can be omitted.

an optional list of character strings giving the units for the response and the primary covariate. The units string for the primary covariate is named \texttt{x} and that for the response is named \texttt{y}. Either units string can be omitted.

some methods for this generic require additional arguments. None are used in this method.

an object of one of the classes \texttt{nfnGroupedData}, \texttt{nffGroupedData}, or \texttt{nmGroupedData}, and also inheriting from classes \texttt{groupedData} and \texttt{data.frame}.

Douglas Bates and Jose Pinheiro

formula, gapply, gsummary, lme, plot.nffGroupedData, plot.nfnGroupedData, plot.nmGroupedData, reStruct
Examples

Orth.new <- # create a new copy of the groupedData object
groupedData( distance ~ age | Subject, 
    data = as.data.frame( Orthodont ),
    FUN = mean,
    outer = ~ Sex,
    labels = list( x = "Age",
                  y = "Distance from pituitary to pterygomaxillary fissure" ),
    units = list( x = "(yr)", y = "(mm)" ) )

## Not run:
plot( Orth.new ) # trellis plot by Subject
## End(Not run)
formula( Orth.new ) # extractor for the formula
gsummary( Orth.new ) # apply summary by Subject
fm1 <- lme( Orth.new ) # fixed and groups formulae extracted from object
Orthodont2 <- update(Orthodont, FUN = mean)

Description

Provide a summary of the variables in a data frame by groups of rows. This is most useful with a groupedData object to examine the variables by group.

Usage

gsummary(object, FUN, omitGroupingFactor, form, level, 
groups, invariantsOnly, ...)

Arguments

object an object to be summarized - usually a groupedData object or a data.frame.
FUN an optional summary function or a list of summary functions to be applied to each variable in the frame. The function or functions are applied only to variables in object that vary within the groups defined by groups. Invariant variables are always summarized by group using the unique value that they assume within that group. If FUN is a single function it will be applied to each non-invariant variable by group to produce the summary for that variable. If FUN is a list of functions, the names in the list should designate classes of variables in the frame such as ordered, factor, or numeric. The indicated function will be applied to any non-invariant variables of that class. The default functions to be used are mean for numeric factors, and Mode for both factor and ordered. The Mode function, defined internally in gsummary, returns the modal or most popular value of the variable. It is different from the mode function that returns the S-language mode of the variable.
omitGroupingFactor an optional logical value. When TRUE the grouping factor itself will be omitted from the group-wise summary but the levels of the grouping factor will continue to be used as the row names for the data frame that is produced by the summary. Defaults to FALSE.
An optional one-sided formula that defines the groups. When this formula is
given, the right-hand side is evaluated in object, converted to a factor if
necessary, and the unique levels are used to define the groups. Defaults to
formula(object).

level

An optional positive integer giving the level of grouping to be used in an object
with multiple nested grouping levels. Defaults to the highest or innermost level
of grouping.

groups

An optional factor that will be used to split the rows into groups. Defaults to
getGroups(object, form, level).

invariantsOnly

An optional logical value. When TRUE only those covariates that are invariant
within each group will be summarized. The summary value for the group is al-
ways the unique value taken on by that covariate within the group. The columns
in the summary are of the same class as the corresponding columns in object.
By definition, the grouping factor itself must be an invariant. When combined
with omitGroupingFactor = TRUE, this option can be used to discover
is there are invariant covariates in the data frame. Defaults to FALSE.

... optional additional arguments to the summary functions that are invoked on the
variables by group. Often it is helpful to specify na.rm = TRUE.

Value

A data.frame with one row for each level of the grouping factor. The number of columns is at
most the number of columns in object.

Examples

gsummary(Orthodont)  # default summary by Subject
## gsummary with invariantsOnly = TRUE and omitGroupingFactor = TRUE
## determines whether there are covariates like Sex that are invariant
## within the repeated observations on the same Subject.
gsummary(Orthodont, inv = TRUE, omit = TRUE)
Description

The Gun data frame has 36 rows and 4 columns.

Format

This data frame contains the following columns:

- **rounds**: a numeric vector
- **Method**: a factor with levels M1 M2
- **Team**: an ordered factor with levels T1S < T3S < T2S < T1A < T2A < T3A < T1H < T3H < T2H
- **Physique**: an ordered factor with levels Slight < Average < Heavy

Details

Hicks (p.180, 1993) reports data from an experiment on methods for firing naval guns. Gunners of three different physiques (slight, average, and heavy) tested two firing methods. Both methods were tested twice by each of nine teams of three gunners with identical physique. The response was the number of rounds fired per minute.

Source

Description

The IGF data frame has 237 rows and 3 columns.

Format

This data frame contains the following columns:

- **Lot**: an ordered factor giving the radioactive tracer lot.
- **age**: a numeric vector giving the age (in days) of the radioactive tracer.
- **conc**: a numeric vector giving the estimated concentration of IGF-I protein (ng/ml)

Details

Davidian and Giltinan (1995) describe data obtained during quality control radioimmunoassays for ten different lots of radioactive tracer used to calibrate the Insulin-like Growth Factor (IGF-I) protein concentration measurements.
Initialize

Source

Initialize Object

Description

This function is generic; method functions can be written to handle specific classes of objects. Classes which already have methods for this function include: corStruct, lmeStruct, reStruct, and varFunc.

Usage

Initialize(object, data, ...)

Arguments

- **object**: any object requiring initialization, e.g. "plug-in" structures such as corStruct and varFunc objects.
- **data**: a data frame to be used in the initialization procedure.
- **...**: some methods for this generic function require additional arguments.

Value

an initialized object with the same class as object. Changes introduced by the initialization procedure will depend on the method function used; see the appropriate documentation.

Author(s)

Jose Pinheiro (Jose.Pinheiro@pharma.novartis.com) and Douglas Bates (bates@stat.wisc.edu)

References

Examples

## see the method function documentation
Initialize.corStruct

Initialize corStruct Object

Description

This method initializes object by evaluating its associated covariate(s) and grouping factor, if any is present, in data, calculating various dimensions and constants used by optimization algorithms involving corStruct objects (see the appropriate Dim method documentation), and assigning initial values for the coefficients in object, if none were present.

Usage

```r
## S3 method for class 'corStruct':
Initialize(object, data, ...)
```

Arguments

- **object**: an object inheriting from class corStruct representing a correlation structure.
- **data**: a data frame in which to evaluate the variables defined in formula(object).
- **...**: this argument is included to make this method compatible with the generic.

Value

an initialized object with the same class as object representing a correlation structure.

Author(s)

Jose Pinheiro (Jose.Pinheiro@pharma.novartis.com) and Douglas Bates (bates@stat.wisc.edu)

References

Examples

```r
cs1 <- corAR1(form = ~ 1 | Subject)
cs1 <- Initialize(cs1, data = Orthodont)
```
Initialize.glsStruct

*Initialize a glsStruct Object*

**Description**

The individual linear model components of the `glsStruct` list are initialized.

**Usage**

```r
## S3 method for class 'glsStruct':
Initialize(object, data, control, ...)
```

**Arguments**

- `object`: an object inheriting from class `glsStruct`, representing a list of linear model components, such as `corStruct` and `varFunc` objects.
- `data`: a data frame in which to evaluate the variables defined in `formula(object)`.
- `control`: an optional list with control parameters for the initialization and optimization algorithms used in `gls`. Defaults to `list(singular.ok = FALSE, qrTol = .Machine$single.eps)`, implying that linear dependencies are not allowed in the model and that the tolerance for detecting linear dependencies among the columns of the regression matrix is `.Machine$single.eps`.
- `...`: some methods for this generic require additional arguments. None are used in this method.

**Value**

A `glsStruct` object similar to `object`, but with initialized model components.

**Author(s)**

Jose Pinheiro (Jose.Pinheiro@pharma.novartis.com) and Douglas Bates (bates@stat.wisc.edu)

**See Also**

`gls`, `Initialize.corStruct`, `Initialize.varFunc`, `Initialize`

Initialize.lmeStruct

*Initialize an lmeStruct Object*

**Description**

The individual linear mixed-effects model components of the `lmeStruct` list are initialized.

**Usage**

```r
## S3 method for class 'lmeStruct':
Initialize(object, data, groups, conLin, control, ...)
```

---

---
Initialize.reStruct

Arguments

- **object**: an object inheriting from class lmeStruct, representing a list of linear mixed-effects model components, such as reStruct, corStruct, and varFunc objects.
- **data**: a data frame in which to evaluate the variables defined in formula(object).
- **groups**: a data frame with the grouping factors corresponding to the lme model associated with object as columns, sorted from innermost to outermost grouping level.
- **conLin**: an optional condensed linear model object, consisting of a list with components "Xy", corresponding to a regression matrix (X) combined with a response vector (y), and "logLik", corresponding to the log-likelihood of the underlying lme model. Defaults to attr(object, "conLin").
- **control**: an optional list with control parameters for the initialization and optimization algorithms used in lme. Defaults to list(niterEM=20, gradHess=TRUE), implying that 20 EM iterations are to be used in the derivation of initial estimates for the coefficients of the reStruct component of object and, if possible, numerical gradient vectors and Hessian matrices for the log-likelihood function are to be used in the optimization algorithm.
- **...**: some methods for this generic require additional arguments. None are used in this method.

Value

An lmeStruct object similar to object, but with initialized model components.

Author(s)

Jose Pinheiro (Jose.Pinheiro@pharma.novartis.com) and Douglas Bates (bates@stat.wisc.edu)

See Also

lme, Initialize.reStruct, Initialize.corStruct, Initialize.varFunc, Initialize

Description

Initial estimates for the parameters in the pdMat objects forming object, which have not yet been initialized, are obtained using the methodology described in Bates and Pinheiro (1998). These estimates may be refined using a series of EM iterations, as described in Bates and Pinheiro (1998). The number of EM iterations to be used is defined in control.

Usage

```r
## S3 method for class 'reStruct':
Initialize(object, data, conLin, control, ...)
```
### Initialize.varFunc

**Initialize varFunc Object**

**Description**

This method initializes `object` by evaluating its associated covariate(s) and grouping factor, if any is present, in `data`; determining if the covariate(s) need to be updated when the values of the coefficients associated with `object` change; initializing the log-likelihood and the weights associated with `object`; and assigning initial values for the coefficients in `object`, if none were present. The covariate(s) will only be initialized if no update is needed when `coef(object)` changes.

**Usage**

```r
## S3 method for class 'varFunc':
Initialize(object, data, ...)
```
intervals

Arguments

object  an object inheriting from class \texttt{varFunc}, representing a variance function structure.
data  a data frame in which to evaluate the variables named in \texttt{formula(object)}.
...  this argument is included to make this method compatible with the generic.

Value

an initialized object with the same class as \texttt{object} representing a variance function structure.

Author(s)

Jose Pinheiro (Jose.Pinheiro@pharma.novartis.com) and Douglas Bates (bates@stat.wisc.edu)

See Also

vf1 <- varPower( form = ~ age | Sex )
vf1 <- Initialize( vf1, Orthodont )
\end{verbatim}

Confidence Intervals on Coefficients

Description

Confidence intervals on the parameters associated with the model represented by \texttt{object} are obtained. This function is generic; method functions can be written to handle specific classes of objects. Classes which already have methods for this function include: \texttt{gls}, \texttt{lme}, and \texttt{lmList}.

Usage

\begin{verbatim}
intervals(object, level, ...)
\end{verbatim}

Arguments

object  a fitted model object from which parameter estimates can be extracted.
level  an optional numeric value for the interval confidence level. Defaults to 0.95.
...  some methods for the generic may require additional arguments.

Value

will depend on the method function used; see the appropriate documentation.

Author(s)

Jose Pinheiro (Jose.Pinheiro@pharma.novartis.com) and Douglas Bates (bates@stat.wisc.edu)
References

See Also

`intervals.lme`, `intervals.lmList`, `intervals.gls`

Examples

```r
## see the method documentation

intervals.gls  # Confidence Intervals on gls Parameters

Description

Approximate confidence intervals for the parameters in the linear model represented by `object` are obtained, using a normal approximation to the distribution of the (restricted) maximum likelihood estimators (the estimators are assumed to have a normal distribution centered at the true parameter values and with covariance matrix equal to the negative inverse Hessian matrix of the (restricted) log-likelihood evaluated at the estimated parameters). Confidence intervals are obtained in an unconstrained scale first, using the normal approximation, and, if necessary, transformed to the constrained scale.

Usage

```r
## S3 method for class 'gls':
intervals(object, level, which, ...)
```

Arguments

- `object`: an object inheriting from class `gls`, representing a generalized least squares fitted linear model.
- `level`: an optional numeric value for the interval confidence level. Defaults to 0.95.
- `which`: an optional character string specifying the subset of parameters for which to construct the confidence intervals. Possible values are "all" for all parameters, "var-cov" for the variance-covariance parameters only, and "coef" for the linear model coefficients only. Defaults to "all".
- `...`: some methods for this generic require additional arguments. None are used in this method.

Value

A list with components given by data frames with rows corresponding to parameters and columns `lower`, `est.`, and `upper` representing respectively lower confidence limits, the estimated values, and upper confidence limits for the parameters. Possible components are:

- `coef`: linear model coefficients, only present when `which` is not equal to "var-cov".
- `corStruct`: correlation parameters, only present when `which` is not equal to "coef" and a correlation structure is used in `object`.
**intervals.lme**

---

**Description**

Approximate confidence intervals for the parameters in the linear mixed-effects model represented by `object` are obtained, using a normal approximation to the distribution of the (restricted) maximum likelihood estimators (the estimators are assumed to have a normal distribution centered at the true parameter values and with covariance matrix equal to the negative inverse Hessian matrix of the (restricted) log-likelihood evaluated at the estimated parameters). Confidence intervals are obtained in an unconstrained scale first, using the normal approximation, and, if necessary, transformed to the constrained scale. The pdNatural parametrization is used for general positive-definite matrices.

**Usage**

```r
## S3 method for class 'lme':
intervals(object, level, which, ...)
```

**Arguments**

- **object**
  - an object inheriting from class `lme`, representing a fitted linear mixed-effects model.

- **level**
  - an optional numeric value with the confidence level for the intervals. Defaults to 0.95.

- **which**
  - an optional character string specifying the subset of parameters for which to construct the confidence intervals. Possible values are "all" for all parameters, "var-cov" for the variance-covariance parameters only, and "fixed" for the fixed effects only. Defaults to "all".

- **...**
  - some methods for this generic require additional arguments. None are used in this method.
Value

A list with components given by data frames with rows corresponding to parameters and columns lower, est., and upper representing respectively lower confidence limits, the estimated values, and upper confidence limits for the parameters. Possible components are:

- **fixed**: fixed effects, only present when which is not equal to "var-cov".
- **reStruct**: random effects variance-covariance parameters, only present when which is not equal to "fixed".
- **corStruct**: within-group correlation parameters, only present when which is not equal to "fixed" and a correlation structure is used in object.
- **varFunc**: within-group variance function parameters, only present when which is not equal to "fixed" and a variance function structure is used in object.
- **sigma**: within-group standard deviation.

intervals.lmList

Confidence Intervals on lmList Coefficients

Description

Confidence intervals on the linear model coefficients are obtained for each lm component of object and organized into a three dimensional array. The first dimension corresponding to the names of the object components. The second dimension is given by lower, est., and upper, corresponding, respectively, to the lower confidence limit, estimated coefficient, and upper confidence limit. The third dimension is given by the coefficients names.

Usage

```r
## S3 method for class 'lmList':
intervals(object, level, pool, ...)
```
isBalanced

Arguments

object an object inheriting from class lmList, representing a list of lm objects with a common model.
level an optional numeric value with the confidence level for the intervals. Defaults to 0.95.
pool an optional logical value indicating whether a pooled estimate of the residual standard error should be used. Default is attr(object, "pool").
... some methods for this generic require additional arguments. None are used in this method.

Value

a three dimensional array with the confidence intervals and estimates for the coefficients of each lm component of object.

isBalanced Check a Design for Balance

Description

Check the design of the experiment or study for balance.

Usage

isBalanced(object, countOnly, level)

Arguments

object A groupedData object containing a data frame and a formula that describes the roles of variables in the data frame. The object will have one or more nested grouping factors and a primary covariate.
countOnly A logical value indicating if the check for balance should only consider the number of observations at each level of the grouping factor(s). Defaults to FALSE.
level an optional integer vector specifying the desired prediction levels. Levels increase from outermost to innermost grouping, with level 0 representing the population (fixed effects) predictions. Defaults to the innermost level.
Details

A design is balanced with respect to the grouping factor(s) if there are the same number of observations at each distinct value of the grouping factor or each combination of distinct levels of the nested grouping factors. If `countOnly` is `FALSE` the design is also checked for balance with respect to the primary covariate, which is often the time of the observation. A design is balanced with respect to the grouping factor and the covariate if the number of observations at each distinct level (or combination of levels for nested factors) is constant and the times at which the observations are taken (in general, the values of the primary covariates) also are constant.

Value

`TRUE` or `FALSE` according to whether the data are balanced or not.

Author(s)

Jose Pinheiro (Jose.Pinheiro@pharma.novartis.com) and Douglas Bates (bates@stat.wisc.edu)

See Also

table, groupedData

Examples

```r
isBalanced(Orthodont) # should return TRUE
isBalanced(Orthodont, countOnly = TRUE) # should return TRUE
isBalanced(Pixel) # should return FALSE
isBalanced(Pixel, level = 1) # should return FALSE
```

---

**isInitialized**

Check if Object is Initialized

Description

Checks if `object` has been initialized (generally through a call to `Initialize`), by searching for components and attributes which are modified during initialization.

Usage

`isInitialized(object)`

Arguments

- `object`: any object requiring initialization.

Value

a logical value indicating whether `object` has been initialized.

Author(s)

Jose Pinheiro and Douglas Bates
LDEsysMat

See Also

Initialize

Examples

```r
pd1 <- pdDiag(~age)
isInitialized(pd1)
```

Description

Generate the system matrix for the linear differential equations determined by a compartment model.

Usage

```r
LDEsysMat(pars, incidence)
```

Arguments

- `pars` a numeric vector of parameter values.
- `incidence` an integer matrix with columns named `From`, `To`, and `Par`. Values in the `Par` column must be in the range 1 to `length(pars)`. Values in the `From` column must be between 1 and the number of compartments. Values in the `To` column must be between 0 and the number of compartments.

Details

A compartment model describes material transfer between \( k \) in a system of \( k \) compartments to a linear system of differential equations. Given a description of the system and a vector of parameter values this function returns the system matrix.

This function is intended for use in a general system for solving compartment models, as described in Bates and Watts (1988).

Value

A \( k \) by \( k \) numeric matrix.

Author(s)

Douglas Bates ⟨bates@stat.wisc.edu⟩

References

Examples

```r
# incidence matrix for a two compartment open system
incidence <-
  matrix(c(1,1,2,2,1,3,2,0), ncol = 3, byrow = TRUE,
      dimnames = list(NULL, c("Par", "From", "To")))
incidence
LDEsysMat(c(1.2, 0.3, 0.4), incidence)
```

### lme

**Linear Mixed-Effects Models**

**Description**

This generic function fits a linear mixed-effects model in the formulation described in Laird and Ware (1982) but allowing for nested random effects. The within-group errors are allowed to be correlated and/or have unequal variances.

**Usage**

```r
lme(fixed, data, random, correlation, weights, subset, method,
  na.action, control, contrasts = NULL, keep.data = TRUE)
```

#### Arguments

- `object`: an object inheriting from class `lme`, representing a fitted linear mixed-effects model.
- `fixed`: a two-sided linear formula object describing the fixed-effects part of the model, with the response on the left of a `~` operator and the terms, separated by `+` operators, on the right, an `lmList` object, or a `groupedData` object. The method functions `lme.lmList` and `lme.groupedData` are documented separately.
- `fixed.`: Changes to the fixed-effects formula – see `update.formula` for details.
- `data`: an optional data frame containing the variables named in `fixed`, `random`, `correlation`, `weights`, and `subset`. By default the variables are taken from the environment from which `lme` is called.
- `random`: optionally, any of the following: (i) a one-sided formula of the form `-x1+...+xn | g1/.../gm`, with `x1+...+xn` specifying the model for the random effects and `g1/.../gm` the grouping structure (`m` may be equal to 1, in which case no `/` is required). The random effects formula will be repeated for all levels of grouping, in the case of multiple levels of grouping; (ii) a list of one-sided formulas of the form `-x1+...+xn | g`, with possibly different random effects models for each grouping level. The order of nesting will be assumed the same as the order of the elements in the list; (iii) a one-sided formula of the form `-x1+...+xn`, or a `pdMat` object with a formula (i.e. a non-NULL value for `formula(object)`), or a list of such formulas or `pdMat` objects. In this case, the grouping structure formula will be derived from the data used to fit the linear mixed-effects model, which should inherit from class `groupedData`; (iv) a named list of formulas or `pdMat` objects as in (iii), with the grouping factors as names. The order of nesting will be assumed the same as
the order of the elements in the list; (v) an reStruct object. See the documentation on pdClasses for a description of the available pdMat classes. Defaults to a formula consisting of the right hand side of fixed.

correlation an optional corStruct object describing the within-group correlation structure. See the documentation of corClasses for a description of the available corStruct classes. Defaults to NULL, corresponding to no within-group correlations.

weights an optional varFunc object or one-sided formula describing the within-group heteroscedasticity structure. If given as a formula, it is used as the argument to varFixed, corresponding to fixed variance weights. See the documentation on varClasses for a description of the available varFunc classes. Defaults to NULL, corresponding to homocedastic within-group errors.

subset an optional expression indicating the subset of the rows of data that should be used in the fit. This can be a logical vector, or a numeric vector indicating which observation numbers are to be included, or a character vector of the row names to be included. All observations are included by default.

method a character string. If "REML" the model is fit by maximizing the restricted log-likelihood. If "ML" the log-likelihood is maximized. Defaults to "REML".

na.action a function that indicates what should happen when the data contain NAs. The default action (na.fail) causes lme to print an error message and terminate if there are any incomplete observations.

control a list of control values for the estimation algorithm to replace the default values returned by the function lmeControl. Defaults to an empty list.

contrasts an optional list. See the contrasts.arg of model.matrix.default.

keep.data logical: should the data argument (if supplied and a data frame) be saved as part of the model object?

... some methods for this generic require additional arguments. None are used in this method.

evaluate If TRUE evaluate the new call else return the call.

Value

an object of class lme representing the linear mixed-effects model fit. Generic functions such as print, plot and summary have methods to show the results of the fit. See lmeObject for the components of the fit. The functions resid, coef, fitted, fixed.effects, and random.effects can be used to extract some of its components.

lme.groupedData  LME fit from groupedData Object

Description

The response variable and primary covariate in \texttt{formula(fixed)} are used to construct the fixed effects model formula. This formula and the \texttt{groupedData} object are passed as the \texttt{fixed} and \texttt{data} arguments to \texttt{lme.formula}, together with any other additional arguments in the function call. See the documentation on \texttt{lme.formula} for a description of that function.

Usage

## S3 method for class 'groupedData':
lme(fixed, data, random, correlation, weights, subset, method, na.action, control, contrasts, keep.data = TRUE)
Arguments

fixed  a data frame inheriting from class groupedData.
data   this argument is included for consistency with the generic function. It is ignored
       in this method function.
random optionally, any of the following: (i) a one-sided formula of the form
        ~x1+...+xn | g1/.../gm, with x1+...+xn specifying the model for
        the random effects and g1/.../gm the grouping structure (m may be equal to
        1, in which case no / is required). The random effects formula will be repeated
        for all levels of grouping, in the case of multiple levels of grouping; (ii) a list
        of one-sided formulas of the form ~x1+...+xn | g, with possibly different
        random effects models for each grouping level. The order of nesting will be
        assumed the same as the order of the elements in the list; (iii) a one-sided for-
        mula of the form ~x1+...+xn, or a pdMat object with a formula (i.e. a non-
        NULL value for formula(object)), or a list of such formulas or pdMat
        objects. In this case, the grouping structure formula will be derived from the
        data used to fit the linear mixed-effects model, which should inherit from class
        groupedData; (iv) a named list of formulas or pdMat objects as in (iii), with
        the grouping factors as names. The order of nesting will be assumed the same
        as the order of the order of the elements in the list; (v) an reStruct object. See
        the documentation on pdClasses for a description of the available pdMat
        classes. Defaults to a formula consisting of the right hand side of fixed.
correlation an optional corStruct object describing the within-group correlation struc-
              ture. See the documentation of corStruct classes. Defaults to NULL, corre-
              sponding to no within-group correlations.
weights   an optional varFunc object or one-sided formula describing the within-group
          heteroscedasticity structure. If given as a formula, it is used as the argument to
          varFixed, corresponding to fixed variance weights. See the documentation
          on varClasses for a description of the available varFunc classes. Defaults
          to NULL, corresponding to homocedastic within-group errors.
subset    an optional expression indicating the subset of the rows of data that should be
          used in the fit. This can be a logical vector, or a numeric vector indicating which
          observation numbers are to be included, or a character vector of the row names
          to be included. All observations are included by default.
method    a character string. If "REML" the model is fit by maximizing the restricted
          log-likelihood. If "ML" the log-likelihood is maximized. Defaults to "REML".
na.action a function that indicates what should happen when the data contain NAs. The
           default action (na.fail) causes lme to print an error message and terminate
           if there are any incomplete observations.
control   a list of control values for the estimation algorithm to replace the default values
          returned by the function lmeControl. Defaults to an empty list.
contrasts an optional list. See the contrasts.arg of model.matrix.default.
keep.data logical: should the data argument (if supplied and a data frame) be saved as
          part of the model object?

Value

an object of class lme representing the linear mixed-effects model fit. Generic functions such
as print, plot and summary have methods to show the results of the fit. See lmeObject
for the components of the fit. The functions resid, coef, fitted, fixed.effects, and random.effects can be used to extract some of its components.

lme, groupedData, lmeObject

Examples

fm1 <- lme(Orthodont)
summary(fm1)
Description

If the random effects names defined in `random` are a subset of the `lmList` object coefficient names, initial estimates for the covariance matrix of the random effects are obtained (overwriting any values given in `random`). The `formula(fixed)` and the `data` argument in the calling sequence used to obtain `fixed` are passed as the `fixed` and `data` arguments to `lme.formula`, together with any other additional arguments in the function call. See the documentation on `lme.formula` for a description of that function.

Usage

```r
## S3 method for class 'lmList':
lme(fixed, data, random, correlation, weights, subset, method, na.action, control, contrasts, keep.data)
```

Arguments

- `fixed` an object inheriting from class `lmList`, representing a list of `lm` fits with a common model.
- `data` this argument is included for consistency with the generic function. It is ignored in this method function.
- `random` an optional one-sided linear formula with no conditioning expression, or a `pdMat` object with a `formula` attribute. Multiple levels of grouping are not allowed with this method function. Defaults to a formula consisting of the right-hand side of `formula(fixed)`.
- `correlation` an optional `corStruct` object describing the within-group correlation structure. See the documentation of `corClasses` for a description of the available `corStruct` classes. Defaults to `NULL`, corresponding to no within-group correlations.
- `weights` an optional `varFunc` object or one-sided formula describing the within-group heteroscedasticity structure. If given as a formula, it is used as the argument to `varFixed`, corresponding to fixed variance weights. See the documentation on `varClasses` for a description of the available `varFunc` classes. Defaults to `NULL`, corresponding to homocedastic within-group errors.
- `subset` an optional expression indicating the subset of the rows of `data` that should be used in the fit. This can be a logical vector, or a numeric vector indicating which observation numbers are to be included, or a character vector of the row names to be included. All observations are included by default.
- `method` a character string. If "REML" the model is fit by maximizing the restricted log-likelihood. If "ML" the log-likelihood is maximized. Defaults to "REML".
- `na.action` a function that indicates what should happen when the data contain NAs. The default action (na.fail) causes `lme` to print an error message and terminate if there are any incomplete observations.
- `control` a list of control values for the estimation algorithm to replace the default values returned by the function `lmeControl`. Defaults to an empty list.
contrasts an optional list. See the contrasts.arg of model.matrix.default.

keep.data logical: should the data argument (if supplied and a data frame) be saved as part of the model object?

Value

an object of class lme representing the linear mixed-effects model fit. Generic functions such as print, plot and summary have methods to show the results of the fit. See lmeObject for the components of the fit. The functions resid, coef, fitted, fixed.effects, and random.effects can be used to extract some of its components.

### lmeControl

**Control Values for lme Fit**

**Description**

The values supplied in the function call replace the defaults and a list with all possible arguments is returned. The returned list is used as the control argument to the lme function.

**Usage**

```r
lmeControl(maxIter, msMaxIter, tolerance, niterEM, msMaxEval, msTol,
msScale, msVerbose, returnObject, gradHess, apVar,
.relStep, minAbsParApVar, nlmStepMax,
opt = c("nlminb", "optim"), optimMethod, natural)
```

**Arguments**

- `maxIter`: maximum number of iterations for the lme optimization algorithm. Default is 50.
- `msMaxIter`: maximum number of iterations for the nlm optimization step inside the lme optimization. Default is 50.
- `tolerance`: tolerance for the convergence criterion in the lme algorithm. Default is 1e-6.
- `niterEM`: number of iterations for the EM algorithm used to refine the initial estimates of the random effects variance-covariance coefficients. Default is 25.
- `msMaxEval`: maximum number of evaluations of the objective function permitted for nlminb. Default is 200.
- `msTol`: tolerance for the convergence criterion in nlm, passed as the rel.tolerance argument to the function (see documentation on nlm). Default is 1e-7.
- `msScale`: scale function passed as the scale argument to the nlm function (see documentation on that function). Default is lmeScale.
- `msVerbose`: a logical value passed as the trace argument to nlm (see documentation on that function). Default is FALSE.
- `returnObject`: a logical value indicating whether the fitted object should be returned when the maximum number of iterations is reached without convergence of the algorithm. Default is FALSE.
- `gradHess`: a logical value indicating whether numerical gradient vectors and Hessian matrices of the log-likelihood function should be used in the nlm optimization. This option is only available when the correlation structure (corStruct) and the variance function structure (varFunc) have no "varying" parameters and the pdMat classes used in the random effects structure are pdSymm (general positive-definite), pdDiag (diagonal), pdIdent (multiple of the identity), or pdCompSymm (compound symmetry). Default is TRUE.
apVar  a logical value indicating whether the approximate covariance matrix of the variance-covariance parameters should be calculated. Default is TRUE.

.relStep  relative step for numerical derivatives calculations. Default is .Machine$double.eps^{(1/3)}.

.nlmStepMax  stepmax value to be passed to nlm. See nlm for details. Default is 100.0

opt  the optimizer to be used, either nlminb (the default since R 2.2.0) or optim (the previous default).

.optimMethod  character - the optimization method to be used with the optim optimizer. The default is "BFGS". An alternative is "L-BFGS-B".

.minAbsParApVar  numeric value - minimum absolute parameter value in the approximate variance calculation. The default is 0.05.

.natural  a logical value indicating whether the pdNatural parametrization should be used for general positive-definite matrices (pdSymm) in reStruct, when the approximate covariance matrix of the estimators is calculated. Default is TRUE.

Value

a list with components for each of the possible arguments.

Author(s)

Jose Pinheiro (Jose.Pinheiro@pharma.novartis.com) and Douglas Bates (bates@stat.wisc.edu)

See Also

lme, nlm, optim, lmeScale

Examples

# decrease the maximum number iterations in the ms call and
# request that information on the evolution of the ms iterations be printed
lmeControl(msMaxIter = 20, msVerbose = TRUE)

lmeObject  Fitted lme Object

Description

An object returned by the lme function, inheriting from class lme and representing a fitted linear mixed-effects model. Objects of this class have methods for the generic functions anova, coef, fitted, fixed.effects, formula, getGroups, getResponse, intervals, logLik, pairs, plot, predict, print, random.effects, residuals, summary, and update.
The following components must be included in a legitimate `lme` object.

**apVar**
- an approximate covariance matrix for the variance-covariance coefficients. If `apVar = FALSE` in the list of control values used in the call to `lme`, this component is equal to `NULL`.

**call**
- a list containing an image of the `lme` call that produced the object.

**coefficients**
- a list with two components, `fixed` and `random`, where the first is a vector containing the estimated fixed effects and the second is a list of matrices with the estimated random effects for each level of grouping. For each matrix in the `random` list, the columns refer to the random effects and the rows to the groups.

**contrasts**
- a list with the contrasts used to represent factors in the fixed effects formula and/or random effects formula. This information is important for making predictions from a new data frame in which not all levels of the original factors are observed. If no factors are used in the `lme` model, this component will be an empty list.

**dims**
- a list with basic dimensions used in the `lme` fit, including the components `N` - the number of observations in the data, `Q` - the number of grouping levels, `qvec` - the number of random effects at each level from innermost to outermost (last two values are equal to zero and correspond to the fixed effects and the response), `ngrps` - the number of groups at each level from innermost to outermost (last two values are one and correspond to the fixed effects and the response), and `ncol` - the number of columns in the model matrix for each level of grouping from innermost to outermost (last two values are equal to the number of fixed effects and one).

**fitted**
- a data frame with the fitted values as columns. The leftmost column corresponds to the population fixed effects (corresponding to the fixed effects only) and successive columns from left to right correspond to increasing levels of grouping.

**fixDF**
- a list with components `X` and `terms` specifying the denominator degrees of freedom for, respectively, t-tests for the individual fixed effects and F-tests for the fixed-effects terms in the models.

**groups**
- a data frame with the grouping factors as columns. The grouping level increases from left to right.

**logLik**
- the (restricted) log-likelihood at convergence.

**method**
- the estimation method: either "ML" for maximum likelihood, or "REML" for restricted maximum likelihood.

**modelStruct**
- an object inheriting from class `lmeStruct`, representing a list of mixed-effects model components, such as `reStruct`, `corStruct`, and `varFunc` objects.

**numIter**
- the number of iterations used in the iterative algorithm.

**residuals**
- a data frame with the residuals as columns. The leftmost column corresponds to the population residuals and successive columns from left to right correspond to increasing levels of grouping.

**sigma**
- the estimated within-group error standard deviation.

**varFix**
- an approximate covariance matrix of the fixed effects estimates.

**Author(s)**

lme, lmeStruct

---

lmeScale

Scale for lme Optimization

Description

This function calculates the scales to be used for each coefficient estimated through an `nlm` optimization in the `lme` function. If all initial values are zero, the scale is set to one for all coefficients; else, the scale for a coefficient with non-zero initial value is equal to the inverse of its initial value and the scale for the coefficients with initial value equal to zero is set to the median of the non-zero initial value coefficients.

Usage

lmeScale(start)

Arguments

- `start` the starting values for the coefficients to be estimated.

Value

a vector with the scales to be used in `nlm` for estimating the coefficients.

Author(s)

Jose Pinheiro (Jose.Pinheiro@pharma.novartis.com) and Douglas Bates (bates@stat.wisc.edu)

See Also

nlm

---

lmeStruct

Linear Mixed-Effects Structure

Description

A linear mixed-effects structure is a list of model components representing different sets of parameters in the linear mixed-effects model. An `lmeStruct` list must contain at least a `reStruct` object, but may also contain `corStruct` and `varFunc` objects. NULL arguments are not included in the `lmeStruct` list.

Usage

lmeStruct(reStruct, corStruct, varStruct)
lmList

Arguments

reStruct a reStruct representing a random effects structure.
corStruct an optional corStruct object, representing a correlation structure. Default is NULL.
varStruct an optional varFunc object, representing a variance function structure. Default is NULL.

Value

a list of model components determining the parameters to be estimated for the associated linear mixed-effects model.

Author(s)

Jose Pinheiro (Jose.Pinheiro@pharma.novartis.com) and Douglas Bates (bates@stat.wisc.edu)

See Also
corClasses, lme, residuals.lmeStruct, reStruct, varFunc

Examples

lms1 <- lmeStruct(reStruct(~age), corAR1(), varPower())

lmList

List of lm Objects with a Common Model

Description

Data is partitioned according to the levels of the grouping factor g and individual lm fits are obtained for each data partition, using the model defined in object.

Usage

lmList(object, data, level, subset, na.action, pool)
## S3 method for class 'lmList':
update(object, formula, ..., evaluate = TRUE)
## S3 method for class 'lmList':
print(x, pool, ...)

Arguments

object For lmList, either a linear formula object of the form y ~ x1+...+xn | g or a groupedData object. In the formula object, y represents the response, x1,...,xn the covariates, and g the grouping factor specifying the partitioning of the data according to which different lm fits should be performed. The grouping factor g may be omitted from the formula, in which case the grouping structure will be obtained from data, which must inherit from class groupedData. The method function lmList.groupedData is documented separately. For the method update.lmList, object is an object inheriting from class lmList.
formula (used in update.lmList only) a two-sided linear formula with the common model for the individuals lm fits.

Changes to the formula – see update.formula for details.

data a data frame in which to interpret the variables named in object.

level an optional integer specifying the level of grouping to be used when multiple nested levels of grouping are present.

an optional expression indicating which subset of the rows of data should be used in the fit. This can be a logical vector, or a numeric vector indicating which observation numbers are to be included, or a character vector of the row names to be included. All observations are included by default.

na.action a function that indicates what should happen when the data contain NAs. The default action (na.fail) causes lmList to print an error message and terminate if there are any incomplete observations.

pool an optional logical value indicating whether a pooled estimate of the residual standard error should be used in calculations of standard deviations or standard errors for summaries.

x an object inheriting from class lmList to be printed.

... some methods for this generic require additional arguments. None are used in this method.

evaluate If TRUE evaluate the new call else return the call.

Value

a list of lm objects with as many components as the number of groups defined by the grouping factor. Generic functions such as coef, fixed.effects, lme, pairs, plot, predict, random.effects, summary, and update have methods that can be applied to an lmList object.

References

See Also

Examples

fml <- lmList(distance ~ age | Subject, Orthodont)
summary(fml)
lmList.groupedData  lmList Fit from a groupedData Object

Description

The response variable and primary covariate in formula(object) are used to construct the linear model formula. This formula and the groupedData object are passed as the object and data arguments to lmList.formula, together with any other additional arguments in the function call. See the documentation on lmList.formula for a description of that function.

Usage

## S3 method for class 'groupedData':
lmList(object, data, level, subset, na.action, pool)

Arguments

object  a data frame inheriting from class groupedData.
data this argument is included for consistency with the generic function. It is ignored in this method function.
level  an optional integer specifying the level of grouping to be used when multiple nested levels of grouping are present.
subset  an optional expression indicating which subset of the rows of data should be used in the fit. This can be a logical vector, or a numeric vector indicating which observation numbers are to be included, or a character vector of the row names to be included. All observations are included by default.
na.action  a function that indicates what should happen when the data contain NAs. The default action (na.fail) causes lmList to print an error message and terminate if there are any incomplete observations.
pool  an optional logical value that is preserved as an attribute of the returned value. This will be used as the default for pool in calculations of standard deviations or standard errors for summaries.

Value

a list of lm objects with as many components as the number of groups defined by the grouping factor. Generic functions such as coef, fixed.effects, lme, pairs, plot, predict, random.effects, summary, and update have methods that can be applied to an lmList object.

See Also

groupedData, lm, lme.lmList, lmList.lmList.formula

Examples

fm1 <- lmList(Orthodont)
summary(fm1)
logDet corStruct

Extract the Logarithm of the Determinant

Description
This function is generic; method functions can be written to handle specific classes of objects. Classes which already have methods for this function include: corStruct, several pdMat classes, and reStruct.

Usage
logDet(object, ...)

Arguments
object any object from which a matrix, or list of matrices, can be extracted
... some methods for this generic function require additional arguments.

Value
will depend on the method function used; see the appropriate documentation.

Author(s)
Jose Pinheiro (Jose.Pinheiro@pharma.novartis.com) and Douglas Bates (bates@stat.wisc.edu)

## see the method function documentation

logDet.corStruct corStruct Log-Determinant

Description
This method function extracts the logarithm of the determinant of a square-root factor of the correlation matrix associated with object, or the sum of the log-determinants of square-root factors of the list of correlation matrices associated with object.

Usage
## S3 method for class 'corStruct':
logDet(object, covariate, ...)

logDet.corStruct corStruct Log-Determinant

Description
This method function extracts the logarithm of the determinant of a square-root factor of the correlation matrix associated with object, or the sum of the log-determinants of square-root factors of the list of correlation matrices associated with object.

Usage
## S3 method for class 'corStruct':
logDet(object, covariate, ...)

**Arguments**

- **object**: an object inheriting from class `corStruct`, representing a correlation structure.
- **covariate**: an optional covariate vector (matrix), or list of covariate vectors (matrices), at which values the correlation matrix, or list of correlation matrices, are to be evaluated. Defaults to `getCovariate(object)`.
- **...**: some methods for this generic require additional arguments. None are used in this method.

**Value**

the log-determinant of a square-root factor of the correlation matrix associated with `object`, or the sum of the log-determinants of square-root factors of the list of correlation matrices associated with `object`.

**Author(s)**

Jose Pinheiro (Jose.Pinheiro@pharma.novartis.com) and Douglas Bates (bates@stat.wisc.edu)

**See Also**

- `logLik.corStruct`, `corMatrix.corStruct`, `logDet`

**Examples**

```r
cs1 <- corAR1(0.3)
logDet(cs1, covariate = 1:4)
```

---

**logDet.pdMat**  
*Extract Log-Determinant from a pdMat Object*

**Description**

This method function extracts the logarithm of the determinant of a square-root factor of the positive-definite matrix represented by `object`.

**Usage**

```r
## S3 method for class 'pdMat':
logDet(object, ...)
```

**Arguments**

- **object**: an object inheriting from class `pdMat`, representing a positive definite matrix.
- **...**: some methods for this generic require additional arguments. None are used in this method.

**Value**

the log-determinant of a square-root factor of the positive-definite matrix represented by `object`. 
Author(s)

Jose Pinheiro (Jose.Pinheiro@pharma.novartis.com) and Douglas Bates (bates@stat.wisc.edu)

See Also

pdMat, logDet

Examples

```r
pd1 <- pdSymm(diag(1:3))
logDet(pd1)
```

Description

Calculates, for each of the pdMat components of object, the logarithm of the determinant of a square-root factor.

Usage

```r
## S3 method for class 'reStruct':
logDet(object, ...)
```

Arguments

- `object` an object inheriting from class reStruct, representing a random effects structure and consisting of a list of pdMat objects.
- `...` some methods for this generic require additional arguments. None are used in this method.

Value

a vector with the log-determinants of square-root factors of the pdMat components of object.

Author(s)

Jose Pinheiro

See Also

reStruct, pdMat, logDet

Examples

```r
rs1 <- reStruct(list(A = pdSymm(diag(1:3), form = ~Score),
                 B = pdDiag(2 * diag(4), form = ~Educ)))
logDet(rs1)
```
Description

This method function extracts the component of a Gaussian log-likelihood associated with the correlation structure, which is equal to the negative of the logarithm of the determinant (or sum of the logarithms of the determinants) of the matrix (or matrices) represented by `object`.

Usage

```r
## S3 method for class 'corStruct':
logLik(object, data, ...)
```

 Arguments

- `object`: an object inheriting from class `corStruct`, representing a correlation structure.
- `data`: this argument is included to make this method function compatible with other `logLik` methods and will be ignored.
- `...`: some methods for this generic require additional arguments. None are used in this method.

Value

The negative of the logarithm of the determinant (or sum of the logarithms of the determinants) of the correlation matrix (or matrices) represented by `object`.

Author(s)

Jose Pinheiro (Jose.Pinheiro@pharma.novartis.com) and Douglas Bates (bates@stat.wisc.edu)

See Also

`logDet.corStruct`, `logLik.lme`.

Examples

```r
cs1 <- corAR1(0.2)
cs1 <- Initialize(cs1, data = Orthodont)
logLik(cs1)
```
**logLik.glsStruct**  
*Log-Likelihood of a glsStruct Object*

**Description**  
`Pars` is used to update the coefficients of the model components of `object` and the individual (restricted) log-likelihood contributions of each component are added together. The type of log-likelihood (restricted or not) is determined by the `settings` attribute of `object`.

**Usage**  
```r
## S3 method for class 'glsStruct':
logLik(object, Pars, conLin, ...)
```

**Arguments**
- `object`: an object inheriting from class `glsStruct`, representing a list of linear model components, such as `corStruct` and `varFunc` objects.
- `Pars`: the parameter values at which the (restricted) log-likelihood is to be evaluated.
- `conLin`: an optional condensed linear model object, consisting of a list with components "Xy", corresponding to a regression matrix (X) combined with a response vector (y), and "logLik", corresponding to the log-likelihood of the underlying linear model. Defaults to `attr(object, "conLin")`.
- `...`: some methods for this generic require additional arguments. None are used in this method.

**Value**
the (restricted) log-likelihood for the linear model described by `object`, evaluated at `Pars`.

**Author(s)**
Jose Pinheiro (Jose.Pinheiro@pharma.novartis.com) and Douglas Bates (bates@stat.wisc.edu)

**See Also**
`gls, glsStruct, logLik.lme`

---

**logLik.gnls**  
*Log-Likelihood of a gnls Object*

**Description**
Returns the log-likelihood value of the nonlinear model represented by `object` evaluated at the estimated coefficients.

**Usage**
```r
## S3 method for class 'gnls':
logLik(object, REML, ...)
```

**Arguments**
- `object`: the nonlinear model object.
- `REML`: a logical value indicating whether the log-likelihood is to be evaluated for the REML estimates (default). If `FALSE`, the value for the maximum likelihood estimates is returned.
- `...`: some methods for this generic require additional arguments. None are used in this method.
The `logLik.gnlsStruct` function calculates the log-likelihood of a `gnlsStruct` object, which is a list of model components, such as `corStruct` and `varFunc` objects, and attributes specifying the underlying nonlinear model and the response variable.

**Arguments**

- **object**: an object inheriting from class `gnlsStruct`, representing a list of model components, such as `corStruct` and `varFunc` objects, and attributes specifying the underlying nonlinear model and the response variable.
- **Pars**: the parameter values at which the log-likelihood is to be evaluated.
- **conLin**: an optional condensed linear model object, consisting of a list with components "Xy", corresponding to a regression matrix (X) combined with a response vector (y), and "logLik", corresponding to the log-likelihood of the underlying nonlinear model. Defaults to `attr(object, "conLin")`.
- **...**: some methods for this generic require additional arguments. None are used in this method.

**Value**

The log-likelihood of the linear model represented by `object` evaluated at the estimated coefficients.

**Author(s)**

Jose Pinheiro (Jose.Pinheiro@pharma.novartis.com) and Douglas Bates (bates@stat.wisc.edu)

**See Also**

- `gnls`, `logLik.lme`
logLik.lme

Log-Likelihood of an lme Object

Description

If REML=FALSE, returns the log-likelihood value of the linear mixed-effects model represented by object evaluated at the estimated coefficients; else, the restricted log-likelihood evaluated at the estimated coefficients is returned.

Usage

```r
## S3 method for class 'lme':
logLik(object, REML, ...)
```

Arguments

- `object`: an object inheriting from class `lme`, representing a fitted linear mixed-effects model.
- `REML`: an optional logical value. If TRUE the restricted log-likelihood is returned, else, if FALSE, the log-likelihood is returned. Defaults to FALSE.
- `...`: some methods for this generic require additional arguments. None are used in this method.

Value

the (restricted) log-likelihood of the model represented by object evaluated at the estimated coefficients.

Author(s)

Jose Pinheiro and Douglas Bates

logLik(fm1)
logLik(fm1, REML = TRUE)
```

logLik.lmeStruct Log-Likelihood of an lmeStruct Object

Description

Pars is used to update the coefficients of the model components of object and the individual (restricted) log-likelihood contributions of each component are added together. The type of log-likelihood (restricted or not) is determined by the settings attribute of object.

Usage

```r
## S3 method for class 'lmeStruct':
logLik(object, Pars, conLin, ...)
```

Arguments

- **object**: an object inheriting from class lmeStruct, representing a list of linear mixed-effects model components, such as reStruct, corStruct, and varFunc objects.
- **Pars**: the parameter values at which the (restricted) log-likelihood is to be evaluated.
- **conLin**: an optional condensed linear model object, consisting of a list with components "Xy", corresponding to a regression matrix (X) combined with a response vector (y), and "logLik", corresponding to the log-likelihood of the underlying lme model. Defaults to attr(object, "conLin").
- **...**: some methods for this generic require additional arguments. None are used in this method.

Value

the (restricted) log-likelihood for the linear mixed-effects model described by object, evaluated at Pars.

Author(s)

Jose Pinheiro (Jose.Pinheiro@pharma.novartis.com) and Douglas Bates (bates@stat.wisc.edu)

See Also

lme, lmeStruct, logLik.lme
logLik.lmList  

**Log-Likelihood of an lmList Object**

**Description**

If `pool=FALSE`, the (restricted) log-likelihoods of the `lm` components of `object` are summed together. Else, the (restricted) log-likelihood of the `lm` fit with different coefficients for each level of the grouping factor associated with the partitioning of the `object` components is obtained.

**Usage**

```r
## S3 method for class 'lmList':
logLik(object, REML, pool, ...)
```

**Arguments**

- `object`  
an object inheriting from class `lmList`, representing a list of `lm` objects with a common model.

- `REML`  
an optional logical value. If `TRUE` the restricted log-likelihood is returned, else, if `FALSE`, the log-likelihood is returned. Defaults to `FALSE`.

- `pool`  
an optional logical value indicating whether all `lm` components of `object` may be assumed to have the same error variance. Default is `attr(object, "pool")`.

- `...`  
some methods for this generic require additional arguments. None are used in this method.

**Value**

either the sum of the (restricted) log-likelihoods of each `lm` component in `object`, or the (restricted) log-likelihood for the `lm` fit with separate coefficients for each component of `object`.

**Author(s)**

Jose Pinheiro (Jose.Pinheiro@pharma.novartis.com) and Douglas Bates (bates@stat.wisc.edu)

**See Also**

- `lmList`, `logLik.lme`

**Examples**

```r
fm1 <- lmList(distance ~ age | Subject, Orthodont)
logLik(fm1)  # returns NA when it should not
```
logLik.reStruct  Calculate reStruct Log-Likelihood

Description

Calculates the log-likelihood, or restricted log-likelihood, of the Gaussian linear mixed-effects model represented by object and conLin (assuming spherical within-group covariance structure), evaluated at coef(object). The settings attribute of object determines whether the log-likelihood, or the restricted log-likelihood, is to be calculated. The computational methods are described in Bates and Pinheiro (1998).

Usage

### S3 method for class 'reStruct':

logLik(object, conLin, ...)

Arguments

- **object**: an object inheriting from class reStruct, representing a random effects structure and consisting of a list of pdMat objects.
- **conLin**: a condensed linear model object, consisting of a list with components "Xy", corresponding to a regression matrix (X) combined with a response vector (y), and "logLik", corresponding to the log-likelihood of the underlying model.
- **...**: some methods for this generic require additional arguments. None are used in this method.

Value

the log-likelihood, or restricted log-likelihood, of linear mixed-effects model represented by object and conLin, evaluated at coef(object).

Author(s)

Jose Pinheiro (Jose_Pinheiro@pharma.novartis.com) and Douglas Bates (bates@stat.wisc.edu)

References

See Also

reStruct, pdMat, logLik.lme
**Description**

This method function extracts the component of a Gaussian log-likelihood associated with the variance function structure represented by `object`, which is equal to the sum of the logarithms of the corresponding weights.

**Usage**

```r
## S3 method for class 'varFunc':
logLik(object, data, ...)
```

**Arguments**

- **object**: an object inheriting from class `varFunc`, representing a variance function structure.
- **data**: this argument is included to make this method function compatible with other `logLik` methods and will be ignored.
- **...**: some methods for this generic require additional arguments. None are used in this method.

**Value**

the sum of the logarithms of the weights corresponding to the variance function structure represented by `object`.

**Author(s)**

Jose Pinheiro (Jose.Pinheiro@pharma.novartis.com) and Douglas Bates (bates@stat.wisc.edu)

**See Also**

`logLik.lme`

**Examples**

```r

vf1 <- Initialize(vf1, Orthodont)
coef(vf1) <- 0.1
logLik(vf1)
```
### Machines

**Productivity Scores for Machines and Workers**

**Description**

The Machines data frame has 54 rows and 3 columns.

**Format**

This data frame contains the following columns:

- **Worker** an ordered factor giving the unique identifier for the worker.
- **Machine** a factor with levels A, B, and C identifying the machine brand.
- **score** a productivity score.

**Details**

Data on an experiment to compare three brands of machines used in an industrial process are presented in Milliken and Johnson (p. 285, 1992). Six workers were chosen randomly among the employees of a factory to operate each machine three times. The response is an overall productivity score taking into account the number and quality of components produced.

**Source**

### MathAchieve

**Mathematics achievement scores**

**Description**

The MathAchieve data frame has 7185 rows and 6 columns.

**Format**

This data frame contains the following columns:

- **School** an ordered factor identifying the school that the student attends
- **Minority** a factor with levels No Yes indicating if the student is a member of a minority racial group.
- **Sex** a factor with levels Male Female
- **SES** a numeric vector of socio-economic status.
- **MathAch** a numeric vector of mathematics achievement scores.
- **MEANSES** a numeric vector of the mean SES for the school.
Details

Each row in this data frame contains the data for one student.

Examples

```r
summary(MathAchieve)
```

---

### MathAchSchool

**School demographic data for MathAchieve**

#### Description

The `MathAchSchool` data frame has 160 rows and 7 columns.

#### Format

This data frame contains the following columns:

- **School**: a factor giving the school on which the measurement is made.
- **Size**: a numeric vector giving the number of students in the school.
- **Sector**: a factor with levels `Public Catholic`.
- **PRACAD**: a numeric vector giving the percentage of students on the academic track.
- **DISCLIM**: a numeric vector measuring the discrimination climate.
- **HIMINTY**: a factor with levels `0 1`.
- **MEANSES**: a numeric vector giving the mean SES score.

#### Details

These variables give the school-level demographic data to accompany the `MathAchieve` data.

---

### Matrix

**Assign Matrix Values**

#### Description

This function is generic; method functions can be written to handle specific classes of objects. Classes which already have methods for this function include `pdMat`, `pdBlocked`, and `reStruct`.

#### Usage

```r
matrix(object) <- value
```

#### Arguments

- **object**: any object to which `as.matrix` can be applied.
- **value**: a matrix, or list of matrices, with the same dimensions as `as.matrix(object)` with the new values to be assigned to the matrix associated with `object`. 
The positive-definite matrix represented by `object` is replaced by `value`. If the original matrix had row and/or column names, the corresponding names for `value` can either be `NULL`, or a permutation of the original names.

### Usage
```r
## S3 replacement method for class 'pdMat':
matrix(object) <- value
```

### Arguments
- `object` an object inheriting from class `pdMat`, representing a positive definite matrix.
- `value` a matrix with the new values to be assigned to the positive-definite matrix represented by `object`. Must have the same dimensions as `as.matrix(object)`.

### Value
a `pdMat` object similar to `object`, but with its coefficients modified to produce the matrix in `value`.

### Examples
```r
d1 <- pdSymm(diag(3))
matrix(d1) <- diag(1:3)
d1
```
Matrix.reStruct  Assign reStruct Matrices

Description
The individual matrices in value are assigned to each pdMat component of object, in the order they are listed. The new matrices must have the same dimensions as the matrices they are meant to replace.

Usage
```r
## S3 replacement method for class 'reStruct':
matrix(object) <- value
```

Arguments
- **object**: an object inheriting from class reStruct, representing a random effects structure and consisting of a list of pdMat objects.
- **value**: a matrix, or list of matrices, with the new values to be assigned to the matrices associated with the pdMat components of object.

Value
an reStruct object similar to object, but with the coefficients of the individual pdMat components modified to produce the matrices listed in value.

Author(s)
Jose Pinheiro (Jose.Pinheiro@pharma.novartis.com) and Douglas Bates (bates@stat.wisc.edu)

See Also
reStruct, pdMat, "matrix<-"

Examples
```r
rs1 <- reStruct(list(Dog = ~day, Side = ~1), data = Pixel)
matrix(rs1) <- list(diag(2), 3)
```

Meat  Tenderness of meat

Description
The Meat data frame has 30 rows and 4 columns.
Milk

Format

This data frame contains the following columns:

- **Storage**: an ordered factor specifying the storage treatment - 1 (0 days), 2 (1 day), 3 (2 days), 4 (4 days), 5 (9 days), and 6 (18 days).
- **Score**: a numeric vector giving the tenderness score of beef roast.
- **Block**: an ordered factor identifying the muscle from which the roast was extracted with levels II < V < I < III < IV.
- **Pair**: an ordered factor giving the unique identifier for each pair of beef roasts with levels II-1 < ... < IV-1.

Details

Cochran and Cox (section 11.51, 1957) describe data from an experiment conducted at Iowa State College (Paul, 1943) to compare the effects of length of cold storage on the tenderness of beef roasts. Six storage periods ranging from 0 to 18 days were used. Thirty roasts were scored by four judges on a scale from 0 to 10, with the score increasing with tenderness. The response was the sum of all four scores. Left and right roasts from the same animal were grouped into pairs, which were further grouped into five blocks, according to the muscle from which they were extracted. Different storage periods were applied to each roast within a pair according to a balanced incomplete block design.

Source

---

Milk

Protein content of cows’ milk

Description

The Milk data frame has 1337 rows and 4 columns.

Format

This data frame contains the following columns:

- **Protein**: a numeric vector giving the protein content of the milk.
- **Time**: a numeric vector giving the time since calving (weeks).
- **Cow**: an ordered factor giving a unique identifier for each cow.
- **Diet**: a factor with levels barley, barley+lupins, and lupins identifying the diet for each cow.

Details

Diggle, Liang, and Zeger (1994) describe data on the protein content of cows’ milk in the weeks following calving. The cattle are grouped according to whether they are fed a diet with barley alone, with barley and lupins, or with lupins alone.
model.matrix.reStruct

reStruct Model Matrix

Description

The model matrices for each element of `formula(object)`, calculated using `data`, are bound together column-wise. When multiple grouping levels are present (i.e. when `length(object) > 1`), the individual model matrices are combined from innermost (at the leftmost position) to outermost (at the rightmost position).

Usage

```
## S3 method for class 'reStruct':
model.matrix(object, data, contrast, ...)
```

Arguments

- **object**: an object inheriting from class `reStruct`, representing a random effects structure and consisting of a list of `pdMat` objects.
- **data**: a data frame in which to evaluate the variables defined in `formula(object)`.
- **contrast**: an optional named list specifying the contrasts to be used for representing the factor variables in `data`. The components names should match the names of the variables in `data` for which the contrasts are to be specified. The components of this list will be used as the `contrasts` attribute of the corresponding factor. If missing, the default contrast specification is used.
- **...**: some methods for this generic require additional arguments. None are used in this method.

Value

A matrix obtained by binding together, column-wise, the model matrices for each element of `formula(object)`.

Author(s)

Jose Pinheiro (Jose.Pinheiro@pharma.novartis.com) and Douglas Bates (bates@stat.wisc.edu)

See Also

- `model.matrix`
- `contrasts`
- `reStruct`
- `formula.reStruct`

Examples

```r
rs1 <- reStruct(list(Dog = ~day, Side = ~1), data = Pixel)
model.matrix(rs1, Pixel)
```
Muscle

Contraction of heart muscle sections

Description

The Muscle data frame has 60 rows and 3 columns.

Format

This data frame contains the following columns:

- **Strip**: an ordered factor indicating the strip of muscle being measured.
- **conc**: a numeric vector giving the concentration of CaCl2
- **length**: a numeric vector giving the shortening of the heart muscle strip.

Details

Baumann and Waldvogel (1963) describe data on the shortening of heart muscle strips dipped in a CaCl2 solution. The muscle strips are taken from the left auricle of a rat’s heart.

Source

Names

Names Associated with an Object

Description

This function is generic; method functions can be written to handle specific classes of objects. Classes which already have methods for this function include: `formula`, `modelStruct`, `pdBlocked`, `pdMat`, and `reStruct`.

Usage

```r
Names(object, ...) 
Names(object, ...) <- value
```

Arguments

- **object**: any object for which names can be extracted and/or assigned.
- **...**: some methods for this generic function require additional arguments.
- **value**: names to be assigned to `object`.

Value

will depend on the method function used; see the appropriate documentation.
SIDE EFFECTS
On the left side of an assignment, sets the names associated with \texttt{object} to \texttt{value}, which must have an appropriate length.

Note
If \texttt{names} were generic, there would be no need for this generic function.

Author(s)
Jose Pinheiro \{Jose.Pinheiro@pharma.novartis.com\} and Douglas Bates \{bates@stat.wisc.edu\}

See Also
\texttt{Names.formula}, \texttt{Names.pdMat}

Examples
```r
## see the method function documentation
```

### Description
This method function returns the names of the terms corresponding to the right hand side of \texttt{object} (treated as a linear formula), obtained as the column names of the corresponding \texttt{model.matrix}.

### Usage
```r
## S3 method for class 'formula':
Names(object, data, exclude, ...)
```

### Arguments
- \texttt{object} an object inheriting from class \texttt{formula}.
- \texttt{data} an optional data frame containing the variables specified in \texttt{object}. By default the variables are taken from the environment from which \texttt{Names.formula} is called.
- \texttt{exclude} an optional character vector with names to be excluded from the returned value. Default is \texttt{c("pi","."}).
- \texttt{...} some methods for this generic require additional arguments. None are used in this method.

### Value
a character vector with the column names of the \texttt{model.matrix} corresponding to the right hand side of \texttt{object} which are not listed in \texttt{excluded}. 

### Examples
```r
## see the method function documentation
```
Author(s)

model.matrix, terms, Names

Examples
Names(distance ~ Sex * age, data = Orthodont)

Names.pdBlocked  

Names of a pdBlocked Object

Description
This method function extracts the first element of the Dimnames attribute, which contains the column names, for each block diagonal element in the matrix represented by object.

Usage
## S3 method for class 'pdBlocked':
Names(object, asList, ...)

Arguments

object  
an object inheriting from class pdBlocked representing a positive-definite matrix with block diagonal structure

asList  
a logical value. If TRUE a list with the names for each block diagonal element is returned. If FALSE a character vector with all column names is returned. Defaults to FALSE.

...  
some methods for this generic require additional arguments. None are used in this method.

Value
if asList is FALSE, a character vector with column names of the matrix represented by object; otherwise, if asList is TRUE, a list with components given by the column names of the individual block diagonal elements in the matrix represented by object.

Author(s)
Jose Pinheiro ⟨Jose.Pinheiro@pharma.novartis.com⟩ and Douglas Bates ⟨bates@stat.wisc.edu⟩

See Also
Names, Names.pdMat

Examples
pdl <- pdBlocked(list(~Sex - 1, ~age - 1), data = Orthodont)
Names(pdl)
Names.pdMat  

Names of a pdMat Object

Description

This method function returns the first element of the Dimnames attribute of object, which contains the column names of the matrix represented by object.

Usage

```r
## S3 method for class 'pdMat':
Names(object, ...)
## S3 replacement method for class 'pdMat':
Names(object, ...) <- value
```

Arguments

- **object**: an object inheriting from class pdMat, representing a positive-definite matrix.
- **value**: a character vector with the replacement values for the column and row names of the matrix represented by object. It must have length equal to the dimension of the matrix represented by object and, if names have been previously assigned to object, it must correspond to a permutation of the original names.
- **...**: some methods for this generic require additional arguments. None are used in this method.

Value

if object has a Dimnames attribute then the first element of this attribute is returned; otherwise NULL.

SIDE EFFECTS

On the left side of an assignment, sets the Dimnames attribute of object to list(value, value).

Author(s)

Jose Pinheiro (Jose.Pinheiro@pharma.novartis.com) and Douglas Bates (bates@stat.wisc.edu)

See Also

Names, Names.pdBlocked

Examples

```r
pd1 <- pdSymm(~age, data = Orthodont)
Names(pd1)
```
Description

This method function extracts the column names of each of the positive-definite matrices represented the `pdMat` elements of `object`.

Usage

```r
## S3 method for class 'reStruct':
Names(object, ...)  
## S3 replacement method for class 'reStruct':
Names(object, ...) <- value
```

Arguments

- `object` an object inheriting from class `reStruct`, representing a random effects structure and consisting of a list of `pdMat` objects.
- `value` a list of character vectors with the replacement values for the names of the individual `pdMat` objects that form `object`. It must have the same length as `object`.
- `...` some methods for this generic require additional arguments. None are used in this method.

Value

a list containing the column names of each of the positive-definite matrices represented by the `pdMat` elements of `object`.

SIDE EFFECTS

On the left side of an assignment, sets the `Names` of the `pdMat` elements of `object` to the corresponding element of `value`.

```
needUpdate  

Check if Update is Needed

Description

This function is generic; method functions can be written to handle specific classes of objects. By default, it tries to extract a `needUpdate` attribute of `object`. If this is `NULL` or `FALSE` it returns `FALSE`; else it returns `TRUE`. Updating of objects usually takes place in iterative algorithms in which auxiliary quantities associated with the object, and not being optimized over, may change.

Usage

```r
needUpdate(object)
```

Arguments

- `object`: any object

Value

A logical value indicating whether `object` needs to be updated.

Author(s)

Jose Pinheiro (Jose.Pinheiro@pharma.novartis.com) and Douglas Bates (bates@stat.wisc.edu)

See Also

`needUpdate.modelStruct`

Examples

```r
vf1 <- varExp()
vf1 <- Initialize(vf1, data = Orthodont)
needUpdate(vf1)
```

needUpdate.modelStruct  

Check if a modelStruct Object Needs Updating

Description

This method function checks if any of the elements of `object` needs to be updated. Updating of objects usually takes place in iterative algorithms in which auxiliary quantities associated with the object, and not being optimized over, may change.

Usage

```r
## S3 method for class 'modelStruct':
needUpdate(object)
```
**Arguments**

`object`  
an object inheriting from class `modelStruct`, representing a list of model components, such as `corStruct` and `varFunc` objects.

**Value**

a logical value indicating whether any element of `object` needs to be updated.

**Author(s)**

Jose Pinheiro (Jose.Pinheiro@pharma.novartis.com) and Douglas Bates (bates@stat.wisc.edu)

**See Also**

`needUpdate`

**Examples**

```r
lms1 <- lmeStruct(reStruct = reStruct(pdDiag(diag(2), ~age)),
                  varStruct = varPower(form = ~age))
needUpdate(lms1)
```

---

### Nitrendipene

**Assay of nitrendipene**

**Description**

The Nitrendipene data frame has 89 rows and 4 columns.

**Format**

This data frame contains the following columns:

- **activity** a numeric vector
- **NIF** a numeric vector
- **Tissue** an ordered factor with levels 2 < 1 < 3 < 4
- **log.NIF** a numeric vector

**Details**

**Source**

**Description**

This generic function fits a nonlinear mixed-effects model in the formulation described in Lindstrom and Bates (1990) but allowing for nested random effects. The within-group errors are allowed to be correlated and/or have unequal variances.

**Usage**

```r
nlme(model, data, fixed, random, groups, start, correlation, weights,
     subset, method, na.action, naPattern, control, verbose)
```

**Arguments**

- `model`  
  a nonlinear model formula, with the response on the left of a `~` operator and an expression involving parameters and covariates on the right, or an `nlsList` object. If `data` is given, all names used in the formula should be defined as parameters or variables in the data frame. The method function `nlme.nlsList` is documented separately.

- `data`  
  an optional data frame containing the variables named in `model`, `fixed`, `random`, `correlation`, `weights`, `subset`, and `naPattern`. By default the variables are taken from the environment from which `nlme` is called.

- `fixed`  
  a two-sided linear formula of the form `f1+...+fn~x1+...+xm`, or a list of two-sided formulas of the form `f1~x1+...+xm`, with possibly different models for different parameters. The `f1,...,fn` are the names of parameters included on the right hand side of `model` and the `x1+...+xm` expressions define linear models for these parameters (when the left hand side of the formula contains several parameters, they all are assumed to follow the same linear model, described by the right hand side expression). A `1` on the right hand side of the formula(s) indicates a single fixed effects for the corresponding parameter(s).

- `random`  
  optionally, any of the following: (i) a two-sided formula of the form `r1+...+rn~x1+...+xm | g1/.../gQ`, with `r1,...,rn` naming parameters included on the right hand side of `model`, `x1+...+xm` specifying the random-effects model for these parameters and `g1/.../gQ` the grouping structure (Q may be equal to 1, in which case no `/` is required). The random effects formula will be repeated for all levels of grouping, in the case of multiple levels of grouping; (ii) a two-sided formula of the form `r1+...+rn~x1+...+xm`, a list of two-sided formulas of the form `r1~x1+...+xm`, with possibly different random-effects models for different parameters, a `pdMat` object with a two-sided formula, or list of two-sided formulas (i.e. a non-NULL value for `formula(random)`), or a list of `pdMat` objects with two-sided formulas, or lists of two-sided formulas. In this case, the grouping structure formula will be given in `groups`, or derived from the data used to fit the nonlinear mixed-effects model, which should inherit from class `groupedData`; (iii) a named list of formulas, lists of formulas, or `pdMat` objects as in (ii), with the grouping factors as names. The order of nesting will be assumed the same as the order of the order of the elements in the list; (iv) an `reStruct` object. See the documentation on `pdClasses` for a description of
the available pdMat classes. Defaults to fixed, resulting in all fixed effects having also random effects.

groups
an optional one-sided formula of the form \(~g1\) (single level of nesting) or \(~g1/\ldots/gQ\) (multiple levels of nesting), specifying the partitions of the data over which the random effects vary. \(g1,\ldots,gQ\) must evaluate to factors in data. The order of nesting, when multiple levels are present, is taken from left to right (i.e. \(g1\) is the first level, \(g2\) the second, etc.).

start
an optional numeric vector, or list of initial estimates for the fixed effects and random effects. If declared as a numeric vector, it is converted internally to a list with a single component fixed, given by the vector. The fixed component is required, unless the model function inherits from class selfStart, in which case initial values will be derived from a call to nlsList. An optional random component is used to specify initial values for the random effects and should consist of a matrix, or a list of matrices with length equal to the number of grouping levels. Each matrix should have as many rows as the number of groups at the corresponding level and as many columns as the number of random effects in that level.

correlation
an optional corStruct object describing the within-group correlation structure. See the documentation of corClasses for a description of the available corStruct classes. Defaults to NULL, corresponding to no within-group correlations.

weights
an optional varFunc object or one-sided formula describing the within-group heteroscedasticity structure. If given as a formula, it is used as the argument to varFixed, corresponding to fixed variance weights. See the documentation on varClasses for a description of the available varFunc classes. Defaults to NULL, corresponding to homoscedastic within-group errors.

subset
an optional expression indicating the subset of the rows of data that should be used in the fit. This can be a logical vector, or a numeric vector indicating which observation numbers are to be included, or a character vector of the row names to be included. All observations are included by default.

method
a character string. If "REML" the model is fit by maximizing the restricted log-likelihood. If "ML" the log-likelihood is maximized. Defaults to "ML".

na.action
a function that indicates what should happen when the data contain NAs. The default action (na.fail) causes nlme to print an error message and terminate if there are any incomplete observations.

naPattern
an expression or formula object, specifying which returned values are to be regarded as missing.

control
a list of control values for the estimation algorithm to replace the default values returned by the function nlmeControl. Defaults to an empty list.

verbose
an optional logical value. If TRUE information on the evolution of the iterative algorithm is printed. Default is FALSE.

Value
an object of class nlme representing the nonlinear mixed-effects model fit. Generic functions such as print, plot and summary have methods to show the results of the fit. See nlmeObject for the components of the fit. The functions resid, coef, fitted, fixed.effects, and random.effects can be used to extract some of its components.

Examples

fm1 <- nlme(height ~ SSasymp(age, Asym, R0, lrc),
            data = Loblolly,
            fixed = Asym + R0 + lrc ~ 1,
            random = Asym ~ 1,
            start = c(Asym = 103, R0 = -8.5, lrc = -3.3))
summary(fm1)
fm2 <- update(fm1, random = pdDiag(Asym + lrc ~ 1))
summary(fm2)
Description

If the random effects names defined in random are a subset of the lmList object coefficient names, initial estimates for the covariance matrix of the random effects are obtained (overwriting any values given in random). formula(fixed) and the data argument in the calling sequence used to obtain fixed are passed as the fixed and data arguments to nlme.formula, together with any other additional arguments in the function call. See the documentation on nlme.formula for a description of that function.

Usage

## S3 method for class 'nlsList':
nlme(model, data, fixed, random, groups, start, correlation, weights, subset, method, na.action, naPattern, control, verbose)

Arguments

model an object inheriting from class nlsList, representing a list of nls fits with a common model.
data this argument is included for consistency with the generic function. It is ignored in this method function.
fixed this argument is included for consistency with the generic function. It is ignored in this method function.
random an optional one-sided linear formula with no conditioning expression, or a pdMat object with a formula attribute. Multiple levels of grouping are not allowed with this method function. Defaults to a formula consisting of the right hand side of formula(fixed).
groups an optional one-sided formula of the form ~g1 (single level of nesting) or ~g1/.../gQ (multiple levels of nesting), specifying the partitions of the data over which the random effects vary. g1, ..., gQ must evaluate to factors in data. The order of nesting, when multiple levels are present, is taken from left to right (i.e. g1 is the first level, g2 the second, etc.).
start an optional numeric vector, or list of initial estimates for the fixed effects and random effects. If declared as a numeric vector, it is converted internally to a list with a single component fixed, given by the vector. The fixed component is required, unless the model function inherits from class selfStart, in which case initial values will be derived from a call to nlsList. An optional random component is used to specify initial values for the random effects and should consist of a matrix, or a list of matrices with length equal to the number of grouping levels. Each matrix should have as many rows as the number of groups at the corresponding level and as many columns as the number of random effects in that level.
correlation an optional corStruct object describing the within-group correlation structure. See the documentation of corClasses for a description of the available corStruct classes. Defaults to NULL, corresponding to no within-group correlations.
weights an optional varFunc object or one-sided formula describing the within-group heteroscedasticity structure. If given as a formula, it is used as the argument to varFixed, corresponding to fixed variance weights. See the documentation on varClasses for a description of the available varFunc classes. Defaults to NULL, corresponding to homoscedastic within-group errors.

subset an optional expression indicating the subset of the rows of data that should be used in the fit. This can be a logical vector, or a numeric vector indicating which observation numbers are to be included, or a character vector of the row names to be included. All observations are included by default.

method a character string. If "REML" the model is fit by maximizing the restricted log-likelihood. If "ML" the log-likelihood is maximized. Defaults to "ML".

na.action a function that indicates what should happen when the data contain NAs. The default action (na.fail) causes nlme to print an error message and terminate if there are any incomplete observations.

naPattern an expression or formula object, specifying which returned values are to be regarded as missing.

control a list of control values for the estimation algorithm to replace the default values returned by the function nlmeControl. Defaults to an empty list.

verbose an optional logical value. If TRUE information on the evolution of the iterative algorithm is printed. Default is FALSE.

Value an object of class nlme representing the linear mixed-effects model fit. Generic functions such as print, plot and summary have methods to show the results of the fit. See nlmeObject for the components of the fit. The functions resid, coef, fitted, fixed.effects, and random.effects can be used to extract some of its components.

nlmeControl

Control Values for nlme Fit

Description
The values supplied in the function call replace the defaults and a list with all possible arguments is returned. The returned list is used as the control argument to the nlme function.

Usage
nlmeControl(maxIter, pnlsMaxIter, msMaxIter, minScale,
tolerance, niterEM, pnlsTol, msTol, msScale,
returnObject, msVerbose, gradHess, apVar, .relStep,
nlmStepMax = 100.0, minAbsParApVar = 0.05,
opt = c("nlminb", "nlm"), natural = TRUE)

Arguments
maxIter maximum number of iterations for the nlme optimization algorithm. Default is 50.
pnlsMaxIter maximum number of iterations for the PNLS optimization step inside the nlme optimization. Default is 7.
msMaxIter maximum number of iterations for the nlm optimization step inside the nlme optimization. Default is 50.
minScale minimum factor by which to shrink the default step size in an attempt to decrease the sum of squares in the PNLS step. Default 0.001.
tolerance tolerance for the convergence criterion in the nlme algorithm. Default is 1e-6.
niterEM number of iterations for the EM algorithm used to refine the initial estimates of the random effects variance-covariance coefficients. Default is 25.
tolerance for the convergence criterion in PNLS step. Default is 1e-3.

tolerance for the convergence criterion in nlm, passed as the rel.tolerance argument to the function (see documentation on nlm). Default is 1e-7.
scale function passed as the scale argument to the nlm function (see documentation on that function). Default is lmeScale.
a logical value indicating whether the fitted object should be returned when the maximum number of iterations is reached without convergence of the algorithm. Default is FALSE.
a logical value passed as the trace argument to nlm (see documentation on that function). Default is FALSE.
a logical value indicating whether numerical gradient vectors and Hessian matrices of the log-likelihood function should be used in the nlm optimization. This option is only available when the correlation structure (corStruct) and the variance function structure (varFunc) have no "varying" parameters and the pdMat classes used in the random effects structure are pdSymm (general positive-definite), pdDiag (diagonal), pdIdent (multiple of the identity), or pdCompSymm (compound symmetry). Default is TRUE.
a logical value indicating whether the approximate covariance matrix of the variance-covariance parameters should be calculated. Default is TRUE.
relative step for numerical derivatives calculations. Default is .Machine$double.eps^(1/3).
stepmax value to be passed to nlm. See nlm for details. Default is 100.0
numeric value - minimum absolute parameter value in the approximate variance calculation. The default is 0.05.
the optimizer to be used, either nlminb (the default since R 2.2.0) or nlm (the previous default).
a logical value indicating whether the pdNatural parametrization should be used for general positive-definite matrices (pdSymm) in reStruct, when the approximate covariance matrix of the estimators is calculated. Default is TRUE.

a list with components for each of the possible arguments.

### Fitted nlme Object

#### Description

An object returned by the `nlme` function, inheriting from class `nlme`, also inheriting from class `lme`, and representing a fitted nonlinear mixed-effects model. Objects of this class have methods for the generic functions `anova`, `coef`, `fitted`, `fixed.effects`, `formula`, `getGroups`, `getResponse`, `intervals`, `logLik`, `pairs`, `plot`, `predict`, `print`, `random.effects`, `residuals`, `summary`, and `update`.

#### Value

The following components must be included in a legitimate `nlme` object.

- **apVar**: an approximate covariance matrix for the variance-covariance coefficients. If `apVar = FALSE` in the list of control values used in the call to `nlme`, this component is equal to `NULL`.

- **call**: a list containing an image of the `nlme` call that produced the object.

- **coefficients**: a list with two components, `fixed` and `random`, where the first is a vector containing the estimated fixed effects and the second is a list of matrices with the estimated random effects for each level of grouping. For each matrix in the `random` list, the columns refer to the random effects and the rows to the groups.

- **contrasts**: a list with the contrasts used to represent factors in the fixed effects formula and/or random effects formula. This information is important for making predictions from a new data frame in which not all levels of the original factors are observed. If no factors are used in the `nlme` model, this component will be an empty list.

- **dims**: a list with basic dimensions used in the `nlme` fit, including the components `N` - the number of observations in the data, `Q` - the number of grouping levels, `qvec` - the number of random effects at each level from innermost to outermost (last two values are equal to zero and correspond to the fixed effects and the response), `ngrps` - the number of groups at each level from innermost to outermost (last two values are one and correspond to the fixed effects and the response), and `ncol` - the number of columns in the model matrix for each level of grouping from innermost to outermost (last two values are equal to the number of fixed effects and one).

- **fitted**: a data frame with the fitted values as columns. The leftmost column corresponds to the population fixed effects (corresponding to the fixed effects only) and successive columns from left to right correspond to increasing levels of grouping.

- **fixDF**: a list with components `X` and `terms` specifying the denominator degrees of freedom for, respectively, t-tests for the individual fixed effects and F-tests for the fixed-effects terms in the models.

- **groups**: a data frame with the grouping factors as columns. The grouping level increases from left to right.

- **logLik**: the (restricted) log-likelihood at convergence.

- **map**: a list with components `fmap`, `rmap`, `rmapRel`, and `bmap`, specifying various mappings for the fixed and random effects, used to generate predictions from the fitted object.
method the estimation method: either "ML" for maximum likelihood, or "REML" for restricted maximum likelihood.
modelStruct an object inheriting from class nlmeStruct, representing a list of mixed-effects model components, such as reStruct, corStruct, and varFunc objects.
numIter the number of iterations used in the iterative algorithm.
residuals a data frame with the residuals as columns. The leftmost column corresponds to the population residuals and successive columns from left to right correspond to increasing levels of grouping.
sigma the estimated within-group error standard deviation.
varFix an approximate covariance matrix of the fixed effects estimates.

nlmeStruct Nonlinear Mixed-Effects Structure

Description
A nonlinear mixed-effects structure is a list of model components representing different sets of parameters in the nonlinear mixed-effects model. An nlmeStruct list must contain at least a reStruct object, but may also contain corStruct and varFunc objects. NULL arguments are not included in the nlmeStruct list.

Usage
nlmeStruct(reStruct, corStruct, varStruct)

Arguments
reStruct a reStruct representing a random effects structure.
corStruct an optional corStruct object, representing a correlation structure. Default is NULL.
varStruct an optional varFunc object, representing a variance function structure. Default is NULL.

Value
a list of model components determining the parameters to be estimated for the associated nonlinear mixed-effects model.

nlsList

List of nls Objects with a Common Model

Description

Data is partitioned according to the levels of the grouping factor defined in model and individual nls fits are obtained for each data partition, using the model defined in model.

Usage

nlsList(model, data, start, control, level, subset, na.action, pool)

## S3 method for class 'nlsList':
update(object, model., ..., evaluate = TRUE)

Arguments

object an object inheriting from class nlsList, representing a list of fitted nls objects.
model either a nonlinear model formula, with the response on the left of a ~ operator and an expression involving parameters, covariates, and a grouping factor separated by the | operator on the right, or a selfStart function. The method function nlsList.selfStart is documented separately.
model. Changes to the model – see update.formula for details.
data a data frame in which to interpret the variables named in model.
start an optional named list with initial values for the parameters to be estimated in model. It is passed as the start argument to each nls call and is required when the nonlinear function in model does not inherit from class selfStart.
control a list of control values passed as the control argument to nls. Defaults to an empty list.
level an optional integer specifying the level of grouping to be used when multiple nested levels of grouping are present.
subset an optional expression indicating the subset of the rows of data that should be used in the fit. This can be a logical vector, or a numeric vector indicating which observation numbers are to be included, or a character vector of the row names to be included. All observations are included by default.
nac.action a function that indicates what should happen when the data contain NAs. The default action (na.fail) causes nlsList to print an error message and terminate if there are any incomplete observations.
pool an optional logical value that is preserved as an attribute of the returned value. This will be used as the default for pool in calculations of standard deviations or standard errors for summaries.
... some methods for this generic require additional arguments. None are used in this method.

**evaluate**
If TRUE evaluate the new call else return the call.

**Value**
a list of nls objects with as many components as the number of groups defined by the grouping factor. Generic functions such as coef, fixed.effects, lme, pairs, plot, predict, random.effects, summary, and update have methods that can be applied to an nlsList object.

**References**

**See Also**
nls, nlme.nlsList, nlsList.selfStart, summary.nlsList

**Examples**
```r
fm1 <- nlsList(uptake ~ SSasympOff(conc, Asym, lrc, c0),
    data = CO2, start = c(Asym = 30, lrc = -4.5, c0 = 52))
summary(fm1)
```

---

**nlsList.selfStart**
*nlsList Fit from a selfStart Function*

**Description**
The response variable and primary covariate in formula(data) are used together with model to construct the nonlinear model formula. This is used in the nls calls and, because a selfStarting model function can calculate initial estimates for its parameters from the data, no starting estimates need to be provided.

**Usage**
```r
## S3 method for class 'selfStart':
nlsList(model, data, start, control, level, subset, na.action, pool)
```

**Arguments**
- `model` a selfStart model function, which calculates initial estimates for the model parameters from data.
- `data` a data frame in which to interpret the variables in model. Because no grouping factor can be specified in model, data must inherit from class groupedData.
- `start` an optional named list with initial values for the parameters to be estimated in model. It is passed as the start argument to each nls call and is required when the nonlinear function in model does not inherit from class selfStart.
control   a list of control values passed as the control argument to nls. Defaults to an empty list.
level     an optional integer specifying the level of grouping to be used when multiple nested levels of grouping are present.
subset    an optional expression indicating the subset of the rows of data that should be used in the fit. This can be a logical vector, or a numeric vector indicating which observation numbers are to be included, or a character vector of the row names to be included. All observations are included by default.
na.action a function that indicates what should happen when the data contain NAs. The default action (na.fail) causes nlsList to print an error message and terminate if there are any incomplete observations.
pool      an optional logical value that is preserved as an attribute of the returned value. This will be used as the default for pool in calculations of standard deviations or standard errors for summaries.

Value

a list of nls objects with as many components as the number of groups defined by the grouping factor. A NULL value is assigned to the components corresponding to clusters for which the nls algorithm failed to converge. Generic functions such as coef, fixed.effects, lme, pairs, plot, predict, random.effects, summary, and update have methods that can be applied to an nlsList object.

Oats

Split-plot Experiment on Varieties of Oats

Description

The Oats data frame has 72 rows and 4 columns.

Format

This data frame contains the following columns:

- **Block** an ordered factor with levels VI < V < III < IV < II < I
- **Variety** a factor with levels Golden Rain Marvellous Victory
- **nitro** a numeric vector
- **yield** a numeric vector
Details

These data have been introduced by Yates (1935) as an example of a split-plot design. The treatment structure used in the experiment was a $3 \times 4$ full factorial, with three varieties of oats and four concentrations of nitrogen. The experimental units were arranged into six blocks, each with three whole-plots subdivided into four subplots. The varieties of oats were assigned randomly to the whole-plots and the concentrations of nitrogen to the subplots. All four concentrations of nitrogen were used on each whole-plot.

Source

Orthodont

**Growth curve data on an orthodontic measurement**

Description

The Orthodont data frame has 108 rows and 4 columns of the change in an orthodontic measurement over time for several young subjects.

Format

This data frame contains the following columns:

- **distance** a numeric vector of distances from the pituitary to the pterygomaxillary fissure (mm). These distances are measured on x-ray images of the skull.
- **age** a numeric vector of ages of the subject (yr).
- **Subject** an ordered factor indicating the subject on which the measurement was made. The levels are labelled M01 to M16 for the males and F01 to F13 for the females. The ordering is by increasing average distance within sex.
- **Sex** a factor with levels Male and Female

Details

Investigators at the University of North Carolina Dental School followed the growth of 27 children (16 males, 11 females) from age 8 until age 14. Every two years they measured the distance between the pituitary and the pterygomaxillary fissure, two points that are easily identified on x-ray exposures of the side of the head.

Source

### Ovary

**Counts of Ovarian Follicles**

**Description**

The `Ovary` data frame has 308 rows and 3 columns.

**Format**

This data frame contains the following columns:

- **Mare** an ordered factor indicating the mare on which the measurement is made.
- **Time** time in the estrus cycle. The data were recorded daily from 3 days before ovulation until 3 days after the next ovulation. The measurement times for each mare are scaled so that the ovulations for each mare occur at times 0 and 1.
- **follicles** the number of ovarian follicles greater than 10 mm in diameter.

**Details**

Pierson and Ginther (1987) report on a study of the number of large ovarian follicles detected in different mares at several times in their estrus cycles.

**Source**

### Oxboys

**Heights of Boys in Oxford**

**Description**

The `Oxboys` data frame has 234 rows and 4 columns.

**Format**

This data frame contains the following columns:

- **Subject** an ordered factor giving a unique identifier for each boy in the experiment
- **age** a numeric vector giving the standardized age (dimensionless)
- **height** a numeric vector giving the height of the boy (cm)
- **Occasion** an ordered factor - the result of converting age from a continuous variable to a count so these slightly unbalanced data can be analyzed as balanced.
Details

These data are described in Goldstein (1987) as data on the height of a selection of boys from Oxford, England versus a standardized age.

Source

---

Oxide | Variability in Semiconductor Manufacturing

Description

The Oxide data frame has 72 rows and 5 columns.

Format

This data frame contains the following columns:

- **Source** a factor with levels 1 and 2
- **Lot** a factor giving a unique identifier for each lot.
- **Wafer** a factor giving a unique identifier for each wafer within a lot.
- **Site** a factor with levels 1, 2, and 3
- **Thickness** a numeric vector giving the thickness of the oxide layer.

Details

These data are described in Littell et al. (1996, p. 155) as coming “from a passive data collection study in the semiconductor industry where the objective is to estimate the variance components to determine the assignable causes of the observed variability.” The observed response is the thickness of the oxide layer on silicon wafers, measured at three different sites of each of three wafers selected from each of eight lots sampled from the population of lots.

Source

pairs.compareFits  Pairs Plot of compareFits Object

Description

Scatter plots of the values being compared are generated for each pair of coefficients in \( x \). Different symbols (colors) are used for each object being compared and values corresponding to the same group are joined by a line, to facilitate comparison of fits. If only two coefficients are present, the `trellis` function `xyplot` is used; otherwise the `trellis` function `splom` is used.

Usage

```r
## S3 method for class 'compareFits':
pairs(x, subset, key, ...)
```

Arguments

- `x` an object of class `compareFits`.
- `subset` an optional logical or integer vector specifying which rows of \( x \) should be used in the plots. If missing, all rows are used.
- `key` an optional logical value, or list. If `TRUE`, a legend is included at the top of the plot indicating which symbols (colors) correspond to which objects being compared. If `FALSE`, no legend is included. If given as a list, `key` is passed down as an argument to the `trellis` function generating the plots (`splom` or `xyplot`). Defaults to `TRUE`.
- `...` optional arguments passed down to the `trellis` function generating the plots.

Value

Pairwise scatter plots of the values being compared, with different symbols (colors) used for each object under comparison.

Author(s)

Jose Pinheiro and Douglas Bates

See Also

`compareFits`, `plot.compareFits`, `pairs.lme`, `pairs.lmList`, `xyplot`, `splom`

Examples

```r
fm1 <- lmList(Orthodont)
fm2 <- lme(Orthodont)
pairs(compareFits(coef(fm1), coef(fm2)))
```
Description

Diagnostic plots for the linear mixed-effects fit are obtained. The `form` argument gives considerable flexibility in the type of plot specification. A conditioning expression (on the right side of a `|` operator) always implies that different panels are used for each level of the conditioning factor, according to a Trellis display. The expression on the right hand side of the formula, before a `|` operator, must evaluate to a data frame with at least two columns. If the data frame has two columns, a scatter plot of the two variables is displayed (the Trellis function `xyplot` is used). Otherwise, if more than two columns are present, a scatter plot matrix with pairwise scatter plots of the columns in the data frame is displayed (the Trellis function `splom` is used).

Usage

```r
## S3 method for class 'lme':
pairs(x, form, label, id, idLabels, grid, ...)
```

Arguments

- `x`: an object inheriting from class `lme`, representing a fitted linear mixed-effects model.
- `form`: an optional one-sided formula specifying the desired type of plot. Any variable present in the original data frame used to obtain `x` can be referenced. In addition, `x` itself can be referenced in the formula using the symbol `"."`. Conditional expressions on the right of a `|` operator can be used to define separate panels in a Trellis display. The expression on the right hand side of `form`, and to the left of the `|` operator, must evaluate to a data frame with at least two columns. Default is `~ coef(.)`, corresponding to a pairs plot of the coefficients evaluated at the innermost level of nesting.
- `label`: an optional character vector of labels for the variables in the pairs plot.
- `id`: an optional numeric value, or one-sided formula. If given as a value, it is used as a significance level for an outlier test based on the Mahalanobis distances of the estimated random effects. Groups with random effects distances greater than the `1 - value` percentile of the appropriate chi-square distribution are identified in the plot using `idLabels`. If given as a one-sided formula, its right hand side must evaluate to a logical, integer, or character vector which is used to identify points in the plot. If missing, no points are identified.
- `idLabels`: an optional vector, or one-sided formula. If given as a vector, it is converted to character and used to label the points identified according to `id`. If given as a one-sided formula, its right hand side must evaluate to a vector which is converted to character and used to label the identified points. Default is the innermost grouping factor.
- `grid`: an optional logical value indicating whether a grid should be added to plot. Default is `FALSE`.
- `...`: optional arguments passed to the Trellis plot function.
pairs.lmList

Value

a diagnostic Trellis plot.

Author(s)

Jose Pinheiro (Jose.Pinheiro@pharma.novartis.com) and Douglas Bates (bates@stat.wisc.edu)

See Also

lme, pairs.compareFits, pairs.lmList, xyplot, splom

Examples

fm1 <- lme(distance ~ age, Orthodont, random = ~ age | Subject)
# scatter plot of coefficients by gender, identifying unusual subjects
pairs(fm1, ~coef(., augFrame = TRUE) | Sex, id = 0.1, adj = -0.5)
# scatter plot of estimated random effects
## Not run:
pairs(fm1, ~ranef(.))
## End(Not run)

pairs.lmList  
Pairs Plot of an lmList Object

Description

Diagnostic plots for the linear model fits corresponding to the \(x\) components are obtained. The form argument gives considerable flexibility in the type of plot specification. A conditioning expression (on the right side of a \(\mid\) operator) always implies that different panels are used for each level of the conditioning factor, according to a Trellis display. The expression on the right hand side of the formula, before a \(\mid\) operator, must evaluate to a data frame with at least two columns. If the data frame has two columns, a scatter plot of the two variables is displayed (the Trellis function xyplot is used). Otherwise, if more than two columns are present, a scatter plot matrix with pairwise scatter plots of the columns in the data frame is displayed (the Trellis function splom is used).

Usage

## S3 method for class 'lmList':
pairs(x, form, label, id, idLabels, grid, ...)

Arguments

x  
an object inheriting from class lmList, representing a list of lm objects with a common model.

form  
an optional one-sided formula specifying the desired type of plot. Any variable present in the original data frame used to obtain \(x\) can be referenced. In addition, \(x\) itself can be referenced in the formula using the symbol ".". Conditional expressions on the right of a \(\mid\) operator can be used to define separate panels in a Trellis display. The expression on the right hand side of form, and to the left of the \(\mid\) operator, must evaluate to a data frame with at least two columns. Default is \(~\text{coef}(\cdot)\) , corresponding to a pairs plot of the coefficients of \(x\).
label

an optional character vector of labels for the variables in the pairs plot.

id

an optional numeric value, or one-sided formula. If given as a value, it is used as a significance level for an outlier test based on the Mahalanobis distances of the estimated random effects. Groups with random effects distances greater than the $1 - value$ percentile of the appropriate chi-square distribution are identified in the plot using idLabels. If given as a one-sided formula, its right hand side must evaluate to a logical, integer, or character vector which is used to identify points in the plot. If missing, no points are identified.

idLabels

an optional vector, or one-sided formula. If given as a vector, it is converted to character and used to label the points identified according to id. If given as a one-sided formula, its right hand side must evaluate to a vector which is converted to character and used to label the identified points. Default is the innermost grouping factor.

grid

an optional logical value indicating whether a grid should be added to plot. Default is FALSE.

...  
optional arguments passed to the Trellis plot function.

Value

a diagnostic Trellis plot.

---

**PBG**

**Effect of Phenylbiguanide on Blood Pressure**

Description

The PBG data frame has 60 rows and 5 columns.
pdBlocked

Format

This data frame contains the following columns:

- **deltaBP**: a numeric vector
- **dose**: a numeric vector
- **Run**: an ordered factor with levels T5 < T4 < T3 < T2 < T1 < P5 < P3 < P2 < P4 < P1
- **Treatment**: a factor with levels MDL 72222, Placebo
- **Rabbit**: an ordered factor with levels 5 < 3 < 2 < 4 < 1

Details

Data on an experiment to examine the effect of an antagonist MDL 72222 on the change in blood pressure experienced with increasing dosage of phenylbiguanide are described in Ludbrook (1994) and analyzed in Venables and Ripley (1999, section 8.8). Each of five rabbits was exposed to increasing doses of phenylbiguanide after having either a placebo or the HD5-antagonist MDL 72222 administered.

Source

Description

This function is a constructor for the `pdBlocked` class, representing a positive-definite block-diagonal matrix. Each block-diagonal element of the underlying matrix is itself a positive-definite matrix and is represented internally as an individual `pdMat` object. When `value` is `numeric(0)`, a list of uninitialized `pdMat` objects, a list of one-sided formulas, or a list of vectors of character strings, `object` is returned as an uninitialized `pdBlocked` object (with just some of its attributes and its class defined) and needs to have its coefficients assigned later, generally using the `coef` or `matrix` replacement functions. If `value` is a list of initialized `pdMat` objects, `object` will be constructed from the list obtained by applying `as.matrix` to each of the `pdMat` elements of `value`. Finally, if `value` is a list of numeric vectors, they are assumed to represent the unrestricted coefficients of the block-diagonal elements of the underlying positive-definite matrix.

Usage

pdBlocked(value, form, nam, data, pdClass)
Arguments

value an optional list with elements to be used as the value argument to other pdMat constructors. These include: pdMat objects, positive-definite matrices, one-sided linear formulas, vectors of character strings, or numeric vectors. All elements in the list must be similar (e.g. all one-sided formulas, or all numeric vectors). Defaults to numeric(0), corresponding to an uninitialized object.

form an optional list of one-sided linear formulas specifying the row/column names for the block-diagonal elements of the matrix represented by object. Because factors may be present in form, the formulas needs to be evaluated on a data.frame to resolve the names they define. This argument is ignored when value is a list of one-sided formulas. Defaults to NULL.

nam an optional list of vector of character strings specifying the row/column names for the block-diagonal elements of the matrix represented by object. Each of its components must have length equal to the dimension of the corresponding block-diagonal element and unreplicated elements. This argument is ignored when value is a list of vector of character strings. Defaults to NULL.

data an optional data frame in which to evaluate the variables named in value and form. It is used to obtain the levels for factors, which affect the dimensions and the row/column names of the underlying matrix. If NULL, no attempt is made to obtain information on any factors appearing in the formulas. Defaults to the parent frame from which the function was called.

pdClass an optional vector of character strings naming the pdMat classes to be assigned to the individual blocks in the underlying matrix. If a single class is specified, it is used for all block-diagonal elements. This argument will only be used when value is missing, or its elements are not pdMat objects. Defaults to "pdSymm".

Value

a pdBlocked object representing a positive-definite block-diagonal matrix, also inheriting from class pdMat.

Author(s)

Jose Pinheiro ⟨Jose.Pinheiro@pharma.novartis.com⟩ and Douglas Bates ⟨bates@stat.wisc.edu⟩

References

See Also

Examples

d1 <- pdBlocked(list(diag(1:2), diag(c(0.1, 0.2, 0.3))),
  nam = list(c("A", "B"), c("a1", "a2", "a3")))
d1
Description

Standard classes of positive-definite matrices (pdMat) structures available in the nlme library.

Value

Available standard classes:

- **pdSymm**: general positive-definite matrix, with no additional structure
- **pdLogChol**: general positive-definite matrix, with no additional structure, using a log-Cholesky parameterization
- **pdDiag**: diagonal
- **pdIdent**: multiple of an identity
- **pdCompSymm**: compound symmetry structure (constant diagonal and constant off-diagonal elements)
- **pdBlocked**: block-diagonal matrix, with diagonal blocks of any "atomic" pdMat class
- **pdNatural**: general positive-definite matrix in natural parametrization (i.e. parametrized in terms of standard deviations and correlations). The underlying coefficients are not unrestricted, so this class should NOT be used for optimization.

Note

Users may define their own pdMat classes by specifying a constructor function and, at a minimum, methods for the functions pdConstruct, pdMatrix and coef. For examples of these functions, see the methods for classes pdSymm and pdDiag.

pdCompSymm

Positive-Definite Matrix with Compound Symmetry Structure

Description

This function is a constructor for the pdCompSymm class, representing a positive-definite matrix with compound symmetry structure (constant diagonal and constant off-diagonal elements). The underlying matrix is represented by 2 unrestricted parameters. When value is numeric(0), an uninitialized pdMat object, a one-sided formula, or a vector of character strings, object is returned as an uninitialized pdCompSymm object (with just some of its attributes and its class defined) and needs to have its coefficients assigned later, generally using the coef or matrix replacement functions. If value is an initialized pdMat object, object will be constructed from as.matrix(value). Finally, if value is a numeric vector of length 2, it is assumed to represent the unrestricted coefficients of the underlying positive-definite matrix.

Usage

pdCompSymm(value, form, nam, data)

Arguments

value
an optional initialization value, which can be any of the following: a pdMat object, a positive-definite matrix, a one-sided linear formula (with variables separated by +), a vector of character strings, or a numeric vector of length 2. Defaults to numeric(0), corresponding to an uninitialized object.

form
an optional one-sided linear formula specifying the row/column names for the matrix represented by object. Because factors may be present in form, the formula needs to be evaluated on a data.frame to resolve the names it defines. This argument is ignored when value is a one-sided formula. Defaults to NULL.

nam
an optional vector of character strings specifying the row/column names for the matrix represented by object. It must have length equal to the dimension of the underlying positive-definite matrix and unreplicated elements. This argument is ignored when value is a vector of character strings. Defaults to NULL.

data
an optional data frame in which to evaluate the variables named in value and form. It is used to obtain the levels for factors, which affect the dimensions and the row/column names of the underlying matrix. If NULL, no attempt is made to obtain information on factors appearing in the formulas. Defaults to the parent frame from which the function was called.

Value

a pdCompSymm object representing a positive-definite matrix with compound symmetry structure, also inheriting from class pdMat.

pdConstruct Construct pdMat Objects

Description

This function is an alternative constructor for the pdMat class associated with object and is mostly used internally in other functions. See the documentation on the principal constructor function, generally with the same name as the pdMat class of object.

Usage

pdConstruct(object, value, form, nam, data, ...)

Arguments

- **object**: an object inheriting from class pdMat, representing a positive definite matrix.
- **value**: an optional initialization value, which can be any of the following: a pdMat object, a positive-definite matrix, a one-sided linear formula (with variables separated by +), a vector of character strings, or a numeric vector. Defaults to numeric(0), corresponding to an uninitialized object.
- **form**: an optional one-sided linear formula specifying the row/column names for the matrix represented by object. Because factors may be present in form, the formula needs to be evaluated on a data.frame to resolve the names it defines. This argument is ignored when value is a one-sided formula. Defaults to NULL.
- **nam**: an optional vector of character strings specifying the row/column names for the matrix represented by object. It must have length equal to the dimension of the underlying positive-definite matrix and unreplicated elements. This argument is ignored when value is a vector of character strings. Defaults to NULL.
- **data**: an optional data frame in which to evaluate the variables named in value and form. It is used to obtain the levels for factors, which affect the dimensions and the row/column names of the underlying matrix. If NULL, no attempt is made to obtain information on factors appearing in the formulas. Defaults to the parent frame from which the function was called.
- **...**: optional arguments for some methods.
Value

a \texttt{pdMat} object representing a positive-definite matrix, inheriting from the same classes as \texttt{object}.

Author(s)

Jose Pinheiro (Jose.Pinheiro@pharma.novartis.com) and Douglas Bates (bates@stat.wisc.edu)

See Also

\texttt{pdCompSymm}, \texttt{pdDiag}, \texttt{pdIdent}, \texttt{pdNatural}, \texttt{pdSymm}

Examples

\begin{verbatim}
pd1 <- pdSymm()
pdConstruct(pd1, diag(1:4))
\end{verbatim}

Description

This function gives an alternative constructor for the \texttt{pdBlocked} class, representing a positive-
definite block-diagonal matrix. Each block-diagonal element of the underlying matrix is itself a positive-definite matrix and is represented internally as an individual \texttt{pdMat} object. When \texttt{value} is \texttt{numeric(0)}, a list of uninitialized \texttt{pdMat} objects, a list of one-sided formulas, or a list of vectors of character strings, \texttt{object} is returned as an uninitialized \texttt{pdBlocked} object (with just some of its attributes and its class defined) and needs to have its coefficients assigned later, generally using the \texttt{coef} or \texttt{matrix} replacement functions. If \texttt{value} is a list of initialized \texttt{pdMat} objects, \texttt{object} will be constructed from the list obtained by applying \texttt{as.matrix} to each of the \texttt{pdMat} elements of \texttt{value}. Finally, if \texttt{value} is a list of numeric vectors, they are assumed to represent the unrestricted coefficients of the block-diagonal elements of the underlying positive-definite matrix.

Usage

\begin{verbatim}
## S3 method for class 'pdBlocked':
pdConstruct(object, value, form, nam, data, pdClass, ...)
\end{verbatim}

Arguments

| \texttt{object} | an object inheriting from class \texttt{pdBlocked}, representing a positive definite block-diagonal matrix. |
| \texttt{value}  | an optional list with elements to be used as the \texttt{value} argument to other \texttt{pdMat} constructors. These include: \texttt{pdMat} objects, positive-definite matrices, one-sided linear formulas, vectors of character strings, or numeric vectors. All elements in the list must be similar (e.g. all one-sided formulas, or all numeric vectors). Defaults to \texttt{numeric(0)}, corresponding to an uninitialized object. |
form

an optional list of one-sided linear formula specifying the row/column names for the block-diagonal elements of the matrix represented by object. Because factors may be present in form, the formulas needs to be evaluated on a data.frame to resolve the names they defines. This argument is ignored when value is a list of one-sided formulas. Defaults to NULL.

nam

an optional list of vector of character strings specifying the row/column names for the block-diagonal elements of the matrix represented by object. Each of its components must have length equal to the dimension of the corresponding block-diagonal element and unreplicated elements. This argument is ignored when value is a list of vector of character strings. Defaults to NULL.

data

an optional data frame in which to evaluate the variables named in value and form. It is used to obtain the levels for factors, which affect the dimensions and the row/column names of the underlying matrix. If NULL, no attempt is made to obtain information on factors appearing in the formulas. Defaults to the parent frame from which the function was called.

pdClass

an optional vector of character strings naming the pdMat classes to be assigned to the individual blocks in the underlying matrix. If a single class is specified, it is used for all block-diagonal elements. This argument will only be used when value is missing, or its elements are not pdMat objects. Defaults to "pdSymm".

... some methods for this generic require additional arguments. None are used in this method.

Value

a pdBlocked object representing a positive-definite block-diagonal matrix, also inheriting from class pdMat.

pdDiag  

**Diagonal Positive-Definite Matrix**

**Description**

This function is a constructor for the pdDiag class, representing a diagonal positive-definite matrix. If the matrix associated with `object` is of dimension \( n \), it is represented by \( n \) unrestricted parameters, given by the logarithm of the square-root of the diagonal values. When `value` is numeric(0), an uninitialized pdMat object, a one-sided formula, or a vector of character strings, `object` is returned as an uninitialized pdDiag object (with just some of its attributes and its class defined) and needs to have its coefficients assigned later, generally using the `coef` or `matrix` replacement functions. If `value` is an initialized pdMat object, `object` will be constructed from `as.matrix(value)`. Finally, if `value` is a numeric vector, it is assumed to represent the unrestricted coefficients of the underlying positive-definite matrix.

**Usage**

```r
pdDiag(value, form, nam, data)
```

**Arguments**

- `value`: an optional initialization value, which can be any of the following: a pdMat object, a positive-definite matrix, a one-sided linear formula (with variables separated by `+`), a vector of character strings, or a numeric vector of length equal to the dimension of the underlying positive-definite matrix. Defaults to numeric(0), corresponding to an uninitialized object.

- `form`: an optional one-sided linear formula specifying the row/column names for the matrix represented by `object`. Because factors may be present in `form`, the formula needs to be evaluated on a data.frame to resolve the names it defines. This argument is ignored when `value` is a one-sided formula. Defaults to NULL.

- `nam`: an optional vector of character strings specifying the row/column names for the matrix represented by `object`. It must have length equal to the dimension of the underlying positive-definite matrix and unreplicated elements. This argument is ignored when `value` is a vector of character strings. Defaults to NULL.

- `data`: an optional data frame in which to evaluate the variables named in `value` and `form`. It is used to obtain the levels for `factors`, which affect the dimensions and the row/column names of the underlying matrix. If NULL, no attempt is made to obtain information on `factors` appearing in the formulas. Defaults to the parent frame from which the function was called.

**Value**

A pdDiag object representing a diagonal positive-definite matrix, also inheriting from class pdMat.

Examples
pd1 <- pdDiag(diag(1:3), nam = c("A", "B", "C"))
pd1

Description
A square-root factor of the positive-definite matrix represented by object is obtained. Letting \( \Sigma \) denote a positive-definite matrix, a square-root factor of \( \Sigma \) is any square matrix \( L \) such that \( \Sigma = L' L \). This function extracts \( L \).

Usage
pdFactor(object)

Arguments
object

an object inheriting from class pdMat, representing a positive definite matrix, which must have been initialized (i.e. length(coef(object)) > 0).

Value
a vector with a square-root factor of the positive-definite matrix associated with object stacked column-wise.

Note
This function is used intensively in optimization algorithms and its value is returned as a vector for efficiency reasons. The pdMatrix function can be used to obtain square-root factors in matrix form.

**pdIdent**  
*Multiple of the Identity Positive-Definite Matrix*

**Description**
This function is a constructor for the `pdIdent` class, representing a multiple of the identity positive-definite matrix. The matrix associated with `object` is represented by 1 unrestricted parameter, given by the logarithm of the square-root of the diagonal value. When `value` is `numeric(0)`, an uninitialized `pdMat` object, a one-sided formula, or a vector of character strings, `object` is returned as an uninitialized `pdIdent` object (with just some of its attributes and its class defined) and needs to have its coefficients assigned later, generally using the `coef` or `matrix` replacement functions. If `value` is an initialized `pdMat` object, `object` will be constructed from `as.matrix(value)`. Finally, if `value` is a numeric value, it is assumed to represent the unrestricted coefficient of the underlying positive-definite matrix.

**Usage**
```
pdIdent(value, form, nam, data)
```

**Arguments**
- `value` an optional initialization value, which can be any of the following: a `pdMat` object, a positive-definite matrix, a one-sided linear formula (with variables separated by `+`), a vector of character strings, or a numeric value. Defaults to `numeric(0)`, corresponding to an uninitialized object.
- `form` an optional one-sided linear formula specifying the row/column names for the matrix represented by `object`. Because factors may be present in `form`, the formula needs to be evaluated on a data.frame to resolve the names it defines. This argument is ignored when `value` is a one-sided formula. Defaults to `NULL`.
- `nam` an optional vector of character strings specifying the row/column names for the matrix represented by `object`. It must have length equal to the dimension of the underlying positive-definite matrix and unreplicated elements. This argument is ignored when `value` is a vector of character strings. Defaults to `NULL`.
- `data` an optional data frame in which to evaluate the variables named in `value` and `form`. It is used to obtain the levels for `factors`, which affect the dimensions and the row/column names of the underlying matrix. If `NULL`, no attempt is made to obtain information on `factors` appearing in the formulas. Defaults to the parent frame from which the function was called.

**Value**
a `pdIdent` object representing a multiple of the identity positive-definite matrix, also inheriting from class `pdMat`.

pdLogChol
General Positive-Definite Matrix

Description
This function is a constructor for the pdLogChol class, representing a general positive-definite matrix. If the matrix associated with object is of dimension n, it is represented by n(n + 1)/2 unrestricted parameters, using the log-Cholesky parametrization described in Pinheiro and Bates (1996). When value is numeric(0), an uninitialized pdMat object, a one-sided formula, or a vector of character strings, object is returned as an uninitialized pdLogChol object (with just some of its attributes and its class defined) and needs to have its coefficients assigned later, generally using the coef or matrix replacement functions. If value is an initialized pdMat object, object will be constructed from as.matrix(value). Finally, if value is a numeric vector, it is assumed to represent the unrestricted coefficients of the matrix-logarithm parametrization of the underlying positive-definite matrix.

Usage
pdLogChol(value, form, nam, data)

Arguments
value an optional initialization value, which can be any of the following: a pdMat object, a positive-definite matrix, a one-sided linear formula (with variables separated by +), a vector of character strings, or a numeric vector. Defaults to numeric(0), corresponding to an uninitialized object.
form an optional one-sided linear formula specifying the row/column names for the matrix represented by object. Because factors may be present in form, the formula needs to be evaluated on a data.frame to resolve the names it defines. This argument is ignored when value is a one-sided formula. Defaults to NULL.
nam an optional vector of character strings specifying the row/column names for the matrix represented by object. It must have length equal to the dimension of the underlying positive-definite matrix and unreplicated elements. This argument is ignored when value is a vector of character strings. Defaults to NULL.
data an optional data frame in which to evaluate the variables named in value and form. It is used to obtain the levels for factors, which affect the dimensions and the row/column names of the underlying matrix. If NULL, no attempt is made to obtain information on factors appearing in the formulas. Defaults to the parent frame from which the function was called.
Value

A pdLogChol object representing a general positive-definite matrix, also inheriting from class pdMat.

Author(s)

Jose Pinheiro (Jose.Pinheiro@pharma.novartis.com) and Douglas Bates (bates@stat.wisc.edu)

References

See Also

as.matrix.pdMat, coef.pdMat, pdClasses, matrix<-.pdMat

Examples

pd1 <- pdLogChol(diag(1:3), nam = c("A","B","C"))
pd1

Description

This function gives an alternative way of constructing an object inheriting from the pdMat class named in pdClass, or from data.class(object) if object inherits from pdMat, and is mostly used internally in other functions. See the documentation on the principal constructor function, generally with the same name as the pdMat class of object.

Usage

pdMat(value, form, nam, data, pdClass)

Arguments

value an optional initialization value, which can be any of the following: a pdMat object, a positive-definite matrix, a one-sided linear formula (with variables separated by +), a vector of character strings, or a numeric vector. Defaults to numeric(0), corresponding to an uninitialized object.

form an optional one-sided linear formula specifying the row/column names for the matrix represented by object. Because factors may be present in form, the formula needs to be evaluated on a data.frame to resolve the names it defines. This argument is ignored when value is a one-sided formula. Defaults to NULL.
pdMatrix

Extract Matrix or Square-Root Factor from a pdMat Object

Description

The positive-definite matrix represented by object, or a square-root factor of it is obtained. Letting \( \Sigma \) denote a positive-definite matrix, a square-root factor of \( \Sigma \) is any square matrix \( L \) such that \( \Sigma = L' L \). This function extracts \( S \) or \( L \).

Usage

pdMatrix(object, factor)
Description

This method function extracts the positive-definite matrices corresponding to the pdMat elements of object, or square-root factors of the positive-definite matrices.

Usage

## S3 method for class 'reStruct':

pdMatrix(object, factor)

Arguments

object: an object inheriting from class pdMat, representing a random effects structure and consisting of a list of pdMat objects.

factor: an optional logical value. If TRUE, square-root factors of the positive-definite matrices represented by the elements of object are returned; else, if FALSE, the positive-definite matrices are returned. Defaults to FALSE.
pdNatural

Value

A list with components given by the positive-definite matrices corresponding to the elements of object, or square-root factors of the positive-definite matrices.

pdNatural

General Positive-Definite Matrix in Natural Parametrization

Description

This function is a constructor for the pdNatural class, representing a general positive-definite matrix, using a natural parametrization. If the matrix associated with object is of dimension n, it is represented by n(n+1)/2 parameters. Letting \( \sigma_{ij} \) denote the \( ij \)-th element of the underlying positive definite matrix and \( \rho_{ij} = \sigma_i / \sqrt{\sigma_{ii} \sigma_{jj}}, i \neq j \) denote the associated "correlations", the "natural" parameters are given by \( \sqrt{\sigma_{ii}}, i = 1, \ldots, n \) and \( \log((1 + \rho_{ij})/(1 - \rho_{ij})), i \neq j \). Note that all natural parameters are individually unrestricted, but not jointly unrestricted (meaning that not all unrestricted vectors would give positive-definite matrices). Therefore, this parametrization should NOT be used for optimization. It is mostly used for deriving approximate confidence intervals on parameters following the optimization of an objective function. When value is numeric(0), an uninitialized pdMat object, a one-sided formula, or a vector of character strings, object is returned as an uninitialized pdSymm object (with just some of its attributes and its class defined) and needs to have its coefficients assigned later, generally using the coef or matrix replacement functions. If value is an initialized pdMat object, object will be constructed from as.matrix(value). Finally, if value is a numeric vector, it is assumed to represent the natural parameters of the underlying positive-definite matrix.

Usage

pdNatural(value, form, nam, data)
**Arguments**

- **value**: an optional initialization value, which can be any of the following: a `pdMat` object, a positive-definite matrix, a one-sided linear formula (with variables separated by +), a vector of character strings, or a numeric vector. Defaults to `numeric(0)`, corresponding to an uninitialized object.

- **form**: an optional one-sided linear formula specifying the row/column names for the matrix represented by `object`. Because factors may be present in `form`, the formula needs to be evaluated on a data.frame to resolve the names it defines. This argument is ignored when `value` is a one-sided formula. Defaults to `NULL`.

- **nam**: an optional vector of character strings specifying the row/column names for the matrix represented by `object`. It must have length equal to the dimension of the underlying positive-definite matrix and unreplicated elements. This argument is ignored when `value` is a vector of character strings. Defaults to `NULL`.

- **data**: an optional data frame in which to evaluate the variables named in `value` and `form`. It is used to obtain the levels for factors, which affect the dimensions and the row/column names of the underlying matrix. If `NULL`, no attempt is made to obtain information on factors appearing in the formulas. Defaults to the parent frame from which the function was called.

**Value**

A `pdNatural` object representing a general positive-definite matrix in natural parametrization, also inheriting from class `pdMat`.

**Author(s)**

Jose Pinheiro (Jose.Pinheiro@pharma.novartis.com) and Douglas Bates (bates@stat.wisc.edu)

**References**

**See Also**

`as.matrix.pdMat`, `coef.pdMat`, `pdClasses`, `matrix<-.pdMat`

**Examples**

```r
pdNatural(diag(1:3))
```
Description

This function is a constructor for the `pdSymm` class, representing a general positive-definite matrix. If the matrix associated with `object` is of dimension `n`, it is represented by `n(n+1)/2` unrestricted parameters, using the matrix-logarithm parametrization described in Pinheiro and Bates (1996). When `value` is numeric(0), an uninitialized `pdMat` object, a one-sided formula, or a vector of character strings, `object` is returned as an uninitialized `pdSymm` object (with just some of its attributes and its class defined) and needs to have its coefficients assigned later, generally using the `coef` or `matrix` replacement functions. If `value` is an initialized `pdMat` object, `object` will be constructed from `as.matrix(value)`. Finally, if `value` is a numeric vector, it is assumed to represent the unrestricted coefficients of the matrix-logarithm parametrization of the underlying positive-definite matrix.

Usage

```r
pdSymm(value, form, nam, data)
```

Arguments

- `value`: an optional initialization value, which can be any of the following: a `pdMat` object, a positive-definite matrix, a one-sided linear formula (with variables separated by `+`), a vector of character strings, or a numeric vector. Defaults to numeric(0), corresponding to an uninitialized object.
- `form`: an optional one-sided linear formula specifying the row/column names for the matrix represented by `object`. Because factors may be present in `form`, the formula needs to be evaluated on a `data.frame` to resolve the names it defines. This argument is ignored when `value` is a one-sided formula. Defaults to NULL.
- `nam`: an optional vector of character strings specifying the row/column names for the matrix represented by `object`. It must have length equal to the dimension of the underlying positive-definite matrix and unreplicated elements. This argument is ignored when `value` is a vector of character strings. Defaults to NULL.
- `data`: an optional `data.frame` in which to evaluate the variables named in `value` and `form`. It is used to obtain the levels for `factors`, which affect the dimensions and the row/column names of the underlying matrix. If NULL, no attempt is made to obtain information on `factors` appearing in the formulas. Defaults to the parent frame from which the function was called.

Value

A `pdSymm` object representing a general positive-definite matrix, also inheriting from class `pdMat`.

References

The Phenobarb data frame has 744 rows and 7 columns.

This data frame contains the following columns:

- **Subject**: an ordered factor identifying the infant.
- **Wt**: a numeric vector giving the birth weight of the infant (kg).
- **Apgar**: an ordered factor giving the the 5-minute Apgar score for the infant. This is an indication of health of the newborn infant.
- **ApgarInd**: a factor indicating whether the 5-minute Apgar score is < 5 or >= 5.
- **time**: a numeric vector giving the time when the sample is drawn or drug administered (hr).
- **dose**: a numeric vector giving the dose of drug administered (ug/kg).
- **conc**: a numeric vector giving the phenobarbital concentration in the serum (ug/L).

Data from a pharmacokinetics study of phenobarbital in neonatal infants. During the first few days of life the infants receive multiple doses of phenobarbital for prevention of seizures. At irregular intervals blood samples are drawn and serum phenobarbital concentrations are determined. The data were originally given in Grasela and Donn (1985) and are analyzed in Boeckmann, Sheiner and Beal (1994), in Davidian and Giltinan (1995), and in Littell et al. (1996).

**Source**

**phenoModel**

*Model function for the Phenobarb data*

**Description**

A model function for a model used with the Phenobarb data. This function uses compiled C code to improve execution speed.

**Usage**

```
phenoModel(Subject, time, dose, lCl, lV)
```

**Arguments**

- **Subject**: an integer vector of subject identifiers. These should be sorted in increasing order.
- **time**: numeric. A vector of the times at which the sample was drawn or the drug administered (hr).
- **dose**: numeric. A vector of doses of drug administered (ug/kg).
- **lCl**: numeric. A vector of values of the natural log of the clearance parameter according to Subject and time.
- **lV**: numeric. A vector of values of the natural log of the effective volume of distribution according to Subject and time.

**Details**

See the details section of Phenobarb for a description of the model function that phenoModel evaluates.

**Value**

a numeric vector of predicted phenobarbital concentrations.

**Examples**
**Pixel**

*X-ray pixel intensities over time*

**Description**

The `Pixel` data frame has 102 rows and 4 columns of data on the pixel intensities of CT scans of dogs over time.

**Format**

This data frame contains the following columns:

- **Dog** a factor with levels 1 to 10 designating the dog on which the scan was made
- **Side** a factor with levels L and R designating the side of the dog being scanned
- **day** a numeric vector giving the day post injection of the contrast on which the scan was made
- **pixel** a numeric vector of pixel intensities

**Source**

**Examples**

```r
fm1 <- lme(pixel ~ day + I(day^2), data = Pixel,
           random = list(Dog = ~ day, Side = ~ 1))
summary(fm1)
VarCorr(fm1)
```

**plot.ACF**

*Plot an ACF Object*

**Description**

An `xyplot` of the autocorrelations versus the lags, with `type = "h"`, is produced. If `alpha > 0`, curves representing the critical limits for a two-sided test of level `alpha` for the autocorrelations are added to the plot.

**Usage**

```r
## S3 method for class 'ACF':
plot(x, alpha, xlab, ylab, grid, ...)
```
Arguments

- **x**: an object inheriting from class `ACF`, consisting of a data frame with two columns named `lag` and `ACF`, representing the autocorrelation values and the corresponding lags.
- **alpha**: an optional numeric value with the significance level for testing if the autocorrelations are zero. Lines corresponding to the lower and upper critical values for a test of level `alpha` are added to the plot. Default is 0, in which case no lines are plotted.
- **xlab, ylab**: optional character strings with the x- and y-axis labels. Default respectively to "Lag" and "Autocorrelation".
- **grid**: an optional logical value indicating whether a grid should be added to plot. Default is `FALSE`.
- **...**: optional arguments passed to the `xyplot` function.

Value

an `xyplot` Trellis plot.

Author(s)

Jose Pinheiro (Jose.Pinheiro@pharma.novartis.com) and Douglas Bates (bates@stat.wisc.edu)

See Also

`ACF`, `xyplot`

Examples

```r
fm1 <- lme(follicles ~ sin(2*pi*Time) + cos(2*pi*Time), Ovary)
plot(ACF(fm1, maxLag = 10), alpha = 0.01)
```

Description

A Trellis `xyplot` of predictions versus the primary covariate is generated, with a different panel for each value of the grouping factor. Predicted values are joined by lines, with different line types (colors) being used for each level of grouping. Original observations are represented by circles.

Usage

```r
## S3 method for class 'augPred':
plot(x, key, grid, ...)
```
Arguments

x  an object of class `augPred`.
key an optional logical value, or list. If `TRUE`, a legend is included at the top of the plot indicating which symbols (colors) correspond to which prediction levels. If `FALSE`, no legend is included. If given as a list, `key` is passed down as an argument to the `trellis` function generating the plots (`xyplot`). Defaults to `TRUE`.
grid an optional logical value indicating whether a grid should be added to plot. Default is `FALSE`.
... optional arguments passed down to the `trellis` function generating the plots.

Value

A Trellis plot of predictions versus the primary covariate, with panels determined by the grouping factor.

Jose Pinheiro (Jose.Pinheiro@pharma.novartis.com) and Douglas Bates (bates@stat.wisc.edu)

See Also

augPred, xyplot

Examples

```r
fm1 <- lme(Orthodont)
plot(augPred(fm1, level = 0:1, length.out = 2))
```

Description

A Trellis dotplot of the values being compared, with different rows per group, is generated, with a different panel for each coefficient. Different symbols (colors) are used for each object being compared.

Usage

```r
## S3 method for class 'compareFits':
plot(x, subset, key, mark, ...)
```

Arguments

x  an object of class `compareFits`.
subset an optional logical or integer vector specifying which rows of `x` should be used in the plots. If missing, all rows are used.
key an optional logical value, or list. If TRUE, a legend is included at the top of the plot indicating which symbols (colors) correspond to which objects being compared. If FALSE, no legend is included. If given as a list, key is passed down as an argument to the `trellis` function generating the plots (dotplot). Defaults to TRUE.

mark an optional numeric vector, of length equal to the number of coefficients being compared, indicating where vertical lines should be drawn in the plots. If missing, no lines are drawn.

... optional arguments passed down to the `trellis` function generating the plots.

Value

A Trellis `dotplot` of the values being compared, with rows determined by the groups and panels by the coefficients.

Author(s)

Jose Pinheiro (Jose.Pinheiro@pharma.novartis.com) and Douglas Bates (bates@stat.wisc.edu)

See Also

compareFits, pairs.compareFits, dotplot

Examples

```r
## Not run:
fm1 <- lmList(Orthodont)
fm2 <- lme(Orthodont)
plot(compareFits(coef(fm1), coef(fm2)))
## End(Not run)
```

Description

Diagnostic plots for the linear model fit are obtained. The `form` argument gives considerable flexibility in the type of plot specification. A conditioning expression (on the right side of a | operator) always implies that different panels are used for each level of the conditioning factor, according to a Trellis display. If `form` is a one-sided formula, histograms of the variable on the right hand side of the formula, before a | operator, are displayed (the Trellis function `histogram` is used). If `form` is two-sided and both its left and right hand side variables are numeric, scatter plots are displayed (the Trellis function `xyplot` is used). Finally, if `form` is two-sided and its left hand side variable is a factor, box-plots of the right hand side variable by the levels of the left hand side variable are displayed (the Trellis function `bwplot` is used).

Usage

```r
## S3 method for class 'gls':
plot(x, form, abline, id, idLabels, idResType, grid, ...)
```
Arguments

x
an object inheriting from class gls, representing a generalized least squares fitted linear model.

form
an optional formula specifying the desired type of plot. Any variable present in the original data frame used to obtain x can be referenced. In addition, x itself can be referenced in the formula using the symbol ".". Conditional expressions on the right of a | operator can be used to define separate panels in a Trellis display. Default is resid(., type = "p") ~ fitted(.) , corresponding to a plot of the standardized residuals versus fitted values, both evaluated at the innermost level of nesting.

abline
an optional numeric value, or numeric vector of length two. If given as a single value, a horizontal line will be added to the plot at that coordinate; else, if given as a vector, its values are used as the intercept and slope for a line added to the plot. If missing, no lines are added to the plot.

id
an optional numeric value, or one-sided formula. If given as a value, it is used as a significance level for a two-sided outlier test for the standardized residuals. Observations with absolute standardized residuals greater than the 1 − value/2 quantile of the standard normal distribution are identified in the plot using idLabels. If given as a one-sided formula, its right hand side must evaluate to a logical, integer, or character vector which is used to identify observations in the plot. If missing, no observations are identified.

idLabels
an optional vector, or one-sided formula. If given as a vector, it is converted to character mode and used to label the observations identified according to id. If given as a one-sided formula, its right hand side must evaluate to a vector which is converted to character mode and used to label the identified observations. Default is the innermost grouping factor.

idResType
an optional character string specifying the type of residuals to be used in identifying outliers, when id is a numeric value. If "pearson", the standardized residuals (raw residuals divided by the corresponding standard errors) are used; else, if "normalized", the normalized residuals (standardized residuals premultiplied by the inverse square-root factor of the estimated error correlation matrix) are used. Partial matching of arguments is used, so only the first character needs to be provided. Defaults to "pearson".

grid
an optional logical value indicating whether a grid should be added to plot. Default depends on the type of Trellis plot used: if xyplot defaults to TRUE, else defaults to FALSE.

... optional arguments passed to the Trellis plot function.

Value
a diagnostic Trellis plot.

**plot.intervals.lmList**

*Plot lmList Confidence Intervals*

Description

A Trellis dot-plot of the confidence intervals on the linear model coefficients is generated, with a different panel for each coefficient. Rows in the dot-plot correspond to the names of the *lm* components of the *lmList* object used to produce *x*. The lower and upper confidence limits are connected by a line segment and the estimated coefficients are marked with a "+". The Trellis function *dotplot* is used in this method function.

Usage

```r
## S3 method for class 'intervals.lmList':
plot(x, ...)
```

Arguments

- `x`: an object inheriting from class *intervals.lmList*, representing confidence intervals and estimates for the coefficients in the *lm* components of the *lmList* object used to produce *x*.
- `...`: optional arguments passed to the Trellis *dotplot* function.

Value

A Trellis plot with the confidence intervals on the coefficients of the individual *lm* components of the *lmList* that generated *x*.

fm1 <- lmList(distance ~ age | Subject, Orthodont)
plot(intervals(fm1))
```
Diagnostic plots for the linear mixed-effects fit are obtained. The form argument gives considerable flexibility in the type of plot specification. A conditioning expression (on the right side of a | operator) always implies that different panels are used for each level of the conditioning factor, according to a Trellis display. If form is a one-sided formula, histograms of the variable on the right hand side of the formula, before a | operator, are displayed (the Trellis function histogram is used). If form is two-sided and both its left and right hand side variables are numeric, scatter plots are displayed (the Trellis function xyplot is used). Finally, if form is two-sided and its left hand side variable is a factor, box-plots of the right hand side variable by the levels of the left hand side variable are displayed (the Trellis function bwplot is used).

Usage

## S3 method for class 'lme':
plot(x, form, abline, id, idLabels, idResType, grid, ...)
## S3 method for class 'nls':
plot(x, form, abline, id, idLabels, idResType, grid, ...)

Arguments

x an object inheriting from class lme, representing a fitted linear mixed-effects model, or from nls, representing an fitted nonlinear least squares model.

form an optional formula specifying the desired type of plot. Any variable present in the original data frame used to obtain x can be referenced. In addition, x itself can be referenced in the formula using the symbol ".". Conditional expressions on the right of a | operator can be used to define separate panels in a Trellis display. Default is resid(., type = "p") ~ fitted(.) , corresponding to a plot of the standardized residuals versus fitted values, both evaluated at the innermost level of nesting.

abline an optional numeric value, or numeric vector of length two. If given as a single value, a horizontal line will be added to the plot at that coordinate; else, if given as a vector, its values are used as the intercept and slope for a line added to the plot. If missing, no lines are added to the plot.

id an optional numeric value, or one-sided formula. If given as a value, it is used as a significance level for a two-sided outlier test for the standardized, or normalized residuals. Observations with absolute standardized (normalized) residuals greater than the 1 − value/2 quantile of the standard normal distribution are identified in the plot using idLabels. If given as a one-sided formula, its right hand side must evaluate to a logical, integer, or character vector which is used to identify observations in the plot. If missing, no observations are identified.

idLabels an optional vector, or one-sided formula. If given as a vector, it is converted to character and used to label the observations identified according to id. If given as a one-sided formula, its right hand side must evaluate to a vector which is converted to character and used to label the identified observations. Default is the innermost grouping factor.
idResType an optional character string specifying the type of residuals to be used in identifying outliers, when \texttt{id} is a numeric value. If "pearson", the standardized residuals (raw residuals divided by the corresponding standard errors) are used; else, if "normalized", the normalized residuals (standardized residuals pre-multiplied by the inverse square-root factor of the estimated error correlation matrix) are used. Partial matching of arguments is used, so only the first character needs to be provided. Defaults to "pearson".

grid an optional logical value indicating whether a grid should be added to plot. Default depends on the type of Trellis plot used: if \texttt{xyplot} defaults to \texttt{TRUE}, else \texttt{FALSE}.

... optional arguments passed to the Trellis plot function.

\section*{Value}
a diagnostic Trellis plot.

\section*{Author(s)}

# box-plots of residuals by Subject
plot(fm1, Subject ~ resid(.))
# observed versus fitted values by Subject
plot(fm1, distance ~ fitted(.) | Subject, abline = c(0,1))
\end{verbatim}

\section*{Description}
Diagnostic plots for the linear model fits corresponding to the $x$ components are obtained. The \texttt{form} argument gives considerable flexibility in the type of plot specification. A conditioning expression (on the right side of a $|$ operator) always implies that different panels are used for each level of the conditioning factor, according to a Trellis display. If \texttt{form} is a one-sided formula, histograms of the variable on the right hand side of the formula, before a $|$ operator, are displayed (the Trellis function \texttt{histogram} is used). If \texttt{form} is two-sided and both its left and right hand side variables are numeric, scatter plots are displayed (the Trellis function \texttt{xyplot} is used). Finally, if \texttt{form} is two-sided and its left hand side variable is a factor, box-plots of the right hand side variable by the levels of the left hand side variable are displayed (the Trellis function \texttt{bwplot} is used).

\section*{Usage}
\begin{verbatim}
## S3 method for class 'lmList':
plot(x, form, abline, id, idLabels, grid, ...)
\end{verbatim}
Arguments

- **x**: an object inheriting from class `lmList`, representing a list of `lm` objects with a common model.

- **form**: an optional formula specifying the desired type of plot. Any variable present in the original data frame used to obtain `x` can be referenced. In addition, `x` itself can be referenced in the formula using the symbol `"."`. Conditional expressions on the right of a `|` operator can be used to define separate panels in a Trellis display. Default is `resid(., type = "pool") ~ fitted(.)`, corresponding to a plot of the standardized residuals (using a pooled estimate for the residual standard error) versus fitted values.

- **abline**: an optional numeric value, or numeric vector of length two. If given as a single value, a horizontal line will be added to the plot at that coordinate; else, if given as a vector, its values are used as the intercept and slope for a line added to the plot. If missing, no lines are added to the plot.

- **id**: an optional numeric value, or one-sided formula. If given as a value, it is used as a significance level for a two-sided outlier test for the standardized residuals. Observations with absolute standardized residuals greater than the $1 - value/2$ quantile of the standard normal distribution are identified in the plot using `idLabels`. If given as a one-sided formula, its right hand side must evaluate to a logical, integer, or character vector which is used to identify observations in the plot. If missing, no observations are identified.

- **idLabels**: an optional vector, or one-sided formula. If given as a vector, it is converted to character and used to label the observations identified according to `id`. If given as a one-sided formula, its right hand side must evaluate to a vector which is converted to character and used to label the identified observations. Default is `getGroups(x)`.

- **grid**: an optional logical value indicating whether a grid should be added to plot. Default depends on the type of Trellis plot used: if `xyplot` defaults to `TRUE`, else defaults to `FALSE`.

- **...**: optional arguments passed to the Trellis plot function.

Value

- a diagnostic Trellis plot.

plot(fm1, Subject ~ resid(.))
# observed versus fitted values by Subject
plot(fm1, distance ~ fitted(.) | Subject, abline = c(0,1))
```
plot.nffGroupedData

Plot an nffGroupedData Object

Description

A Trellis dot-plot of the response by group is generated. If outer variables are specified, the combination of their levels are used to determine the panels of the Trellis display. The Trellis function dotplot is used.

Usage

## S3 method for class 'nffGroupedData':
plot(x, outer, inner, innerGroups, xlab, ylab, strip, panel, key, grid, ...)

Arguments

- **x**: an object inheriting from class nffGroupedData, representing a groupedData object with a factor primary covariate and a single grouping level.
- **outer**: an optional logical value or one-sided formula, indicating covariates that are outer to the grouping factor, which are used to determine the panels of the Trellis plot. If equal to TRUE, attr(object, "outer") is used to indicate the outer covariates. An outer covariate is invariant within the sets of rows defined by the grouping factor. Ordering of the groups is done in such a way as to preserve adjacency of groups with the same value of the outer variables. Defaults to NULL, meaning that no outer covariates are to be used.
- **inner**: an optional logical value or one-sided formula, indicating a covariate that is inner to the grouping factor, which is used to associate points within each panel of the Trellis plot. If equal to TRUE, attr(object, "inner") is used to indicate the inner covariate. An inner covariate can change within the sets of rows defined by the grouping factor. Defaults to NULL, meaning that no inner covariate is present.
- **innerGroups**: an optional one-sided formula specifying a factor to be used for grouping the levels of the inner covariate. Different colors, or symbols, are used for each level of the innerGroups factor. Default is NULL, meaning that no innerGroups covariate is present.
- **xlab**: an optional character string with the label for the horizontal axis. Default is the y elements of attr(object, "labels") and attr(object, "units") pasted together.
- **ylab**: an optional character string with the label for the vertical axis. Default is the grouping factor name.
- **strip**: an optional function passed as the strip argument to the dotplot function. Default is strip.default(..., style = 1) (see trellis.args).
- **panel**: an optional function used to generate the individual panels in the Trellis display, passed as the panel argument to the dotplot function.
plot.nfnGroupedData

key

An optional logical function or function. If TRUE and either inner or innerGroups are non-NULL, a legend for the different inner (innerGroups) levels is included at the top of the plot. If given as a function, it is passed as the key argument to the dotplot function. Default is TRUE if either inner or innerGroups are non-NULL and FALSE otherwise.

grid

This argument is included for consistency with the plot.nfnGroupedData method calling sequence. It is ignored in this method function.

... optional arguments passed to the dotplot function.

Value

A Trellis dot-plot of the response by group.

plot.nfnGroupedData

Plot an nfnGroupedData Object

Description

A Trellis plot of the response versus the primary covariate is generated. If outer variables are specified, the combination of their levels are used to determine the panels of the Trellis display. Otherwise, the levels of the grouping variable determine the panels. A scatter plot of the response versus the primary covariate is displayed in each panel, with observations corresponding to same inner group joined by line segments. The Trellis function xyplot is used.

Usage

```r
## S3 method for class 'nfnGroupedData':
plot(x, outer, inner, innerGroups, xlab, ylab, strip, aspect, panel,
     key, grid, ...)
```
plot.nfnGroupedData

Arguments

x
an object inheriting from class nfnGroupedData, representing a
groupedData object with a numeric primary covariate and a single
grouping level.

outer
an optional logical value or one-sided formula, indicating covariates that are
outer to the grouping factor, which are used to determine the panels of the Trellis
plot. If equal to TRUE, attr(object, "outer") is used to indicate the
outer covariates. An outer covariate is invariant within the sets of rows defined
by the grouping factor. Ordering of the groups is done in such a way as to pre-
serve adjacency of groups with the same value of the outer variables. Defaults
to NULL, meaning that no outer covariates are to be used.

inner
an optional logical value or one-sided formula, indicating a covariate that is
inner to the grouping factor, which is used to associate points within each panel
of the Trellis plot. If equal to TRUE, attr(object, "inner") is used to
indicate the inner covariate. An inner covariate can change within the sets of
rows defined by the grouping factor. Defaults to NULL, meaning that no inner
covariate is present.

innerGroups
an optional one-sided formula specifying a factor to be used for grouping the
levels of the inner covariate. Different colors, or line types, are used for
each level of the innerGroups factor. Default is NULL, meaning that no
innerGroups covariate is present.

xlab, ylab
optional character strings with the labels for the plot. Default is the corre-
sponding elements of attr(object, "labels") and attr(object,
"units") pasted together.

strip
an optional function passed as the strip argument to the xyplot function.
Default is strip.default(..., style = 1) (see trellis.args).

aspect
an optional character string indicating the aspect ratio for the plot passed
as the aspect argument to the xyplot function. Default is "xy" (see
trellis.args).

panel
an optional function used to generate the individual panels in the Trellis display,
passed as the panel argument to the xyplot function.

key
an optional logical function or function. If TRUE and innerGroups is non-
NULL, a legend for the different innerGroups levels is included at the top
of the plot. If given as a function, it is passed as the key argument to the
xyplot function. Default is TRUE if innerGroups is non-NULL and FALSE
otherwise.

grid
an optional logical value indicating whether a grid should be added to plot. De-
fault is TRUE.

...
optional arguments passed to the xyplot function.

Value

ea Trellis plot of the response versus the primary covariate.

groupedData, xyplot

Examples

# different panels per Subject
plot(Orthodont)
# different panels per gender
plot(Orthodont, outer = TRUE)
covariate is invariant within the sets of rows defined by the grouping factor. Ordering of the groups is done in such a way as to preserve adjacency of groups with the same value of the outer variables. Defaults to NULL, meaning that no outer covariates are to be used.

**inner**

an optional logical value or one-sided formula, indicating a covariate that is inner to the displayLevel grouping factor, which is used to associate points within each panel of the Trellis plot. If equal to TRUE, attr(object, "outer") is used to indicate the inner covariate. An inner covariate can change within the sets of rows defined by the grouping factor. Defaults to NULL, meaning that no inner covariate is present.

**preserve**

an optional one-sided formula indicating a covariate whose levels should be preserved when collapsing the data according to the collapseLevel grouping factor. The collapsing factor is obtained by pasting together the levels of the collapseLevel grouping factor and the values of the covariate to be preserved. Default is NULL, meaning that no covariates need to be preserved.

**FUN**

an optional summary function or a list of summary functions to be used for collapsing the data. The function or functions are applied only to variables in object that vary within the groups defined by collapseLevel. Invariant variables are always summarized by group using the unique value that they assume within that group. If FUN is a single function it will be applied to each non-invariant variable by group to produce the summary for that variable. If FUN is a list of functions, the names in the list should designate classes of variables in the data such as ordered, factor, or numeric. The indicated function will be applied to any non-invariant variables of that class. The default functions to be used are mean for numeric factors, and Mode for both factor and ordered. The Mode function, defined internally in gsummary, returns the modal or most popular value of the variable. It is different from the mode function that returns the S-language mode of the variable.

**subset**

an optional named list. Names can be either positive integers representing grouping levels, or names of grouping factors. Each element in the list is a vector indicating the levels of the corresponding grouping factor to be used for plotting the data. Default is NULL, meaning that all levels are used.

**key**

an optional logical value, or list. If TRUE, a legend is included at the top of the plot indicating which symbols (colors) correspond to which prediction levels. If FALSE, no legend is included. If given as a list, key is passed down as an argument to the trellis function generating the plots (xyplot). Defaults to TRUE.

**grid**

an optional logical value indicating whether a grid should be added to plot. Default is TRUE.

... optional arguments passed to the Trellis plot function.

**Value**

a Trellis display of the data collapsed over the values of the collapseLevel grouping factor and grouped according to the displayLevel grouping factor.

Examples

# no collapsing, panels by Dog
plot(Pixel, display = "Dog", inner = ~Side)

# collapsing by Dog, preserving day
plot(Pixel, collapse = "Dog", preserve = ~day)

Description

If form is missing, or is given as a one-sided formula, a Trellis dot-plot of the random effects is generated, with a different panel for each random effect (coefficient). Rows in the dot-plot are determined by the form argument (if not missing) or by the row names of the random effects (coefficients). If a single factor is specified in form, its levels determine the dot-plot rows (with possibly multiple dots per row); otherwise, if form specifies a crossing of factors, the dot-plot rows are determined by all combinations of the levels of the individual factors in the formula. The Trellis function dotplot is used in this method function.

If form is a two-sided formula, a Trellis display is generated, with a different panel for each variable listed in the right hand side of form. Scatter plots are generated for numeric variables and boxplots are generated for categorical (factor or ordered) variables.

Usage

## S3 method for class 'ranef.lme':
plot(x, form, omitFixed, level, grid, control, ...)

Arguments

x

an object inheriting from class ranef.lme, representing the estimated coefficients or estimated random effects for the lme object from which it was produced.

form

an optional formula specifying the desired type of plot. If given as a one-sided formula, a dotplot of the estimated random effects (coefficients) grouped according to all combinations of the levels of the factors named in form is returned. Single factors (~g) or crossed factors (~g1*g2) are allowed. If given as a two-sided formula, the left hand side must be a single random effects (coefficient) and the right hand side is formed by covariates in x separated by +.
A Trellis display of the random effect (coefficient) versus the named covariates is returned in this case. Default is NULL, in which case the row names of the random effects (coefficients) are used.

omitFixed an optional logical value indicating whether columns with values that are constant across groups should be omitted. Default is TRUE.

level an optional integer value giving the level of grouping to be used for x. Only used when x is a list with different components for each grouping level. Defaults to the highest or innermost level of grouping.

grid an optional logical value indicating whether a grid should be added to plot. Only applies to plots associated with two-sided formulas in form. Default is FALSE.

control an optional list with control values for the plot, when form is given as a two-sided formula. The control values are referenced by name in the control list and only the ones to be modified from the default need to be specified. Available values include: drawLine, a logical value indicating whether a loess smoother should be added to the scatter plots and a line connecting the medians should be added to the boxplots (default is TRUE); span.loess, used as the span argument in the call to panel.loess (default is 2/3); degree.loess, used as the degree argument in the call to panel.loess (default is 1); cex.axis, the character expansion factor for the x-axis (default is 0.8); srt.axis, the rotation factor for the x-axis (default is 0); and mgp.axis, the margin parameters for the x-axis (default is c(2, 0.5, 0)).

Value

a Trellis plot of the estimated random-effects (coefficients) versus covariates, or groups.

plot(fm1RE, form = age ~ Sex)
## End(Not run)
plot.ranef.lmList  

Plot a ranef.lmList Object

Description

If form is missing, or is given as a one-sided formula, a Trellis dot-plot of the random effects is generated, with a different panel for each random effect (coefficient). Rows in the dot-plot are determined by the form argument (if not missing) or by the row names of the random effects (coefficients). If a single factor is specified in form, its levels determine the dot-plot rows (with possibly multiple dots per row); otherwise, if form specifies a crossing of factors, the dot-plot rows are determined by all combinations of the levels of the individual factors in the formula. The Trellis function dotplot is used in this method function.

If form is a two-sided formula, a Trellis display is generated, with a different panel for each variable listed in the right hand side of form. Scatter plots are generated for numeric variables and boxplots are generated for categorical (factor or ordered) variables.

Usage

```r
## S3 method for class 'ranef.lmList':
plot(x, form, grid, control, ...)
```

Arguments

- **x**: an object inheriting from class ranef.lmList, representing the estimated coefficients or estimated random effects for the lmList object from which it was produced.

- **form**: an optional formula specifying the desired type of plot. If given as a one-sided formula, a dotplot of the estimated random effects (coefficients) grouped according to all combinations of the levels of the factors named in form is returned. Single factors (~g) or crossed factors (~g1*g2) are allowed. If given as a two-sided formula, the left hand side must be a single random effects (coefficient) and the right hand side is formed by covariates in x separated by +. A Trellis display of the random effect (coefficient) versus the named covariates is returned in this case. Default is NULL, in which case the row names of the random effects (coefficients) are used.

- **grid**: an optional logical value indicating whether a grid should be added to plot. Only applies to plots associated with two-sided formulas in form. Default is FALSE.

- **control**: an optional list with control values for the plot, when form is given as a two-sided formula. The control values are referenced by name in the control list and only the ones to be modified from the default need to be specified. Available values include: drawLine, a logical value indicating whether a loess smoother should be added to the scatter plots and a line connecting the medians should be added to the boxplots (default is TRUE); span.loess, used as the span argument in the call to panel.loess (default is 2/3); degree.loess, used as the degree argument in the call to panel.loess (default is 1); cex.axis, the character expansion factor for the x-axis (default is c(2, 0.5, 0)); srt.axis, the rotation factor for the x-axis (default is 0); and mgp.axis, the margin parameters for the x-axis (default is c(2, 0.5, 0)).

- **...**: optional arguments passed to the Trellis dotplot function.
plot>Variogram

Value

a Trellis plot of the estimated random-effects (coefficients) versus covariates, or groups.

lmList, dotplot

Examples

```r
fm1 <- lmList(distance ~ age | Subject, Orthodont)
plot(ranef(fm1))
fm1RE <- ranef(fm1, aug = TRUE)
plot(fm1RE, form = ~ Sex)
## Not run:
plot(fm1RE, form = age ~ Sex)
## End(Not run)
```

plot.Variogram

Plot a Variogram Object

Description

an xyplot of the semi-variogram versus the distances is produced. If smooth = TRUE, a loess smoother is added to the plot. If showModel = TRUE and x includes an "modelVariog" attribute, the corresponding semi-variogram is added to the plot.

Usage

```r
## S3 method for class 'Variogram':
plot(x, smooth, showModel, sigma, span, xlab,
     ylab, type, ylim, grid, ...)
```

Arguments

- `x`: an object inheriting from class `Variogram`, consisting of a data frame with two columns named `variog` and `dist`, representing the semi-variogram values and the corresponding distances.
- `smooth`: an optional logical value controlling whether a loess smoother should be added to the plot. Defaults to TRUE, when showModel is FALSE.
- `showModel`: an optional logical value controlling whether the semi-variogram corresponding to an "modelVariog" attribute of x, if any is present, should be added to the plot. Defaults to TRUE, when the "modelVariog" attribute is present.
- `sigma`: an optional numeric value used as the height of a horizontal line displayed in the plot. Can be used to represent the process standard deviation. Default is NULL, implying that no horizontal line is drawn.
- `span`: an optional numeric value with the smoothing parameter for the loess fit. Default is 0.6.
xlab, ylab

optional character strings with the x- and y-axis labels. Default respectively to "Distance" and "SemiVariogram".

type

an optional character indicating the type of plot. Defaults to "p".

ylim

an optional numeric vector with the limits for the y-axis. Defaults to c(0, max(x$variog)).

grid

an optional logical value indicating whether a grid should be added to plot. Default is FALSE.

... optional arguments passed to the Trellis xyplot function.

Value

an xyplot Trellis plot.

pooledSD

Extract Pooled Standard Deviation

Description

The pooled estimated standard deviation is obtained by adding together the residual sum of squares for each non-null element of object, dividing by the sum of the corresponding residual degrees-of-freedom, and taking the square-root.

Usage

pooledSD(object)

Arguments

object an object inheriting from class lmList.

Value

the pooled standard deviation for the non-null elements of object, with an attribute df with the number of degrees-of-freedom used in the estimation.

Author(s)

Jose Pinheiro (Jose.Pinheiro@pharma.novartis.com) and Douglas Bates (bates@stat.wisc.edu)
Description

The predictions for the linear model represented by `object` are obtained at the covariate values defined in `newdata`.

Usage

```r
## S3 method for class 'gls':
predict(object, newdata, na.action, ...)
```

Arguments

- `object`: an object inheriting from class `gls`, representing a generalized least squares fitted linear model.
- `newdata`: an optional data frame to be used for obtaining the predictions. All variables used in the linear model must be present in the data frame. If missing, the fitted values are returned.
- `na.action`: a function that indicates what should happen when `newdata` contains NAs. The default action (na.fail) causes the function to print an error message and terminate if there are any incomplete observations.
- `...`: some methods for this generic require additional arguments. None are used in this method.

Value

a vector with the predicted values.

Author(s)

Jose Pinheiro (Jose.Pinheiro@pharma.novartis.com) and Douglas Bates (bates@stat.wisc.edu)

newOvary <- data.frame(Time = c(-0.75, -0.5, 0, 0.5, 0.75))
predict(fm1, newOvary)
```
Predictions from a gnls Object

Description

The predictions for the nonlinear model represented by object are obtained at the covariate values defined in newdata.

Usage

```r
## S3 method for class 'gnls':
predict(object, newdata, na.action, naPattern, ...)
```

Arguments

- **object**: an object inheriting from class `gnls`, representing a generalized nonlinear least squares fitted model.
- **newdata**: an optional data frame to be used for obtaining the predictions. All variables used in the nonlinear model must be present in the data frame. If missing, the fitted values are returned.
- **na.action**: a function that indicates what should happen when `newdata` contains NAs. The default action (`na.fail`) causes the function to print an error message and terminate if there are any incomplete observations.
- **naPattern**: an expression or formula object, specifying which returned values are to be regarded as missing.
- **...**: some methods for this generic require additional arguments. None are used in this method.

Value

a vector with the predicted values.

gnls

Examples

```r
fm1 <- gnls(weight ~ SSlogis(Time, Asym, xmid, scal), Soybean,
             weights = varPower())
newSoybean <- data.frame(Time = c(10,30,50,80,100))
predict(fm1, newSoybean)
```
predict.lme Predictions from an lme Object

Description
The predictions at level \( i \) are obtained by adding together the population predictions (based only on
the fixed effects estimates) and the estimated contributions of the random effects to the predictions at
grouping levels less or equal to \( i \). The resulting values estimate the best linear unbiased predictions
(BLUPs) at level \( i \). If group values not included in the original grouping factors are present in
newdata, the corresponding predictions will be set to NA for levels greater or equal to the level at
which the unknown groups occur.

Usage
## S3 method for class 'lme':
predict(object, newdata, level, asList, na.action, ...)

Arguments
object an object inheriting from class lme, representing a fitted linear mixed-effects
model.
newdata an optional data frame to be used for obtaining the predictions. All variables
used in the fixed and random effects models, as well as the grouping factors,
must be present in the data frame. If missing, the fitted values are returned.
level an optional integer vector giving the level(s) of grouping to be used in obtaining
the predictions. Level values increase from outermost to innermost grouping,
with level zero corresponding to the population predictions. Defaults to the
highest or innermost level of grouping.
asList an optional logical value. If TRUE and a single value is given in level, the
returned object is a list with the predictions split by groups; else the returned
value is either a vector or a data frame, according to the length of level.
na.action a function that indicates what should happen when newdata contains NAs.
The default action (na.fail) causes the function to print an error message
and terminate if there are any incomplete observations.
...
some methods for this generic require additional arguments. None are used in
this method.

Value
if a single level of grouping is specified in level, the returned value is either a list with the predic-
tions split by groups (asList = TRUE) or a vector with the predictions (asList = FALSE);
else, when multiple grouping levels are specified in level, the returned object is a data frame with
columns given by the predictions at different levels and the grouping factors.

Author(s)
Jose Pinheiro (Jose.Pinheiro@pharma.novartis.com) and Douglas Bates (bates@stat.wisc.edu)

lme, fitted.lme
Examples

```r
fm1 <- lme(distance ~ age, Orthodont, random = ~ age | Subject)
newOrth <- data.frame(Sex = c("Male","Male","Female","Female","Male","Male"),
                      age = c(15, 20, 10, 12, 2, 4),
                      Subject = c("M01","M01","F30","F30","M04","M04"))
predict(fm1, newOrth, level = 0:1)
```

**predict.lmList**  
**Predictions from an lmList Object**

**Description**

If the grouping factor corresponding to **object** is included in **newdata**, the data frame is partitioned according to the grouping factor levels; else, **newdata** is repeated for all lm components. The predictions and, optionally, the standard errors for the predictions, are obtained for each lm component of **object**, using the corresponding element of the partitioned **newdata**, and arranged into a list with as many components as **object**, or combined into a single vector or data frame (if se.fit=TRUE).

**Usage**

```r
## S3 method for class 'lmList':
predict(object, newdata, subset, pool, asList, se.fit, ...)
```

**Arguments**

- **object**: an object inheriting from class lmList, representing a list of lm objects with a common model.
- **newdata**: an optional data frame to be used for obtaining the predictions. All variables used in the **object** model formula must be present in the data frame. If missing, the same data frame used to produce **object** is used.
- **subset**: an optional character or integer vector naming the lm components of **object** from which the predictions are to be extracted. Default is NULL, in which case all components are used.
- **asList**: an optional logical value. If TRUE, the returned object is a list with the predictions split by groups; else the returned value is a vector. Defaults to FALSE.
- **pool**: an optional logical value indicating whether a pooled estimate of the residual standard error should be used. Default is attr(object, "pool").
- **se.fit**: an optional logical value indicating whether pointwise standard errors should be computed along with the predictions. Default is FALSE.
- `...`: some methods for this generic require additional arguments. None are used in this method.

**Value**

A list with components given by the predictions (and, optionally, the standard errors for the predictions) from each lm component of **object**, a vector with the predictions from all lm components of **object**, or a data frame with columns given by the predictions and their corresponding standard errors.

lmList, predict.lm

Examples

fm1 <- lmList(distance ~ age | Subject, Orthodont)
predict(fm1, se.fit = TRUE)

Description

The predictions at level i are obtained by adding together the contributions from the estimated fixed effects and the estimated random effects at levels less or equal to i and evaluating the model function at the resulting estimated parameters. If group values not included in the original grouping factors are present in newdata, the corresponding predictions will be set to NA for levels greater or equal to the level at which the unknown groups occur.

Usage

## S3 method for class 'nlme':
predict(object, newdata, level, asList, na.action, naPattern, ...)

Arguments

object an object inheriting from class nlme, representing a fitted nonlinear mixed-effects model.

newdata an optional data frame to be used for obtaining the predictions. All variables used in the nonlinear model, the fixed and the random effects models, as well as the grouping factors, must be present in the data frame. If missing, the fitted values are returned.

level an optional integer vector giving the level(s) of grouping to be used in obtaining the predictions. Level values increase from outermost to innermost grouping, with level zero corresponding to the population predictions. Defaults to the highest or innermost level of grouping.

asList an optional logical value. If TRUE and a single value is given in level, the returned object is a list with the predictions split by groups; else the returned value is either a vector or a data frame, according to the length of level.

na.action a function that indicates what should happen when newdata contains NAs. The default action (na.fail) causes the function to print an error message and terminate if there are any incomplete observations.

naPattern an expression or formula object, specifying which returned values are to be regarded as missing.

... some methods for this generic require additional arguments. None are used in this method.
Value

if a single level of grouping is specified in level, the returned value is either a list with the predictions split by groups (asList = TRUE) or a vector with the predictions (asList = FALSE); else, when multiple grouping levels are specified in level, the returned object is a data frame with columns given by the predictions at different levels and the grouping factors.

            random = Asym ~ 1,
            start = c(Asym = 103, R0 = -8.5, lrc = -3.3))
newLoblolly <- data.frame(age = c(5,10,15,20,25,30),
                           Seed = rep(301,6))
predict(fm1, newLoblolly, level = 0:1)

print.summary.pdMat

Print a summary.pdMat Object

Description

The standard deviations and correlations associated with the positive-definite matrix represented by object (considered as a variance-covariance matrix) are printed, together with the formula and the grouping level associated object, if any are present.

Usage

### S3 method for class 'summary.pdMat':
print(x, sigma, rdig, Level, resid, ...)

Arguments

x an object inheriting from class summary.pdMat, generally resulting from applying summary to an object inheriting from class pdMat.

sigma an optional numeric value used as a multiplier for the square-root factor of the positive-definite matrix represented by object (usually the estimated within-group standard deviation from a mixed-effects model). Defaults to 1.

rdig an optional integer value with the number of significant digits to be used in printing correlations. Defaults to 3.
Level an optional character string with a description of the grouping level associated with object (generally corresponding to levels of grouping in a mixed-effects model). Defaults to NULL.

resid an optional logical value. If TRUE an extra row with the "residual" standard deviation given in sigma will be included in the output. Defaults to FALSE.

... optional arguments passed to print.default; see the documentation on that method function.

Examples

vf1 <- varPower(0.3, form = ~age)
vf1 <- Initialize(vf1, Orthodont)
print(vf1)
qqnorm.gls

Normal Plot of Residuals from a gls Object

Description

Diagnostic plots for assessing the normality of residuals the generalized least squares fit are obtained. The `form` argument gives considerable flexibility in the type of plot specification. A conditioning expression (on the right side of a `|` operator) always implies that different panels are used for each level of the conditioning factor, according to a Trellis display.

Usage

```r
## S3 method for class 'gls':
qqnorm(y, form, abline, id, idLabels, grid, ...)
```

Arguments

- `y`: an object inheriting from class `gls`, representing a generalized least squares fitted model.
- `form`: an optional one-sided formula specifying the desired type of plot. Any variable present in the original data frame used to obtain `y` can be referenced. In addition, `y` itself can be referenced in the formula using the symbol `"."`. Conditional expressions on the right of a `|` operator can be used to define separate panels in a Trellis display. The expression on the right hand side of `form` and to the left of a `|` operator must evaluate to a residuals vector. Default is `~ resid(.,, type = "p")`, corresponding to a normal plot of the standardized residuals.
- `abline`: an optional numeric value, or numeric vector of length two. If given as a single value, a horizontal line will be added to the plot at that coordinate; else, if given as a vector, its values are used as the intercept and slope for a line added to the plot. If missing, no lines are added to the plot.
- `id`: an optional numeric value, or one-sided formula. If given as a value, it is used as a significance level for a two-sided outlier test for the standardized residuals (random effects). Observations with absolute standardized residuals (random effects) greater than the `1 - value/2` quantile of the standard normal distribution are identified in the plot using `idLabels`. If given as a one-sided formula, its right hand side must evaluate to a logical, integer, or character vector which is used to identify observations in the plot. If missing, no observations are identified.
- `idLabels`: an optional vector, or one-sided formula. If given as a vector, it is converted to character and used to label the observations identified according to `id`. If given as a one-sided formula, its right hand side must evaluate to a vector which is converted to character and used to label the identified observations. Default is the innermost grouping factor.
- `grid`: an optional logical value indicating whether a grid should be added to plot. Default depends on the type of Trellis plot used: if `xyplot` defaults to `TRUE`, else defaults to `FALSE`.
- `...`: optional arguments passed to the Trellis plot function.
qqnorm.lme

a diagnostic Trellis plot for assessing normality of residuals.

Author(s)
Jose Pinheiro (Jose.Pinheiro@pharma.novartis.com) and Douglas Bates (bates@stat.wisc.edu)

See Also
gls, plot.gls

Examples

```r
fm1 <- gls(follicles ~ sin(2*pi*Time) + cos(2*pi*Time), Ovary,
           correlation = corAR1(form = ~ 1 | Mare))
qqnorm(fm1, abline = c(0,1))
```

Description
Diagnostic plots for assessing the normality of residuals and random effects in the linear mixed-effects fit are obtained. The `form` argument gives considerable flexibility in the type of plot specification. A conditioning expression (on the right side of a `|` operator) always implies that different panels are used for each level of the conditioning factor, according to a Trellis display.

Usage

```r
## S3 method for class 'lme':
qqnorm(y, form, abline, id, idLabels, grid, ...)
```

Arguments

- `y`: an object inheriting from class `lme`, representing a fitted linear mixed-effects model or from class `lmList`, representing a list of `lm` objects, or from class `lm`, representing a fitted linear model, or from class `nls`, representing a nonlinear least squares fitted model.
- `form`: an optional one-sided formula specifying the desired type of plot. Any variable present in the original data frame used to obtain `y` can be referenced. In addition, `y` itself can be referenced in the formula using the symbol `"."`. Conditional expressions on the right of a `|` operator can be used to define separate panels in a Trellis display. The expression on the right hand side of `form` and to the left of a `|` operator must evaluate to a residuals vector, or a random effects matrix. Default is `~ resid(., type = "p")`, corresponding to a normal plot of the standardized residuals evaluated at the innermost level of nesting.
- `abline`: an optional numeric value, or numeric vector of length two. If given as a single value, a horizontal line will be added to the plot at that coordinate; else, if given as a vector, its values are used as the intercept and slope for a line added to the plot. If missing, no lines are added to the plot.
Quinidine

id

an optional numeric value, or one-sided formula. If given as a value, it is used as a significance level for a two-sided outlier test for the standardized residuals (random effects). Observations with absolute standardized residuals (random effects) greater than the $1 - \frac{\text{value}}{2}$ quantile of the standard normal distribution are identified in the plot using \texttt{idLabels}. If given as a one-sided formula, its right hand side must evaluate to a logical, integer, or character vector which is used to identify observations in the plot. If missing, no observations are identified.

\texttt{idLabels}
an optional vector, or one-sided formula. If given as a vector, it is converted to character and used to label the observations identified according to \texttt{id}. If given as a one-sided formula, its right hand side must evaluate to a vector which is converted to character and used to label the identified observations. Default is the innermost grouping factor.

\texttt{grid}
an optional logical value indicating whether a grid should be added to plot. Default is \texttt{FALSE}.

\texttt{...}
optional arguments passed to the Trellis plot function.

\textbf{Value}

a diagnostic Trellis plot for assessing normality of residuals or random effects.

Quinidine

\textit{Quinidine Kinetics}

\textbf{Description}

The Quinidine data frame has 1471 rows and 14 columns.
Format

This data frame contains the following columns:

- **Subject**: a factor identifying the patient on whom the data were collected.
- **time**: a numeric vector giving the time (hr) at which the drug was administered or the blood sample drawn. This is measured from the time the patient entered the study.
- **conc**: a numeric vector giving the serum quinidine concentration (mg/L).
- **dose**: a numeric vector giving the dose of drug administered (mg). Although there were two different forms of quinidine administered, the doses were adjusted for differences in salt content by conversion to milligrams of quinidine base.
- **interval**: a numeric vector giving the when the drug has been given at regular intervals for a sufficiently long period of time to assume steady state behavior, the interval is recorded.
- **Age**: a numeric vector giving the age of the subject on entry to the study (yr).
- **Height**: a numeric vector giving the height of the subject on entry to the study (in.).
- **Weight**: a numeric vector giving the body weight of the subject (kg).
- **Race**: a factor with levels Caucasian, Latin, and Black identifying the race of the subject.
- **Smoke**: a factor with levels no and yes giving smoking status at the time of the measurement.
- **Ethanol**: a factor with levels none, current, former giving ethanol (alcohol) abuse status at the time of the measurement.
- **Heart**: a factor with levels No/Mild, Moderate, and Severe indicating congestive heart failure for the subject.
- **Creatinine**: an ordered factor with levels < 50 < = 50 indicating the creatine clearance (mg/min).
- **glyco**: a numeric vector giving the alpha-1 acid glycoprotein concentration (mg/dL). Often measured at the same time as the quinidine concentration.

Details

Verme et al. (1992) analyze routine clinical data on patients receiving the drug quinidine as a treatment for cardiac arrhythmia (atrial fibrillation of ventricular arrhythmias). All patients were receiving oral quinidine doses. At irregular intervals blood samples were drawn and serum concentrations of quinidine were determined. These data are analyzed in several publications, including Davidian and Giltinan (1995, section 9.3).

Source

quinModel  

Model function for the Quinidine data

Description

A model function for a model used with the Quinidine data. This function calls compiled C code.

Usage

quinModel(Subject, time, conc, dose, interval, lV, lKa, lCl)

Arguments

Subject  
a factor identifying the patient on whom the data were collected.

time  
a numeric vector giving the time (hr) at which the drug was administered or the blood sample drawn. This is measured from the time the patient entered the study.

conc  
a numeric vector giving the serum quinidine concentration (mg/L).

dose  
a numeric vector giving the dose of drug administered (mg). Although there were two different forms of quinidine administered, the doses were adjusted for differences in salt content by conversion to milligrams of quinidine base.

interval  
a numeric vector giving the when the drug has been given at regular intervals for a sufficiently long period of time to assume steady state behavior, the interval is recorded.

lV  
numeric. A vector of values of the natural log of the effective volume of distribution according to Subject and time.

lKa  
numeric. A vector of values of the natural log of the absorption rate constant according to Subject and time.

lCl  
numeric. A vector of values of the natural log of the clearance parameter according to Subject and time.

Details

See the details section of Quinidine for a description of the model function that quinModel evaluates.

Value

a numeric vector of predicted quinidine concentrations.

Examples

\begin{itemize}
\item \texttt{Rail} \hspace{1cm} \textit{Evaluation of Stress in Railway Rails}
\end{itemize}

Description

The \texttt{Rail} data frame has 18 rows and 2 columns.

Format

This data frame contains the following columns:

- \textbf{Rail} \hspace{1cm} an ordered factor identifying the rail on which the measurement was made.
- \textbf{travel} \hspace{1cm} a numeric vector giving the travel time for ultrasonic head-waves in the rail (nanoseconds).
  The value given is the original travel time minus 36,100 nanoseconds.

Details

Devore (2000, Example 10.10, p. 427) cites data from an article in \textit{Materials Evaluation} on “a study of travel time for a certain type of wave that results from longitudinal stress of rails used for railroad track.”

Examples

## see the method function documentation

---

ranef.lme Extract lme Random Effects

Description

The estimated random effects at level $i$ are represented as a data frame with rows given by the different groups at that level and columns given by the random effects. If a single level of grouping is specified, the returned object is a data frame; else, the returned object is a list of such data frames. Optionally, the returned data frame(s) may be augmented with covariates summarized over groups.

Usage

## S3 method for class 'lme':
ransf(object, augFrame, level, data, which, FUN,
standard, omitGroupingFactor, subset, ...)

Arguments

object an object inheriting from class lme, representing a fitted linear mixed-effects model.

augFrame an optional logical value. If TRUE, the returned data frame is augmented with variables defined in data; else, if FALSE, only the coefficients are returned. Defaults to FALSE.

level an optional vector of positive integers giving the levels of grouping to be used in extracting the random effects from an object with multiple nested grouping levels. Defaults to all levels of grouping.

data an optional data frame with the variables to be used for augmenting the returned data frame when augFrame = TRUE. Defaults to the data frame used to fit object.

which an optional positive integer vector specifying which columns of data should be used in the augmentation of the returned data frame. Defaults to all columns in data.
an optional summary function or a list of summary functions to be applied to group-varying variables, when collapsing data by groups. Group-invariant variables are always summarized by the unique value that they assume within that group. If FUN is a single function it will be applied to each non-invariant variable by group to produce the summary for that variable. If FUN is a list of functions, the names in the list should designate classes of variables in the frame such as ordered, factor, or numeric. The indicated function will be applied to any group-varying variables of that class. The default functions to be used are mean for numeric factors, and Mode for both factor and ordered. The Mode function, defined internally in gsummary, returns the modal or most popular value of the variable. It is different from the mode function that returns the S-language mode of the variable.

an optional logical value indicating whether the estimated random effects should be "standardized" (i.e. divided by the estimate of the standard deviation of that group of random effects). Defaults to FALSE.

an optional logical value. When TRUE the grouping factor itself will be omitted from the group-wise summary of data but the levels of the grouping factor will continue to be used as the row names for the returned data frame. Defaults to FALSE.

an optional expression indicating for which rows the random effects should be extracted.

some methods for this generic require additional arguments. None are used in this method.

a data frame, or list of data frames, with the estimated random effects at the grouping level(s) specified in level and, optionally, other covariates summarized over groups. The returned object inherits from classes random_effects.lme and data.frame.

Jose Pinheiro (Jose.Pinheiro@pharma.novartis.com) and Douglas Bates (bates@stat.wisc.edu)

Examples
```r
fm1 <- lme(distance ~ age, Orthodont, random = ~ age | Subject)
ranef(fm1)
random.effects(fm1) # same as above
random.effects(fm1, augFrame = TRUE)
```
Description

The difference between the individual lm components coefficients and their average is calculated.

Usage

```r
## S3 method for class 'lmList':
ranef(object, augFrame, data, which, FUN, standard,
      omitGroupingFactor, ...)
```

Arguments

- `object`: an object inheriting from class `lmList`, representing a list of `lm` objects with a common model.
- `augFrame`: an optional logical value. If `TRUE`, the returned data frame is augmented with variables defined in `data`; else, if `FALSE`, only the coefficients are returned. Defaults to `FALSE`.
- `data`: an optional data frame with the variables to be used for augmenting the returned data frame when `augFrame = TRUE`. Defaults to the data frame used to fit `object`.
- `which`: an optional positive integer vector specifying which columns of `data` should be used in the augmentation of the returned data frame. Defaults to all columns in `data`.
- `FUN`: an optional summary function or a list of summary functions to be applied to group-varying variables, when collapsing `data` by groups. Group-invariant variables are always summarized by the unique value that they assume within that group. If `FUN` is a single function it will be applied to each non-invariant variable by group to produce the summary for that variable. If `FUN` is a list of functions, the names in the list should designate classes of variables in the frame such as `ordered`, `factor`, or `numeric`. The indicated function will be applied to any group-varying variables of that class. The default functions to be used are `mean` for numeric factors, and `Mode` for both `factor` and `ordered`. The `Mode` function, defined internally in `gsummary`, returns the modal or most popular value of the variable. It is different from the `mode` function that returns the S-language mode of the variable.
- `standard`: an optional logical value indicating whether the estimated random effects should be "standardized" (i.e. divided by the corresponding estimated standard error). Defaults to `FALSE`.
- `omitGroupingFactor`: an optional logical value. When `TRUE` the grouping factor itself will be omitted from the group-wise summary of `data` but the levels of the grouping factor will continue to be used as the row names for the returned data frame. Defaults to `FALSE`.
- `...`: some methods for this generic require additional arguments. None are used in this method.
Value

a vector with the differences between the individual \texttt{lm} coefficients in \texttt{object} and their average.

Recalculate Condensed Linear Model Object

Description

This function is generic; method functions can be written to handle specific classes of objects. Classes which already have methods for this function include: corStruct, modelStruct, reStruct, and varFunc.

Usage

recalc(object, conLin, ...)

Arguments

object any object which induces a recalculation of the condensed linear model object conLin.

conLin a condensed linear model object, consisting of a list with components "Xy", corresponding to a regression matrix (X) combined with a response vector (y), and "logLik", corresponding to the log-likelihood of the underlying model.

... some methods for this generic can take additional arguments.

Value

the recalculated condensed linear model object.

Note

This function is only used inside model fitting functions, such as lme and gls, that require recalculation of a condensed linear model object.

Author(s)

Jose Pinheiro (Jose.Pinheiro@pharma.novartis.com) and Douglas Bates (bates@stat.wisc.edu)

See Also

recalc.corStruct, recalc.modelStruct, recalc.reStruct, recalc.varFunc

Examples

## see the method function documentation
Recalculate for corStruct Object

Description

This method function pre-multiples the "Xy" component of conLin by the transpose square-root factor(s) of the correlation matrix (matrices) associated with object and adds the log-likelihood contribution of object, given by logLik(object), to the "logLik" component of conLin.

Usage

```r
## S3 method for class 'corStruct':
recalc(object, conLin, ...)
```

Arguments

- `object`: an object inheriting from class `corStruct`, representing a correlation structure.
- `conLin`: a condensed linear model object, consisting of a list with components "Xy", corresponding to a regression matrix (X) combined with a response vector (y), and "logLik", corresponding to the log-likelihood of the underlying model.
- `...`: some methods for this generic require additional arguments. None are used in this method.

Value

the recalculated condensed linear model object.

Note

This method function is only used inside model fitting functions, such as `lme` and `gls`, that allow correlated error terms.

Jose Pinheiro (Jose.Pinheiro@pharma.novartis.com) and Douglas Bates (bates@stat.wisc.edu)

See Also

corFactor, logLik.corStruct
recalc.modelStruct  

Recalculate for a modelStruct Object

Description

This method function recalculates the condensed linear model object using each element of object sequentially from last to first.

Usage

```r
# S3 method for class 'modelStruct':
recalc(object, conLin, ...)
```

Arguments

- `object` an object inheriting from class `modelStruct`, representing a list of model components, such as `corStruct` and `varFunc` objects.
- `conLin` an optional condensed linear model object, consisting of a list with components "Xy", corresponding to a regression matrix (X) combined with a response vector (y), and "logLik", corresponding to the log-likelihood of the underlying model. Defaults to `attr(object, "conLin")`.
- `...` some methods for this generic require additional arguments. None are used in this method.

Value

the recalculated condensed linear model object.

Note

This method function is generally only used inside model fitting functions, such as `lme` and `gls`, that allow model components, such as correlated error terms and variance functions.

Author(s)

Jose Pinheiro (Jose.Pinheiro@pharma.novartis.com) and Douglas Bates (bates@stat.wisc.edu)

See Also

- `recalc.corStruct`
- `recalc.reStruct`
- `recalc.varFunc`
Recalculate for an reStruct Object

Description

The log-likelihood, or restricted log-likelihood, of the Gaussian linear mixed-effects model represented by object and conLin (assuming spherical within-group covariance structure), evaluated at coef(object) is calculated and added to the logLik component of conLin. The settings attribute of object determines whether the log-likelihood, or the restricted log-likelihood, is to be calculated. The computational methods for the (restricted) log-likelihood calculations are described in Bates and Pinheiro (1998).

Usage

```r
## S3 method for class 'reStruct':
recalc(object, conLin, ...)
```

Arguments

- `object`: an object inheriting from class reStruct, representing a random effects structure and consisting of a list of pdMat objects.
- `conLin`: a condensed linear model object, consisting of a list with components "Xy", corresponding to a regression matrix (X) combined with a response vector (y), and "logLik", corresponding to the log-likelihood of the underlying model.
- `...`: some methods for this generic require additional arguments. None are used in this method.

Value

the condensed linear model with its logLik component updated.

Jose Pinheiro (Jose.Pinheiro@pharma.novartis.com) and Douglas Bates (bates@stat.wisc.edu)

References

See Also

`logLik`, `lme`, `recalc`, `reStruct`
Recalculate for varFunc Object

Description

This method function pre-multiplies the "Xy" component of conLin by a diagonal matrix with diagonal elements given by the weights corresponding to the variance structure represented by object and adds the log-likelihood contribution of object, given by logLik(object), to the "logLik" component of conLin.

Usage

## S3 method for class 'varFunc':
recalc(object, conLin, ...)

Arguments

object an object inheriting from class varFunc, representing a variance function structure.

conLin a condensed linear model object, consisting of a list with components "Xy", corresponding to a regression matrix (X) combined with a response vector (y), and "logLik", corresponding to the log-likelihood of the underlying model.

... some methods for this generic require additional arguments. None are used in this method.

Value

the recalculated condensed linear model object.

Note

This method function is only used inside model fitting functions, such as lme and gls, that allow heteroscedastic error terms.

residuals.gls

Details

Source

residuals.gls Extract gls Residuals

Description

The residuals for the linear model represented by object are extracted.

Usage

```r
## S3 method for class 'gls':
residuals(object, type, ...)
```

Arguments

- **object**: an object inheriting from class gls, representing a generalized least squares fitted linear model, or from class gnls, representing a generalized nonlinear least squares fitted linear model.
- **type**: an optional character string specifying the type of residuals to be used. If "response", the "raw" residuals (observed - fitted) are used; else, if "pearson", the standardized residuals (raw residuals divided by the corresponding standard errors) are used; else, if "normalized", the normalized residuals (standardized residuals pre-multiplied by the inverse square-root factor of the estimated error correlation matrix) are used. Partial matching of arguments is used, so only the first character needs to be provided. Defaults to "pearson".

... some methods for this generic function require additional arguments. None are used in this method.

Value

a vector with the residuals for the linear model represented by object.

residuals.lme

Extract lme Residuals

Description

The residuals at level $i$ are obtained by subtracting the fitted levels at that level from the response vector (and dividing by the estimated within-group standard error, if type="pearson"). The fitted values at level $i$ are obtained by adding together the population fitted values (based only on the fixed effects estimates) and the estimated contributions of the random effects to the fitted values at grouping levels less or equal to $i$. 
## S3 method for class 'lme':
residuals(object, level, type, asList, ...)

### Arguments

- **object**: an object inheriting from class `lme`, representing a fitted linear mixed-effects model.
- **level**: an optional integer vector giving the level(s) of grouping to be used in extracting the residuals from `object`. Level values increase from outermost to innermost grouping, with level zero corresponding to the population residuals. Defaults to the highest or innermost level of grouping.
- **type**: an optional character string specifying the type of residuals to be used. If "response", the "raw" residuals (observed - fitted) are used; else, if "pearson", the standardized residuals (raw residuals divided by the corresponding standard errors) are used; else, if "normalized", the normalized residuals (standardized residuals pre-multiplied by the inverse square-root factor of the estimated error correlation matrix) are used. Partial matching of arguments is used, so only the first character needs to be provided. Defaults to "pearson".
- **asList**: an optional logical value. If `TRUE` and a single value is given in `level`, the returned object is a list with the residuals split by groups (`asList = TRUE`) or a vector with the residuals (`asList = FALSE`); else the returned value is either a vector or a data frame, according to the length of `level`. Defaults to `FALSE`.
- **...**: some methods for this generic require additional arguments. None are used in this method.

### Value

- if a single level of grouping is specified in `level`, the returned value is either a list with the residuals split by groups (`asList = TRUE`) or a vector with the residuals (`asList = FALSE`); else, when multiple grouping levels are specified in `level`, the returned object is a data frame with columns given by the residuals at different levels and the grouping factors.

### Author(s)

- Jose Pinheiro (Jose.Pinheiro@pharma.novartis.com) and Douglas Bates ⟨bates@stat.wisc.edu⟩

### References

### See Also

- `lme`, `fitted.lme`

### Examples

```r
fm1 <- lme(distance ~ age + Sex, data = Orthodont, random = ~ 1)
residuals(fm1, level = 0:1)
```
residuals.lmeStruct

Calculate lmeStruct Residuals

Description

The residuals at level $i$ are obtained by subtracting the fitted values at that level from the response vector. The fitted values at level $i$ are obtained by adding together the population fitted values (based only on the fixed effects estimates) and the estimated contributions of the random effects to the fitted values at grouping levels less or equal to $i$.

Usage

## S3 method for class 'lmeStruct':
residuals(object, level, conLin, lmeFit, ...)

Arguments

- **object**: an object inheriting from class `lmeStruct`, representing a list of linear mixed-effects model components, such as `reStruct`, `corStruct`, and `varFunc` objects.
- **level**: an optional integer vector giving the level(s) of grouping to be used in extracting the residuals from `object`. Level values increase from outermost to innermost grouping, with level zero corresponding to the population fitted values. Defaults to the highest or innermost level of grouping.
- **conLin**: an optional condensed linear model object, consisting of a list with components "Xy", corresponding to a regression matrix ($X$) combined with a response vector ($y$), and "logLik", corresponding to the log-likelihood of the underlying line model. Defaults to `attr(object, "conLin")`.
- **lmeFit**: an optional list with components `beta` and `b` containing respectively the fixed effects estimates and the random effects estimates to be used to calculate the residuals. Defaults to `attr(object, "lmeFit")`.
- **...**: some methods for this generic accept optional arguments.

Value

If a single level of grouping is specified in `level`, the returned value is a vector with the residuals at the desired level; else, when multiple grouping levels are specified in `level`, the returned object is a matrix with columns given by the residuals at different levels.

Note

This method function is primarily used within the `lme` function.

residuals.lmList  Extract lmList Residuals

Description

The residuals are extracted from each \texttt{lm} component of \texttt{object} and arranged into a list with as many components as \texttt{object}, or combined into a single vector.

Usage

\begin{verbatim}
## S3 method for class 'lmList':
residuals(object, type, subset, asList, ...)
\end{verbatim}

Arguments

\begin{itemize}
\item \texttt{object}  an object inheriting from class \texttt{lmList}, representing a list of \texttt{lm} objects with a common model.
\item \texttt{subset}  an optional character or integer vector naming the \texttt{lm} components of \texttt{object} from which the residuals are to be extracted. Default is \texttt{NULL}, in which case all components are used.
\item \texttt{type}  an optional character string specifying the type of residuals to be extracted. Options include "\texttt{response}" for the "raw" residuals (observed - fitted), "\texttt{pearson}" for the standardized residuals (raw residuals divided by the estimated residual standard error) using different standard errors for each \texttt{lm} fit, and "\texttt{pooled.pearson}" for the standardized residuals using a pooled estimate of the residual standard error. Partial matching of arguments is used, so only the first character needs to be provided. Defaults to "\texttt{response}".
\item \texttt{asList}  an optional logical value. If \texttt{TRUE}, the returned object is a list with the residuals split by groups; else the returned value is a vector. Defaults to \texttt{FALSE}.
\item \texttt{...}  some methods for this generic require additional arguments. None are used in this method.
\end{itemize}

Value

\begin{itemize}
\item a list with components given by the residuals of each \texttt{lm} component of \texttt{object}, or a vector with the residuals for all \texttt{lm} components of \texttt{object}.
\end{itemize}

Author(s)

Jose Pinheiro (Jose.Pinheiro@pharma.novartis.com) and Douglas Bates (bates@stat.wisc.edu)
**See Also**

`lmList`, `fitted.lmList`

**Examples**

```r
fm1 <- lmList(distance ~ age | Subject, Orthodont)
residuals(fm1)
```

---

**Description**

The residuals at level $i$ are obtained by subtracting the fitted values at that level from the response vector. The fitted values at level $i$ are obtained by adding together the contributions from the estimated fixed effects and the estimated random effects at levels less or equal to $i$ and evaluating the model function at the resulting estimated parameters.

**Usage**

```r
## S3 method for class 'nlmeStruct':
residuals(object, level, conLin, ...)
```

**Arguments**

- `object`: an object inheriting from class `nlmeStruct`, representing a list of mixed-effects model components, such as `reStruct`, `corStruct`, and `varFunc` objects.
- `level`: an optional integer vector giving the level(s) of grouping to be used in extracting the residuals from `object`. Level values increase from outermost to innermost grouping, with level zero corresponding to the population fitted values. Defaults to the highest or innermost level of grouping.
- `conLin`: an optional condensed linear model object, consisting of a list with components "Xy", corresponding to a regression matrix ($X$) combined with a response vector ($y$), and "logLik", corresponding to the log-likelihood of the underlying `nlme` model. Defaults to `attr(object, "conLin")`.
- `...`: optional arguments to the residuals generic. Not used.

**Value**

- if a single level of grouping is specified in `level`, the returned value is a vector with the residuals at the desired level; else, when multiple grouping levels are specified in `level`, the returned object is a matrix with columns given by the residuals at different levels.

**Note**

This method function is primarily used within the `nlme` function.

reStruct

Random Effects Structure

Description

This function is a constructor for the reStruct class, representing a random effects structure and consisting of a list of pdMat objects, plus a settings attribute containing information for the optimization algorithm used to fit the associated mixed-effects model.

Usage

reStruct(object, pdClass, REML, data)

## S3 method for class 'reStruct':
print(x, sigma, reEstimates, verbose, ...)

Arguments

object any of the following: (i) a one-sided formula of the form ~x1+...+xn | g1/.../gm, with x1+...+xn specifying the model for the random effects and g1/.../gm the grouping structure (m may be equal to 1, in which case no / is required). The random effects formula will be repeated for all levels of grouping, in the case of multiple levels of grouping; (ii) a list of one-sided formulas of the form ~x1+...+xn | g, with possibly different random effects models for each grouping level. The order of nesting will be assumed the same as the order of the elements in the list; (iii) a one-sided formula of the form ~x1+...+xn, or a pdMat object with a formula (i.e. a non-NULL value for formula(object)), or a list of such formulas or pdMat objects. In this case, the grouping structure formula will be derived from the data used to to fit the mixed-effects model, which should inherit from class groupedData; (iv) a named list of formulas or pdMat objects as in (iii), with the grouping factors as names. The order of nesting will be assumed the same as the order of the order of the elements in the list; (v) an reStruct object.

pdClass an optional character string with the name of the pdMat class to be used for the formulas in object. Defaults to "pdSymm" which corresponds to a general positive-definite matrix.

REML an optional logical value. If TRUE, the associated mixed-effects model will be fitted using restricted maximum likelihood; else, if FALSE, maximum likelihood will be used. Defaults to FALSE.
simulate.lme

data an optional data frame in which to evaluate the variables used in the random effects formulas in object. It is used to obtain the levels for factors, which affect the dimensions and the row/column names of the underlying pdMat objects. If NULL, no attempt is made to obtain information on factors appearing in the formulas. Defaults to the parent frame from which the function was called.

x an object inheriting from class reStruct to be printed.

sigma an optional numeric value used as a multiplier for the square-root factors of the pdMat components (usually the estimated within-group standard deviation from a mixed-effects model). Defaults to 1.

reEstimates an optional list with the random effects estimates for each level of grouping. Only used when verbose = TRUE.

verbose an optional logical value determining if the random effects estimates should be printed. Defaults to FALSE.

... Optional arguments can be given to other methods for this generic. None are used in this method.

Value

an object inheriting from class reStruct, representing a random effects structure.

simulate.lme Simulate results from lme models

Description

The model object is fit to the data. Using the fitted values of the parameters, nsim new data vectors from this model are simulated. Both m1 and m2 are fit by maximum likelihood (ML) and/or by restricted maximum likelihood (REML) to each of the simulated data vectors.

Usage

simulate.lme(object, nsim, seed, m2, method, niterEM, useGen, ...)
simulate.lme

Arguments

object an object inheriting from class lme, representing a fitted linear mixed-effects model, or a list containing an lme model specification. If given as a list, it should contain components fixed, data, and random with values suitable for a call to lme. This argument defines the null model.

m2 an lme object, or a list, like m1 containing a second lme model specification. This argument defines the alternative model. If given as a list, only those parts of the specification that change between model m1 and m2 need to be specified.

seed an optional integer that is passed to set.seed. Defaults to a random integer.

method an optional character array. If it includes "REML" the models are fit by maximizing the restricted log-likelihood. If it includes "ML" the log-likelihood is maximized. Defaults to c("REML", "ML"), in which case both methods are used.

nsim an optional positive integer specifying the number of simulations to perform. Defaults to 1. This has changed. Previously the default was 1000.

niterEM an optional integer vector of length 2 giving the number of iterations of the EM algorithm to apply when fitting the m1 and m2 to each simulated set of data. Defaults to c(40,200).

useGen an optional logical value. If TRUE, numerical derivatives are used to obtain the gradient and the Hessian of the log-likelihood in the optimization algorithm in the ms function. If FALSE, the default algorithm in ms for functions that do not incorporate gradient and Hessian attributes is used. Default depends on the pdMat classes used in m1 and m2: if both are standard classes (see pdClasses) then defaults to TRUE, otherwise defaults to FALSE.

... optional additional arguments. None are used.

Value

an object of class simulate.lme with components null and alt. Each of these has components ML and/or REML which are matrices. An attribute called Random.seed contains the seed that was used for the random number generator.

Examples

```r
## Not run:
orthSim <-
simulate.lme(list(fixed = distance ~ age, data = Orthodont,
random = ~ 1 | Subject), nsim = 1000,
m2 = list(random = ~ age | Subject))
## End(Not run)
```
solve.pdMat  Calculate Inverse of a Positive-Definite Matrix

Description

The positive-definite matrix represented by \( a \) is inverted and assigned to \( a \).

Usage

```r
## S3 method for class 'pdMat':
solve(a, b, ...)
```

Arguments

- \( a \) an object inheriting from class `pdMat`, representing a positive definite matrix.
- \( b \) this argument is only included for consistency with the generic function and is not used in this method function.
- \( ... \) some methods for this generic require additional arguments. None are used in this method.

Value

\( a \) `pdMat` object similar to \( a \), but with coefficients corresponding to the inverse of the positive-definite matrix represented by \( a \).

Author(s)

Jose Pinheiro (Jose.Pinheiro@pharma.novartis.com) and Douglas Bates (bates@stat.wisc.edu)

See Also

`pdMat`

Examples

```r
pdl <- pdCompSymm(3 * diag(3) + 1)
solve(pdl)
```

solve.reStruct  Apply Solve to an reStruct Object

Description

`Solve` is applied to each `pdMat` component of \( a \), which results in inverting the positive-definite matrices they represent.

Usage

```r
## S3 method for class 'reStruct':
solve(a, b, ...)
```
Arguments

a  an object inheriting from class `reStruct`, representing a random effects structure and consisting of a list of `pdMat` objects.

b  this argument is only included for consistency with the generic function and is not used in this method function.

...  some methods for this generic require additional arguments. None are used in this method.

Value

an `reStruct` object similar to `a`, but with the `pdMat` components representing the inverses of the matrices represented by the components of `a`.

### Soybean

#### Growth of soybean plants

**Description**

The `Soybean` data frame has 412 rows and 5 columns.

**Format**

This data frame contains the following columns:

- **Plot**  a factor giving a unique identifier for each plot.
- **Variety**  a factor indicating the variety; Forrest (F) or Plant Introduction #416937 (P).
- **Year**  a factor indicating the year the plot was planted.
- **Time**  a numeric vector giving the time the sample was taken (days after planting).
- **weight**  a numeric vector giving the average leaf weight per plant (g).

**Details**

These data are described in Davidian and Giltinan (1995, 1.1.3, p.7) as “Data from an experiment to compare growth patterns of two genotypes of soybeans: Plant Introduction #416937 (P), an experimental strain, and Forrest (F), a commercial variety.”
Source

Examples

```r
summary(fm1 <- nlsList(SSlogis, data = Soybean))

splitFormula(~ g1/g2/g3)
```

**Description**

Splits the right hand side of `form` into a list of subformulas according to the presence of `sep`. The left hand side of `form`, if present, will be ignored. The length of the returned list will be equal to the number of occurrences of `sep` in `form` plus one.

**Usage**

```r
splitFormula(form, sep)
```

**Arguments**

- `form`: a formula object.
- `sep`: an optional character string specifying the separator to be used for splitting the formula. Defaults to "/".

**Value**

A list of formulas, corresponding to the split of `form` according to `sep`.

**Author(s)**

Jose Pinheiro (Jose.Pinheiro@pharma.novartis.com) and Douglas Bates (bates@stat.wisc.edu)

**See Also**

splitFormula(~ g1/g2/g3)
```
Spruce  

**Growth of Spruce Trees**

**Description**

The Spruce data frame has 1027 rows and 4 columns.

**Format**

This data frame contains the following columns:

- **Tree**  a factor giving a unique identifier for each tree.
- **days** a numeric vector giving the number of days since the beginning of the experiment.
- **logSize** a numeric vector giving the logarithm of an estimate of the volume of the tree trunk.
- **plot**  a factor identifying the plot in which the tree was grown.

**Details**

Diggle, Liang, and Zeger (1994, Example 1.3, page 5) describe data on the growth of spruce trees that have been exposed to an ozone-rich atmosphere or to a normal atmosphere.

---

**summary.corStruct**  

**Summarize a corStruct Object**

**Description**

This method function prepares object to be printed using the print.summary method, by changing its class and adding a structName attribute to it.

**Usage**

```r
## S3 method for class 'corStruct':
summary(object, structName, ...)
```

**Arguments**

- **object** an object inheriting from class corStruct, representing a correlation structure.
- **structName** an optional character string defining the type of correlation structure associated with object, to be used in the print.summary method. Defaults to class(object)[1].
- **...** some methods for this generic require additional arguments. None are used in this method.
**summary.gls**

**Value**

an object identical to `object`, but with its class changed to `summary.corStruct` and an additional attribute `structName`. The returned value inherits from the same classes as `object`.

**Author(s)**

Jose Pinheiro and Douglas Bates

**See Also**

**Examples**

cs1 <- corAR1(0.2)
summary(cs1)

---

**summary.gls**

*Summarize a gls Object*

**Description**

Additional information about the linear model fit represented by `object` is extracted and included as components of `object`.

**Usage**

```r
## S3 method for class 'gls':
summary(object, verbose, ...)
```

**Arguments**

- `object`: an object inheriting from class `gls`, representing a generalized least squares fitted linear model.
- `verbose`: an optional logical value used to control the amount of output when the object is printed. Defaults to `FALSE`.
- `...`: some methods for this generic require additional arguments. None are used in this method.

**Value**

an object inheriting from class `summary.gls` with all components included in `object` (see `glsObject` for a full description of the components) plus the following components:

- `corBeta`: approximate correlation matrix for the coefficients estimates
- `tTable`: a data frame with columns `Value`, `Std. Error`, `t-value`, and `p-value` representing respectively the coefficients estimates, their approximate standard errors, the ratios between the estimates and their standard errors, and the associated p-value under a t approximation. Rows correspond to the different coefficients.
residuals  if more than five observations are used in the gls fit, a vector with the minimum, first quartile, median, third quartile, and maximum of the residuals distribution; else the residuals.
AIC        the Akaike Information Criterion corresponding to object.
BIC        the Bayesian Information Criterion corresponding to object.

summary.lme  Summarize an lme Object

Description
Additional information about the linear mixed-effects fit represented by object is extracted and included as components of object. The returned object is suitable for printing with the print.summary.lme method.

Usage
## S3 method for class 'lme':
summary(object, adjustSigma, verbose, ...)

Arguments
object  an object inheriting from class lme, representing a fitted linear mixed-effects model.
adjustSigma an optional logical value. If TRUE and the estimation method used to obtain object was maximum likelihood, the residual standard error is multiplied by \( \sqrt{\frac{n_{obs}}{n_{obs} - n_{par}}} \), converting it to a REML-like estimate. This argument is only used when a single fitted object is passed to the function. Default is TRUE.
verbose  an optional logical value used to control the amount of output in the print.summary.lme method. Defaults to FALSE.
...  some methods for this generic require additional arguments. None are used in this method.
Value

an object inheriting from class `summary.lme` with all components included in `object` (see `lmeObject` for a full description of the components) plus the following components:

- `corFixed`: approximate correlation matrix for the fixed effects estimates
- `tTable`: a data frame with columns `Value`, `Std. Error`, `DF`, `t-value`, and `p-value` representing respectively the fixed effects estimates, their approximate standard errors, the denominator degrees of freedom, the ratios between the estimates and their standard errors, and the associated p-value from a t distribution. Rows correspond to the different fixed effects.
- `residuals`: if more than five observations are used in the `lme` fit, a vector with the minimum, first quartile, median, third quartile, and maximum of the innermost grouping level residuals distribution; else the innermost grouping level residuals.
- `AIC`: the Akaike Information Criterion corresponding to `object`.
- `BIC`: the Bayesian Information Criterion corresponding to `object`.

**summary.lmList**

**Summarize an lmList Object**

Description

The `summary.lm` method is applied to each `lm` component of `object` to produce summary information on the individual fits, which is organized into a list of summary statistics. The returned object is suitable for printing with the `print.summary.lmList` method.

Usage

```r
## S3 method for class 'lmList':
summary(object, pool, ...)
```

Arguments

- `object`: an object inheriting from class `lmList`, representing a list of `lm` fitted objects.
- `pool`: an optional logical value indicating whether a pooled estimate of the residual standard error should be used. Default is `attr(object, "pool")`.
- `...`: some methods for this generic require additional arguments. None are used in this method.
Value

A list with summary statistics obtained by applying `summary.lm` to the elements of `object`, inheriting from class `summary.lmList`. The components of `value` are:

- **call**: a list containing an image of the `lmList` call that produced `object`.
- **coefficients**: a three-dimensional array with summary information on the `lm` coefficients. The first dimension corresponds to the names of the `object` components, the second dimension is given by "Value", "Std. Error", "t value", and "Pr(>|t|)". corresponding, respectively, to the coefficient estimates and their associated standard errors, t-values, and p-values. The third dimension is given by the coefficients names.
- **correlation**: a three-dimensional array with the correlations between the individual `lm` coefficient estimates. The first dimension corresponds to the names of the `object` components. The third dimension is given by the coefficients names. For each coefficient, the rows of the associated array give the correlations between that coefficient and the remaining coefficients, by `lm` component.
- **cov.unscaled**: a three-dimensional array with the unscaled variances/covariances for the individual `lm` coefficient estimates (giving the estimated variance/covariance for the coefficients, when multiplied by the estimated residual errors). The first dimension corresponds to the names of the `object` components. The third dimension is given by the coefficients names. For each coefficient, the rows of the associated array give the unscaled covariances between that coefficient and the remaining coefficients, by `lm` component.
- **df**: an array with the number of degrees of freedom for the model and for residuals, for each `lm` component.
- **df.residual**: the total number of degrees of freedom for residuals, corresponding to the sum of residuals df of all `lm` components.
- **fstatistics**: an array with the F test statistics and corresponding degrees of freedom, for each `lm` component.
- **pool**: the value of the `pool` argument to the function.
- **r.squared**: a vector with the multiple R-squared statistics for each `lm` component.
- **residuals**: a list with components given by the residuals from individual `lm` fits.
- **RSE**: the pooled estimate of the residual standard error.
- **sigma**: a vector with the residual standard error estimates for the individual `lm` fits.
- **terms**: the terms object used in fitting the individual `lm` components.

**Summary of modelStruct**

*Summarize a modelStruct Object*

**Description**

This method function applies `summary` to each element of `object`.

**Usage**

```r
## S3 method for class 'modelStruct':
summary(object, ...)
```

**Arguments**

- `object`: an object inheriting from class `modelStruct`, representing a list of model components, such as `reStruct`, `corStruct` and `varFunc` objects.

- `...`: some methods for this generic require additional arguments. None are used in this method.

**Value**

A list with elements given by the summarized components of `object`. The returned value is of class `summary.modelStruct`, also inheriting from the same classes as `object`.

**Author(s)**

Jose Pinheiro (Jose.Pinheiro@pharma.novartis.com) and Douglas Bates (bates@stat.wisc.edu)

**See Also**

`reStruct`, `summary`

**Examples**

```r
lms1 <- lmeStruct(reStruct = reStruct(pdDiag(diag(2), ~age)),

summary(lms1)
```

---

**Summary of nlsList**

*Summarize an nlsList Object*

**Description**

The `summary` function is applied to each `nls` component of `object` to produce summary information on the individual fits, which is organized into a list of summary statistics. The returned object is suitable for printing with the `print.summary.nlsList` method.
Usage

```r
## S3 method for class 'nlsList':
summary(object, ...)
```

Arguments

- `object`: an object inheriting from class `nlsList`, representing a list of `nls` fitted objects.
- `...`: optional arguments to the `summary.lmList` method. One such optional argument is `pool`, a logical value indicating whether a pooled estimate of the residual standard error should be used. Default is `attr(object, "pool")`.

Value

A list with summary statistics obtained by applying `summary` to the elements of `object`, inheriting from class `summary.nlsList`. The components of `value` are:

- `call`: a list containing an image of the `nlsList` call that produced `object`.
- `parameters`: a three dimensional array with summary information on the `nls` coefficients. The first dimension corresponds to the names of the `object` components, the second dimension is given by "Value", "Std. Error", "t value", and "Pr(>|t|)", corresponding, respectively, to the coefficient estimates and their associated standard errors, t-values, and p-values. The third dimension is given by the coefficients names.
- `correlation`: a three dimensional array with the correlations between the individual `nls` coefficient estimates. The first dimension corresponds to the names of the `object` components. The third dimension is given by the coefficients names. For each coefficient, the rows of the associated array give the correlations between that coefficient and the remaining coefficients, by `nls` component.
- `cov.unscaled`: a three dimensional array with the unscaled variances/covariances for the individual `lm` coefficient estimates (giving the estimated variance/covariance for the coefficients, when multiplied by the estimated residual errors). The first dimension corresponds to the names of the `object` components. The third dimension is given by the coefficients names. For each coefficient, the rows of the associated array give the unscaled covariances between that coefficient and the remaining coefficients, by `nls` component.
- `df`: an array with the number of degrees of freedom for the model and for residuals, for each `nls` component.
- `df.residual`: the total number of degrees of freedom for residuals, corresponding to the sum of residuals `df` of all `nls` components.
- `pool`: the value of the `pool` argument to the function.
- `RSE`: the pooled estimate of the residual standard error.
- `sigma`: a vector with the residual standard error estimates for the individual `lm` fits.

fm1 <- nlsList(SSasymp, Loblolly)
summary(fm1)
```

---

### Description

Attributes `structName` and `noCorrelation`, with the values of the corresponding arguments to the method function, are appended to `object` and its class is changed to `summary.pdMat`.

#### Usage

```r
## S3 method for class 'pdMat':
summary(object, structName, noCorrelation, ...)
```

#### Arguments

- **object**: an object inheriting from class `pdMat`, representing a positive definite matrix.
- **structName**: an optional character string with a description of the `pdMat` class. Default depends on the method function: "Blocked" for `pdBlocked`, "Compound Symmetry" for `pdCompSymm`, "Diagonal" for `pdDiag`, "Multiple of an Identity" for `pdIdent`, "General Positive-Definite, Natural Parametrization" for `pdNatural`, "General Positive-Definite" for `pdSymm`, and `data.class(object)` for `pdMat`.
- **noCorrelation**: an optional logical value indicating whether correlations are to be printed in `print.summary.pdMat`. Default depends on the method function: `FALSE` for `pdDiag` and `pdIdent`, and `TRUE` for all other classes.
- **...**: some methods for this generic require additional arguments. None are used in this method.

#### Value

An object similar to `object`, with additional attributes `structName` and `noCorrelation`, inheriting from class `summary.pdMat`.

Summary varFunc Object

Description

A structName attribute, with the value of corresponding argument, is appended to object and its class is changed to summary.varFunc.

Usage

## S3 method for class 'varFunc':
summary(object, structName, ...)

Arguments

object an object inheriting from class varFunc, representing a variance function structure.

structName an optional character string with a description of the varFunc class. Default depends on the method function: "Combination of variance functions" for varComb, "Constant plus power of covariate" for varConstPower, "Exponential of variance covariate" for varExp, "Different standard deviations per stratum" for varIdent, "Power of variance covariate" for varPower, and data.class(object) for varFunc.

... some methods for this generic require additional arguments. None are used in this method.

Value

an object similar to object, with an additional attribute structName, inheriting from class summary.varFunc.

**update.modelStruct**  
*Update a modelStruct Object*

**Description**
This method function updates each element of object, allowing the access to data.

**Usage**
```r
## S3 method for class 'modelStruct':
update(object, data, ...)
```

**Arguments**
- **object**: an object inheriting from class `modelStruct`, representing a list of model components, such as `corStruct` and `varFunc` objects.
- **data**: a data frame in which to evaluate the variables needed for updating the elements of `object`.
- **...**: some methods for this generic require additional arguments. None are used in this method.

**Value**
an object similar to `object` (same class, length, and names), but with updated elements.

**Note**
This method function is primarily used within model fitting functions, such as `lme` and `gls`, that allow model components such as variance functions.

**Author(s)**

`reStruct`

---

**update.varFunc**  
*Update varFunc Object*

**Description**
If the `formula(object)` includes a "." term, representing a fitted object, the variance covariate needs to be updated upon completion of an optimization cycle (in which the variance function weights are kept fixed). This method function allows a reevaluation of the variance covariate using the current fitted object and, optionally, other variables in the original data.
## S3 method for class 'varFunc':
update(object, data, ...)

### Arguments

- **object**: an object inheriting from class varFunc, representing a variance function structure.
- **data**: a list with a component named "." with the current version of the fitted object (from which fitted values, coefficients, and residuals can be extracted) and, if necessary, other variables used to evaluate the variance covariate(s).
- **...**: some methods for this generic require additional arguments. None are used in this method.

### Value

If `formula(object)` includes a "." term, an varFunc object similar to `object`, but with the variance covariate reevaluated at the current fitted object value; else `object` is returned unchanged.

### Author(s)

Jose Pinheiro (Jose.Pinheiro@pharma.novartis.com) and Douglas Bates (bates@stat.wisc.edu)

### See Also

`needUpdate`, `covariate<-.varFunc`

---

### Description

Standard classes of variance function structures (varFunc) available in the nlme library. Covariates included in the variance function, denoted by variance covariates, may involve functions of the fitted model object, such as the fitted values and the residuals. Different coefficients may be assigned to the levels of a classification factor.

### Value

Available standard classes ():

- **varExp**: exponential of a variance covariate.
- **varPower**: power of a variance covariate.
- **varConstPower**: constant plus power of a variance covariate.
- **varIdent**: constant variance(s), generally used to allow different variances according to the levels of a classification factor.
- **varFixed**: fixed weights, determined by a variance covariate.
- **varComb**: combination of variance functions.
Note

Users may define their own `varFunc` classes by specifying a constructor function and, at a minimum, methods for the functions `coef`, `coef<-`, and `initialize`. For examples of these functions, see the methods for class `varPower`.

**varComb**

Combination of Variance Functions

Description

This function is a constructor for the `varComb` class, representing a combination of variance functions. The corresponding variance function is equal to the product of the variance functions of the `varFunc` objects listed in ...

Usage

`varComb(...)`

Arguments

`...` objects inheriting from class `varFunc` representing variance function structures.

Value

A `varComb` object representing a combination of variance functions, also inheriting from class `varFunc`.

Author(s)

Jose Pinheiro (Jose.Pinheiro@pharma.novartis.com) and Douglas Bates (bates@stat.wisc.edu)

Examples

```r
vf1 <- varComb(varIdent(form = ~1|Sex), varPower())
```

---

**varConstPower**

**Constant Plus Power Variance Function**

**Description**

This function is a constructor for the `varConstPower` class, representing a constant plus power variance function structure. Letting \( v \) denote the variance covariate and \( \sigma^2(v) \) denote the variance function evaluated at \( v \), the constant plus power variance function is defined as \( \sigma^2(v) = (\theta_1 + |v|^{2})^{2} \), where \( \theta_1, \theta_2 \) are the variance function coefficients. When a grouping factor is present, different \( \theta_1, \theta_2 \) are used for each factor level.

**Usage**

```r
varConstPower(const, power, form, fixed)
```

**Arguments**

- `const, power` optional numeric vectors, or lists of numeric values, with, respectively, the coefficients for the constant and the power terms. Both arguments must have length one, unless a grouping factor is specified in `form`. If either argument has length greater than one, it must have names which identify its elements to the levels of the grouping factor defined in `form`. If a grouping factor is present in `form` and the argument has length one, its value will be assigned to all grouping levels. Only positive values are allowed for `const`. Default is `numeric(0)`, which results in a vector of zeros of appropriate length being assigned to the coefficients when `object` is initialized (corresponding to constant variance equal to one).

- `form` an optional one-sided formula of the form `~ v`, or `~ v | g`, specifying a variance covariate \( v \) and, optionally, a grouping factor \( g \) for the coefficients. The variance covariate must evaluate to a numeric vector and may involve expressions using `\( \cdot \)`, representing a fitted model object from which fitted values (`fitted(.)`) and residuals (`resid(.)`) can be extracted (this allows the variance covariate to be updated during the optimization of an object function). When a grouping factor is present in `form`, a different coefficient value is used for each of its levels. Several grouping variables may be simultaneously specified, separated by the `\*` operator, as in `~ v | g1 * g2 * g3`. In this case, the levels of each grouping variable are pasted together and the resulting factor is used to group the observations. Defaults to `~ fitted(.)` representing a variance covariate given by the fitted values of a fitted model object and no grouping factor.

- `fixed` an optional list with components `const` and/or `power`, consisting of numeric vectors, or lists of numeric values, specifying the values at which some or all of the coefficients in the variance function should be fixed. If a grouping factor is specified in `form`, the components of `fixed` must have names identifying which coefficients are to be fixed. Coefficients included in `fixed` are not allowed to vary during the optimization of an objective function. Defaults to `NULL`, corresponding to no fixed coefficients.
Value

A `varConstPower` object representing a constant plus power variance function structure, also inheriting from class `varFunc`.

Examples

vf1 <- varConstPower(1.2, 0.2, form = ~age|Sex)

```
VarCorr

Extract variance and correlation components
```

Description

This function calculates the estimated variances, standard deviations, and correlations between the random-effects terms in a linear mixed-effects model, of class `lme`, or a nonlinear mixed-effects model, of class `nlme`. The within-group error variance and standard deviation are also calculated.

Usage

`VarCorr(x, sigma, rdig)`

Arguments

- `x`: a fitted model object, usually an object inheriting from class `lme`.
- `sigma`: an optional numeric value used as a multiplier for the standard deviations. Default is 1.
- `rdig`: an optional integer value specifying the number of digits used to represent correlation estimates. Default is 3.

Value

A matrix with the estimated variances, standard deviations, and correlations for the random effects. The first two columns, named `Variance` and `StdDev`, give, respectively, the variance and the standard deviations. If there are correlation components in the random effects model, the third column, named `Corr`, and the remaining unnamed columns give the estimated correlations among random effects within the same level of grouping. The within-group error variance and standard deviation are included as the last row in the matrix.
varExp

lme, nlme

Examples

fm1 <- lme(distance ~ age, data = Orthodont, random = ~age)
VarCorr(fm1)

Description

This function is a constructor for the varExp class, representing an exponential variance function structure. Letting \( v \) denote the variance covariate and \( \sigma^2(v) \) denote the variance function evaluated at \( v \), the exponential variance function is defined as \( \sigma^2(v) = \exp(2\theta v) \), where \( \theta \) is the variance function coefficient. When a grouping factor is present, a different \( \theta \) is used for each factor level.

Usage

varExp(value, form, fixed)

Arguments

value

an optional numeric vector, or list of numeric values, with the variance function coefficients. Value must have length one, unless a grouping factor is specified in form. If value has length greater than one, it must have names which identify its elements to the levels of the grouping factor defined in form. If a grouping factor is present in form and value has length one, its value will be assigned to all grouping levels. Default is numeric(0), which results in a vector of zeros of appropriate length being assigned to the coefficients when object is initialized (corresponding to constant variance equal to one).

form

an optional one-sided formula of the form \( ~ v \), or \( ~ v | g \), specifying a variance covariate \( v \) and, optionally, a grouping factor \( g \) for the coefficients. The variance covariate must evaluate to a numeric vector and may involve expressions using ",", representing a fitted model object from which fitted values (fitted(.)) and residuals (resid(.)) can be extracted (this allows the variance covariate to be updated during the optimization of an object function). When a grouping factor is present in form, a different coefficient value is used for each of its levels. Several grouping variables may be simultaneously specified, separated by the \( * \) operator, like in \( ~ v | g1 * g2 * g3 \). In this case, the levels of each grouping variable are pasted together and the resulting
This function is a constructor for the `varFixed` class, representing a variance function with fixed variances. Letting $v$ denote the variance covariate defined in `value`, the variance function $\sigma^2(v)$ for this class is $\sigma^2(v) = |v|$. The variance covariate $v$ is evaluated once at initialization and remains fixed thereafter. No coefficients are required to represent this variance function.

**Usage**

```r
varFixed(value)
```

**Arguments**

- `value` a one-sided formula of the form $\sim v$ specifying a variance covariate $v$. Grouping factors are ignored.
varFunc

Value

a varFixed object representing a fixed variance function structure, also inheriting from class varFunc.

summary.varFunc, varFixed, varWeights.varFunc, coef.varFunc

Examples

vf1 <- varFunc(~age)
Description

This function is a constructor for the `varIdent` class, representing a constant variance function structure. If no grouping factor is present in `form`, the variance function is constant and equal to one, and no coefficients required to represent it. When `form` includes a grouping factor with \( M > 1 \) levels, the variance function allows \( M \) different variances, one for each level of the factor. For identifiability reasons, the coefficients of the variance function represent the ratios between the variances and a reference variance (corresponding to a reference group level). Therefore, only \( M - 1 \) coefficients are needed to represent the variance function. By default, if the elements in `value` are unnamed, the first group level is taken as the reference level.

Usage

```r
varIdent(value, form, fixed)
```

Arguments

- `value`: an optional numeric vector, or list of numeric values, with the variance function coefficients. If no grouping factor is present in `form`, this argument is ignored, as the resulting variance function contains no coefficients. If `value` has length one, its value is repeated for all coefficients in the variance function. If `value` has length greater than one, it must have length equal to the number of grouping levels minus one and names which identify its elements to the levels of the grouping factor. Only positive values are allowed for this argument. Default is `numeric(0)`, which results in a vector of zeros of appropriate length being assigned to the coefficients when `object` is initialized (corresponding to constant variance equal to one).

- `form`: an optional one-sided formula of the form `~ v`, or `~ v | g`, specifying a variance covariate `v` and, optionally, a grouping factor `g` for the coefficients. The variance covariate is ignored in this variance function. When a grouping factor is present in `form`, a different coefficient value is used for each of its levels less one reference level (see description section below). Several grouping variables may be simultaneously specified, separated by the `*` operator, like in `~ v | g1 * g2 * g3`. In this case, the levels of each grouping variable are pasted together and the resulting factor is used to group the observations. Defaults to `~ 1`.

- `fixed`: an optional numeric vector, or list of numeric values, specifying the values at which some or all of the coefficients in the variance function should be fixed. It must have names identifying which coefficients are to be fixed. Coefficients included in `fixed` are not allowed to vary during the optimization of an objective function. Defaults to `NULL`, corresponding to no fixed coefficients.

Value

A `varIdent` object representing a constant variance function structure, also inheriting from class `varFunc`.

Variogram Calculate Semi-variogram

Description
This function is generic; method functions can be written to handle specific classes of objects. Classes which already have methods for this function include default, gls and lme. See the appropriate method documentation for a description of the arguments.

Usage
Variogram(object, distance, ...)

Arguments
object  
a numeric vector with the values to be used for calculating the semi-variogram, usually a residual vector from a fitted model.
distance  
a numeric vector with the pairwise distances corresponding to the elements of object. The order of the elements in distance must correspond to the pairs (1,2), (1,3), ..., (n-1,n), with n representing the length of object, and must have length n(n-1)/2.
...

Value
will depend on the method function used; see the appropriate documentation.

Variogram.corSpher Calculate Semi-variogram for a corSpher Object

Description

This method function calculates the semi-variogram values corresponding to the Spherical correlation model, using the estimated coefficients corresponding to object, at the distances defined by distance.

Usage

## S3 method for class 'corSpher':
Variogram(object, distance, sig2, length.out, ...)

Arguments

object an object inheriting from class corSpher, representing an Spherical spatial correlation structure.
distance an optional numeric vector with the distances at which the semi-variogram is to be calculated. Defaults to NULL, in which case a sequence of length length.out between the minimum and maximum values of getCovariate(object) is used.
sig2 an optional numeric value representing the process variance. Defaults to 1.
length.out an optional integer specifying the length of the sequence of distances to be used for calculating the semi-variogram, when distance = NULL. Defaults to 50.
...

Value

a data frame with columns variog and dist representing, respectively, the semi-variogram values and the corresponding distances. The returned value inherits from class Variogram.
Variogram.default

Description

This method function calculates the semi-variogram for an arbitrary vector `object`, according to the distances in `distance`. For each pair of elements $x,y$ in `object`, the corresponding semi-variogram is $(x - y)^2/2$. The semi-variogram is useful for identifying and modeling spatial correlation structures in observations with constant expectation and constant variance.

Usage

```r
## Default S3 method:
Variogram(object, distance, ...)
```

Arguments

- `object` a numeric vector with the values to be used for calculating the semi-variogram, usually a residual vector from a fitted model.
- `distance` a numeric vector with the pairwise distances corresponding to the elements of `object`. The order of the elements in `distance` must correspond to the pairs $(1,2), (1,3), \ldots, (n-1,n)$, with $n$ representing the length of `object`, and must have length $n(n-1)/2$.
- `...` some methods for this generic require additional arguments. None are used in this method.

Value

A data frame with columns `variog` and `dist` representing, respectively, the semi-variogram values and the corresponding distances. The returned value inherits from class `Variogram`.

## End(Not run)

Variogram.gls

Calculate Semi-variogram for Residuals from a gls Object

Description

This method function calculates the semi-variogram for the residuals from a gls fit. The semi-variogram values are calculated for pairs of residuals within the same group level, if a grouping factor is present. If collapse is different from "none", the individual semi-variogram values are collapsed using either a robust estimator (robust = TRUE) defined in Cressie (1993), or the average of the values within the same distance interval. The semi-variogram is useful for modeling the error term correlation structure.

Usage

## S3 method for class 'gls':
Variogram(object, distance, form, resType, data,
          na.action, maxDist, length.out, collapse, nint, breaks,
          robust, metric, ...)

Arguments

object an object inheriting from class gls, representing a generalized least squares fitted model.
distance an optional numeric vector with the distances between residual pairs. If a grouping variable is present, only the distances between residual pairs within the same group should be given. If missing, the distances are calculated based on the values of the arguments form, data, and metric, unless object includes a corSpatial element, in which case the associated covariate (obtained with the getCovariate method) is used.
form an optional one-sided formula specifying the covariate(s) to be used for calculating the distances between residual pairs and, optionally, a grouping factor for partitioning the residuals (which must appear to the right of a | operator in form). Default is -1, implying that the observation order within the groups is used to obtain the distances.
an optional character string specifying the type of residuals to be used. If "response", the "raw" residuals (observed - fitted) are used; else, if "pearson", the standardized residuals (raw residuals divided by the corresponding standard errors) are used; else, if "normalized", the normalized residuals (standardized residuals pre-multiplied by the inverse square-root factor of the estimated error correlation matrix) are used. Partial matching of arguments is used, so only the first character needs to be provided. Defaults to "pearson".

data an optional data frame in which to interpret the variables in form. By default, the same data used to fit object is used.

na.action a function that indicates what should happen when the data contain NAs. The default action (na.fail) causes an error message to be printed and the function to terminate, if there are any incomplete observations.

maxDist an optional numeric value for the maximum distance used for calculating the semi-variogram between two residuals. By default all residual pairs are included.

length.out an optional integer value. When object includes a corSpatial element, its semi-variogram values are calculated and this argument is used as the length.out argument to the corresponding Variogram method. Defaults to 50.

collapse an optional character string specifying the type of collapsing to be applied to the individual semi-variogram values. If equal to "quantiles", the semi-variogram values are split according to quantiles of the distance distribution, with equal number of observations per group, with possibly varying distance interval lengths. Else, if "fixed", the semi-variogram values are divided according to distance intervals of equal lengths, with possibly different number of observations per interval. Else, if "none", no collapsing is used and the individual semi-variogram values are returned. Defaults to "quantiles".

nint an optional integer with the number of intervals to be used when collapsing the semi-variogram values. Defaults to 20.

robust an optional logical value specifying if a robust semi-variogram estimator should be used when collapsing the individual values. If TRUE the robust estimator is used. Defaults to FALSE.

breaks an optional numeric vector with the breakpoints for the distance intervals to be used in collapsing the semi-variogram values. If not missing, the option specified in collapse is ignored.

metric an optional character string specifying the distance metric to be used. The currently available options are "euclidean" for the root sum-of-squares of distances; "maximum" for the maximum difference; and "manhattan" for the sum of the absolute differences. Partial matching of arguments is used, so only the first three characters need to be provided. Defaults to "euclidean".

Value

a data frame with columns variog and dist representing, respectively, the semi-variogram values and the corresponding distances. If the semi-variogram values are collapsed, an extra column, n.pairs, with the number of residual pairs used in each semi-variogram calculation, is included in the returned data frame. If object includes a corSpatial element, a data frame with its
corresponding semi-variogram is included in the returned value, as an attribute "modelVariog". The returned value inherits from class Variogram.

Variogram.lme
Calculate Semi-variogram for Residuals from an lme Object

Description
This method function calculates the semi-variogram for the within-group residuals from an lme fit. The semi-variogram values are calculated for pairs of residuals within the same group. If collapse is different from "none", the individual semi-variogram values are collapsed using either a robust estimator (robust = TRUE) defined in Cressie (1993), or the average of the values within the same distance interval. The semi-variogram is useful for modeling the error term correlation structure.

Usage
## S3 method for class 'lme':
Variogram(object, distance, form, resType, data, na.action, maxDist, length.out, collapse, nint, breaks, robust, metric, ...)

Arguments
object an object inheriting from class lme, representing a fitted linear mixed-effects model.
distance an optional numeric vector with the distances between residual pairs. If a grouping variable is present, only the distances between residual pairs within the same group should be given. If missing, the distances are calculated based on the values of the arguments form, data, and metric, unless object includes a corSpatial element, in which case the associated covariate (obtained with the getCovariate method) is used.
form  an optional one-sided formula specifying the covariate(s) to be used for calculating the distances between residual pairs and, optionally, a grouping factor for partitioning the residuals (which must appear to the right of a | operator in form). Default is -1, implying that the observation order within the groups is used to obtain the distances.

resType  an optional character string specifying the type of residuals to be used. If "response", the "raw" residuals (observed - fitted) are used; else, if "pearson", the standardized residuals (raw residuals divided by the corresponding standard errors) are used; else, if "normalized", the normalized residuals (standardized residuals pre-multiplied by the inverse square-root factor of the estimated error correlation matrix) are used. Partial matching of arguments is used, so only the first character needs to be provided. Defaults to "pearson".

data  an optional data frame in which to interpret the variables in form. By default, the same data used to fit object is used.

na.action  a function that indicates what should happen when the data contain NAs. The default action (na.fail) causes an error message to be printed and the function to terminate, if there are any incomplete observations.

maxDist  an optional numeric value for the maximum distance used for calculating the semi-variogram between two residuals. By default all residual pairs are included.

length.out  an optional integer value. When object includes a corSpatial element, its semi-variogram values are calculated and this argument is used as the length.out argument to the corresponding Variogram method. Defaults to 50.

collapse  an optional character string specifying the type of collapsing to be applied to the individual semi-variogram values. If equal to "quantiles", the semi-variogram values are split according to quantiles of the distance distribution, with equal number of observations per group, with possibly varying distance interval lengths. Else, if "fixed", the semi-variogram values are divided according to distance intervals of equal lengths, with possibly different number of observations per interval. Else, if "none", no collapsing is used and the individual semi-variogram values are returned. Defaults to "quantiles".

nint  an optional integer with the number of intervals to be used when collapsing the semi-variogram values. Defaults to 20.

robust  an optional logical value specifying if a robust semi-variogram estimator should be used when collapsing the individual values. If TRUE the robust estimator is used. Defaults to FALSE.

breaks  an optional numeric vector with the breakpoints for the distance intervals to be used in collapsing the semi-variogram values. If not missing, the option specified in collapse is ignored.

metric  an optional character string specifying the distance metric to be used. The currently available options are "euclidean" for the root sum-of-squares of distances; "maximum" for the maximum difference; and "manhattan" for the sum of the absolute differences. Partial matching of arguments is used, so only the first three characters need to be provided. Defaults to "euclidean".

... some methods for this generic require additional arguments. None are used in this method.
Value

a data frame with columns `variog` and `dist` representing, respectively, the semi-variogram values and the corresponding distances. If the semi-variogram values are collapsed, an extra column, `n.pairs`, with the number of residual pairs used in each semi-variogram calculation, is included in the returned data frame. If `object` includes a `corSpatial` element, a data frame with its corresponding semi-variogram is included in the returned value, as an attribute "modelVariog". The returned value inherits from class `Variogram`.

### varPower

**Power Variance Function**

This function is a constructor for the `varPower` class, representing a power variance function structure. Letting $v$ denote the variance covariate and $\sigma^2(v)$ denote the variance function evaluated at $v$, the power variance function is defined as $\sigma^2(v) = |v|^\theta$, where $\theta$ is the variance function coefficient. When a grouping factor is present, a different $\theta$ is used for each factor level.

#### Usage

```r
varPower(value, form, fixed)
```

#### Arguments

- **value**: an optional numeric vector, or list of numeric values, with the variance function coefficients. Value must have length one, unless a grouping factor is specified in `form`. If `value` has length greater than one, it must have names which identify its elements to the levels of the grouping factor defined in `form`. If a grouping factor is present in `form` and `value` has length one, its value will be assigned to all grouping levels. Default is `numeric(0)`, which results in a vector of zeros of appropriate length being assigned to the coefficients when `object` is initialized (corresponding to constant variance equal to one).
an optional one-sided formula of the form \(~ v\) or \(~ v \mid g\), specifying a variance covariate \(v\) and, optionally, a grouping factor \(g\) for the coefficients. The variance covariate must evaluate to a numeric vector and may involve expressions using ",", representing a fitted model object from which fitted values (fitted(.)) and residuals (resid(.)) can be extracted (this allows the variance covariate to be updated during the optimization of an object function). When a grouping factor is present in form, a different coefficient value is used for each of its levels. Several grouping variables may be simultaneously specified, separated by the \(*\) operator, like in \(~ v \mid g1 \ast g2 \ast g3\). In this case, the levels of each grouping variable are pasted together and the resulting factor is used to group the observations. Defaults to \(~ \text{fitted(.)}\) representing a variance covariate given by the fitted values of a fitted model object and no grouping factor.

Value

- a varPower object representing a power variance function structure, also inheriting from class varFunc.

[.pdMat Subscript a pdMat Object

Description

This method function extracts sub-matrices from the positive-definite matrix represented by x.

Usage

```r
## S3 method for class 'pdMat':
x[i, j, drop = TRUE]
## S3 replacement method for class 'pdMat':
x[i, j] <- value
```
Arguments

\texttt{x} \hspace{1cm} \text{an object inheriting from class \texttt{pdMat} representing a positive-definite matrix.}

\texttt{i, j} \hspace{1cm} \text{optional subscripts applying respectively to the rows and columns of the positive-definite matrix represented by \texttt{object}. When \texttt{i (j)} is omitted, all rows (columns) are extracted.}

\texttt{drop} \hspace{1cm} \text{a logical value. If \texttt{TRUE}, single rows or columns are converted to vectors. If \texttt{FALSE} the returned value retains its matrix representation.}

\texttt{value} \hspace{1cm} \text{a vector, or matrix, with the replacement values for the relevant piece of the matrix represented by \texttt{x}.}

Value

if \texttt{i} and \texttt{j} are identical, the returned value will be \texttt{pdMat} object with the same class as \texttt{x}. Otherwise, the returned value will be a matrix. In the case a single row (or column) is selected, the returned value may be converted to a vector, according to the rules above.

class.ind  Generates Class Indicator Matrix from a Factor

Description

Generates a class indicator function from a given factor.

Usage

class.ind(cl)

Arguments

cl  factor or vector of classes for cases.

Value

a matrix which is zero except for the column corresponding to the class.

References

Examples

# The function is currently defined as
class.ind <- function(cl)
{
  n <- length(cl)
  cl <- as.factor(cl)
  x <- matrix(0, n, length(levels(cl)) )
  x[(1:n) + n*(unclass(cl)-1)] <- 1
  dimnames(x) <- list(names(cl), levels(cl))
  x
}

2333
Description

Fits multinomial log-linear models via neural networks.

Usage

multinom(formula, data, weights, subset, na.action,
          contrasts = NULL, Hess = FALSE, summ = 0, censored = FALSE,
          model = FALSE, ...)

Arguments

- **formula**: a formula expression as for regression models, of the form `response ~ predictors`. The response should be a factor or a matrix with K columns, which will be interpreted as counts for each of K classes. A log-linear model is fitted, with coefficients zero for the first class. An offset can be included: it should be a numeric matrix with K columns if the response is either a matrix with K columns or a factor with K > 2 classes, or a numeric vector for a response factor with 2 levels. See the documentation of `formula()` for other details.

- **data**: an optional data frame in which to interpret the variables occurring in `formula`.

- **weights**: optional case weights in fitting.

- **subset**: expression saying which subset of the rows of the data should be used in the fit. All observations are included by default.

- **na.action**: a function to filter missing data.

- **contrasts**: a list of contrasts to be used for some or all of the factors appearing as variables in the model formula.

- **Hess**: logical for whether the Hessian (the observed/expected information matrix) should be returned.

- **summ**: integer; if non-zero summarize by deleting duplicate rows and adjust weights. Methods 1 and 2 differ in speed (2 uses `C`); method 3 also combines rows with the same X and different Y, which changes the baseline for the deviance.

- **censored**: If Y is a matrix with K > 2 columns, interpret the entries as one for possible classes, zero for impossible classes, rather than as counts.

- **model**: logical. If true, the model frame is saved as component `model` of the returned object.

- **...**: additional arguments for `nnet`

Details

`multinom` calls `nnet`. The variables on the rhs of the formula should be roughly scaled to [0,1] or the fit will be slow or may not converge at all.
nnet

Value

A nnet object with additional components:

- **deviance**: the residual deviance, compared to the full saturated model (that explains individual observations exactly). Also, minus twice log-likelihood.
- **edf**: the (effective) number of degrees of freedom used by the model.
- **AIC**: the AIC for this fit.
- **Hessian**: (if Hess is true).
- **model**: (if model is true).

## End(Not run)
```

nnet

*Fit Neural Networks*

Description

Fit single-hidden-layer neural network, possibly with skip-layer connections.

Usage

nnet(x, ...)

## S3 method for class 'formula':
nnet(formula, data, weights, ..., 
  subset, na.action, contrasts = NULL)
## Default S3 method:
nnet(x, y, weights, size, Wts, mask,  
linout = FALSE, entropy = FALSE, softmax = FALSE,  
censored = FALSE, skip = FALSE, rang = 0.7, decay = 0,  
maxit = 100, Hess = FALSE, trace = TRUE, MaxNWts = 1000,  
abstol = 1.0e-4, reltol = 1.0e-8, ...)

**Arguments**

- **formula**: A formula of the form class ~ x1 + x2 + ...
- **x**: matrix or data frame of x values for examples.
- **y**: matrix or data frame of target values for examples.
- **weights**: (case) weights for each example – if missing defaults to 1.
- **size**: number of units in the hidden layer. Can be zero if there are skip-layer units.
- **data**: Data frame from which variables specified in formula are preferentially to be taken.
- **subset**: An index vector specifying the cases to be used in the training sample. (NOTE: If given, this argument must be named.)
- **na.action**: A function to specify the action to be taken if NAs are found. The default action is for the procedure to fail. An alternative is na.omit, which leads to rejection of cases with missing values on any required variable. (NOTE: If given, this argument must be named.)
- **contrasts**: a list of contrasts to be used for some or all of the factors appearing as variables in the model formula.
- **Wts**: initial parameter vector. If missing chosen at random.
- **mask**: logical vector indicating which parameters should be optimized (default all).
- **linout**: switch for linear output units. Default logistic output units.
- **entropy**: switch for entropy (= maximum conditional likelihood) fitting. Default by least-squares.
- **softmax**: switch for softmax (log-linear model) and maximum conditional likelihood fitting. linout,entropy,softmax and censored are mutually exclusive.
- **censored**: A variant on softmax, in which non-zero targets mean possible classes. Thus for softmax a row of (0, 1, 1) means one example each of classes 2 and 3, but for censored it means one example whose class is only known to be 2 or 3.
- **skip**: switch to add skip-layer connections from input to output.
- **rang**: Initial random weights on [-rang,rang]. Value about 0.5 unless the inputs are large, in which case it should be chosen so that rang * max(|x|) is about 1.
- **decay**: parameter for weight decay. Default 0.
- **maxit**: maximum number of iterations. Default 100.
- **Hess**: If true, the Hessian of the measure of fit at the best set of weights found is returned as component Hessian.
- **trace**: switch for tracing optimization. Default TRUE.
- **MaxNWts**: The maximum allowable number of weights. There is no intrinsic limit in the code, but increasing MaxNWts will probably allow fits that are very slow and time-consuming (and perhaps uninterruptable).
Stop if the fit criterion falls below abstol, indicating an essentially perfect fit.

Stop if the optimizer is unable to reduce the fit criterion by a factor of at least \(1 - \text{reltol}\).

... arguments passed to or from other methods.

Details

If the response in formula is a factor, an appropriate classification network is constructed: this has one output and entropy fit if the number of levels is two, and a number of outputs equal to the number of classes and a softmax output stage for more levels. If the response is not a factor, it is passed on unchanged to nnet.default.

Optimization is done via the BFGS method of optim.

Value

object of class "nnet" or "nnet.formula". Mostly internal structure, but has components

wts the best set of weights found

value value of fitting criterion plus weight decay term.

fitted.values the fitted values for the training data.

residuals the residuals for the training data.

# or
ird <- data.frame(rbind(iris3[,1], iris3[,2], iris3[,3]),
  species = factor(c(rep("s",50), rep("c", 50), rep("v", 50))))
ir.nn2 <- nnet(species ~ ., data = ird, subset = samp, size = 2, rang = 0.1,
decay = 5e-4, maxit = 200)
table(ird$species[-samp], predict(ir.nn2, ird[-samp,], type = "class"))
**nnetHess**

*Evaluates Hessian for a Neural Network*

**Description**

Evaluates the Hessian (matrix of second derivatives) of the specified neural network. Normally called via argument `Hess=TRUE` to `nnet` or via `vcov.multinom`.

**Usage**

```
nnetHess(net, x, y, weights)
```

**Arguments**

- `net`: object of class `nnet` as returned by `nnet`.
- `x`: training data.
- `y`: classes for training data.
- `weights`: the (case) weights used in the `nnet` fit.

**Value**

square symmetric matrix of the Hessian evaluated at the weights stored in the net.

**References**

**See Also**

`nnet`, `predict.nnet`

**Examples**

```r
data(iris3)
# use half the iris data
ir <- rbind(iris3[,1], iris3[,2], iris3[,3])
targets <- matrix(c(rep(c(1,0,0),50), rep(c(0,1,0),50), rep(c(0,0,1),50)),
150, 3, byrow=TRUE)
samp <- c(sample(1:50,25), sample(51:100,25), sample(101:150,25))
ir1 <- nnet(ir[samp,], targets[samp,], size=2, rang=0.1, decay=5e-4, maxit=200)
eigen(nnetHess(ir1, ir[samp,], targets[samp,]), TRUE)$values
```
predict.nnet

**Predict New Examples by a Trained Neural Net**

**Description**
Predict new examples by a trained neural net.

**Usage**

```r
## S3 method for class 'nnet':
predict(object, newdata, type = c("raw", "class"), ...)```

**Arguments**

- `object` an object of class `nnet` as returned by `nnet`.
- `newdata` matrix or data frame of test examples. A vector is considered to be a row vector comprising a single case.
- `type` Type of output
- `...` arguments passed to or from other methods.

**Details**
This function is a method for the generic function `predict()` for class "nnet". It can be invoked by calling `predict(x)` for an object `x` of the appropriate class, or directly by calling `predict.nnet(x)` regardless of the class of the object.

**Value**
If `type = "raw"`, the matrix of values returned by the trained network; if `type = "class"`, the corresponding class (which is probably only useful if the net was generated by `nnet.formula`).

**References**

samp <- c(sample(1:50,25), sample(51:100,25), sample(101:150,25))
ir1 <- nnet(ir[samp,], targets[samp,], size = 2, rang = 0.1,
            decay = 9e-4, maxit = 280)
test.cl <- function(true, pred){
```
true <- max.col(true)
cres <- max.col(pred)
table(true, cres)
}
test.cl(targets[-samp,], predict(irl, ir[-samp,]))

# or
ird <- data.frame(rbind(iris3[,1], iris3[,2], iris3[,3]),
    species=factor(c(rep("s",50), rep("c", 50), rep("v", 50))))
ir.nn2 <- nnet(species ~ ., data = ird, subset = samp, size = 2, rang = 0.1,
    decay = 5e-4, maxit = 200)
table(ird$species[-samp], predict(ir.nn2, ird[-samp,], type = "class"))

---

which.is.max  
Find Maximum Position in Vector

Description

Find the maximum position in a vector, breaking ties at random.

Usage

which.is.max(x)

Arguments

x  
a vector

Details

Ties are broken at random.

Value

index of a maximal value.

References

See Also

max.col, which.max which takes the first of ties.

Examples

## Not run:
pred <- predict(nnet, test)
table(true, apply(pred,1,which.is.max))
## End(Not run)
Chapter 21

The `rcompgen` package

---

rcompgen  A completion generator for R

---

Description

This package provides a mechanism to generate relevant completions from a partially completed command line. It is not intended to be useful by itself, but rather in conjunction with other mechanisms that use it as a backend. The functions listed in the usage section provide a simple control and query mechanism. The actual interface consists of a few unexported functions described further down.

Usage

```r
rc.settings(ops, ns, args, func, ipck, S3, data, help, argdb, files)
rc.status()
rc.getOption(name)
r
```n

Arguments

- `ops, ns, args, func, ipck, S3, data, help, argdb, files` logical, turning some optional completion features on and off.
- `ops`: activates completion after the `$` and `@` operators
- `ns`: controls namespace related completions
- `args`: enables completion of function arguments
- `func`: enables detection of functions. If enabled, a customizable extension (`"(" by default) is appended to function names. The process of determining whether a potential completion is a function requires evaluation, including for lazy loaded symbols. This is extremely undesirable for large objects, because of potentially wasteful use of memory in addition to the time overhead associated with loading. For this reason, this feature is disabled by default.
- `S3`: when `args=TRUE`, activates completion on arguments of all S3 methods (otherwise just the generic, which usually has very few arguments)

---

2341
ipck: enables completion of installed package names inside `library` and `require`

data: enables completion of data sets (including those already visible) inside `data`

help: enables completion of help requests starting with a question mark, by looking inside help index files

argdb: when `args=TRUE`, completion is attempted on function arguments. Generally, the list of valid arguments is determined by dynamic calls to `args`. While this gives results that are technically correct, the use of the `...` argument often hides some useful arguments. To give more flexibility in this regard, `rcompgen` internally retains an optional table of valid arguments names for specific functions. Setting `argdb=TRUE` enables preferential lookup in this internal data base for functions with an entry in it. Of course, this is useful only when the data base contains information about the function of interest. Some functions are included in the package (the maintainer is happy to add more upon request), and more can be added by the user through the unexported function `.addFunctionInfo` (see below).

files: enables filename completion in R code. This is initially set to `FALSE`, in which case the underlying completion front-end can take over (and hopefully do a better job than we would have done). For systems where no such facilities exist, this can be set to `TRUE` if file name completion is desired. This is currently experimental and may not work very well.

All settings are turned on by default except `ipck`, `func` and `files`. Turn more off if your CPU cycles are valuable; you will still retain basic completion on names of objects in the search list. See below for additional details.

name, ... user-settable options. Currently valid names are

function.suffix: default "(" 
funarg.suffix: default " = "
package.suffix default "::"

See `options` for detailed usage description

Details

There are several types of completion, some of which can be disabled using `rc.settings`. The most basic level, which can not be turned off once the package is loaded, provides completion on names visible on the search path, along with a few special keywords (e.g. `TRUE`). This type of completion is not attempted if the partial ‘word’ (a.k.a. token) being completed is empty (since there would be too many completions). The more advanced types of completion are described below.

Completion after extractors $ and @: When the `ops` setting is turned on, completion after $ and @ is attempted. This requires the prefix to be evaluated, which is attempted unless it involves an explicit function call (implicit function calls involving the use of [ , $, etc do not inhibit evaluation).

Completion inside namespaces: When the `ns` setting is turned on, completion inside namespaces is attempted when a token is preceded by the :: or ::: operators. Additionally, the basic completion mechanism is extended to include attached namespaces, or more precisely, `foopkg::` becomes a valid completion of `foo` if the return value of `search()` includes the string "package:foopkg".
The completion of package namespaces applies only to attached packages, i.e. if MASS is not attached (whether or not it is loaded), MASS will not complete to MASS::. However, attempted completion inside an apparent namespace will attempt to load the namespace if it is not already loaded, e.g. trying to complete on MASS::fr will load MASS (but not necessarily attach it) even if it is not already loaded.

**Completion of function arguments:** When the args setting is turned on, completion on function arguments is attempted whenever deemed appropriate. The mechanism used will currently fail if the relevant function (at the point where completion is requested) was entered on a previous prompt (which implies in particular that the current line is being typed in response to a continuation prompt, usually +). Note that separation by newlines is fine.

The list of possible argument completions that is generated can be misleading. There is no problem for non-generic functions (except that ... is listed as a completion; this is intentional as it signals the fact that the function can accept further arguments). However, for generic functions, it is practically impossible to give a reliable argument list without evaluating arguments (and not even then, in some cases), which is risky (in addition to being difficult to code, which is the real reason it hasn’t even been tried), especially when that argument is itself an inline function call. Our compromise is to consider arguments of all currently available methods of that generic. This has two drawbacks. First, not all listed completions may be appropriate in the call currently being constructed. Second, for generics with many methods (like print and plot), many matches will need to be considered, which may take a noticeable amount of time. Despite these drawbacks, we believe this behaviour to be more useful than the only other practical alternative, which is to list arguments of the generic only.

Only S3 methods are currently supported in this fashion, and that can be turned off using the S3 setting.

Since arguments can be unnamed in R function calls, other types of completion are also appropriate whenever argument completion is. Since there are usually many many more visible objects than formal arguments of any particular function, possible argument completions are often buried in a bunch of other possibilities. However, recall that basic completion is suppressed for blank tokens. This can be useful to list possible arguments of a function. For example, trying to complete seq([TAB] and seq(from = 1, [TAB]) will both list only the arguments of seq (or any of its methods), whereas trying to complete seq(length[TAB] will list both the length.out argument and the length() function as possible completions. Note that no attempt is made to remove arguments already supplied, as that would incur a further speed penalty.

**Special functions:** For a few special functions (library, data, etc), the first argument is treated specially, in the sense that normal completion is suppressed, and some function specific completions are enabled if so requested by the settings. The ipck setting, which controls whether library and require will complete on installed packages, is disabled by default because the first call to installed.packages is potentially time consuming (e.g. when packages are installed on a remote network file server). Note, however, that the results of a call to installed.packages is cached, so subsequent calls are usually fast, so turning this option on is not particularly onerous even in such situations.

Needless to say, the details above describe intended behaviour; whether actual behaviour matches it remains to be seen.

**Value**

rc.status returns, as a list, the contents of an internal (unexported) environment that is used to record the results of the last completion attempt. This can be useful for debugging. For such use, one must resist the temptation to use completion when typing the call to rc.status itself, as that then becomes the last attempt by the time the call is executed.
The items of primary interest in the returned list are:

comps  the possible completions generated by the last call to .completeToken, as a character vector

token  the token that was (or, is to be) completed, as set by the last call to .assignToken (possibly inside a call to .guessTokenFromLine)

linebuffer  the full line, as set by the last call to .assignLinebuffer

start  the start position of the token in the line buffer, as set by the last call to .assignStart

dend  the end position of the token in the line buffer, as set by the last call to .assignEnd

fileName  logical, indicating whether the cursor is currently inside quotes. If so, no completion is attempted. A reasonable default behaviour for the backend in that case is to fall back to filename completion.

fguess  the name of the function rcompgen thinks the cursor is currently inside

isFirstArg  logical. If cursor is inside a function, is it the first argument?

In addition, the components settings and options give the current values of settings and options respectively.

rc.getOption and rc.options behave much like getOption and options respectively.

Unexported API

There are several unexported functions in the package. Of these, a few are special because they provide the API through which other mechanisms can make use of the facilities provided by this package (they are unexported because they are not meant to be called directly by users). The usage of these functions are:

  .assignToken(text)
  .assignLinebuffer(line)
  .assignStart(start)
  .assignEnd(end)

  .completeToken()
  .retrieveCompletions()
  .getFileComp()

  .guessTokenFromLine()
  .win32consoleCompletion(linebuffer, cursorPosition, check.repeat = TRUE)

  .addFunctionInfo(...)

The first four functions set up a completion attempt by specifying the token to be completed (text), and indicating where (start and end, which should be integers) the token is placed within the complete line typed so far (line).

Potential completions of the token are generated by .completeToken, and the completions can be retrieved as an R character vector using .retrieveCompletions.
If the cursor is inside quotes, no completion is attempted. The function `getFileComp` can be used after a call to `completeToken` to determine if this is the case (returns `TRUE`), and alternative completions generated as deemed useful. In most cases, filename completion is a reasonable fallback.

The `guessTokenFromLine` function is provided for use with backends that do not already break a line into tokens. It requires the linebuffer and endpoint (cursor position) to be already set, and itself sets the token and the start position. It returns the token as a character string. (This is used by the ESS completion hook example given in the `examples/altesscomp.el` file.)

The `win32consoleCompletion` is similar in spirit, but is more geared towards the Windows GUI. It requires the linebuffer and cursor position as arguments, and returns a list with three components, `addition`, `possible` and `comps`. If there is an unambiguous extension at the current position, `addition` contains the additional text that should be inserted at the cursor. If there is more than one possibility, these are available either as a character vector of preformatted strings in `possible`, or as a single string in `comps`. `possible` consists of lines formatted using the current `width` option, so that printing them on the console one line at a time will be a reasonable way to list them. `comps` is a space separated (collapsed) list of the same completions, in case the front-end wishes to display it in some other fashion.

As the various front-end interfaces evolve, the details of these functions are likely to change as well.

The function `addFunctionInfo` can be used to add information about the permitted argument names for specific functions. Multiple named arguments are allowed in calls to it, where the tags are names of functions and values are character vectors representing valid arguments. When the `argdb` setting is `TRUE`, these are used as a source of valid argument names for the relevant functions.

**Note**

If you are uncomfortable with unsolicited evaluation of pieces of code, you should set `ops = FALSE`. Otherwise, trying to complete `foo@ba` will evaluate `foo`, trying to complete `foo[i,1:10]$ba` will evaluate `foo[i,1:10]`, etc. This should not be too bad, as explicit function calls (involving parentheses) are not evaluated in this manner. However, this will affect lazy loaded symbols (and presumably other promise type thingies).

Chapter 22

The rpart package

---

**car.test.frame**  
*Automobile Data from 'Consumer Reports' 1990*

**Description**

The `car.test.frame` data frame has 60 rows and 8 columns, giving data on makes of cars taken from the April, 1990 issue of *Consumer Reports*. This is part of a larger dataset, some columns of which are given in `cu.summary`.

**Usage**

`car.test.frame`

**Format**

This data frame contains the following columns:

- **Price** a numeric vector giving the list price in US dollars of a standard model
- **Country** of origin, a factor with levels France Germany Japan Japan/USA Korea Mexico Sweden USA
- **Reliability** a numeric vector coded 1 to 5.
- **Mileage** fuel consumption miles per US gallon, as tested.
- **Type** a factor with levels Compact Large Medium Small Sporty Van
- **Weight** kerb weight in pounds.
- **Disp.** the engine capacity (displacement) in litres.
- **HP** the net horsepower of the vehicle.

**Source**

*Consumer Reports*, April, 1990, pp. 235–288 quoted in

**cu.summary**

Automobile Data from 'Consumer Reports' 1990

Description

The `cu.summary` data frame has 117 rows and 5 columns, giving data on makes of cars taken from the April, 1990 issue of *Consumer Reports*.

Usage

`cu.summary`

Format

This data frame contains the following columns:

- **Price**: a numeric vector giving the list price in US dollars of a standard model
- **Country**: of origin, a factor with levels Brazil England France Germany Japan Japan/USA Korea Mexico Sweden USA
- **Reliability**: an ordered factor with levels Much worse < worse < average < better < Much better
- **Mileage**: fuel consumption miles per US gallon, as tested.
- **Type**: a factor with levels Compact Large Medium Small Sporty Van

Source

*Consumer Reports*, April, 1990, pp. 235–288 quoted in

`car.test.frame`

Examples

```r
fit <- rpart(Price ~ Mileage + Type + Country, cu.summary)
plot(fit, compress=TRUE)
text(fit, use.n=TRUE)
```
kyphosis  

Data on Children who have had Corrective Spinal Surgery

Description

The kyphosis data frame has 81 rows and 4 columns, representing data on children who have had corrective spinal surgery.

Usage

kyphosis

Format

This data frame contains the following columns:

- **Kyphosis**: a factor with levels *absent*, *present* indicating if a kyphosis (a type of deformation) was present after the operation.
- **Age**: in months
- **Number**: the number of vertebrae involved
- **Start**: the number of the first (topmost) vertebra operated on.

Source

Examples

```
fit <- rpart(Kyphosis ~ Age + Number + Start, data=kyphosis)
fit2 <- rpart(Kyphosis ~ Age + Number + Start, data=kyphosis, 
              parms=list(prior=c(.65,.35), split='information'))
fit3 <- rpart(Kyphosis ~ Age + Number + Start, data=kyphosis, 
              control=rpart.control(cp=.05))
par(mfrow=c(1,2))
plot(fit)
text(fit, use.n=TRUE)
plot(fit2)
text(fit2, use.n=TRUE)
```

labels.rpart  

Create Split Labels For an Rpart Object

Description

This function provides labels for the branches of an rpart tree.

Usage

```
## S3 method for class 'rpart':
labels(object, digits=4, minlength=1, pretty, collapse=TRUE, ...)
```
Arguments

object  fitted model object of class rpart. This is assumed to be the result of some function that produces an object with the same named components as that returned by the rpart function.

digits  the number of digits to be used for numeric values. All of the rpart functions that call labels explicitly set this value, with options("digits") as the default.

minlength  the minimum length for abbreviation of character or factor variables. If 0 no abbreviation is done; if 1 then single letters are used with "a" for the first level, "b:" for the second and so on. If the value is greater than 1, the abbreviate function is used.

pretty  an argument included for backwards compatibility: pretty=0 implies minlength=0, pretty=NULL implies minlength=1, and pretty=TRUE implies minlength=4.

collapse  logical. The returned set of labels is always of the same length as the number of nodes in the tree. If collapse=TRUE (default), the returned value is a vector of labels for the branch leading into each node, with "root" as the label for the top node. If FALSE, the returned value is a two column matrix of labels for the left and right branches leading out from each node, with "leaf" as the branch labels for terminal nodes.

...  optional arguments to abbreviate.

Value

Vector of split labels (collapse=TRUE) or matrix of left and right splits (collapse=FALSE) for the supplied rpart object. This function is called by printing methods for rpart and is not intended to be called directly by the users.

See Also

abbreviate

Description

Creates a plot on the current graphics device of the deviance of the node divided by the number of observations at the node. Also returns the node number.

Usage

meanvar(tree, ...)

## S3 method for class 'rpart'
meanvar(tree, xlab="ave(y)", ylab="ave(deviance)", ...)
Arguments

- **tree**: fitted model object of class `rpart`. This is assumed to be the result of some function that produces an object with the same named components as that returned by the `rpart` function.
- **xlab**: x-axis label for the plot.
- **ylab**: y-axis label for the plot.
- **...**: additional graphical parameters may be supplied as arguments to this function.

Value

An invisible list containing the following vectors is returned.

- **x**: fitted value at terminal nodes (`yval`).
- **y**: deviance of node divided by number of observations at node.
- **label**: node number.

Side Effects

A plot is put on the current graphics device.

See Also

`plot.rpart`.

Examples

```r
z.auto <- rpart(Mileage ~ Weight, car.test.frame)
meanvar(z.auto, log='xy')
```

---

**na.rpart**  
*Handles Missing Values in an Rpart Object*

Description

Handles missing values in an `rpart` object.

Usage

```r
na.rpart(x)
```

Arguments

- **x**: a model frame.

Details

Internal function that handles missing values when calling the function `rpart`.
path.rpart

Follow Paths to Selected Nodes of an Rpart Object

Description

Returns a names list where each element contains the splits on the path from the root to the selected
nodes.

Usage

path.rpart(tree, nodes, pretty=0, print.it=TRUE)

Arguments

tree fitted model object of class rpart. This is assumed to be the result of some
function that produces an object with the same named components as that re-
turned by the rpart function.
nodes an integer vector containing indices (node numbers) of all nodes for which paths
are desired. If missing, user selects nodes as described below.
pretty an integer denoting the extent to which factor levels in split labels will be abbre-
viated. A value of (0) signifies no abbreviation. A NULL, the default, signifies
using elements of letters to represent the different factor levels.
print.it Logical. Denotes whether paths will be printed out as nodes are interactively
selected. Irrelevant if nodes argument is supplied.

Details

The function has a required argument as an rpart object and a list of nodes as optional arguments.
Omitting a list of nodes will cause the function to wait for the user to select nodes from the dendro-
gram. It will return a list, with one component for each node specified or selected. The component
contains the sequence of splits leading to that node. In the graphical interaction, the individual paths
are printed out as nodes are selected.

Value

A named (by node) list, each element of which contains all the splits on the path from the root to
the specified or selected nodes.

Graphical Interaction

A dendrogram of the rpart object is expected to be visible on the graphics device, and a graphics
input device (eg a mouse) is required. Clicking (the selection button) on a node selects that node.
This process may be repeated any number of times. Clicking the exit button will stop the selection
process and return the list of paths.

References

This function was modified from path.tree in S.

rpart
Examples

```r
fit <- rpart(Kyphosis ~ Age + Number + Start, data=kyphosis)
summary(fit)
path.rpart(fit, node=c(11, 22))
```

---

**Description**

Plots an rpart object on the current graphics device.

**Usage**

```r
## S3 method for class 'rpart':
plot(x, uniform=FALSE, branch=1, compress=FALSE, nspace,
     margin=0, minbranch=.3, ...)
```

**Arguments**

- `x` a fitted object of class `rpart`, containing a classification, regression, or rate tree.
- `uniform` if `TRUE`, uniform vertical spacing of the nodes is used; this may be less cluttered when fitting a large plot onto a page. The default is to use a non-uniform spacing proportional to the error in the fit.
- `branch` controls the shape of the branches from parent to child node. Any number from 0 to 1 is allowed. A value of 1 gives square shouldered branches, a value of 0 give V shaped branches, with other values being intermediate.
- `compress` if `FALSE`, the leaf nodes will be at the horizontal plot coordinates of 1:nleaves. If `TRUE`, the routine attempts a more compact arrangement of the tree. The compaction algorithm assumes `uniform=TRUE`; surprisingly, the result is usually an improvement even when that is not the case.
- `nspace` the amount of extra space between a node with children and a leaf, as compared to the minimal space between leaves. Applies to compressed trees only. The default is the value of `branch`.
- `margin` an extra percentage of white space to leave around the borders of the tree. (Long labels sometimes get cut off by the default computation).
- `minbranch` set the minimum length for a branch to `minbranch` times the average branch length. This parameter is ignored if `uniform=TRUE`. Sometimes a split will give very little improvement, or even (in the classification case) no improvement at all. A tree with branch lengths strictly proportional to improvement leaves no room to squeeze in node labels.
- `...` arguments to be passed to or from other methods.

**Details**

This function is a method for the generic function `plot`, for objects of class `rpart`. The y-coordinate of the top node of the tree will always be 1.
the coordinates of the nodes are returned as a list, with components \( x \) and \( y \).

Side Effects

an unlabeled plot is produced on the current graphics device.

rpart, printcp, rpart.object

---

post.rpart  PostScript Presentation Plot of an Rpart Object

Description

Generates a PostScript presentation plot of an rpart object.

Usage

post(tree, ...)

## S3 method for class 'rpart':
post(tree, title.,
filename = paste(deparse(substitute(tree)), ".ps", sep = ""),
digits = getOption("digits") - 3, pretty = TRUE,
use.n = TRUE, horizontal = TRUE, ...)

Arguments

tree  fitted model object of class rpart. This is assumed to be the result of some function that produces an object with the same named components as that returned by the rpart function.

title.  a title which appears at the top of the plot. By default, the name of the rpart endpoint is printed out.

filename  ASCII file to contain the output. By default, the name of the file is the name of the object given by rpart (with the suffix .ps added). If filename = "", the plot appears on the current graphical device.

digits  number of significant digits to include in numerical data.

pretty  an integer denoting the extent to which factor levels will be abbreviated in the character strings defining the splits; (0) signifies no abbreviation of levels. A NULL signifies using elements of letters to represent the different factor levels. The default (TRUE) indicates the maximum possible abbreviation.

use.n  Logical. If TRUE (default), adds to label (#events level1/#events level2/etc. for method class, n for method anova, and #events/n for methods poisson and exp).

horizontal  Logical. If TRUE (default), plot is horizontal. If FALSE, plot appears as landscape.

...  other arguments to the postscript function.
predict.rpart

**Details**

The plot created uses the functions `plot.rpart` and `text.rpart` (with the `fancy` option). The settings were chosen because they looked good to us, but other options may be better, depending on the `rpart` object. Users are encouraged to write their own function containing favorite options.

**Side Effects**

A plot of `rpart` is created using the `postscript` driver, or the current device if `filename = ""`.

**See Also**

`plot.rpart`, `rpart`, `text.rpart`, `abbreviate`

**Examples**

```r
z.auto <- rpart(Mileage ~ Weight, car.test.frame)
post(z.auto, file = "")  # display tree on active device
   # now construct postscript version on file "pretty.ps"
   # with no title
post(z.auto, file = "pretty.ps", title = "")
z.hp <- rpart(Mileage ~ Weight + HP, car.test.frame)
post(z.hp)
```

**predict.rpart**

Predictions from a Fitted Rpart Object

**Description**

Returns a vector of predicted responses from a fitted `rpart` object.

**Usage**

```r
## S3 method for class 'rpart':
predict(object, newdata = list(),
    type = c("vector", "prob", "class", "matrix"),
    na.action = na.pass, ...)
```

**Arguments**

- **object**
  - fitted model object of class `rpart`. This is assumed to be the result of some function that produces an object with the same named components as that returned by the `rpart` function.

- **newdata**
  - data frame containing the values at which predictions are required. The predictors referred to in the right side of `formula(object)` must be present by name in `newdata`. If missing, the fitted values are returned.

- **type**
  - character string denoting the type of predicted value returned. If the `rpart` object is a classification tree, then the default is to return `prob` predictions, a matrix whose columns are the probability of the first, second, etc. class. (This agrees with the default behavior of `tree`). Otherwise, a vector result is returned.
predict.rpart

na.action a function to determine what should be done with missing values in newdata. The default is to pass them down the tree using surrogates in the way selected when the model was built. Other possibilities are na.omit and na.fail.

... further arguments passed to or from other methods.

Details

This function is a method for the generic function predict for class rpart. It can be invoked by calling predict for an object of the appropriate class, or directly by calling predict.rpart regardless of the class of the object.

Value

A new object is obtained by dropping newdata down the object. For factor predictors, if an observation contains a level not used to grow the tree, it is left at the deepest possible node and frame$yval at the node is the prediction.

If type="vector":
vector of predicted responses. For regression trees this is the mean response at the node, for Poisson trees it is the estimated response rate, and for classification trees it is the predicted class (as a number).

If type="prob":
(for a classification tree) a matrix of class probabilities.

If type="matrix":
a matrix of the full responses (frame$yval2 if this exists, otherwise frame$yval). For regression trees, this is the mean response, for Poisson trees it is the response rate and the number of events at that node in the fitted tree, and for classification trees it is the concatenation of the predicted class, the class counts at that node in the fitted tree, and the class probabilities.

If type="class":
(for a classification tree) a factor of classifications based on the responses.

predict, rpart.object

Examples

z.auto <- rpart(Mileage ~ Weight, car.test.frame)
predict(z.auto)

fit <- rpart(Kyphosis ~ Age + Number + Start, data=kyphosis)
predict(fit, type="prob") # class probabilities (default)
predict(fit, type="vector") # level numbers
predict(fit, type="class") # factor
predict(fit, type="matrix") # level number, class frequencies, probabilities

sub <- c(sample(1:50, 25), sample(51:100, 25), sample(101:150, 25))
fit <- rpart(Species ~ ., data=iris, subset=sub)
fit
table(predict(fit, iris[-sub,], type="class"), iris[-sub, "Species"])
print.rpart  

Print an Rpart Object

Description

This function prints an rpart object. It is a method for the generic function print of class rpart.

Usage

## S3 method for class 'rpart':
print(x, minlength=0, spaces=2, cp, digits=getOption("digits"), ...)  

Arguments

- **x**: fitted model object of class rpart. This is assumed to be the result of some function that produces an object with the same named components as that returned by the rpart function.
- **minlength**: Controls the abbreviation of labels: see labels.rpart.
- **spaces**: the number of spaces to indent nodes of increasing depth.
- **digits**: the number of digits of numbers to print.
- **cp**: prune all nodes with a complexity less than cp from the printout. Ignored if unspecified.
- **...**: arguments to be passed to or from other methods.

Details

This function is a method for the generic function print for class "rpart". It can be invoked by calling print for an object of the appropriate class, or directly by calling print.rpart regardless of the class of the object.

Side Effects

A semi-graphical layout of the contents of x$frame is printed. Indentation is used to convey the tree topology. Information for each node includes the node number, split, size, deviance, and fitted value. For the "class" method, the class probabilities are also printed.

  4) Weight>=3087.5 22 61.31818 20.40909 *
printcp

Displays CP table for Fitted Rpart Object

Description
Displays the cp table for fitted rpart object.

Usage
printcp(x, digits=getOption("digits") - 2)

Arguments
x  fitted model object of class rpart. This is assumed to be the result of some function that produces an object with the same named components as that returned by the rpart function.
digits  the number of digits of numbers to print.

Details
Prints a table of optimal prunings based on a complexity parameter.

## End(Not run)
prune.rpart  

Cost-complexity Pruning of an Rpart Object

Description

Determines a nested sequence of subtrees of the supplied rpart object by recursively snipping off the least important splits, based on the complexity parameter (cp).

Usage

prune(tree, ...)

## S3 method for class 'rpart':
prune(tree, cp, ...)

Arguments

tree  
fitted model object of class rpart. This is assumed to be the result of some function that produces an object with the same named components as that returned by the rpart function.

cp  
Complexity parameter to which the rpart object will be trimmed.

...  
further arguments passed to or from other methods.

Value

A new rpart object that is trimmed to the value cp.

See Also

rpart

Examples

z.auto <- rpart(Mileage ~ Weight, car.test.frame)
zp <- prune(z.auto, cp=0.1)
plot(zp) #plot smaller rpart object

residuals.rpart  

Residuals From a Fitted Rpart Object

Description

Method for residuals for an rpart object.

Usage

## S3 method for class 'rpart':
residuals(object, type = c("usual", "pearson", "deviance"), ...)

Arguments

- **object**: fitted model object of class "rpart".
- **type**: Indicates the type of residual desired.
  - For regression or anova trees all three residual definitions reduce to \( y - \text{fitted} \). This is the residual returned for user method trees as well.
  - For classification trees the usual residuals are the misclassification losses \( L(\text{actual}, \text{predicted}) \) where \( L \) is the loss matrix. With default losses this residual is 0/1 for correct/incorrect classification. The Pearson residual is \( (1 - \text{fitted})/\sqrt{\text{fitted}(1-\text{fitted})} \) and the deviance residual is \( \sqrt{-2 \ln \text{fitted}} \).
  - For poisson and exp (or survival) trees, the usual residual is the observed - expected number of events. The Pearson and deviance residuals are as defined in McCullagh and Nelder.

... further arguments passed to or from other methods.

Value

- vector of residuals of type **type** from a fitted **rpart** object.

References

Examples

```r
fit <- rpart(skips ~ Opening + Solder + Mask + PadType + Panel,
data = solder, method = 'anova')
summary(residuals(fit))
plot(predict(fit), residuals(fit))
```

rpart

*Recursive Partitioning and Regression Trees*

Description

Fit a rpart model

Usage

```r
rpart(formula, data, weights, subset, na.action = na.rpart, method,
model = FALSE, x = FALSE, y = TRUE, parms, control, cost, ...)
```

Arguments

- **formula**: a formula, as in the `lm` function.
- **data**: an optional data frame in which to interpret the variables named in the formula.
- **weights**: optional case weights.
- **subset**: optional expression saying that only a subset of the rows of the data should be used in the fit.
The default action deletes all observations for which \( y \) is missing, but keeps those in which one or more predictors are missing.

If \( \text{method} \) is missing then the routine tries to make an intelligent guess. If \( y \) is a survival object, then \( \text{method} = \text{"exp"} \) is assumed, if \( y \) has 2 columns then \( \text{method} = \text{"poisson"} \) is assumed, if \( y \) is a factor then \( \text{method} = \text{"class"} \) is assumed, otherwise \( \text{method} = \text{"anova"} \) is assumed. It is wisest to specify the method directly, especially as more criteria are added to the function. Alternatively, \( \text{method} \) can be a list of functions named \text{init}, \text{split} and \text{eval}.

If logical: keep a copy of the model frame in the result? If the input value for \( \text{model} \) is a model frame (likely from an earlier call to the \text{rpart} function), then this frame is used rather than constructing new data.

Keep a copy of the \( x \) matrix in the result.

Keep a copy of the dependent variable in the result. If missing and \( \text{model} \) is supplied this defaults to \text{FALSE}.

Optional parameters for the splitting function. Anova splitting has no parameters. Poisson splitting has a single parameter, the coefficient of variation of the prior distribution on the rates. The default value is 1. Exponential splitting has the same parameter as Poisson. For classification splitting, the list can contain any of: the vector of prior probabilities (component \text{prior}), the loss matrix (component \text{loss}) or the splitting index (component \text{split}). The priors must be positive and sum to 1. The loss matrix must have zeros on the diagonal and positive off-diagonal elements. The splitting index can be \text{gini} or \text{information}. The default priors are proportional to the data counts, the losses default to 1, and the split defaults to \text{gini}.

Options that control details of the \text{rpart} algorithm.

A vector of non-negative costs, one for each variable in the model. Defaults to one for all variables. These are scalings to be applied when considering splits, so the improvement on splitting on a variable is divided by its cost in deciding which split to choose.

Arguments to \text{rpart.control} may also be specified in the call to \text{rpart}. They are checked against the list of valid arguments.

This differs from the \text{tree} function mainly in its handling of surrogate variables. In most details it follows Breiman et. al. quite closely.

An object of class \text{rpart}, a superset of class \text{tree}.

See Also

\text{rpart.control}, \text{rpart.object}, \text{summary.rpart}, \text{print.rpart}
rpart.control

Examples

```r
fit <- rpart(Kyphosis ~ Age + Number + Start, data=kyphosis)
fitted2 <- rpart(Kyphosis ~ Age + Number + Start, data=kyphosis, 
      parms=list(prior=c(.65,.35), split='information'))
fitted3 <- rpart(Kyphosis ~ Age + Number + Start, data=kyphosis, 
      control=rpart.control(cp=.05))
par(mfrow=c(1,2), xpd=NA) # otherwise on some devices the text is clipped
plot(fit)
text(fit, use.n=TRUE)
plot(fitted2)
text(fitted2, use.n=TRUE)
```

rpart.control

Control for Rpart Models

Description

Various parameters that control aspects of the rpart fit.

Usage

```r
rpart.control(minsplit=20, minbucket=round(minsplit/3), cp=0.01, 
      maxcompete=4, maxsurrogate=5, usesurrogate=2, xval=10, 
      surrogatestyle=0, maxdepth=30, ...)
```

Arguments

- `minsplit` the minimum number of observations that must exist in a node, in order for a split to be attempted.
- `minbucket` the minimum number of observations in any terminal <leaf> node. If only one of `minbucket` or `minsplit` is specified, the code either sets `minsplit` to `minbucket*3` or `minbucket` to `minsplit/3`, as appropriate.
- `cp` complexity parameter. Any split that does not decrease the overall lack of fit by a factor of `cp` is not attempted. For instance, with anova splitting, this means that the overall Rsquare must increase by `cp` at each step. The main role of this parameter is to save computing time by pruning off splits that are obviously not worthwhile. Essentially, the user informs the program that any split which does not improve the fit by `cp` will likely be pruned off by cross-validation, and that hence the program need not pursue it.
- `maxcompete` the number of competitor splits retained in the output. It is useful to know not just which split was chosen, but which variable came in second, third, etc.
- `maxsurrogate` the number of surrogate splits retained in the output. If this is set to zero the compute time will be shortened, since approximately half of the computational time (other than setup) is used in the search for surrogate splits.
- `usesurrogate` how to use surrogates in the splitting process. 0= display only; an observation with a missing value for the primary split rule is not sent further down the tree. 1= use surrogates, in order, to split subjects missing the primary variable; if all surrogates are missing the observation is not split. 2= if all surrogates are missing, then send the observation in the majority direction. A value of 0 corresponds to the action of `tree`, and 2 to the recommendations of Breiman, et.al.
xval number of cross-validations
surrogatestyle controls the selection of a best surrogate. If set to 0 (default) the program uses the total number of correct classification for a potential surrogate variable, if set to 1 it uses the percent correct, calculated over the non-missing values of the surrogate. The first option more severely penalizes covariates with a large number of missing values.

maxdepth Set the maximum depth of any node of the final tree, with the root node counted as depth 0 (past 30 rpart will give nonsense results on 32-bit machines).

... mop up other arguments.

Value
a list containing the options.

See Also
rpart

rpart.object

Recursive Partitioning and Regression Trees Object

Description
These are objects representing fitted rpart trees.

Value
frame data frame with one row for each node in the tree. The row.names of frame contain the (unique) node numbers that follow a binary ordering indexed by node depth. Elements of frame include var, the variable used in the split at each node (leaf nodes are denoted by the string <leaf>), n, the size of each node, wt, the sum of case weights for the node, dev, the deviance of each node, yval, the fitted value of the response at each node, and splits, a two column matrix of left and right split labels for each node. All of these are the same as for an rpart object.

Extra response information is in yval2, which contains the number of events at the node (poisson), or a matrix containing the fitted class, the class counts for each node and the class probabilities (classification). Also included in the frame are complexity, the complexity parameter at which this split will collapse, ncompete, the number of competitor splits retained, and nsurrogate, the number of surrogate splits retained.

where vector, the same length as the number of observations in the root node, containing the row number of frame corresponding to the leaf node that each observation falls into.

splits a matrix describing the splits. The row label is the name of the split variable, and columns are count, the number of observations sent left or right by the split (for competitor splits this is the number that would have been sent left or right had this split been used, for surrogate splits it is the number missing the primary split variable which were decided using this surrogate), ncat, the
number of categories or levels for the variable (\(\pm 1\) for a continuous variable),
improve, which is the improvement in deviance given by this split, or, for
surrogates, the concordance of the surrogate with the primary, and split, the
numeric split point. The last column adj gives the adjusted concordance for
surrogate splits. For a factor, the split column contains the row number of the
csplit matrix. For a continuous variable, the sign of ncat determines whether
the subset \(x < \text{cutpoint}\) or \(x > \text{cutpoint}\) is sent to the left.

\textbf{csplit} this will be present only if one of the split variables is a factor. There is one
row for each such split, and column \(i = 1\) if this level of the factor goes to the
left, 3 if it goes to the right, and 2 if that level is not present at this node of the
tree. For an ordered categorical variable all levels are marked as R/L, including
levels that are not present.

\textbf{method} the method used to grow the tree.

\textbf{cptable} the table of optimal prunings based on a complexity parameter.

\textbf{terms} an object of mode \texttt{expression} and class \texttt{term} summarizing the formula.
Used by various methods, but typically not of direct relevance to users.

\textbf{call} an image of the call that produced the object, but with the arguments all named
and with the actual formula included as the formula argument. To re-evaluate
the call, say \texttt{update(tree)}.
Optional components include the matrix of predictors (\(x\)) and the response vari-
able (\(y\)) used to construct the \texttt{rpart} object.

\section*{Structure}

The following components must be included in a legitimate \texttt{rpart} object. Of these, only the
\texttt{where} component has the same length as the data used to fit the \texttt{rpart} object.

\section*{See Also}

\texttt{rpart}.

---

\textbf{Description}

Rpart objects changed (slightly) in their internal format in order to accommodate the changes for
user-written split functions. This routine updates an old object to the new format.

\section*{Usage}

\texttt{rpconvert(x)}

\section*{Arguments}

\begin{itemize}
  \item \texttt{x} an \texttt{rpart} object
\end{itemize}

\section*{Value}

an updated object

rpart

rsq.rpart | *Plots the Approximate R-Square for the Different Splits*

**Description**

Produces 2 plots. The first plots the r-square (apparent and apparent - from cross-validation) versus the number of splits. The second plots the Relative Error(cross-validation) +/- 1-SE from cross-validation versus the number of splits.

**Usage**

rsq.rpart(x)

**Arguments**

x fitted model object of class rpart. This is assumed to be the result of some function that produces an object with the same named components as that returned by the rpart function.

**Side Effects**

Two plots are produced.

**Note**

The labels are only appropriate for the "anova" method.

**Examples**

```r
z.auto <- rpart(Mileage ~ Weight, car.test.frame)
rsq.rpart(z.auto)
```

**snip.rpart | Snip Subtrees of an Rpart Object**

**Description**

Creates a "snipped" rpart object, containing the nodes that remain after selected subtrees have been snipped off. The user can snip nodes using the toss argument, or interactively by clicking the mouse button on specified nodes within the graphics window.

**Usage**

snip.rpart(x, toss)
Arguments

x  fitted model object of class rpart. This is assumed to be the result of some function that produces an object with the same named components as that returned by the rpart function.

toss  an integer vector containing indices (node numbers) of all subtrees to be snipped off. If missing, user selects branches to snip off as described below.

Details

A dendrogram of rpart is expected to be visible on the graphics device, and a graphics input device (e.g., a mouse) is required. Clicking (the selection button) on a node displays the node number, sample size, response yvalue, and Error (dev). Clicking a second time on the same node snips that subtree off and visually erases the subtree. This process may be repeated an number of times. Warnings result from selecting the root or leaf nodes. Clicking the exit button will stop the snipping process and return the resulting rpart object.

See the documentation for the specific graphics device for details on graphical input techniques.

Value

a rpart object containing the nodes that remain after specified or selected subtrees have been snipped off.

Warning

Visually erasing the plot is done by over-plotting with the background colour. This will do nothing if the background is transparent (often true for screen devices).

plot.rpart

Examples

## dataset not in R
## Not run:
z.survey <- rpart(market.survey) #grow the rpart object
plot(z.survey) #plot the tree
z.survey2 <- snip.rpart(z.survey,toss=2) #trim subtree at node 2
plot(z.survey2) #plot new tree

# can also interactively select the node using the mouse in the
# graphics window
## End(Not run)

describe Soldering of Components on Printed-Circuit Boards

Description

The solder data frame has 720 rows and 6 columns, representing a balanced subset of a designed experiment varying 5 factors on the soldering of components on printed-circuit boards.
Usage

solder

Format

This data frame contains the following columns:

**Opening** a factor with levels L M S indicating the amount of clearance around the mounting pad.

**Solder** a factor with levels Thick Thin giving the thickness of the solder used.

**Mask** a factor with levels A1.5 A3 B3 B6 indicating the type and thickness of mask used.

**PadType** a factor with levels D4 D6 D7 L4 L6 L7 L8 L9 W4 W9 giving the size and geometry of the mounting pad.

**Panel** 1:3 indicating the panel on a board being tested.

**skips** a numeric vector giving the number of visible solder skips.

Source

Examples

```r
fit <- rpart(skips ~ Opening + Solder + Mask + PadType + Panel, 
  data=solder, method='anova')
summary(residuals(fit))
plot(predict(fit),residuals(fit))
```

### summary.rpart

*Summarize a Fitted Rpart Object*

Description

Returns a detailed listing of a fitted `rpart` object.

Usage

```r
## S3 method for class 'rpart':
summary(object, cp=0, digits=getOption("digits"), file, ...)
```

Arguments

- **object**: fitted model object of class `rpart`. This is assumed to be the result of some function that produces an object with the same named components as that returned by the `rpart` function.
- **digits**: Number of significant digits to be used in the result.
- **cp**: trim nodes with a complexity of less than `cp` from the listing.
- **file**: write the output to a given file name. (Full listings of a tree are often quite long).
- **...**: arguments to be passed to or from other methods.
Details

This function is a method for the generic function summary for class "rpart". It can be invoked by calling `summary` for an object of the appropriate class, or directly by calling `summary.rpart` regardless of the class of the object.

See Also

`summary.rpart.object`, `printcp`.

Examples

```r
z.auto <- rpart(Mileage ~ Weight, car.test.frame)
summary(z.auto)
```

---

**text.rpart**

Place Text on a Dendrogram

Description

Labels the current plot of the tree dendrogram with text.

Usage

```r
## S3 method for class 'rpart':
text(x, splits=TRUE, label, FUN=text, all=FALSE,
    pretty=NULL, digits=getOption("digits") - 3, use.n=FALSE,
    fancy=FALSE, fwidth=0.8, fheight=0.8, ...)
```

Arguments

- **x**: fitted model object of class `rpart`. This is assumed to be the result of some function that produces an object with the same named components as that returned by the `rpart` function.
- **splits**: logical flag. If `TRUE` (default), then the splits in the tree are labeled with the criterion for the split.
- **label**: For compatibility with `rpart2`, ignored in this version (with a warning).
- **FUN**: the name of a labeling function, e.g. `text`.
- **all**: Logical. If `TRUE`, all nodes are labeled, otherwise just terminal nodes.
- **pretty**: an integer denoting the extent to which factor levels in split labels will be abbreviated. A value of (0) signifies no abbreviation. A `NULL`, the default, signifies using elements of letters to represent the different factor levels.
- **digits**: number of significant digits to include in numerical labels.
- **use.n**: Logical. If `TRUE`, adds to label (#events level1/ #events level2/etc. for class, n for anova, and #events/n for poisson and exp).
- **fancy**: Logical. If `TRUE`, nodes are represented by ellipses (interior nodes) and rectangles (leaves) and labeled by `yval`. The edges connecting the nodes are labeled by left and right splits.
fwidth Relates to option fancy and the width of the ellipses and rectangles. If fwidth < 1 then it is a scaling factor (default = 0.8). If fwidth > 1 then it represents the number of character widths (for current graphical device) to use.

fheight Relates to option fancy and the height of the ellipses and rectangles. If fheight < 1 then it is a scaling factor (default = 0.8). If fheight > 1 then it represents the number of character heights (for current graphical device) to use.

... Graphical parameters may also be supplied as arguments to this function (see par). As labels often extend outside the plot region it can be helpful to specify xpd = TRUE.

Side Effects

the current plot of a tree dendrogram is labeled.

plot(freen.tr)
text(freen.tr, use.n=TRUE, all=TRUE)

xpred.rpart Return Cross-Validated Predictions

Description

Gives the predicted values for an rpart fit, under cross validation, for a set of complexity parameter values.

Usage

xpred.rpart(fit, xval=10, cp)

Arguments

fit a rpart object.
xval number of cross-validation groups. This may also be an explicit list of integers that define the cross-validation groups.
cp the desired list of complexity values. By default it is taken from the cptable component of the fit.

Details

Complexity penalties are actually ranges, not values. If the cp values found in the table were .36, .28, and .13, for instance, this means that the first row of the table holds for all complexity penalties in the range [.36, 1], the second row for cp in the range [.28, .36) and the third row for [.13, .28). By default, the geometric mean of each interval is used for cross validation.
Value

a matrix with one row for each observation and one column for each complexity value.

rpart

Examples

fit <- rpart(Mileage ~ Weight, car.test.frame)
xmat <- xpred.rpart(fit)
xerr <- (xmat - car.test.frame$Mileage)^2
apply(xerr, 2, sum)  # cross-validated error estimate

# approx same result as rel. error from printcp(fit)
apply(xerr, 2, sum)/var(car.test.frame$Mileage)
printcp(fit)
Chapter 23

The spatial package

---

anova.trls

Anova tables for fitted trend surface objects

Description

Compute analysis of variance tables for one or more fitted trend surface model objects: where anova.trls is called with multiple objects, it passes on the arguments to anovalist.trls.

Usage

```r
## S3 method for class 'trls':
anova(object, ...)
anovalist.trls(object, ...)
```

Arguments

- `object`: A fitted trend surface model object from `surf.ls`
- `...`: Further objects of the same kind

Value

`anova.trls` and `anovalist.trls` return objects corresponding to their printed tabular output.

References

See Also

- `surf.ls`

2373
correlogram

Examples

```r
library(stats)
data(topo, package="MASS")
topo0 <- surf.ls(0, topo)
topo1 <- surf.ls(1, topo)
topo2 <- surf.ls(2, topo)
topo3 <- surf.ls(3, topo)
topo4 <- surf.ls(4, topo)
anova(topo0, topo1, topo2, topo3, topo4)
summary(topo4)
```

correlogram

**Compute Spatial Correlograms**

**Description**

Compute spatial correlograms of spatial data or residuals.

**Usage**

```r
correlogram(krig, nint, plotit = TRUE, ...)
```

**Arguments**

- `krig`: trend-surface or kriging object with columns `x`, `y`, and `z`
- `nint`: number of bins used
- `plotit`: logical for plotting
- `...`: parameters for the plot

**Details**

Divides range of data into `nint` bins, and computes the covariance for pairs with separation in each bin, then divides by the variance. Returns results for bins with 6 or more pairs.

**Value**

`x` and `y` coordinates of the correlogram, and `cnt`, the number of pairs averaged per bin.

**Side Effects**

Plots the correlogram if `plotit = TRUE`.

**References**

lines(d, expcov(d, 0.7))

expcov  

Spatial Covariance Functions

Description

Spatial covariance functions for use with surf.gls.

Usage

expcov(r, d, alpha = 0, se = 1)
gaucov(r, d, alpha = 0, se = 1)
sphercov(r, d, alpha = 0, se = 1, D = 2)

Arguments

r  vector of distances at which to evaluate the covariance
d  range parameter
alpha proportion of nugget effect
se  standard deviation at distance zero
D  dimension of spheres.

Value

vector of covariance values.

**Kfn**

*Compute K-fn of a Point Pattern*

**Description**

Actually computes \( L = \sqrt{K/\pi} \).

**Usage**

```r
Kfn(pp, fs, k=100)
```

**Arguments**

- `pp` a list such as a `pp` object, including components `x` and `y`
- `fs` full scale of the plot
- `k` number of regularly spaced distances in \((0, fs)\)

**Details**

relies on the domain D having been set by `ppinit` or `ppregion`.

**Value**

A list with components

- `x` vector of distances
- `y` vector of L-fn values
- `k` number of distances returned – may be less than \( k \) if \( fs \) is too large
- `dmin` minimum distance between pair of points
- `lm` maximum deviation from \( L(t) = t \)

**References**

**See Also**

`ppinit`, `ppregion`, `Kaver`, `Kenvl`

**Examples**

```r
towns <- ppinit("towns.dat")
par(pty="s")
plot(Kfn(towns, 10), type="s", xlab="distance", ylab="L(t)")
```
**ppgetregion**  
*Get Domain for Spatial Point Pattern Analyses*

**Description**

Retrieves the rectangular domain \((x_l, x_u) \times (y_l, y_u)\) from the underlying C code.

**Usage**

```r
ppgetregion()
```

**Value**

A vector of length four with names \(c("x_l", "x_u", "y_l", "y_u")\).

**References**

**See Also**

`ppregion`  
`ppinit`  

---

**ppinit**  
*Read a Point Process Object from a File*

**Description**

Read a file in standard format and create a point process object.

**Usage**

```r
ppinit(file)
```

**Arguments**

- `file`  
  string giving file name

**Details**

The file should contain

- the number of points
- a header (ignored)
- \(x_l\ xu\ yl\ yu\ scale\)  
  \(x\ y\) (repeated \(n\) times)

**Value**

`class "pp"` object with components \(x, y, x_l, xu, y_l, y_u\)
Side Effects

Calls \texttt{ppregion} to set the domain.

References

\end{verbatim}

\textit{Pseudo-likelihood Estimation of a Strauss Spatial Point Process}

Description

Pseudo-likelihood estimation of a Strauss spatial point process.

Usage

\begin{verbatim}
pplik(pp, R, ng=50, trace=FALSE)
\end{verbatim}

Arguments

- \texttt{pp}:
  - a \texttt{pp} object
- \texttt{R}:
  - the fixed parameter \( R \)
- \texttt{ng}:
  - use a \( \text{ng} \times \text{ng} \) grid with border \( R \) in the domain for numerical integration.
- \texttt{trace}:
  - logical? Should function evaluations be printed?

Value

estimate for \( c \) in the interval \([0, 1]\).

Set Domain for Spatial Point Pattern Analyses

Description
Sets the rectangular domain \((x_l, x_u) \times (y_l, y_u)\).

Usage
ppregion(xl = 0, xu = 1, yl = 0, yu = 1)

Arguments
- \(x_l\): Either \(x_l\) or a list containing components \(x_l, x_u, y_l, y_u\) (such as a point-process object)
- \(x_u\)
- \(y_l\)
- \(y_u\)

Value
none

Side Effects
initializes variables in the C subroutines.

References

ppinit, ppgetregion

predict.trls
Predict method for trend surface fits

Description
Predicted values based on trend surface model object

Usage
```r
## S3 method for class 'trls':
predict(object, x, y, ...)
```
Arguments

- **object**: Fitted trend surface model object returned by `surf.ls`
- **x**: Vector of prediction location eastings (x coordinates)
- **y**: Vector of prediction location northings (y coordinates)
- **...**: further arguments passed to or from other methods.

Value

`predict.trls` produces a vector of predictions corresponding to the prediction locations. To display the output with `image` or `contour`, use `trmat` or convert the returned vector to matrix form.

References

See Also

- `surf.ls`, `trmat`

Examples

```r
data(topo, package="MASS")
topo2 <- surf.ls(2, topo)
topo4 <- surf.ls(4, topo)
x <- c(1.78, 2.21)
y <- c(6.15, 6.15)
z2 <- predict(topo2, x, y)
z4 <- predict(topo4, x, y)
cat("2nd order predictions:", z2, "\n4th order predictions:", z4, "\n")
```

---

**prmat**

*Evaluate Kriging Surface over a Grid*

Description

Evaluate Kriging surface over a grid.

Usage

```
prmat(obj, xl, xu, yl, yu, n)
```

Arguments

- **obj**: object returned by `surf.gls`
- **xl**: limits of the rectangle for grid
- **xu**: limits of the rectangle for grid
- **yl**: limits of the rectangle for grid
- **yu**: limits of the rectangle for grid
- **n**: use \( n \times n \) grid within the rectangle
Value

list with components x, y and z suitable for contour and image.

References

See Also

`surf.gls, trmat, semat`

Examples

data(topo, package="MASS")
topo.kr <- surf.gls(2, expcov, topo, d=0.7)
prsurf <- prmat(topo.kr, 0, 6.5, 0, 6.5, 50)
contour(prsurf, levels=seq(700, 925, 25))

---

**Psim**  
*Simulate Binomial Spatial Point Process*

Description

Simulate Binomial spatial point process.

Usage

`Psim(n)`

Arguments

n  
number of points

Details

relies on the region being set by `ppinit` or `ppregion`.

Value

list of vectors of x and y coordinates.

Side Effects

uses the random number generator.

References

semat

**Evaluate Kriging Standard Error of Prediction over a Grid**

**Description**

Evaluate Kriging standard error of prediction over a grid.

**Usage**

```r
semat(obj, xl, xu, yl, yu, n, se)
```

**Arguments**

- `obj`  
  object returned by `surf.gls`
- `xl`  
  limits of the rectangle for grid
- `xu`  
- `yl`  
- `yu`  
- `n`  
  use \( n \times n \) grid within the rectangle
- `se`  
  standard error at distance zero as a multiple of the supplied covariance. Otherwise estimated, and it assumed that a correlation function was supplied.

**Value**

list with components `x`, `y` and `z` suitable for `contour` and `image`.

**References**

**See Also**

- `surf.gls`, `trmat`, `prmat`
SSI

Simulates Sequential Spatial Inhibition Point Process

Description

Simulates SSI (sequential spatial inhibition) point process.

Usage

SSI(n, r)

Arguments

n  number of points
r  inhibition distance

Details

uses the region set by ppinit or ppregion.

Value

list of vectors of x and y coordinates

Side Effects

uses the random number generator.

Warnings

will never return if r is too large and it cannot place n points.

References

Examples

data(topo, package="MASS")
topo.kr <- surf.gls(2, expcov, topo, d=0.7)
prsurf <- prmat(topo.kr, 0, 6.5, 0, 6.5, 50)
contour(prsurf, levels=seq(700, 925, 25))

sesurf <- semat(topo.kr, 0, 6.5, 0, 6.5, 30)
contour(sesurf, levels=c(22,25))
Examples

towns <- ppinit("towns.dat")
par(pty = "s")
plot(Kfn(towns, 10), type = "b", xlab = "distance", ylab = "L(t)")
lines(Kaver(10, 25, SSI(69, 1.2)))

---

Strauss

Simulates Strauss Spatial Point Process

Description

Simulates Strauss spatial point process.

Usage

Strauss(n, c=0, r)

Arguments

n       number of points

c       parameter c in [0, 1]. c = 0 corresponds to complete inhibition at distances up
to r.

r       inhibition distance

Details

Uses spatial birth-and-death process for 4n steps, or for 40n steps starting from a binomial pattern
on the first call from an other function. Uses the region set by ppinit or ppregion.

Value

list of vectors of x and y coordinates

Side Effects

uses the random number generator

surf.gls

Fits a Trend Surface by Generalized Least-squares

Description
Fits a trend surface by generalized least-squares.

Usage
surf.gls(np, covmod, x, y, z, nx = 1000, ...)

Arguments
- np: degree of polynomial surface
- covmod: function to evaluate covariance or correlation function
- x: x coordinates or a data frame with columns x, y, z
- y: y coordinates
- z: z coordinates. Will supersede x$z
- nx: Number of bins for table of the covariance. Increasing adds accuracy, and increases size of the object.
- ...: parameters for covmod

Value
list with components
- beta: the coefficients
- x
- y
- z: and others for internal use only.

**trls.influence**  
Regression diagnostics for trend surfaces

**Description**

This function provides the basic quantities which are used in forming a variety of diagnostics for checking the quality of regression fits for trend surfaces calculated by `surf.ls`.

**Usage**

```r
trls.influence(object)
```

## S3 method for class 'trls':

```r
plot(x, border = "red", col = NA, pch = 4, cex = 0.6,
     add = FALSE, div = 8, ...)```

**Arguments**

- `object, x` Fitted trend surface model from `surf.ls`
- `div` scaling factor for influence circle radii in `plot.trls`
- `add` add influence plot to existing graphics if TRUE
- `border, col, pch, cex, ...` additional graphical parameters

**Value**

`trls.influence` returns a list with components:

- `r` raw residuals as given by `residuals.trls`
- `hii` diagonal elements of the Hat matrix
- `stresid` standardised residuals
- `Di` Cook’s statistic

trmat

Evaluate Trend Surface over a Grid

Description

Evaluate trend surface over a grid.

Usage

trmat(obj, xl, xu, yl, yu, n)

Arguments

obj object returned by surf.ls or surf.gls
xl limits of the rectangle for grid
xu
yl
yu
n use n x n grid within the rectangle

Value

list with components x, y and z suitable for contour and image.

```

---

variogram  Compute Spatial Variogram

Description

Compute spatial (semi-)variogram of spatial data or residuals.

Usage

```r
variogram(krig, nint, plotit = TRUE, ...)
```

Arguments

- `krig`: trend-surface or kriging object with columns `x`, `y`, and `z`
- `nint`: number of bins used
- `plotit`: logical for plotting
- `...`: parameters for the plot

Details

Divides range of data into `nint` bins, and computes the average squared difference for pairs with separation in each bin. Returns results for bins with 6 or more pairs.

Value

- `x` and `y` coordinates of the variogram and `cnt`, the number of pairs averaged per bin.

Side Effects

Plots the variogram if `plotit = TRUE`

correlogram

Examples

```r
data(topo, package="MASS")
topo.kr <- surf.ls(2, topo)
variogram(topo.kr, 25)
```
Chapter 24

The splines package

splines-package  Regression Spline Functions and Classes

Description

Regression spline functions and classes.

Details

This package provides functions for working with regression splines using the B-spline basis, the natural cubic spline basis.

For a complete list of functions, use library(help="splines").

Author(s)

Douglas M. Bates ⟨bates@stat.wisc.edu⟩ and William N. Venables ⟨Bill.Venables@cmis.csiro.au⟩

Maintainer: R Core Team ⟨R-core@r-project.org⟩

asVector  Coerce an Object to a Vector

Description

This is a generic function. Methods for this function coerce objects of given classes to vectors.

Usage

asVector(object)

Arguments

object  An object.
Details

Methods for vector coercion in new classes must be created for the `asVector` generic instead of `as.vector`. The `as.vector` function is internal and not easily extended. Currently the only class with an `asVector` method is the `xyVector` class.

Value

a vector

Author(s)

Douglas Bates and Bill Venables

See Also

`xyVector`

Examples

```r
ispl <- interpSpline( weight ~ height, women )
pred <- predict(ispl)
class(pred)
utils::str(pred)
asVector(pred)
```

Description

Create a monotone inverse of a monotone natural spline.

Usage

`backSpline(object)`

Arguments

- `object`: an object that inherits from class `nbSpline` or `npolySpline`. That is, the object must represent a natural interpolation spline but it can be either in the B-spline representation or the piecewise polynomial one. The spline is checked to see if it represents a monotone function.

Value

An object of class `polySpline` that contains the piecewise polynomial representation of a function that has the appropriate values and derivatives at the knot positions to be an inverse of the spline represented by `object`. Technically this object is not a spline because the second derivative is not constrained to be continuous at the knot positions. However, it is often a much better approximation to the inverse than fitting an interpolation spline to the y/x pairs.
bs

Author(s)
Douglas Bates and Bill Venables

See Also
interpSpline

Examples

ispl <- interpSpline( women$height, women$weight )
bspl <- backSpline( ispl )
plot( bspl )  # plots over the range of the knots
points( women$weight, women$height )

bs

B-Spline Basis for Polynomial Splines

Description
Generate the B-spline basis matrix for a polynomial spline.

Usage

bs(x, df = NULL, knots = NULL, degree = 3, intercept = FALSE,
   Boundary.knots = range(x))

Arguments

x the predictor variable. Missing values are allowed.
df degrees of freedom; one can specify df rather than knots; bs() then chooses
df-degree-1 knots at suitable quantiles of x (which will ignore missing val-
ues).
knots the internal breakpoints that define the spline. The default is NULL, which re-
results in a basis for ordinary polynomial regression. Typical values are the mean
or median for one knot, quantiles for more knots. See also Boundary.knots.
degree degree of the piecewise polynomial—default is 3 for cubic splines.
intercept if TRUE, an intercept is included in the basis; default is FALSE.
Boundary.knots boundary points at which to anchor the B-spline basis (default the range of the
data). If both knots and Boundary.knots are supplied, the basis para-
ters do not depend on x. Data can extend beyond Boundary.knots.

Value
A matrix of dimension length(x) * df, where either df was supplied or if knots were
supplied, df = length(knots) + 3 + intercept. Attributes are returned that corre-
spond to the arguments to bs, and explicitly give the knots, Boundary.knots etc for use
by predict.bs().

bs() is based on the function spline.des(). It generates a basis matrix for representing the
family of piecewise polynomials with the specified interior knots and degree, evaluated at the values
of x. A primary use is in modeling formulas to directly specify a piecewise polynomial term in a
model.
References

See Also

ns, poly, smooth.spline, predict.bs, SafePrediction

Examples

require(stats)
bs(women$height, df = 5)
summary(fm1 <- lm(weight ~ bs(height, df = 5), data = women))

## example of safe prediction
plot(women, xlab = "Height (in)", ylab = "Weight (lb)"
ht <- seq(57, 73, len = 200)
lines(ht, predict(fm1, data.frame(height=ht)))

## Consistency:
x <- c(1:3,5:6)
stopifnot(identical(bs(x), bs(x, df = 3)),
!is.null(kk <- attr(bs(x), "knots")),# not true till 1.5.1
 length(kk) == 0)

interpSpline

Create an Interpolation Spline

Description

Create an interpolation spline, either from x and y vectors, or from a formula/data.frame combination.

Usage

interpSpline(obj1, obj2, bSpline = FALSE, period = NULL,
na.action = na.fail)

Arguments

obj1
Either a numeric vector of x values or a formula.

obj2
If obj1 is numeric this should be a numeric vector of the same length. If obj1 is a formula this can be an optional data frame in which to evaluate the names in the formula.

bSpline
If TRUE the b-spline representation is returned, otherwise the piecewise polynomial representation is returned. Defaults to FALSE.

period
An optional positive numeric value giving a period for a periodic interpolation spline.

na.action
a optional function which indicates what should happen when the data contain NAs. The default action (na.omit) is to omit any incomplete observations. The alternative action na.fail causes interpSpline to print an error message and terminate if there are any incomplete observations.
Value

An object that inherits from class spline. The object can be in the B-spline representation, in which case it will be of class nbSpline for natural B-spline, or in the piecewise polynomial representation, in which case it will be of class npolySpline.

Author(s)

Douglas Bates and Bill Venables

See Also

splineKnots, splineOrder, periodicSpline.

Examples

ispl <- interpSpline( women$height, women$weight )
ispl2 <- interpSpline( weight ~ height, women )
# ispl and ispl2 should be the same
plot( predict( ispl, seq( 55, 75, len = 51 ) ), type = "l" )
points( women$height, women$weight )
plot( ispl )  # plots over the range of the knots
points( women$height, women$weight )
splineKnots( ispl )

ns

Generate a Basis Matrix for Natural Cubic Splines

Description

Generate the B-spline basis matrix for a natural cubic spline.

Usage

ns(x, df = NULL, knots = NULL, intercept = FALSE,
Boundary.knots = range(x))

Arguments

x

df

the predictor variable. Missing values are allowed.
degrees of freedom. One can supply df rather than knots; ns() then chooses

if TRUE, an intercept is included in the basis; default is FALSE.

breakpoints that define the spline. The default is no knots; together with the
natural boundary conditions this results in a basis for linear regression on x.
Typical values are the mean or median for one knot, quantiles for more knots.
See also Boundary.knots.

boundary points at which to impose the natural boundary conditions and an-
cor the B-spline basis (default the range of the data). If both knots and
Boundary.knots are supplied, the basis parameters do not depend on x.
Data can extend beyond Boundary.knots.
periodicSpline

Create a Periodic Interpolation Spline

Description

Create a periodic interpolation spline, either from \( x \) and \( y \) vectors, or from a formula/data.frame combination.

Usage

\[
\text{periodicSpline(obj1, obj2, knots, period = 2*\pi, ord = 4)}
\]

Arguments

- **obj1**: either a numeric vector of \( x \) values or a formula.
- **obj2**: if \( obj1 \) is numeric this should be a numeric vector of the same length. If \( obj1 \) is a formula this can be an optional data frame in which to evaluate the names in the formula.
- **knots**: optional numeric vector of knot positions.

Value

A matrix of dimension \( \text{length}(x) \times df \) where either \( df \) was supplied or if \( \text{knots} \) were supplied, \( df = \text{length}(\text{knots}) + 1 + \text{intercept} \). Attributes are returned that correspond to the arguments to \( \text{ns} \), and explicitly give the \( \text{knots}, \text{Boundary.knots} \) etc for use by \( \text{predict.ns}() \).

\( \text{ns}() \) is based on the function \( \text{spline.des} \). It generates a basis matrix for representing the family of piecewise-cubic splines with the specified sequence of interior knots, and the natural boundary conditions. These enforce the constraint that the function is linear beyond the boundary knots, which can either be supplied, else default to the extremes of the data. A primary use is in modeling formula to directly specify a natural spline term in a model.

Examples

\begin{verbatim}
require(stats)
ns(women$height, df = 5)
summary(fm1 <- lm(weight ~ ns(height, df = 5), data = women))

## example of safe prediction
plot(women, xlab = "Height (in)", ylab = "Weight (lb)")
ht <- seq(57, 73, len = 200)
lines(ht, predict(fm1, data.frame(height=ht)))
\end{verbatim}
**polySpline**

Piecewise Polynomial Spline Representation

**Description**

Create the piecewise polynomial representation of a spline object.

**Usage**

```r
polySpline(object, ...) as.polySpline(object, ...)
```

**Arguments**

- `object` An object that inherits from class `spline`.
- `...` Optional additional arguments. At present no additional arguments are used.

**Value**

An object that inherits from class `spline`. The object can be in the B-spline representation, in which case it will be a `pbSpline` object, or in the piecewise polynomial representation (a `ppolySpline` object).

**Author(s)**

Douglas Bates and Bill Venables

**See Also**

`splineKnots`, `interpSpline`

**Examples**

```r
xx <- seq(-pi, pi, len = 16)[-1]
yy <- sin(xx)
frm <- data.frame(xx, yy)
(pispl <- periodicSpline(xx, yy, period = 2 * pi))
pispl2 <- periodicSpline(yy ~ xx, frm, period = 2 * pi)
stopifnot(all.equal(pispl, pispl2))# pispl and pispl2 are the same
plot(pispl) # displays over one period
points(yy ~ xx, col = "brown")
plot(predict(pispl, seq(-3*pi, 3*pi, len = 101)), type = "l")
```
Value

An object that inherits from class `polySpline`. This is the piecewise polynomial representation of a univariate spline function. It is defined by a set of distinct numeric values called knots. The spline function is a polynomial function between each successive pair of knots. At each interior knot the polynomial segments on each side are constrained to have the same value of the function and some of its derivatives.

Author(s)

Douglas Bates and Bill Venables

See Also

`interpSpline`, `periodicSpline`, `splineKnots`, `splineOrder`

Examples

```r
ispl <- polySpline( interpSpline( weight ~ height, women, bSpline = TRUE ) )
print( ispl ) # print the piecewise polynomial representation
plot( ispl ) # plots over the range of the knots
points( women$height, women$weight )
```

Description

Evaluate a predefined spline basis at given values.

Usage

```r
## S3 method for class 'bs':
predict(object, newx, ...)
## S3 method for class 'ns':
predict(object, newx, ...)
```

Arguments

- `object` the result of a call to `bs` or `ns` having attributes describing `knots`, `degree`, etc.
- `newx` the x values at which evaluations are required.
- `...` Optional additional arguments. At present no additional arguments are used.

Value

An object just like `object`, except evaluated at the new values of x.

These are methods for the generic function `predict` for objects inheriting from classes "bs" or "ns". See `predict` for the general behavior of this function.
**predict.bSpline**

**Evaluate a Spline at New Values of x**

The `predict` methods for the classes that inherit from the virtual classes `bSpline` and `polySpline` are used to evaluate the spline or its derivatives. The `plot` method for a spline object first evaluates `predict` with the `x` argument missing, then plots the resulting `xyVector` with `type = "l"`.

**Usage**

```r
## S3 method for class 'bSpline':
predict(object, x, nseg=50, deriv=0, ...)  
## S3 method for class 'nbSpline':
predict(object, x, nseg=50, deriv=0, ...)  
## S3 method for class 'pbSpline':
predict(object, x, nseg=50, deriv=0, ...)  
## S3 method for class 'npolySpline':
predict(object, x, nseg=50, deriv=0, ...)  
## S3 method for class 'ppolySpline':
predict(object, x, nseg=50, deriv=0, ...)  
```

**Arguments**

- `object` An object that inherits from the `bSpline` or the `polySpline` class.
- `x` A numeric vector of `x` values at which to evaluate the spline. If this argument is missing a suitable set of `x` values is generated as a sequence of `nseg` segments spanning the range of the knots.
- `nseg` A positive integer giving the number of segments in a set of equally-spaced `x` values spanning the range of the knots in `object`. This value is only used if `x` is missing.
- `deriv` An integer between 0 and `splineOrder(object) - 1` specifying the derivative to evaluate.
- `...` further arguments passed to or from other methods.

**Value**

An `xyVector` with components

- `x` the supplied or inferred numeric vector of `x` values
- `y` the value of the spline (or its `deriv`th derivative) at the `x` vector

**See Also**

`bs, ns, poly`.

**Examples**

```r
basis <- ns(women$height, df = 5)  
newX <- seq(58, 72, len = 51)  
# evaluate the basis at the new data  
predict(basis, newX)
```
Author(s)
Douglas Bates and Bill Venables

See Also
xyVector, interpSpline, periodicSpline

Examples
ispl <- interpSpline(weight ~ height, women)
opar <- par(mfrow = c(2, 2), las = 1)
plot(predict(ispl, nseg = 201), # plots over the range of the knots
     main = "Original data with interpolating spline", type = "l",
     xlab = "height", ylab = "weight")
points(women$height, women$weight, col = 4)
plot(predict(ispl, nseg = 201, deriv = 1),
     main = "First derivative of interpolating spline", type = "l",
     xlab = "height", ylab = "weight")
plot(predict(ispl, nseg = 201, deriv = 2),
     main = "Second derivative of interpolating spline", type = "l",
     xlab = "height", ylab = "weight")
plot(predict(ispl, nseg = 401, deriv = 3),
     main = "Third derivative of interpolating spline", type = "l",
     xlab = "height", ylab = "weight")
par(opar)

splineDesign

Design Matrix for B-splines

Description
Evaluate the design matrix for the B-splines defined by knots at the values in x.

Usage
splineDesign(knots, x, ord = 4, derivs, outer.ok = FALSE)
spline.des(knots, x, ord = 4, derivs, outer.ok = FALSE)

Arguments

knots a numeric vector of knot positions with non-decreasing values.

x a numeric vector of values at which to evaluate the B-spline functions or
    derivatives. Unless outer.ok is true, the values in x must be between
    knots[ord] and knots[ length(knots) + 1 - ord ].

ord a positive integer giving the order of the spline function. This is the number of
    coefficients in each piecewise polynomial segment, thus a cubic spline has order
    4. Defaults to 4.

derivs an integer vector of the same length as x and with values between 0 and ord -
    1. The derivative of the given order is evaluated at the x positions. Defaults to a
    vector of zeroes of the same length as x.

outer.ok logical indicating if x should be allowed outside the inner knots, see the x argu-

ment.
splineKnots

Value

A matrix with length( x ) rows and length( knots ) - ord columns. The i'th row of
the matrix contains the coefficients of the B-splines (or the indicated derivative of the B-splines)
defined by the knot vector and evaluated at the i'th value of x. Each B-spline is defined by a set
of ord successive knots so the total number of B-splines is length(knots) - ord.

Note

The older spline.des function takes the same arguments but returns a list with several compo-
nents including knots, ord, derivs, and design. The design component is the same as the
value of the splineDesign function.

Author(s)

Douglas Bates and Bill Venables

Examples

splineDesign(knots = 1:10, x = 4:7)

knots <- c(1,1.8,3:5,6.5,7,8.1,9.2,10)# 10 => 10-4 = 6 Basis splines
x <- seq(min(knots)-1, max(knots)+1, length=501)
bb <- splineDesign(knots, x=x, outer.ok = TRUE)

plot(range(x), c(0,1), type="n", xlab="x", ylab="",
     main= "B-splines - sum to 1 inside inner knots")
 mtext(expression(B[j](x) * and * sum(B[j](x), j==1, 6)), adj=0)
 abline(v=knots, lty=3, col="light gray")
 abline(v=knots[c(4,length(knots)-3)], lty=3, col="gray10")
 lines(x, rowSums(bb), col="gray", lwd=2)
 matlines(x, bb, ylim = c(0,1), lty=1)

splineKnots

Knot Vector from a Spline

Description

Return the knot vector corresponding to a spline object.

Usage

splineKnots(object)

Arguments

object an object that inherits from class "spline".

Value

A non-decreasing numeric vector of knot positions.
Author(s)
Douglas Bates and Bill Venables

Examples

```r
ispl <- interpSpline( weight ~ height, women )
splineKnots( ispl )
```

---

**splineOrder**

*Determine the Order of a Spline*

**Description**
Return the order of a spline object.

**Usage**

```r
splineOrder(object)
```

**Arguments**

- `object`  
  An object that inherits from class "spline".

**Details**

The order of a spline is the number of coefficients in each piece of the piecewise polynomial representation. Thus a cubic spline has order 4.

**Value**

A positive integer.

**Author(s)**
Douglas Bates and Bill Venables

**See Also**

`splineKnots`, `interpSpline`, `periodicSpline`

**Examples**

```r
splineOrder( interpSpline( weight ~ height, women ) )
```
Construct an xyVector Object

Description

Create an object to represent a set of x-y pairs. The resulting object can be treated as a matrix or as a data frame or as a vector. When treated as a vector it reduces to the y component only.

The result of functions such as predict.spline is returned as an xyVector object so the x-values used to generate the y-positions are retained, say for purposes of generating plots.

Usage

xyVector(x, y)

Arguments

x

a numeric vector

y

a numeric vector of the same length as x

Value

An object of class xyVector with components

x

a numeric vector

y

a numeric vector of the same length as x

Author(s)

Douglas Bates and Bill Venables

Examples

ispl <- interpSpline( weight ~ height, women )
weights <- predict( ispl, seq( 55, 75, len = 51 ))
class( weights )
plot( weights, type = "l", xlab = "height", ylab = "weight" )
points( women$height, women$weight )
weights
Chapter 25

The \texttt{stats4} package

\begin{itemize}
\item \texttt{stats4-package} \quad Statistical Functions using S4 Classes
\end{itemize}

\textbf{Description}

Statistical Functions using S4 classes.

\textbf{Details}

This package contains functions and classes for statistics using the S version 4 class system.

The methods currently support maximum likelihood (function \texttt{mle()} returning class "\texttt{mle}") including methods for \texttt{AIC} and \texttt{BIC} for model selection.

\textbf{Author(s)}

R Development Core Team and contributors worldwide
Maintainer: R Core Team <R-core@r-project.org>

\begin{itemize}
\item \texttt{AIC-methods} \quad Methods for Function ‘AIC’ in Package ‘stats4’
\end{itemize}

\textbf{Description}

Calculate the Akaike information criterion for a fitted model object.

\textbf{Methods}

\texttt{object} = "ANY"  Generic function: see \texttt{AIC}
BIC  

Bayesian Information Criterion

Description
This generic function calculates the Bayesian information criterion, also known as Schwarz’s Bayesian criterion (SBC), for one or several fitted model objects for which a log-likelihood value can be obtained, according to the formula \(-2\log\text{-likelihood} + n_{\text{par}} \log(n_{\text{obs}})\), where \(n_{\text{par}}\) represents the number of parameters and \(n_{\text{obs}}\) the number of observations in the fitted model.

Usage

BIC(object, ...)

Arguments

object  
An object of a suitable class for the BIC to be calculated - usually a "logLik" object or an object for which a logLik method exists.

...  
Some methods for this generic function may take additional, optional arguments. At present none do.

Value

Returns a numeric value with the corresponding BIC.

References

See Also

logLik-methods, AIC-methods

Examples

```r
lm1 <- lm(Fertility ~ ., data = swiss)
AIC(lm1)
BIC(lm1)
```
coef-methods

Methods for Function 'coef' in Package 'stats4'

Description

Extract the coefficient vector from "mle" objects.

Methods

object = "ANY"  Generic function: see coef.
object = "mle"  Extract the full coefficient vector (including any fixed coefficients) from the fit.
object = "summary.mle"  Extract the coefficient vector and standard errors from the summary of the fit.

confint-methods

Methods for Function 'confint' in Package 'stats4'

Description

Generate confidence intervals

Methods

object = "ANY"  Generic function: see confint.
object = "mle"  First generate profile and then confidence intervals from the profile.
object = "profile.mle"  Generate confidence intervals based on likelihood profile.

logLik-methods

Methods for Function 'logLik' in Package 'stats4'

Description

Extract the maximized log-likelihood from "mle" objects.

Methods

object = "ANY"  Generic function: see logLik.
object = "mle"  Extract log-likelihood from the fit.
mle

Maximum Likelihood Estimation

Description

Estimate parameters by the method of maximum likelihood.

Usage

mle(minuslogl, start = formals(minuslogl), method = "BFGS",
     fixed = list(), ...)

Arguments

minuslogl Function to calculate negative log-likelihood.
start Named list. Initial values for optimizer.
method Optimization method to use. See optim.
fixed Named list. Parameter values to keep fixed during optimization.
... Further arguments to pass to optim.

Details

The optim optimizer is used to find the minimum of the negative log-likelihood. An approximate covariance matrix for the parameters is obtained by inverting the Hessian matrix at the optimum.

Value

An object of class mle-class.

Note

Be careful to note that the argument is -log L (not -2 log L). It is for the user to ensure that the likelihood is correct, and that asymptotic likelihood inference is valid.

See Also

mle-class

Examples

x <- 0:10
y <- c(26, 17, 13, 12, 20, 5, 9, 8, 5, 4, 8)
ll <- function(ymax=15, xhalf=6)
    -sum(stats::dpois(y, lambda=ymax/(1+x/xhalf), log=TRUE))
(fit <- mle(ll))
mle(ll, fixed=list(xhalf=6))

summary(fit)
logLik(fit)
vcov(fit)
plot(profile(fit), absVal=FALSE)
confint(fit)
## use bounded optimization
## the lower bounds are really > 0, but we use >=0 to stress-test profiling
(fit1 <- mle(ll, method="L-BFGS-B", lower=c(0, 0)))
plot(profile(fit1), absVal=FALSE)

## a better parametrization:
ll2 <- function(lymax=log(15), lxhalf=log(6))
  -sum(stats::dpois(y, lambda=exp(lymax)/(1+x/exp(lxhalf)), log=TRUE))
(fit2 <- mle(ll2))
plot(profile(fit2), absVal=FALSE)
exp(confint(fit2))

---

### mle-class

**Class "mle" for Results of Maximum Likelihood Estimation**

**Description**

This class encapsulates results of a generic maximum likelihood procedure.

**Objects from the Class**

Objects can be created by calls of the form `new("mle", ...)`, but most often as the result of a call to `mle`.

**Slots**

- `call`: Object of class "language". The call to `mle`.
- `coef`: Object of class "numeric". Estimated parameters.
- `fullcoef`: Object of class "numeric". Fixed and estimated parameters.
- `vcov`: Object of class "matrix". Approximate variance-covariance matrix.
- `min`: Object of class "numeric". Minimum value of objective function.
- `details`: Object of class "list". List returned from `optim`.
- `minuslogl`: Object of class "function". The negative loglikelihood function.
- `method`: Object of class "character". The optimization method used.

**Methods**

- `confint` signature(object = "mle"): Confidence intervals from likelihood profiles.
- `logLik` signature(object = "mle"): Extract maximized log-likelihood.
- `profile` signature(fitted = "mle"): Likelihood profile generation.
- `show` signature(object = "mle"): Display object briefly.
- `summary` signature(object = "mle"): Generate object summary.
- `update` signature(object = "mle"): Update fit.
- `vcov` signature(object = "mle"): Extract variance-covariance matrix.
### plot-methods

**Methods for Function 'plot' in Package 'stats4'**

#### Description

Plot profile likelihoods for "mle" objects.

#### Usage

```r
## S4 method for signature 'profile.mle, missing':
plot(x, levels, conf = c(99, 95, 90, 80, 50)/100, nseg = 50,
     absVal = TRUE, ...)
```

#### Arguments

- **x**: an object of class "profile.mle"
- **levels**: levels, on the scale of the absolute value of a t statistic, at which to interpolate intervals. Usually `conf` is used instead of giving `levels` explicitly.
- **conf**: a numeric vector of confidence levels for profile-based confidence intervals on the parameters.
- **nseg**: an integer value giving the number of segments to use in the spline interpolation of the profile t curves.
- **absVal**: a logical value indicating whether or not the plots should be on the scale of the absolute value of the profile t. Defaults to `TRUE`.
- **...**: other arguments to the `plot` function can be passed here.

#### Methods

- `x = "ANY", y = "ANY"` Generic function: see `plot`.
- `x = "profile.mle", y = "missing"` Plot likelihood profiles for `x`.

### profile-methods

**Methods for Function profile in Package 'stats4'**

#### Description

Profile likelihood

#### Methods

- `fitted = "ANY"` Generic function
- `fitted = "mle"` Profile the likelihood in the vicinity of the optimum
profile.mle-class  

Class "profile.mle"; Profiling information for "mle" object

Description

Likelihood profiles along each parameter of likelihood function

Objects from the Class

Objects can be created by calls of the form new("profile.mle", ...), but most often by invoking profile on an "mle" object.

Slots

profile: Object of class "list". List of profiles, one for each requested parameter. Each profile is a data frame with the first column called \(z\) being the signed square root of the \(-2\) log likelihood ratio, and the others being the parameters with names prefixed by \(\text{par.vals}\).

summary: Object of class "summary.mle". Summary of object being profiled.

Methods

confint signature(object = "profile.mle"): Use profile to generate approximate confidence intervals for parameters.

plot signature(x = "profile.mle", y = "missing"): Plot profiles for each parameter.

See Also

mle, mle-class, summary.mle-class

show-methods  

Methods for Function show in Package 'stats4'

Description

Show objects of classes mle and summary.mle

Methods

object = "mle"  Print simple summary of mle object. Just the coefficients and the call.

object = "summary.mle"  Shows call, table of coefficients and standard errors, and \(-2\) log L
Methods for Function summary in Package 'stats4'

**Summary**

**Description**

Summarize objects

**Methods**

- `object = "ANY"` Generic function
- `object = "mle"` Generate a summary as an object of class "summary.mle", containing estimates, asymptotic SE, and value of -2 log L.

**summary.mle-class**

**Description**

Extract of "mle" object

**Objects from the Class**

Objects can be created by calls of the form `new("summary.mle", ...)`, but most often by invoking `summary` on an "mle" object. They contain values meant for printing by `show`.

**Slots**

- `call`: Object of class "language" The call that generated the "mle" object.
- `coef`: Object of class "matrix". Estimated coefficients and standard errors
- `m2logL`: Object of class "numeric". Minus twice the log likelihood.

**Methods**

- `show` signature(object = "summary.mle"): Pretty-prints object
- `coef` signature(object = "summary.mle"): Extracts the contents of the `coef` slot

**See Also**

`summary.mle, mle, mle-class`
Methods for Function 'update' in Package 'stats4'

Description
Update "mle" objects.

Usage

```r
## S4 method for signature 'mle':
update(object, ..., evaluate = TRUE)
```

Arguments
- `object`: An existing fit.
- `...`: Additional arguments to the call, or arguments with changed values. Use `name=NULL` to remove the argument `name`.
- `evaluate`: If true evaluate the new call else return the call.

Methods
- `object = "ANY"` Generic function: see `update`.
- `object = "mle"` Update a fit.

Examples
```r
x <- 0:10
y <- c(26, 17, 13, 12, 20, 5, 9, 8, 5, 4, 8)
ll <- function(ymax=15, xhalf=6)
  -sum(stats::dpois(y, lambda=ymax/(1+x/xhalf), log=TRUE))
fit <- mle(ll)
## note the recorded call contains ..1, a problem with S4 dispatch
update(fit, fixed=list(xhalf=3))
```

Methods for Function 'vcov' in Package 'stats4'

Description
Extract the approximate variance-covariance matrix from "mle" objects.

Methods
- `object = "ANY"` Generic function: see `vcov`.
- `object = "mle"` Extract the estimated variance-covariance matrix for the estimated parameters (if any).
Chapter 26

The survival package

am 

Acute Myelogenous Leukemia survival data

Description

Survival in patients with Acute Myelogenous Leukemia

Usage

am 
leukemia

Format

time: survival or censoring time
status: censoring status
x: maintenance chemotherapy given? (factor)

Source

anova.coxph

Analysis of Deviance for Cox model.

Description

Compute an analysis of deviance table for one Cox model fit.

Usage

## S3 method for class 'coxph':
anova(object, ..., test = NULL)
Arguments

object

An object of class coxph

... Further coxph objects

test

A character string, (partially) matching one of "Chisq", "F" or "Cp". See stat.anova.

Details

Specifying a single object gives a sequential analysis of deviance table for that fit. That is, the reductions in the residual deviance as each term of the formula is added in turn are given in as the rows of a table, plus the residual deviances themselves.

If more than one object is specified, the table has a row for the residual degrees of freedom and deviance for each model. For all but the first model, the change in degrees of freedom and deviance is also given. (This only make statistical sense if the models are nested.) It is conventional to list the models from smallest to largest, but this is up to the user.

The table will optionally contain test statistics (and P values) comparing the reduction in deviance for the row to the residuals. Mallows’ C_p statistic is the residual deviance plus twice the residual degrees of freedom, which is closely related to AIC. Don’t use test=F, it doesn’t make sense.

Value

An object of class "anova" inheriting from class "data.frame".

Warning

The comparison between two or more models by anova or will only be valid if they are fitted to the same dataset. This may be a problem if there are missing values.

See Also

coxph, anova.

Examples

fit <- coxph(Surv(futime, fustat) ~ resid.ds * rx + ecog.ps, data = ovarian)
anova(fit)
anova(fit,test="Chisq")
fit2 <- coxph(Surv(futime, fustat) ~ resid.ds + rx + ecog.ps, data = ovarian)
anova(fit2,fit)

as.date

Coerce Data to Dates

Description

Converts any of the following character forms to a Julian date: 8/31/56, 8-31-1956, 31 8 56, 083156, 31Aug56, or August 31 1956.
Usage

as.date(x, order = "mdy", ...)  

Arguments

x input data vector.
order if x is character, defines the order in which the terms are assumed to appear in a xx/xx/xx date. The default is month/day/year; any permutation of mdy is legal.
... if x is character, then any other arguments from mdy.date() can be used as well.

Details

If x is numeric, then floor(x) is returned, e.g., as.date(35) is the same as as.date(35.2) and gives Feb 2, 1960. If x is character, the program attempts to parse it.

Value

For each date, the number of days between it and January 1, 1960. The date will be missing if the string is not interpretable.

See Also

mdy.date, date.mmddyy, date.ddmmmyy

Examples

as.date(c("1jan1960", "2jan1960", "31mar1960", "30jul1960"))

attrassign

Create new-style "assign" attribute

Description

The "assign" attribute on model matrices describes which columns come from which terms in the model formula. It has two version. R uses the original version, but the newer version is sometimes useful.

Usage

## Default S3 method:
attrassign(object, tt,...)
## S3 method for class 'lm':
attrassign(object,...)

Arguments

object model matrix or linear model object
tt terms object
... ignored
Value

A list with names corresponding to the term names and elements that are vectors indicating which columns come from which terms.

See Also
terms, model.matrix

Examples

```r
formula <- Surv(time, status) ~ factor(edtrt)
tt <- terms(formula)
mf <- model.frame(tt, data = pbc)
mm <- model.matrix(tt, mf)
## a few rows of data
mm[1:3,]
## old-style assign attribute
attr(mm, "assign")
## new-style assign attribute
attrassign(mm, tt)
```

### bladder

**Bladder Cancer Recurrences**

Data on recurrences of bladder cancer, used by many people to demonstrate methodology for recurrent event modelling.

**Usage**

```r
bladder
bladder2
```

**Format**

**bladder**

- **id**: Patient id
- **rx**: Treatment 1=placebo 2=thiotepa
- **number**: Initial number of tumours (8=8 or more)
- **size**: size (cm) of largest initial tumour
- **stop**: recurrence or censoring time
- **enum**: which recurrence (up to 4)

**bladder2**

- **id**: Patient id
- **rx**: Treatment 1=placebo 2=thiotepa
- **number**: Initial number of tumours (8=8 or more)
- **size**: size (cm) of largest initial tumour
- **start**: start of interval (0 or previous recurrence time)
cch

stop: recurrence or censoring time
enum: which recurrence (up to 4)

Source

cch

 Fits proportional hazards regression model to case-cohort data

Description

Returns estimates and standard errors from relative risk regression fit to data from case-cohort studies. A choice is available among the Prentice, Self-Prentice and Lin-Ying methods for unstratified data. For stratified data the choice is between Borgan I, a generalization of the Self-Prentice estimator for unstratified case-cohort data, and Borgan II, a generalization of the Lin-Ying estimator.

Usage

cch(formula, data = sys.parent(), subcoh, id, stratum=NULL, cohort.size, method =c("Prentice","SelfPrentice","LinYing","I.Borgan","II.Borgan"), robust=FALSE)

Arguments

formula A formula object that must have a Surv object as the response. The Surv object must be of type "right", or of type "counting".
subcoh Vector of indicators for subjects sampled as part of the sub-cohort. Code 1 or TRUE for members of the sub-cohort, 0 or FALSE for others. If data is a data frame then subcoh may be a one-sided formula.
id Vector of unique identifiers, or formula specifying such a vector.
stratum A vector of stratum indicators or a formula specifying such a vector.
cohort.size Vector with size of each stratum original cohort from which subcohort was sampled.
data An optional data frame in which to interpret the variables occurring in the formula.
method Three procedures are available. The default method is "Prentice", with options for "SelfPrentice" or "LinYing".
robust For "LinYing" only, if robust=TRUE, use design-based standard errors even for phase I.
Details

Implements methods for case-cohort data analysis described by Therneau and Li (1999). The three methods differ in the choice of "risk sets" used to compare the covariate values of the failure with those of others at risk at the time of failure. "Prentice" uses the sub-cohort members "at risk" plus the failure if that occurs outside the sub-cohort and is score unbiased. "SelfPren" (Self-Prentice) uses just the sub-cohort members "at risk". These two have the same asymptotic variance-covariance matrix. "LinYing" (Lin-Ying) uses the all members of the sub-cohort and all failures outside the sub-cohort who are "at risk". The methods also differ in the weights given to different score contributions.

The data argument must not have missing values for any variables in the model. There must not be any censored observations outside the subcohort.

Value

An object of class "cch" incorporating a list of estimated regression coefficients and two estimates of their asymptotic variance-covariance matrix.

- coef: regression coefficients.
- naive.var: Self-Prentice model based variance-covariance matrix.
- var: Lin-Ying empirical variance-covariance matrix.

            method="I.Borgan")

summary(fit.BI)

---

clogit

*Conditional logistic regression*

**Description**

Estimates a logistic regression model by maximising the conditional likelihood. Uses a model formula of the form `case.status~exposure+strata(matched.set)`. The default is to use the exact conditional likelihood, but a commonly used approximate conditional likelihood is provided for compatibility with older software.

**Usage**

```r
clogit(formula, data, method=c("exact", "approximate"), na.action=getOption("na.
```

**Arguments**

- `formula`: Model formula
- `data`: data frame
method: correct or approximate conditional likelihood?
na.action: missing value handling
subset: subset of records to use
control: control values

Value
An object of class "clogit", which is a wrapper for a "coxph" object.

Author(s)
Thomas Lumley

See Also
strata, coxph, glm

Examples
clogit(case~spontaneous+induced+strata(stratum),data=infert)

Description
This is a special function used in the context of survival models. It identifies correlated groups of observations, and is used on the right hand side of a formula. Using cluster() in a formula implies that robust sandwich variance estimators are desired.

Usage
cluster(x)

Arguments
x: A character, factor, or numeric variable.

Value
x

coxph, Surv
Chemotherapy for Stage B/C colon cancer

Description

These are data from one of the first successful trials of adjuvant chemotherapy for colon cancer. Levamisole is a low-toxicity compound previously used to treat worm infestations in animals; 5-FU is a moderately toxic (as these things go) chemotherapy agent. There are two records per person, one for recurrence and one for death.

Usage

colon

Format

| id     | id                        |
| study  | 1 for all patients        |
| rx     | Treatment - Obs(ervation), Lev(amisole), Lev(amisole)+5-FU |
| sex    | 1=male                   |
| age    | in years                 |
| obstruct | obstruction of colon by tumour |
| perfor | perforation of colon     |
| adhere | adherence to nearby organs |
| nodes  | number of lymph nodes with detectable cancer |
| status | censoring status         |
| differ | differentiation of tumour (1=well, 2=moderate, 3=poor) |
| extent | Extent of local spread (1=submucosa, 2=muscle, 3=serosa, 4=contiguous structures) |
| surg   | time from surgery to registration (0=short, 1=long) |
| node4  | more than 4 positive lymph nodes |
| time   | days until death         |
| etype  | 1=recurrence, 2=death    |

Danyu Lin
Test the Proportional Hazards Assumption of a Cox Regression

Description

Test the proportional hazards assumption for a Cox regression model fit (coxph).

Usage

```r
cox.zph(fit, transform="km", global=TRUE)
```

Arguments

- `fit`: the result of fitting a Cox regression model, using the `coxph` function.
- `transform`: a character string specifying how the survival times should be transformed before the test is performed. Possible values are "km", "rank", "identity" or a function of one argument. The default is "km" for right-censored data and "identity" for counting-processing data.
- `global`: should a global chi-square test be done, in addition to the per-variable tests.

Value

An object of class "cox.zph", with components:

- `table`: a matrix with one row for each variable, and optionally a last row for the global test. Columns of the matrix contain the correlation coefficient between transformed survival time and the scaled Schoenfeld residuals, a chi-square, and the two-sided p-value. For the global test there is no appropriate correlation, so an NA is entered into the matrix as a placeholder.
- `x`: the transformed time axis.
- `y`: the matrix of scaled Schoenfeld residuals. There will be one column per variable and one row per event. The row labels contain the original event times (for the identity transform, these will be the same as `x`).
- `call`: the calling sequence for the routine.

The computations require the original `x` matrix of the Cox model fit. Thus it saves time if the `x=TRUE` option is used in `coxph`. This function would usually be followed by both a plot and a print of the result. The plot gives an estimate of the time-dependent coefficient `beta(t)`. If the proportional hazards assumption is true, `beta(t)` will be a horizontal line. The printout gives a test for `slope=0`.

References

See Also

- `coxph`, `Surv`
Examples

```r
fit <- coxph( Surv(futime, fustat) ~ age + rx, ovarian)
temp <- cox.zph(fit)
print(temp)  # display the results
plot(temp)   # plot curves
```

Description

Fits a Cox proportional hazards regression model. Time dependent variables, time dependent strata, multiple events per subject, and other extensions are incorporated using the counting process formulation of Andersen and Gill.

Usage

```r
coxph(formula, data=parent.frame(), weights, subset,
      na.action, init, control, method=c("efron","breslow","exact"),
      singular.ok=TRUE, robust=FALSE,
      model=FALSE, x=FALSE, y=TRUE,...
)
```

Arguments

- **formula**: a formula object, with the response on the left of a `~` operator, and the terms on the right. The response must be a survival object as returned by the `Surv` function.
- **data**: a data.frame in which to interpret the variables named in the formula, or in the subset and the weights argument.
- **subset**: expression saying that only a subset of the rows of the data should be used in the fit.
- **na.action**: a missing-data filter function, applied to the model.frame, after any subset argument has been used. Default is `options()$na.action`.
- **weights**: case weights.
- **init**: vector of initial values of the iteration. Default initial value is zero for all variables.
- **control**: Object of class `coxph.control` specifying iteration limit and other control options. Default is `coxph.control(...)`.  
- **method**: a character string specifying the method for tie handling. If there are no tied death times all the methods are equivalent. Nearly all Cox regression programs use the Breslow method by default, but not this one. The Efron approximation is used as the default here, as it is much more accurate when dealing with tied death times, and is as efficient computationally. The exact method computes the exact partial likelihood, which is equivalent to a conditional logistic model. If there are a large number of ties the computational time will be excessive.
singular.ok

logical value indicating how to handle collinearity in the model matrix. If TRUE, the program will automatically skip over columns of the X matrix that are linear combinations of earlier columns. In this case the coefficients for such columns will be NA, and the variance matrix will contain zeros. For ancillary calculations, such as the linear predictor, the missing coefficients are treated as zeros.

robust

if TRUE a robust variance estimate is returned. Default is TRUE if the model includes a cluster() operative, FALSE otherwise.

model

flags to control what is returned. If these are true, then the model frame, the model matrix, and/or the response is returned as components of the fitted model, with the same names as the flag arguments.

x

Return the design matrix in the model object?

y

return the response in the model object?

... Other arguments will be passed to coxph.control

Details

The proportional hazards model is usually expressed in terms of a single survival time value for each person, with possible censoring. Andersen and Gill reformulated the same problem as a counting process; as time marches onward we observe the events for a subject, rather like watching a Geiger counter. The data for a subject is presented as multiple rows or "observations", each of which applies to an interval of observation [start, stop].

Value

an object of class "coxph". See coxph.object for details.

Side Effects

Depending on the call, the predict, residuals, and survfit routines may need to reconstruct the x matrix created by coxph. Differences in the environment, such as which data frames are attached or the value of options()$contrasts, may cause this computation to fail or worse, to be incorrect. See the survival overview document for details.

SPECIAL TERMS

There are two special terms that may be used in the model equation. A 'strata' term identifies a stratified Cox model; separate baseline hazard functions are fit for each strata. The cluster term is used to compute a robust variance for the model. The term + cluster(id), where id == unique(id), is equivalent to specifying the robust=T argument, and produces an approximate jackknife estimate of the variance. If the id variable were not unique, but instead identifies clusters of correlated observations, then the variance estimate is based on a grouped jackknife.

CONVERGENCE

In certain data cases the actual MLE estimate of a coefficient is infinity, e.g., a dichotomous variable where one of the groups has no events. When this happens the associated coefficient grows at a steady pace and a race condition will exist in the fitting routine: either the log likelihood converges, the information matrix becomes effectively singular, an argument to exp becomes too large for the computer hardware, or the maximum number of interactions is exceeded. The routine attempts to detect when this has happened, not always successfully.
PENALISED REGRESSION

`coxph` can now maximise a penalised partial likelihood with arbitrary user-defined penalty. Supplied penalty functions include ridge regression (`ridge`), smoothing splines (`pspline`), and frailty models (`frailty`).

References

`cluster`, `survfit`, `Surv`, `strata`, `ridge`, `pspline`, `frailty`.

Examples

```r
# Create the simplest test data set
#
test1 <- list(time= c(4, 3,1,1,2,2,3),
              status=c(1,NA,1,0,1,1,0),
              x= c(0, 2,1,1,0,0),
              sex= c(0, 0,0,0,1,1))
coxph( Surv(time, status) ~ x + strata(sex), test1) #stratified model

# # Create a simple data set for a time-dependent model
#
test2 <- list(start=c(1, 2, 5, 2, 1, 7, 3, 4, 8, 8),
              stop =c(2, 3, 6, 7, 8, 9, 9, 9,14,17),
              event=c(1, 1, 1, 1, 1, 1, 0, 0, 0, 0),
              x =c(1, 0, 0, 0, 1, 1, 1, 0, 0 ) )
summary( coxph( Surv(start, stop, event) ~ x, test2))
```

details of a Cox Model Fit

Description

Details of a Cox model fit. Returns the individual contributions to the first and second derivative matrix, at each unique event time.

Usage

`coxph.detail(object)`

Arguments

`object` a Cox model object, i.e., the result of `coxph`.
Details

This function may be useful for those who wish to investigate new methods or extensions to the Cox model. The example below shows one way to calculate the Schoenfeld residuals.

Value

a list with components

- **time**: the vector of unique event times
- **n.event**: the number of events at each of these time points.
- **means**: a matrix with one row for each event time and one column for each variable in the Cox model, containing the weighted mean of the variable at that time, over all subjects still at risk at that time. The weights are the risk weights \( \exp(x \* \% \% fit$\text{coef}) \).
- **n.risk**: number of subjects at risk.
- **hazard**: the hazard increment.
- **score**: the contribution to the score vector (first derivative of the log partial likelihood) at each time point.
- **imat**: the contribution to the information matrix (second derivative of the log partial likelihood) at each time point.
- **var.haz**: the variance of the hazard increment.
- **x,y**: copies of the input data.
- **strata**: only present for a stratified Cox model, this is a table giving the number of time points of component **time** that were contributed by each of the strata.

See Also

- **coxph.residuals.coxph**

Examples

```r
fit <- coxph(Surv(futime,fustat) ~ age + rx + ecog.ps, ovarian, x=TRUE)
fitd <- coxph.detail(fit)
events <- fit$y[,2]==1
etime <- fit$y[events,1]  #the event times --- may have duplicates
indx <- match(etime, fitd$time)
sresid <- fit$x[events,] - fitd$means[indx,]
```

---

**Description**

This class of objects is returned by the `coxph` class of functions to represent a fitted proportional hazards model.

Objects of this class have methods for the functions `print`, `summary`, `residuals`, `predict` and `survfit`. 
COMPONENTS

The following components must be included in a legitimate coxph object.

coefficients the coefficients of the linear predictor, which multiply the columns of the model matrix. If the model is over-determined there will be missing values in the vector corresponding to the redundant columns in the model matrix.

var the variance matrix of the coefficients. Rows and columns corresponding to any missing coefficients are set to zero.

naive.var this component will be present only if the robust option was true. If so, the var component will contain the robust estimate of variance, and this component will contain the ordinary estimate.

loglik a vector of length 2 containing the log-likelihood with the initial values and with the final values of the coefficients.

score value of the efficient score test, at the initial value of the coefficients.

rscore the robust log-rank statistic, if a robust variance was requested.

wald.test the Wald test of whether the final coefficients differ from the initial values.

iter number of iterations used.

linear.predictors the vector of linear predictors, one per subject.

residuals the martingale residuals.

means vector of column means of the X matrix. Subsequent survival curves are adjusted to this value.

n the number of observations used in the fit.

weights the vector of case weights, if one was used.

method the computation method used.

na.action the na.action attribute, if any, that was returned by the na.action routine.

The object will also contain the following, for documentation see the lm object: terms, assign, formula, call, and, optionally, x, y, and/or frame.

date.ddmmmyy  Format a Julian date

Description

Given a vector of Julian dates, this returns them in the form “10Nov89”, “28Jul54”, etc.

Usage

date.ddmmmyy(sdate)

Arguments

sdate A vector of Julian dates, e.g., as returned by mdy.date().
Value
A vector of character strings containing the formatted dates.

See Also
mdy.date, date.mdy

Examples
date.ddmmmyy(1:10)

date.mdy  Convert from Julian Dates to Month, Day, and Year

Description
Convert a vector of Julian dates to a list of vectors with the corresponding values of month, day and year, and optionally weekday.

Usage
date.mdy(sdate, weekday = FALSE)

Arguments
sdate  a Julian date value, as returned by mdy.date(), number of days since 1/1/1960.
weekday  if TRUE, then the returned list also will contain the day of the week (Sunday=1, Saturday=7).

Value
A list with components month, day, and year.

References

Examples
day <- 7
temp <- date.mdy(mdy.date(month = 7, day = day, year = 1960))
## Check for illegal dates, such as 29 Feb in a non leap year
if (temp$day != day) {
  cat("Some illegal dates\n")
} else {
  cat("All days are legal\n")
}
**date.mmddyy**  
*Format a Julian date*

**Description**  
Given a vector of Julian dates, this returns them in the form “10/11/89”, “28/7/54”, etc.

**Usage**  
```r
date.mmddyy(sdate, sep = "/")
```

**Arguments**  
- **sdate**: A vector of Julian dates, e.g., as returned by `mdy.date()`.
- **sep**: Character string used to separate the month, day, and year portions of the returned string.

**Value**  
A vector of character strings containing the formatted dates.

**See Also**  
`date.mdy`, `mdy.date`, `date.ddmmmyy`

**Examples**  
```r
date.mmddyy(as.date(10))
```

---

**date.mmddyyyy**  
*Format a Julian date*

**Description**  
Given a vector of Julian dates, this returns them in the form “10/11/1989”, “28/7/1854”, etc.

**Usage**  
```r
date.mmddyyyy(sdate, sep = "/")
```

**Arguments**  
- **sdate**: A vector of Julian dates, e.g., as returned by `mdy.date()`.
- **sep**: Character string used to separate the month, day, and year portions of the returned string.

**Value**  
A vector of character strings containing the formatted dates.
See Also

date.mdy, mdy.date, date.ddmmyy

Examples

date.mmddyyyy(as.date(1:10))

Date Objects

Description

Objects of class "date".

Usage

is.date(x)

Arguments

x any R object.

Details

Dates are stored as the number of days since 1/1/1960, and are kept in integer format. (This is the
same baseline value as is used by SAS). The numerical methods for dates treat date - date as
a numeric, and date +- numeric as a date.

is.date returns TRUE if x has class "date", and FALSE otherwise. Its behavior is unaf-
fected by any attributes of x; for example, x could be a date array (in contrast to the behavior of
is.vector).

as.date returns x if x is a simple object of class "date", and otherwise a date vector of the
same length as x and with data resulting from coercing the elements of x to class "date". See the
manual page for as.date() for details.

Logical operations as well as the numeric functions exp(), log(), and so on are invalid.

Other methods exist for missing value, as.character(), printing, and summarizing.

See Also

date.mdy, mdy.date, date.ddmmyy, as.date.
Description

When included in a \texttt{coxph} or \texttt{survreg}, fits by penalised likelihood a random effects (frailty) model. \texttt{frailty} is generic, with methods for \texttt{t}, Gaussian and Gamma distributions.

Usage

\begin{verbatim}
frailty(x, distribution="gamma", ...)  
frailty.gamma(x, sparse = (nclass > 5), theta, df, eps = 1e-05, method = c("em"),  
frailty.gaussian(x, sparse = (nclass > 5), theta, df, method = c("reml","aic", ...)  
frailty.t(x, sparse = (nclass > 5), theta, df, eps = 1e-05, tdf = 5,method = c(")
\end{verbatim}

Arguments

- \textit{x} group indicator
- \textit{distribution} frailty distribution
- \ldots Arguments for specific distribution, including (but not limited to)
- \textit{sparse} Use sparse Newton-Raphson algorithm
- \textit{df} Approximate degrees of freedom
- \textit{theta} Penalty
- \textit{eps} Accuracy of \textit{df}
- \textit{method} maximisation algorithm
- \textit{tdf} df of t-distribution

Details

The penalised likelihood method is equivalent to maximum (partial) likelihood for the gamma frailty but not for the others.

The sparse algorithm uses the diagonal of the information matrix for the random effects, which saves a lot of space.

The frailty distributions are really the log-t and lognormal: $t$ and Gaussian are random effects on the scale of the linear predictor.

Value

An object of class \texttt{coxph.penalty} containing a factor with attributes specifying the control functions.

References

\texttt{coxph,survreg,ridge,pspline}
Examples

```r
kfit <- coxph(Surv(time, status) ~ age + sex + disease + frailty(id), kidney)
kfit0 <- coxph(Surv(time, status) ~ age + sex + disease, kidney)
kfitm1 <- coxph(Surv(time, status) ~ age + sex + disease +
    frailty(id, dist='gauss'), kidney)
coxph(Surv(time, status) ~ age + sex + frailty(id, dist='gauss', method='aic', caic=TRUE),
    # uncorrected aic
coxph(Surv(time, status) ~ age + sex + frailty(id, method='aic', caic=FALSE), kidney)
rfit2a <- survreg(Surv(time, status) ~ rx +
    frailty.gaussian(litter, df=13, sparse=FALSE), rats )
rfit2b <- survreg(Surv(time, status) ~ rx +
    frailty.gaussian(litter, df=13, sparse=TRUE), rats )
rfit2a
rfit2b
```

heart  

Stanford Heart Transplant data

Description

Survival of patients on the waiting list for the Stanford heart transplant program.

Usage

heart
jasa
jasa1

Format

jasa: original data

birth.dt: birth date
accept.dt: acceptance into program
tx.date: transplant date
fu.date: end of followup
fustat: dead or alive
surgery: prior bypass surgery
age: age (in days)
futime: followup time
wait.time: time before transplant
transplant: transplant indicator
mismatch: mismatch score
hla.a2: particular type of mismatch
mscore: another mismatch score
reject: rejection occurred

jasa1, heart: processed data

start, stop, event: Entry and exit time and status for this interval of time
age: age-48 years
is.ratetable  

year: year of acceptance (in years after 1 Nov 1967)
surgery: prior bypass surgery 1=yes
transplant: received transplant 1=yes
id: patient id

is.ratetable  

Verify that an Object is of Class 'ratetable'

Description

The function verifies not only the class attribute, but the structure of the object.

Usage

is.ratetable(x, verbose=FALSE)

Arguments

x the object to be verified.
verbose if TRUE and the object is not a ratetable, then return a character string describing the way(s) in which x fails to be a proper ratetable object.

Details

Rate tables are used by the pyears and survexp functions, and normally contain death rates for some population, categorized by age, sex, or other variables. They have a fairly rigid structure, and the verbose option can help in creating a new rate table.

Value

returns TRUE if x is a ratetable, and FALSE or a description if it is not.

See Also

pyears, survexp

Examples

is.ratetable(survexp.us)  ##Yes
is.ratetable(cancer)  ##No
Kidney data from survival5

Description

Data on the recurrence times to infection, at the point of insertion of the catheter, for kidney patients using portable dialysis equipment. Catheters may be removed for reasons other than infection, in which case the observation is censored. Each patient has exactly 2 observations.

Format

patient: id
time: time
status: event status
age: in years
sex: 1=male, 2=female
disease: disease type (0=GN, 1=AN, 2=PKD, 3=Other)
frail: frailty estimate from original paper

Note

The original analysis had incorrect handling of ties and so is not exactly reproduced by survival.

Source

Examples

kfit <- coxph(Surv(time, status) ~ age + sex + disease + frailty(id), kidney)
kfit0 <- coxph(Surv(time, status) ~ age + sex + disease, kidney)
kfitm1 <- coxph(Surv(time, status) ~ age + sex + disease + frailty(id, dist='gauss'), kidney)

lines.survfit

Add Lines or Points to a Survival Plot

Description

Often used to add the expected survival curve(s) to a Kaplan-Meier plot generated with plot.survfit.
### lines.survfit

#### Usage

```r
## S3 method for class 'survfit':
lines(x, type="s", mark=3, col=1, lty=1,
     lwd=1, mark.time=TRUE , xscale=1, firstx=0, firsty=1, xmax, fun, conf.int=FALSE,
## S3 method for class 'survfit':
points(x, ...)
```

#### Arguments

- `x`  
a survival object, generated from the `survfit` or `survexp` functions.
- `type`  
the line type, as described in `lines`. The default is a step function for `survfit` objects, and a connected line for `survexp` objects.
- `mark`  
vectors giving the mark symbol, color, line type and line width for the added curves.
- `mark.time`  
controls the labeling of the curves. If `FALSE`, no labeling is done. If `TRUE`, then curves are marked at each censoring time. If `mark.time` is a numeric vector, then curves are marked at the specified time points.
- `xscale`  
a number used to divide the x values. If time was originally in days, a value of 365.24 would give a plotted scale in years.
- `firstx`, `firsty`  
the starting point for the survival curves. If either of these is set to `NA` or `<blank>`, the plot will start at the first time point of the curve.
- `col`, `lty`, `lwd`, ...
  passed to `lines`
- `xmax`  
the maximum horizontal plot coordinate. This shortens the curve before plotting it, so unlike using the `xlim` graphical parameter, warning messages about out of bounds points are not generated.
- `fun`  
an arbitrary function defining a transformation of the survival curve. For example `fun=log` is an alternative way to draw a log-survival curve (but with the axis labeled with log(S) values). Four often used transformations can be specified with a character argument instead: "log" is the same as using the `log=T` option, "event" plots cumulative events (f(y) =1-y), "cumhaz" plots the cumulative hazard function (f(y) = -log(y)) and "cloglog" creates a complementary log-log survival plot (f(y) = log(-log(y)) along with log scale for the x-axis).
- `conf.int`  
if `TRUE`, confidence bands for the curves are also plotted. If set to "only", then only the CI bands are plotted, and the curve itself is left off. This can be useful for fine control over the colors or line types of a plot.

#### Value

a list with components `x` and `y`, containing the coordinates of the last point on each of the curves (but not of the confidence limits). This may be useful for labeling.

#### Side Effects

one or more curves are added to the current plot.

#### See Also

`lines`, `par`, `plot.survfit`, `survfit`, `survexp`
Examples

```r
fit <- survfit(Surv(time, status) ~ sex, pbc, subset=1:312)
plot(fit, mark.time=FALSE, xscale=365.24, xlab='Years', ylab='Survival')
lines(fit[1], lwd=2, xscale=365.24)  # darken the first curve and add marks

# add expected survival curves for the two groups,
# based on the US census data
tdata <- data.frame(age=pbc$age *365.24, sex=pbc$sex +1,
                    year= rep(mdy.date(1,1,1976), nrow(pbc)))
tdata<-tdata[1:312,] ## only the randomised people, with no missing data
efit <- survexp(~ sex+ratetable(sex=sex,age=age,year=year), data=tdata, ratetable=survexp)
temp <- lines(efit, lty=2, xscale=365.24, lwd=2:1)
text(temp, c("Male", "Female"), adj= -.1) # labels just past the ends
title(main="Primary Biliary Cirrhosis, Observed and Expected")
```

---

**lung**

*Mayo Clinic Lung Cancer Data*

**Description**

Survival in patients with lung cancer at Mayo Clinic. Performance scores rate how well the patient can perform usual daily activities.

**Usage**

```r
lung
cancer
```

**Format**

- `inst`: Institution code
- `time`: Survival time in days
- `status`: censoring status 1=censored, 2=dead
- `age`: Age in years
- `sex`: Male=1 Female=2
- `ph.ecog`: ECOG performance score (0=good 5=dead)
- `ph.karno`: Karnofsky performance score (bad=0-good=100) rated by physician
- `pat.karno`: Karnofsky performance score rated by patient
- `meal.cal`: Calories consumed at meals
- `wt.loss`: Weight loss in last six months

**Source**

Terry Therneau
**mdy.date**

Convert to Julian Dates

**Description**

Given a month, day, and year, returns the number of days since January 1, 1960.

**Usage**

```r
mdy.date(month, day, year, nineteen = TRUE, fillday = FALSE, fillmonth = FALSE)
```

**Arguments**

- `month`: vector of months.
- `day`: vector of days.
- `year`: vector of years.
- `nineteen`: if `TRUE`, year values between 0 and 99 are assumed to be in the 20th century A.D.; otherwise, if `FALSE`, they are assumed to be in the 1st century A.D.
- `fillday`: if `TRUE`, then missing days are replaced with 15.
- `fillmonth`: if `TRUE`, then a missing month causes the month and day to be set to 7/1.

**Details**

The date functions are particularly useful in computing time spans, such as number of days on test, and similar functions can be found in other statistical packages. The baseline date of Jan 1, 1960 is, of course, completely arbitrary (it is the same one used by SAS).

The `fillday` and `fillmonth` options are perhaps useful only to the author and a very few others: we sometimes deal with patients whose birth date was in the 1800’s, and only the month or even only the year is known. When the interval is greater than 80 years, a filler seems defensible.

**Value**

A vector of Julian dates.

**References**

**See Also**

date.mmddyy, date.ddmmmyy, date.mmddyyyy

**Examples**

```r
mdy.date(3, 10, 53)
xzt <- 1:10
xzy <- as.date(xzt)
test <- data.frame(x = xzt, date = xzy)
summary(test)
```
Data from the National Wilm’s Tumor Study

Description

Missing data/measurement error example. Tumor histology predicts survival, but prediction is stronger with central lab histology than with the local institution determination.

Usage

nwtco

Format

A data frame with 4028 observations on the following 9 variables.

- seqno  id number
- instit  Histology from local institution
- histol  Histology from central lab
- stage  Disease stage
- study  study
- rel  indicator for relapse
- edrel  time to relapse
- age  age in months
- in.subcohort  Included in the subcohort for the example in the paper

plot.cox.zph  

*Graphical Test of Proportional Hazards*

Description

Displays a graph of the scaled Schoenfeld residuals, along with a smooth curve.

Usage

```r
## S3 method for class 'cox.zph':
plot(x, resid=TRUE, se=TRUE, df=4, nsmo=40, var, ...)
```

Arguments

- `x`  
  result of the `cox.zph` function.

- `resid`  
  a logical value, if `TRUE` the residuals are included on the plot, as well as the smooth fit.

- `se`  
  a logical value, if `TRUE`, confidence bands at two standard errors will be added.

- `df`  
  the degrees of freedom for the fitted natural spline, `df=2` leads to a linear fit.

**plot.survfit**

### Description

A plot of survival curves is produced, one curve for each strata. The `log=T` option does extra work to avoid log(0), and to try to create a pleasing result. If there are zeros, they are plotted by default at 0.8 times the smallest non-zero value on the curve(s).

If `legend.text` is supplied a legend is created.

### Usage

```r
## S3 method for class 'survfit':
plot(x, conf.int=, mark.time=TRUE,
     mark=3, col=1, lty=1, lwd=1, cex=1, log=FALSE, xscale=1, yscale=1,
     firstx=0, firsty=1, xmax, ymin=0, fun,
     xlab="", ylab="", xaxs="S", bty=NULL,
     legend.text=NULL, legend.pos=0,legend.bty="n",main=NULL,...)
```

### Examples

```r
vfit <- coxph(Surv(time,status) ~ trt + factor(celltype) +
               karno + age, data=veteran, x=TRUE)
temp <- cox.zph(vfit)
plot(temp, var=5)  # Look at Karnofsy score, old way of doing plot
plot(temp[5])     # New way with subscripting
abline(0, 0, lty=3)
# Add the linear fit as well
abline(lm(temp$y[,5] ~ temp$x)$coefficients, lty=4, col=3)
title(main="VA Lung Study")
```

---

**Side Effects**

A plot is produced on the current graphics device.

**See Also**

`cox.zph, coxph`

---

The set of variables for which plots are desired. By default, plots are produced in turn for each variable of a model. Selection of a single variable allows other features to be added to the plot, e.g., a horizontal line at zero or a main title. This has been superseded by a subscripting method; see the example below.

Additional arguments passed to the `plot` function.
Arguments

x
an object of class `survfit`, usually returned by the `survfit` function.

conf.int
determines whether confidence intervals will be plotted. The default is to do so if there is only 1 curve, i.e., no strata.

mark.time
controls the labeling of the curves. If set to `FALSE`, no labeling is done. If `TRUE`, then curves are marked at each censoring time which is not also a death time. If `mark.time` is a numeric vector, then curves are marked at the specified time points.

mark
vector of mark parameters, which will be used to label the curves. The `lines` help file contains examples of the possible marks. The vector is reused cyclically if it is shorter than the number of curves.

col
a vector of integers specifying colors for each curve. The default value is 1.

lty
a vector of integers specifying line types for each curve. The default value is 1.

lwd
a vector of numeric values for line widths. The default value is 1.

cex
a numeric value specifying the size of the marks. Not a vector; all marks have the same size.

log
a logical value, if `TRUE` the y axis will be on a log scale. Alternately, one of the standard character strings "x", "y", or "xy" can be given to specific logarithmic horizontal and/or vertical axes.

xscale
scale the x-axis values before plotting. If time were in days, then a value of 365.25 will give labels in years instead of the original days.

yscale
will be used to multiply the labels on the y axis. A value of 100, for instance, would be used to give a percent scale. Only the labels are changed, not the actual plot coordinates, so that adding a curve with "lines(surv.exp(...{}))", say, will perform as it did without the `yscale` argument.

firstx,firsty
the starting point for the survival curves. If either of these is set to `NA` the plot will start at the first time point of the curve.

xmax
the maximum horizontal plot coordinate. This can be used to shrink the range of a plot. It shortens the curve before plotting it, so that unlike using the `xlim` graphical parameter, warning messages about out of bounds points are not generated.

ymin
lower boundary for y values. Survival curves are most often drawn in the range of 0-1, even if none of the curves approach zero. The parameter is ignored if the `fun` argument is present, or if it has been set to `NA`.

fun
an arbitrary function defining a transformation of the survival curve. For example `fun=log` is an alternative way to draw a log-survival curve (but with the axis labeled with log(S) values), and `fun=sqrt` would generate a curve on square root scale. Four often used transformations can be specified with a character argument instead: "log" is the same as using the `log=T` option, "event" plots cumulative events (f(y) = 1-y), "cumhaz" plots the cumulative hazard function (f(y) = -log(y)), and "cloglog" creates a complimentary log-log survival plot (f(y) = log(-log(y)) along with log scale for the x-axis).

xlab
label given to the x-axis.

ylab
label given to the y-axis.
xaxis  either "S" for a survival curve or a standard x axis style as listed in `par`. Survival curves are usually displayed with the curve touching the y-axis, but not touching the bounding box of the plot on the other 3 sides. Type "S" accomplishes this by manipulating the plot range and then using the "i" style internally.

bty  see `par`

legend.pos  position for the legend: a vector of length 2, or 0 to put the legend in the lower left, 1 to put it in the upper right. These may not work well with transformed curves.

legend.bty  Box type, see `legend`

legend.text  Text for legend, see `legend`

main  Plot title

...  other graphical parameters

Value

a list with components `x` and `y`, containing the coordinates of the last point on each of the curves (but not the confidence limits). This may be useful for labeling.

BUGS

Survival curve objects created from a `coxph` model does not include the censoring times. Therefore, specifying `mark.time=T` does not work. If you want to mark censoring times on the curve(s) resulting from a `coxph` fit, provide a vector of times as the `mark.time` argument in the call to `plot.survfit` or `lines.survfit`.

See Also

`par`, `survfit`, `lines.survfit`, `legend`.

Examples

```r
leukemia.surv <- survfit(Surv(time, status) ~ x, data = aml)
plot(leukemia.surv, lty = 2:3)
legend(100, .9, c("Maintenance", "No Maintenance"), lty = 2:3)
title("Kaplan-Meier Curves for AML Maintenance Study")

lsurv2 <- survfit(Surv(time, status) ~ x, aml, type='fleming')
plot(lsurv2, lty=2:3, fun="cumhaz",
     xlab="Months", ylab="Cumulative Hazard")

plot(leukemia.surv,lty=1:2,legend.pos=0,col=c("Red","Blue"),legend.text=c("Maintenance", "No Maintenance"))
if (interactive()){
cat("Click on the graphics device to place a legend\n")
plot(leukemia.surv,lty=2:3,legend.pos=locator(1),legend.text=c("Maintenance", "No Maintenance"))
}
```
predict.coxph

Predictions for Cox model

Description

Compute fitted values and regression terms for a model fitted by `coxph`

Usage

```r
## S3 method for class 'coxph':
predict(object, newdata, type=c("lp", "risk", "expected", "terms"), se.fit=FALSE, terms=names(object$assign), collapse, safe=FALSE,...)
```

Arguments

- `object`: A `coxph` object
- `newdata`: Optional new data to predict at
- `type`: Type of prediction wanted
- `se.fit`: Return standard errors as well?
- `terms`: If `type="terms"`, which terms to return.
- `collapse`: Identifier for which rows correspond to different individuals
- `safe`: Use a more intensive ‘safe’ prediction method
- `...`: Other unused arguments

Value

A vector or matrix of fitted values. If `se.fit=TRUE` a list whose first component is the fitted values and second is the standard errors.

See Also

`predict`, `coxph`, `termplot`

Examples

```r
fit<-coxph(Surv(time,status)~x, data=aml)
predict(fit,type="lp")
predict(fit,type="risk")
predict(fit,type="expected")
predict(fit,type="terms")
predict(fit,type="lp", se.fit=TRUE)
predict(fit,type="risk", se.fit=TRUE)
predict(fit,type="expected", se.fit=TRUE)
predict(fit,type="terms", se.fit=TRUE)
```
**predict.survreg**

**Predicted Values for a ‘survreg’ Object**

**Description**

Predicted values for a `survreg` object

**Usage**

```
## S3 method for class 'survreg':
predict(object, newdata,
type=c("response", "link", "lp", "linear", "terms", "quantile",
"uquantile"),
se.fit=FALSE, terms=NULL, p=c(0.1, 0.9),...)
```

**Arguments**

- **object**: result of a model fit using the `survreg` function.
- **newdata**: data for prediction. If absent, predictions are for the subjects used in the original fit.
- **type**: the type of predicted value. This can be on the original scale of the data (response), the linear predictor ("linear", with "lp" as an allowed abbreviation), a predicted quantile on the original scale of the data ("quantile"), a quantile on the linear predictor scale ("uquantile"), or the matrix of terms for the linear predictor ("terms"). At this time "link" and linear predictor ("lp") are identical.
- **se.fit**: if TRUE, include the standard errors of the prediction in the result.
- **terms**: subset of terms. The default for residual type "terms" is a matrix with one column for every term (excluding the intercept) in the model.
- **p**: vector of percentiles. This is used only for quantile predictions.
- **...**: other arguments

**Value**

A vector or matrix of predicted values.

**References**

**See Also**

`survreg`, `residuals.survreg`
Examples

```r
# Draw figure 1 from Escobar and Meeker
fit <- survreg(Surv(time,status) ~ age + age^2, data=stanford2, 
               dist='lognormal')
plot(stanford2$age, stanford2$time, xlab='Age', ylab='Days', 
     xlim=c(0,65), ylim=c(.01, 10^6), log='y')
pred <- predict(fit, newdata=list(age=1:65), type='quantile', 
                 p=c(.1, .5, .9))
matlines(1:65, pred, lty=c(2,1,2), col=1)
```

print.survfit

Print a Short Summary of a Survival Curve

Description

Print number of observations, number of events, the restricted mean survival and its standard error, and the median survival with confidence limits for the median.

Usage

```r
## S3 method for class 'survfit':
print(x, scale=1,digits = max(options()$digits - 4, 
3), print.n=getOption("survfit.print.n"), show.rmean=getOption("survfit.print.mean"),...)
```

Arguments

- `x` the result of a call to the `survfit` function.
- `print.n` What to use for number of subjects (see below)
- `digits` Number of digits to print
- `scale` a numeric value to rescale the survival time, e.g., if the input data to `survfit` were in days, `scale=365` would scale the printout to years.
- `show.rmean` Show the restricted mean survival?
- `...` other unused arguments

Details

The restricted mean (\(rmean\)) and its standard error \(se(rmean)\) are based on a truncated estimator. If the last observation(s) is not a death, then the survival curve estimate does not go to zero and the mean survival time cannot be estimated. Instead, the quantity reported is the mean of survival restricted to the time before the last censoring. When the last censoring time is not random this quantity is occasionally of interest.

Any randomness in the last censoring time is not taken into account in computing the standard error of the restricted mean. The restricted mean is available mainly for compatibility with S, and is not shown by default.

The median and its confidence interval are defined by drawing a horizontal line at 0.5 on the plot of the survival curve and its confidence bands. The intersection of the line with the lower CI band defines the lower limit for the median's interval, and similarly for the upper band. If any of the intersections is not a point, then we use the smallest point of intersection, e.g., if the survival curve were exactly equal to 0.5 over an interval.
The "number of observations" is not well-defined for counting process data. Previous versions of this code used the number at risk at the first time point. This is misleading if many individuals enter late or change strata. The original S code for the current version uses the number of records, which is misleading when the counting process data actually represent a fixed cohort with time-dependent covariates.

Four possibilities are provided, controlled by `print.n` or by `options(survfit.print.n)`:
- "none" prints NA,
- "records" prints the number of records,
- "start" prints the number at the first time point and
- "max" prints the maximum number at risk. The initial default is "start".

### Value

- `x`, with the invisible flag set.

### Side Effects

The number of observations (see Details), the number of events, the median survival with its confidence interval, and optionally the restricted mean survival (rmean) and its standard error, are printed. If there are multiple curves, there is one line of output for each.

### See Also

- `summary.survfit`
- `survfit.object`
- `survfit`

### Examples

```r
## effect of print.n and show.rmean
a <- coxph(Surv(start, stop, event) ~ age + strata(transplant), data=heart)
b <- survfit(a)
print(b, print.n="none")
print(b, print.n="records")
print(b, print.n="start")
print(b, print.n="max")
print(b, show.rmean=TRUE)
```

---

**pspline**

---

**Penalised smoothing splines**

### Description

Specifies a penalised spline basis for the predictor. This is done by fitting a comparatively small set of splines and penalising the integrated second derivative. Results are similar to smoothing splines with a knot at each data point but computationally simpler.

### Usage

```r
pspline(x, df=4, theta, nterm=2.5 * df, degree=3, eps=0.1, method, ...)
```
Arguments

- `x`: predictor
- `df`: approximate degrees of freedom. `df=0` means use AIC
- `theta`: roughness penalty
- `nterm`: number of splines in the basis
- `degree`: degree of splines
- `eps`: accuracy for `df`
- `method`: Method for automatic choice of `theta`
- ...: I don’t know what this does

Value

Object of class `coxph.penalty` containing the spline basis with attributes specifying control functions.

coxph, survreg, ridge, frailty

Examples

```r
lfit6 <- survreg(Surv(time, status)~pspline(age, df=2), cancer)
plot(cancer$age, predict(lfit6), xlab='Age', ylab='Spline prediction')
title("Cancer Data")
fit0 <- coxph(Surv(time, status) ~ ph.ecog + age, cancer)
fit1 <- coxph(Surv(time, status) ~ ph.ecog + pspline(age,3), cancer)
fit3 <- coxph(Surv(time, status) ~ ph.ecog + pspline(age,8), cancer)
fit0
fit1
fit3
```

Description

This function computes the person-years of follow-up time contributed by a cohort of subjects, stratified into subgroups. It also computes the number of subjects who contribute to each cell of the output table, and optionally the number of events and/or expected number of events in each cell.

Usage

```r
pyears(formula, data, weights, subset, na.action, ratetable=survexp.us, scale=365.25, expect=c('event', 'pyears'), model=FALSE, x=FALSE, y=FALSE)
```
Arguments

- **formula**: a formula object. The response variable will be a vector of follow-up times for each subject, or a `Surv` object containing the follow-up time and an event indicator. The predictors consist of optional grouping variables separated by `+` operators (exactly as in `survfit`), time-dependent grouping variables such as age (specified with `tcut`), and optionally a `ratetable()` term. This latter matches each subject to his/her expected cohort.

- **data**: a data frame in which to interpret the variables named in the formula, or in the subset and the weights argument.

- **weights**: case weights.

- **subset**: expression saying that only a subset of the rows of the data should be used in the fit.

- **na.action**: a missing-data filter function, applied to the model.frame, after any subset argument has been used. Default is `options()$na.action`.

- **ratetable**: a table of event rates, such as `survexp.uswhite`.

- **scale**: a scaling for the results. As most rate tables are in units/day, the default value of 365.25 causes the output to be reported in years.

- **expect**: should the output table include the expected number of events, or the expected number of person-years of observation. This is only valid with a rate table.

- **model, x, y**: If any of these is true, then the model frame, the model matrix, and/or the vector of response times will be returned as components of the final result.

Details

Because `pyears` may have several time variables, it is necessary that all of them be in the same units. For instance, in the call `py <- pyears(futime rx + ratetable(age=age, sex=sex, year=entry.dt))` with a `ratetable` whose natural unit is days, it is important that `futime`, `age` and `entry.dt` all be in days. Given the wide range of possible inputs, it is difficult for the routine to do sanity checks of this aspect.

A special function `tcut` is needed to specify time-dependent cutpoints. For instance, assume that age is in years, and that the desired final arrays have as one of their margins the age groups 0-2, 2-10, 10-25, and 25+. A subject who enters the study at age 4 and remains under observation for 10 years will contribute follow-up time to both the 2-10 and 10-25 subsets. If `cut(age, c(0,2,10,25,100))` were used in the formula, the subject would be classified according to his starting age only. The `tcut` function has the same arguments as `cut`, but produces a different output object which allows the `pyears` function to correctly track the subject.

The results of `pyears` are normally used as input to further calculations. The example below is from a study of hip fracture rates from 1930 - 1990 in Rochester, Minnesota. Survival post hip fracture has increased over that time, but so has the survival of elderly subjects in the population at large. A model of relative survival helps to clarify what has happened: Poisson regression is used, but replacing exposure time with expected exposure (for an age and sex matched control). Death rates change with age, of course, so the result is carved into 1 year increments of time. Males and females were done separately.

Value

A list with components:

- **`pyears`**: an array containing the person-years of exposure. (Or other units, depending on the rate table and the scale).
2454

ratetable

n

an array containing the number of subjects who contribute time to each cell of
the pyears array.

event

an array containing the observed number of events. This will be present only if
the response variable is a Surv object.

expected

an array containing the expected number of events (or person years). This will
be present only if there was a ratetable term.

offtable

the number of person-years of exposure in the cohort that was not part of any
cell in the pyears array. This is often useful as an error check; if there is a
mismatch of units between two variables, nearly all the person years may be off
table.

summary

a summary of the rate-table matching. This is also useful as an error check.

call

an image of the call to the function.

na.action

the na.action attribute contributed by an na.action routine, if any.

fit <- survfit(Surv(time, status) ~ sex, pbc, subset=1:312)
if (require(date)){
tdata <- data.frame(agedays=pbc$age*365.24, sex=pbc$sex +1,
                    year= rep(mdy.date(1,1,1976), nrow(pbc)))
tdata<-tdata[1:312 ,] ## only the randomised people, with no missing data
efit <- survexp(~ sex+ratetable(sex=sex, age=agedays, year=year), data=tdata, ratetable=survexp.us, times=(0:24) *182)
}
```

Description

Census data sets for the expected survival and person years functions.

Details

**us** total United States population, by age and sex, 1960 to 1980.

**uswhite** United States white population, by age and sex, 1950 to 1980. This is no longer included, but can be extracted from `survexp.usr` as shown in the examples.

**usr** United States population, by age, sex and race, 1960 to 1980. Race is white, nonwhite, or black. For 1960 and 1970 the black population values were not reported separately, so the nonwhite values were used.

**mn** total Minnesota population, by age and sex, 1970 and 1980.

**mnwhite** Minnesota white population, by age and sex, 1960 to 1980.

**fl** total Florida population, by age and sex, 1970 and 1980.

**flr** Florida population, by age, sex and race, 1970-1980. Race is white, nonwhite, or black. For 1970 the black population values were not reported separately, so the nonwhite values were used.

**az** total Arizona population, by age and sex, 1970 and 1980.
azr  Arizona population, by age, sex and race, 1970-1980. Race is white versus nonwhite. For 1970
the nonwhite population values were not reported separately. In order to make the rate table
be a matrix, the 1980 values were repeated. (White and non-white values are quite different).
Each of these tables contains the daily hazard rate for a matched subject from the population, defined
as \(-\log(1 - q)/365.24\) where \(q\) is the 1 year probability of death as reported in the original tables.
For age 25 in 1970, for instance, \(p = 1 - q\) is the probability that a subject who becomes 25 years
of age in 1970 will achieve his/her 26th birthday. The tables are recast in terms of hazard per day
entirely for computational convenience. (The fraction .24 in the denominator is based on 24 leap
years per century.)
Each table is stored as an array, with additional attributes, and can be subset and manipulated as
standard S arrays. Interpolation between calendar years is done “on the fly” by the \texttt{survexp}
routine.
Some of the deficiencies, e.g., 1970 Arizona non-white, are a result of local (Mayo Clinic) condi-
tions. The data probably exists, but we don’t have a copy it in the library.
The tables have been augmented to contain extrapolated values for 1990 and 2000. The details can
be found in Mayo Clinic Biostatistics technical report 63 at \texttt{http://www.mayo.edu/hsr/
techrpt.html}.

Examples

\begin{verbatim}
  survexp.uswhite <- survexp.usr[,]"white",]
\end{verbatim}

\begin{verbatim}
rats    Rat data from survival5
\end{verbatim}

Description

48 rats were injected with a carcinogen, and then randomized to either drug or placebo. The number
of tumors ranges from 0 to 13; all rats were censored at 6 months after randomization.

Usage

\texttt{rats}

Format

\begin{verbatim}
  rat: id
  rx: treatment,(1=drug, 0=control)
  observation: within rat
  start: entry time
  stop: exit time
  status: event status
\end{verbatim}

Source

MH Gail, TJ Santner, and CC Brown (1980), An analysis of comparative carcinogenesis experi-
ments based on multiple times to tumor. \textit{Biometrics} \textbf{36}, 255–266.
Calculates martingale, deviance, score or Schoenfeld residuals for a Cox proportional hazards model.

Usage

## S3 method for class 'coxph':
residuals(object,
        type = c("martingale", "deviance", "score", "schoenfeld",
                 "dfbeta", "dfbetas", "scaledsch", "partial"),
        collapse = FALSE, weighted = FALSE, ...)

## S3 method for class 'coxph.null':
residuals(object,
        type = c("martingale", "deviance", "score", "schoenfeld"),
        collapse = FALSE, weighted = FALSE, ...)

Arguments

object
  an object inheriting from class coxph, representing a fitted Cox regression model. Typically this is the output from the coxph function.

type
  character string indicating the type of residual desired. Possible values are "martingale", "deviance", "score", "schoenfeld", "dfbeta", "dfbetas", and "scaledsch". Only enough of the string to determine a unique match is required.

collapse
  vector indicating which rows to collapse (sum) over. In time-dependent models more than one row data can pertain to a single individual. If there were 4 individuals represented by 3, 1, 2 and 4 rows of data respectively, then collapse = c(1, 1, 1, 2, 3, 3, 4, 4, 4) could be used to obtain per subject rather than per observation residuals.

weighted
  if TRUE and the model was fit with case weights, then the weighted residuals are returned.

... other unused arguments

Value

For martingale and deviance residuals, the returned object is a vector with one element for each subject (without collapse). For score residuals it is a matrix with one row per subject and one column per variable. The row order will match the input data for the original fit. For Schoenfeld residuals, the returned object is a matrix with one row for each event and one column per variable. The rows are ordered by time within strata, and an attribute strata is attached that contains the number of observations in each strata. The scaled Schoenfeld residuals are used in the cox.zph function.

The score residuals are each individual’s contribution to the score vector. Two transformations of this are often more useful: dfbeta is the approximate change in the coefficient vector if that observation were dropped, and dfbetas is the approximate change in the coefficients, scaled by the standard error for the coefficients.
NOTE

For deviance residuals, the status variable may need to be reconstructed. For score and Schoenfeld residuals, the X matrix will need to be reconstructed.

mresid <- resid(fit, collapse=heart$id)
```

residuals.survreg  Compute Residuals for ’survreg’ Objects

Description

This is a method for the function `residuals` for objects inheriting from class `survreg`.

Usage

```r
## S3 method for class 'survreg':
residuals(object, type=c("response", "deviance", "dfbeta", "dfbetas", "working", "ldcase", "ldresp", "ldshape", "matrix"), rsigma=TRUE, collapse=FALSE, weighted=FALSE, ...)
```

Arguments

- `object` an object inheriting from class `survreg`.
- `type` type of residuals, with choices of "response", "deviance", "dfbeta", "dfbetas", "working", "ldcase", "ldresp", "ldshape", and "matrix". See the LaTeX documentation (survival/doc/survival.ps.gz) for more detail.
- `rsigma` include the scale parameters in the variance matrix, when doing computations. (I can think of no good reason not to).
- `collapse` optional vector of subject groups. If given, this must be of the same length as the residuals, and causes the result to be per group residuals.
- `weighted` give weighted residuals? Normally residuals are unweighted.
- `...` other unused arguments
Value

A vector or matrix of residuals is returned. Response residuals are on the scale of the original data, working residuals are on the scale of the linear predictor, and deviance residuals are on log-likelihood scale. The dfbeta residuals are a matrix, where the ith row gives the approximate change in the coefficients due to the addition of subject i. The dfbetas matrix contains the dfbeta residuals, with each column scaled by the standard deviation of that coefficient.

The matrix type produces a matrix based on derivatives of the log-likelihood function. Let $L$ be the log-likelihood, $p$ be the linear predictor $X\beta$, and $s$ be $\log(\sigma)$. Then the 6 columns of the matrix are $L$, $dL/dp$, $\partial^2 L/\partial p^2$, $dL/ds$, $\partial^2 L/\partial s^2$ and $\partial^2 L/\partial p\partial s$. Diagnostics based on these quantities are discussed in an article by Escobar and Meeker. The main ones are the likelihood displacement residuals for perturbation of a case weight ($ldcase$), the response value ($ldresp$), and the shape.

`predict.survreg`

Examples

```r
fit <- survreg(Surv(time,status) ~ x, aml)
rr <- residuals(fit, type='matrix')
```

ridge

**Ridge regression**

Description

When used in a `coxph` or `survreg` model formula, specifies a ridge regression term. The likelihood is penalised by $\theta/2$ time the sum of squared coefficients. If `scale=T` the penalty is calculated for coefficients based on rescaling the predictors to have unit variance. If `df` is specified then $\theta$ is chosen based on an approximate degrees of freedom.

Usage

```r
ridge(..., theta, df=nvar/2, eps=0.1, scale=TRUE)
```

Arguments

- `...` predictors to be ridged
- `theta` penalty is $\theta/2$ time sum of squared coefficients
- `df` Approximate degrees of freedom
- `eps` Accuracy required for `df`
- `scale` Scale variables before applying penalty?
Value

An object of class `coxph.penalty` containing the data and control functions.

**strata**

*Identify Stratum Variables*

**Description**
This is a special function used in the context of the Cox survival model. It identifies stratification variables when they appear on the right hand side of a formula.

**Usage**

```
strata(..., na.group=FALSE, shortlabel=FALSE)
```

**Arguments**

- `...` any number of variables. All must be the same length.
- `na.group` a logical variable, if TRUE, then missing values are treated as a distinct level of each variable.
- `shortlabel` if TRUE omit variable names from resulting factor labels

**Details**
The result is identical to the `interaction` function, but for the labeling of the factors (strata is more verbose).

**Value**
a new factor, whose levels are all possible combinations of the factors supplied as arguments.

**See Also**
coxph, interaction

**Examples**

```
a<-factor(rep(1:3,4))
b<-factor(rep(1:4,3))
levels(strata(a))
levels(strata(a,b,shortlabel=TRUE))
coxph(Surv(futime, fustat) ~ age + strata(rx), data=ovarian)
```
Description

Returns a list containing the survival curve, confidence limits for the curve, and other information.

Usage

```r
## S3 method for class 'survfit':
summary(object, times, censored=FALSE, scale=1, ...)
```

Arguments

- `object`: output from a call to `survfit`.
- `times`: vector of times; the returned matrix will contain 1 row for each time. This must be in increasing order and missing values are not allowed. If `censored=T`, the default `times` vector contains all the unique times in `fit`, otherwise the default `times` vector uses only the event (death) times.
- `censored`: logical flag: should the censoring times be included in the output? This is ignored if the `times` argument is present.
- `scale`: rescale the survival time, e.g., if the input data to `survfit` were in days, `scale=365.25` would scale the output to years.
- `...`: other unused arguments

Value

A list with the following components:

- `time`: the timepoint on the curve.
- `surv`: the value of the survival curve at time t+0.
- `n.risk`: the number of subjects at risk at time t-0 (but see the comments on weights in the `survfit` help file).
- `n.event`: if the `times` argument is missing, then this column is the number of events that occurred at time t. Otherwise, it is the cumulative number of events that have occurred since the last time listed until time t+0.
- `std.err`: the standard error of the survival value.
- `conf.int`: level of confidence for the confidence intervals of survival.
- `lower`: lower confidence limits for the curve.
- `upper`: upper confidence limits for the curve.
- `strata`: indicates stratification of curve estimation. If `strata` is not NULL, there are multiple curves in the result and the `surv`, `time`, `n.risk`, etc. vectors will contain multiple curves, pasted end to end. The levels of `strata` (a factor) are the labels for the curves.
- `call`: the statement used to create the `fit` object.
- `na.action`: passed through from `fit`, if present.
Surv

**See Also**

`survfit`, `print.summary.survfit`.

**Examples**

summary( survfit( Surv(futime, fustat),data=ovarian))
summary( survfit( Surv(futime, fustat)-rx,data=ovarian))
```

---

**Surv**  
*Create a Survival Object*

**Description**

Create a survival object, usually used as a response variable in a model formula.

**Usage**

```r
Surv(time, time2, event, type =, origin = 0)
is.Surv(x)
```

**Arguments**

- `time` for right censored data, this is the follow up time. For interval data, the first argument is the starting time for the interval.
- `x` any R object.
- `event` The status indicator, normally 0=alive, 1=dead. Other choices are TRUE/FALSE (TRUE = death) or 1/2 (2=death). For interval censored data, the status indicator is 0=right censored, 1=event at time, 2=left censored, 3=interval censored. Although unusual, the event indicator can be omitted, in which case all subjects are assumed to have an event.
- `time2` ending time of the interval for interval censored or counting process data only. Intervals are assumed to be open on the left and closed on the right, \{start, end\}. For counting process data, `event` indicates whether an event occurred at the end of the interval.
- `type` character string specifying the type of censoring. Possible values are "right", "left", "counting", "interval", or "interval2". The default is "right" or "counting" depending on whether the `time2` argument is absent or present, respectively.
- `origin` for counting process data, the hazard function origin. This is most often used in conjunction with a model containing time dependent strata in order to align the subjects properly when they cross over from one strata to another.

**Details**

Typical usages are

```r
Surv(time, event)
Surv(time, time2, event, type=, origin=0)
```
In theory it is possible to represent interval censored data without a third column containing the explicit status. Exact, right censored, left censored and interval censored observation would be represented as intervals of (a,a), (a, infinity), (-infinity,b), and (a,b) respectively; each specifying the interval within which the event is known to have occurred.

If `type = "interval2"` then the representation given above is assumed, with NA taking the place of infinity. If `type="interval"` event must be given. If `event` is 0, 1, or 2, the relevant information is assumed to be contained in `time`, the value in `time2` is ignored, and the second column of the result will contain a placeholder.

Presently, the only methods allowing interval censored data are the parametric models computed by `survreg`, so the distinction between open and closed intervals is unimportant. The distinction is important for counting process data and the Cox model.

The function tries to distinguish between the use of 0/1 and 1/2 coding for left and right censored data using `if (max(status)==2)`. If 1/2 coding is used and all the subjects are censored, it will guess wrong. Use 0/1 coding in this case.

**Value**

An object of class `Surv`. There are methods for `print`, `is.na`, and subscripting survival objects. `Surv` objects are implemented as a matrix of 2 or 3 columns.

In the case of `is.Surv`, a logical value `TRUE` if `x` inherits from class "Surv", otherwise an `FALSE`.

**See Also**

`coxph`, `survfit`, `survreg`.

**Examples**

```r
with(aml, Surv(time, status))
with(heart, Surv(start,stop,event))
```

**Description**

Tests if there is a difference between two or more survival curves using the $G$ family of tests, or for a single curve against a known alternative.

**Usage**

```r
survdiff(formula, data, subset, na.action, rho=0)
```

**Arguments**

- `formula`: a formula expression as for other survival models, of the form `Surv(time, status) ~ predictors`. For a one-sample test, the predictors must consist of a single `offset(sp)` term, where `sp` is a vector giving the survival probability of each subject. For a k-sample test, each unique combination of predictors defines a subgroup. A `strata` term may be used to produce a stratified test. To cause missing values in the predictors to be treated as a separate group,
rather than being omitted, use the `strata` function with its `na.group=T` argument.

data: an optional data frame in which to interpret the variables occurring in the formula.

subset: an expression indicating which subset of the rows of data should be used in the fit. This can be a logical vector (which is replicated to have length equal to the number of observations), a numeric vector indicating which observation numbers are to be included (or excluded if negative), or a character vector of row names to be included. All observations are included by default.

na.action: a missing-data filter function. This is applied to the `model.frame` after any subset argument has been used. Default is `options()$na.action`.

rho: a scalar parameter that controls the type of test.

Value

a list with components:

- `n`: the number of subjects in each group.
- `obs`: the weighted observed number of events in each group. If there are strata, this will be a matrix with one column per stratum.
- `exp`: the weighted expected number of events in each group. If there are strata, this will be a matrix with one column per stratum.
- `chisq`: the chisquare statistic for a test of equality.
- `var`: the variance matrix of the test.
- `strata`: optionally, the number of subjects contained in each stratum.

METHOD

This function implements the G-rho family of Harrington and Fleming (1982), with weights on each death of $S(t)^\rho$, where $S(t)$ is the Kaplan-Meier estimate of survival. With $\rho = 0$ this is the log-rank or Mantel-Haenszel test, and with $\rho = 1$ it is equivalent to the Peto & Peto modification of the Gehan-Wilcoxon test.

If the right hand side of the formula consists only of an offset term, then a one sample test is done. To cause missing values in the predictors to be treated as a separate group, rather than being omitted, use the `factor` function with its `exclude` argument.

References

Examples

```r
## Two-sample test
survdiff(Surv(futime, fustat) ~ rx, data=ovarian)

## Stratified 7-sample test
survdiff(Surv(time, status) ~ pat.karno + strata(inst), data=lung)

## Expected survival for heart transplant patients based on
```
## US mortality tables

```r
expect <- survexp(futime ~ ratetable(age=(accept.dt - birth.dt),
       sex=1, year=accept.dt, race="white"), jasa, cohort=FALSE,
       ratetable=survexp.us)
```

## actual survival is much worse (no surprise)

```r
survdiff(Surv(jasa$futime, jasa$fustat) ~ offset(expect))
```

---

### survexp

**Compute Expected Survival**

**Description**

Returns either the expected survival of a cohort of subjects, or the individual expected survival for each subject.

**Usage**

```r
survexp(formula, data, weights, subset, na.action, times, cohort=TRUE,
         conditional=FALSE, ratetable=survexp.us, scale=1, npoints,
         se.fit=, model=FALSE, x=FALSE, y=FALSE)
```

**Arguments**

- `formula` 
  - formula object. The response variable is a vector of follow-up times and is optional. The predictors consist of optional grouping variables separated by the `+` operator (as in `survfit`), along with a `ratetable` term. The `ratetable` term matches each subject to his/her expected cohort.

- `data` 
  - data frame in which to interpret the variables named in the `formula`, `subset` and `weights` arguments.

- `weights` 
  - case weights.

- `subset` 
  - expression indicating a subset of the rows of `data` to be used in the fit.

- `na.action` 
  - function to filter missing data. This is applied to the model frame after `subset` has been applied. Default is `options()$na.action`. A possible value for `na.action` is `na.omit`, which deletes observations that contain one or more missing values.

- `times` 
  - vector of follow-up times at which the resulting survival curve is evaluated. If absent, the result will be reported for each unique value of the vector of follow-up times supplied in `formula`.

- `cohort` 
  - logical value: if `FALSE`, each subject is treated as a subgroup of size 1. The default is `TRUE`.

- `conditional` 
  - logical value: if `TRUE`, the follow-up times supplied in `formula` are death times and conditional expected survival is computed. If `FALSE`, the follow-up times are potential censoring times. If follow-up times are missing in `formula`, this argument is ignored.

- `ratetable` 
  - a table of event rates, such as `survexp.uswhite`, or a fitted Cox model.

- `scale` 
  - numeric value to scale the results. If `ratetable` is in units/day, `scale = 365.25` causes the output to be reported in years.
number of points at which to calculate intermediate results, evenly spaced over
the range of the follow-up times. The usual (exact) calculation is done at each
unique follow-up time. For very large data sets specifying `npoints` can reduce
the amount of memory and computation required. For a prediction from a Cox
model `npoints` is ignored.

compute the standard error of the predicted survival. The default is to compute
this whenever the routine can, which at this time is only for the Ederer method
and a Cox model as the rate table.

flags to control what is returned. If any of these is true, then the model frame,
the model matrix, and/or the vector of response times will be returned as com-
ponents of the final result, with the same names as the flag arguments.

Individual expected survival is usually used in models or testing, to ‘correct’ for the age and sex
composition of a group of subjects. For instance, assume that birth date, entry date into the study,
sex and actual survival time are all known for a group of subjects. The `survexp.uswhite`
population tables contain expected death rates based on calendar year, sex and age. Then `haz <-
-log(survexp(death.time rateable(sex=sex, year=entry.dt, age=(birth.dt-entry.dt)), cohort=F))` gives
for each subject the total hazard experienced up to their observed death time or censoring time.
This probability can be used as a rescaled time value in models: `glm(status 1 + offset(log(haz)),
family=poisson)` `glm(status x + offset(log(haz)), family=poisson)` In the first model, a test for
intercept=0 is the one sample log-rank test of whether the observed group of subjects has equiv-
alent survival to the baseline population. The second model tests for an effect of variable `x` after
adjustment for age and sex.

Cohort survival is used to produce an overall survival curve. This is then added to the Kaplan-Meier
plot of the study group for visual comparison between these subjects and the population at large.
There are three common methods of computing cohort survival. In the “exact method” of Ederer the
cohort is not censored; this corresponds to having no response variable in the formula. Hakulinen
recommends censoring the cohort at the anticipated censoring time of each patient, and Verheul
recommends censoring the cohort at the actual observation time of each patient. The last of these
is the conditional method. These are obtained by using the respective time values as the follow-up
time or response in the formula.

if `cohort=T` an object of class `survexp`, otherwise a vector of per-subject expected survival
values. The former contains the number of subjects at risk and the expected survival for the cohort
at each requested time.

Ederer, L Axtell, and S Cutler. The relative survival rate: a statistical methodology. *Natl Cancer

`survfit`, `survexp.us`, `survexp.fit`, `pyears`, `date`
Examples

```r
## compare survival to US population
cancer$year <- rep(as.date("1/1/1980"), nrow(cancer))
efit <- survexp(~ ratetable(sex=sex, year=year, age=age*365), times=(1:4)*365, data=cancer)
plot(survfit(Surv(time, status) ~ 1, data=cancer))
lines(efit)

## compare data to Cox model
## fit to randomised patients in Mayo PBC data
m <- coxph(Surv(time, status) ~ edtrt + log(bili) + log(protime) + age + platelet, data=pbc, subset=trt>0)
## compare Kaplan-Meier to fitted model for 2 edema groups in
## unrandomised patients
plot(survfit(Surv(time, status) ~ edtrt, data=pbc, subset=trt==-9))
lines(survexp(~ edtrt + ratetable(edtrt=edtrt, bili=bili, platelet=platelet, age=age, protime=protime), data=pbc, subset=trt==-9, ratetable=m, cohort=TRUE), col="purple")
```

---

**survexp.fit**

*Work Function to Compute Expected Survival*

**Description**

Compute expected survival. This function is not to be called by the user.

**Usage**

```r
survexp.fit(x, y, times, death, ratetable)
```

**Arguments**

- `x`: a matrix. The first column contains the group, an integer value that divides the subjects into subsets. Remaining columns must match the dimensions of the `ratetable`, in the correct order.
- `y`: the follow up time for each subject.
- `times`: the vector of times at which a result will be computed.
- `death`: death indicator
- `ratetable`: a rate table, such as `survexp.uswhite`.

**Details**

For cohort survival it must be the potential censoring time for each subject, ignoring death.

For an exact estimate `times` should be a superset of `y`, so that each subject at risk is at risk for the entire sub-interval of time. For a large data set, however, this can use an inordinate amount of storage and/or compute time. If the `times` spacing is more coarse than this, an actuarial approximation is used which should, however, be extremely accurate as long as all of the returned values are > .99.

For a subgroup of size 1 and `times > y`, the conditional method reduces to `exp(-h)` where `h` is the expected cumulative hazard for the subject over his/her observation time. This is used to compute individual expected survival.
Value

A list containing the number of subjects and the expected survival(s) at each time point. If there are multiple groups, these will be matrices with one column per group.

WARNING

Most users will call the higher level routine survexp. Consequently, this function has very few error checks on its input arguments.

survexp, survexp.us

survfit

Compute a Survival Curve for Censored Data

Description

Computes an estimate of a survival curve for censored data using either the Kaplan-Meier or the Fleming-Harrington method or computes the predicted survivor function for a Cox proportional hazards model.

Usage

survfit(formula, data, weights, subset, na.action, newdata, individual=F, conf.int=.95, se.fit=T, type=c("kaplan-meier","fleming-harrington", "fh2"), error=c("greenwood","tsiatis"), conf.type=c("log","log-log","plain","none"), conf.lower=c("usual", "peto", "modified"))

## S3 method for class 'survfit':

x[...drop=FALSE]

basehaz(fit,centered=TRUE)

Arguments

formula A formula object or a coxph object. If a formula object is supplied it must have a Surv object as the response on the left of the ~ operator and, if desired, terms separated by + operators on the right. One of the terms may be a strata object. For a single survival curve the "~ 1" part of the formula is not required.

data a data frame in which to interpret the variables named in the formula, or in the subset and the weights argument.

weights The weights must be nonnegative and it is strongly recommended that they be strictly positive, since zero weights are ambiguous, compared to use of the subset argument.

subset expression saying that only a subset of the rows of the data should be used in the fit.

na.action a missing-data filter function, applied to the model frame, after any subset argument has been used. Default is options()$na.action.
newdata a data frame with the same variable names as those that appear in the coxph formula. Only applicable when formula is a coxph object. The curve(s) produced will be representative of a cohort who’s covariates correspond to the values in newdata. Default is the mean of the covariates used in the coxph fit.

individual a logical value indicating whether the data frame represents different time epochs for only one individual (T), or whether multiple rows indicate multiple individuals (F, the default). If the former only one curve will be produced; if the latter there will be one curve per row in newdata.

conf.int the level for a two-sided confidence interval on the survival curve(s). Default is 0.95.

se.fit a logical value indicating whether standard errors should be computed. Default is TRUE.

type a character string specifying the type of survival curve. Possible values are "kaplan-meier", "fleming-harrington" or "fh2" if a formula is given and "aalen" or "kaplan-meier" if the first argument is a coxph object, (only the first two characters are necessary). The default is "aalen" when a coxph object is given, and it is "kaplan-meier" otherwise.

error either the string "greenwood" for the Greenwood formula or "tsiatis" for the Tsiatis formula, (only the first character is necessary). The default is "tsiatis" when a coxph object is given, and it is "greenwood" otherwise.

conf.type One of "none", "plain", "log" (the default), or "log-log". Only enough of the string to uniquely identify it is necessary. The first option causes confidence intervals not to be generated. The second causes the standard intervals curve +- k *se(curve), where k is determined from conf.int. The log option calculates intervals based on the cumulative hazard or log(survival). The last option bases intervals on the log hazard or log(-log(survival)). These last will never extend past 0 or 1.

conf.lower controls modified lower limits to the curve, the upper limit remains unchanged. The modified lower limit is based on an ‘effective n’ argument. The confidence bands will agree with the usual calculation at each death time, but unlike the usual bands the confidence interval becomes wider at each censored observation. The extra width is obtained by multiplying the usual variance by a factor m/n, where n is the number currently at risk and m is the number at risk at the last death time. (The bands thus agree with the un-modified bands at each death time.) This is especially useful for survival curves with a long flat tail. The Peto lower limit is based on the same ‘effective n’ argument as the modified limit, but also replaces the usual Greenwood variance term with a simple approximation. It is known to be conservative.

x a survfit object

fit a coxph object

centered Compute the baseline hazard at the covariate mean rather than at zero?

drop Only FALSE is supported

... Other arguments for future expansion

Details

Actually, the estimates used are the Kalbfeisch-Prentice (Kalbfeisch and Prentice, 1980, p.86) and the Tsiatis/Link/Breslow, which reduce to the Kaplan-Meier and Fleming-Harrington estimates,
respectively, when the weights are unity. When curves are fit for a Cox model, subject weights of \( \exp\{\text{sum}(\text{coef}*(x-center))\} \) are used, ignoring any value for weights input by the user. There is also an extra term in the variance of the curve, due to the variance of the coefficients and hence variance in the computed weights.

The Greenwood formula for the variance is a sum of terms \( d/(n*(n-m)) \), where \( d \) is the number of deaths at a given time point, \( n \) is the sum of weights for all individuals still at risk at that time, and \( m \) is the sum of weights for the deaths at that time. The justification is based on a binomial argument when weights are all equal to one; extension to the weighted case is ad hoc. Tsiatis (1981) proposes a sum of terms \( d/(n*n) \), based on a counting process argument which includes the weighted case.

The two variants of the F-H estimate have to do with how ties are handled. If there were 3 deaths out of 10 at risk, then the first would increment the hazard by 3/10 and the second by 1/10 + 1/9 + 1/8. For curves created after a Cox model these correspond to the Breslow and Efron estimates, respectively, and the proper choice is made automatically. The \texttt{fh2} method will give results closer to the Kaplan-Meier.

Based on the work of Link (1984), the log transform is expected to produce the most accurate confidence intervals. If there is heavy censoring, then based on the work of Dorey and Korn (1987) the modified estimate will give a more reliable confidence band for the tails of the curve.

**Value**

a \texttt{survfit} object; see the help on \texttt{survfit.object} for details. Methods defined for \texttt{survfit} objects are provided for \texttt{print}, \texttt{plot}, \texttt{lines}, and \texttt{points}.

For \texttt{basehaz}, a dataframe with the baseline hazard, times, and strata.

The "[" method returns a \texttt{survfit} object giving survival for the selected groups.

**Examples**

```r
# fit a Kaplan-Meier and plot it
fit <- survfit(Surv(time, status) ~ x, data=aml)
plot(fit)
# plot only 1 of the 2 curves from above
plot(fit[2])
```
# fit a cox proportional hazards model and plot the
# predicted survival curve
fit <- coxph( Surv(futime,fustat)~resid.ds+rx+ecog.ps, data=ovarian)
plot( survfit( fit))

## survfit.object

**Survival Curve Object**

### Description

This class of objects is returned by the `survfit` class of functions to represent a fitted survival curve.

Objects of this class have methods for the functions `print`, `summary`, `plot`, `points` and `lines`. The `print.survfit` method does more computation than is typical for a print method and is documented on a separate page.

### COMPONENTS

The following components must be included in a legitimate `survfit` object.

- **time** the time points at which the curve has a step.
- **n.risk** the number of subjects at risk at t.
- **n.event** the number of events that occur at time t.
- **surv** the estimate of survival at time t+0. This may be a vector or a matrix.
- **strata** if there are multiple curves, this component gives the number of elements of the `time` etc. vectors corresponding to the first curve, the second curve, and so on. The names of the elements are labels for the curves.
- **std.err** the standard error of the cumulative hazard or -log(survival).
- **upper** upper confidence limit for the survival curve.
- **lower** lower confidence limit for the survival curve.
- **conf.type** the approximation used to compute the confidence limits.
- **conf.int** the level of the confidence limits, e.g. 90 or 95%.
- **na.action** the returned value from the `na.action` function, if any. It will be used in the printout of the curve, e.g., the number of observations deleted due to missing values.
- **call** the call that produced the object.

### SUBSCRIPTS

Survfit objects that contain multiple survival curves can be subscripted. This is most often used to plot a subset of the curves. Usually a single subscript will be used. In one particular case – survival curves for multiple covariate values, from a Cox model that includes a `strata` statement – there is a matrix of curves and 2 subscripts may be used. (In this case `summary.survfit` will also print the data as a matrix).

### See Also

`survfit`, `plot.survfit`, `summary.survfit`, `print.survfit`. 
O’Brien’s Test for Association of a Single Variable with Survival

Description

Peter O’Brien’s test for association of a single variable with survival. This test is proposed in Biometrics, June 1978.

Usage

survobrien(formula, data)

Arguments

formula a valid formula for a cox model, without time dependent covariates.
data a data frame.

Value

A new data frame. The original time and status variables are removed, and have been replaced with start, stop, and event. If a predictor variable is a factor or is protected with I(), it is retained as is. Other predictor variables have been replaced with time-dependent logit scores.

Because of the time dependent variables, the new data frame will have many more rows that the original data, approximately #rows * #deaths /2.

METHOD

A time-dependent cox model can now be fit to the new data. The univariate statistic, as originally proposed, is equivalent to single variable score tests from the time-dependent model. This equivalence is the rationale for using the time dependent model as a multivariate extension of the original paper.

In O’Brien’s method, the x variables are re-ranked at each death time. A simpler method, proposed by Prentice, ranks the data only once at the start. The results are usually similar.

coxph(Surv(start, stop, event) ~ age, data=xx)
coxph(Surv(start, stop, event) ~ age + rx + ecog.ps, data=xx)
survreg

Regression for a Parametric Survival Model

Description

Regression for a parametric survival model. These are all time-transformed location models, with the most useful case being the accelerated failure models that use a log transformation.

Usage

```
survreg(formula=formula(data), data=parent.frame(), weights, subset, na.action, dist="weibull", init=NULL, scale=0, control=survreg.control(), parms=NULL, model=FALSE, x=FALSE, y=TRUE, robust=FALSE, ...)
```

Arguments

- **formula**: a formula expression as for other regression models. See the documentation for `lm` and `formula` for details.
- **data**: optional data frame in which to interpret the variables occurring in the formula.
- **weights**: Optional observation weights
- **subset**: subset of the observations to be used in the fit.
- **na.action**: function to be used to handle any NAs in the data.
- **dist**: assumed distribution for y variable. If the argument is a character string, then it is assumed to name an element from `survreg.distributions`. These include "weibull", "exponential", "gaussian", "logistic", "lognormal" and "loglogistic". Otherwise, it is assumed to be a user defined list conforming to the format described in `survreg.distributions`.
- **parms**: a list of fixed parameters. For the t-distribution for instance this is the degrees of freedom; most of the distributions have no parameters.
- **init**: optional vector of initial values for the parameters.
- **scale**: optional fixed value for the scale. If set to <=0 then the scale is estimated.
- **control**: a list of control values, in the format produced by `survreg.control`.
- **model**: if TRUE, the model frame is returned.
- **x**: if TRUE, then the X matrix is returned.
- **y**: if TRUE, then the y vector (or survival times) is returned.
- **robust**: if TRUE, sandwich standard errors are computed. Defaults to TRUE when `formula` contains a `cluster` term.
- **...**: other arguments which will be passed to `survreg.control`.

Value

an object of class `survreg` is returned.
survreg.control

Compatibility note

This routine underwent significant changes from survival4 to survival5. The `survreg.old` function gives a backwards-compatible interface. In S-PLUS the new function is called `survReg` and the old one `survreg`.

See Also

`survreg.object, survreg.distributions, pspline, frailty, ridge, survreg.old`

Examples

```r
## These are all the same
survreg(Surv(futime, fustat) ~ ecog.ps + rx, ovarian, dist='weibull',scale=1)
survreg(Surv(futime, fustat) ~ ecog.ps + rx, ovarian, dist="exponential")
survreg.old(Surv(futime, fustat) ~ ecog.ps + rx, ovarian, dist='extreme',fixed=list(scale=1),link="log")
```

survreg.control

Package options for survreg and coxph

Description

These functions check and package the fitting options for `survreg` and `coxph`

Usage

```r
survreg.control(maxiter=30, rel.tolerance=1e-09, failure=1, toler.chol=1e-10, iter.max, debug=0, outer.max=10)
coxph.control (eps = 1e-09, toler.chol = .Machine$double.eps^0.75, iter.max = 20, toler.inf = sqrt(eps), outer.max = 10)
```

Arguments

- `maxiter`: maximum number of iterations
- `rel.tolerance`: relative tolerance to declare convergence
- `failure`: value of status variable indicating failure
- `toler.chol`: Tolerance to declare Cholesky decomposition singular
- `iter.max`: same as `maxiter`
- `debug`: print debugging information
- `outer.max`: maximum number of outer iterations for choosing penalty parameters
- `eps`: Tolerance to declare convergence for Cox model
- `toler.inf`: An undocumented parameter

Value

A list with the same elements as the input
survreg.distributions

Description

List of distributions for accelerated failure models. These are location-scale families for some transformation of time. The entry describes the cdf $F$ and density $f$ of a canonical member of the family.

Usage

survreg.distributions

Format

There are three basic formats; only the first two are used in the built-in distributions

- name: name of distribution
- variance: Variance
- init(x,weights,...): Function returning an initial mean and variance
- deviance(y,scale,parms): Function returning the deviance
- density(x,parms): Function returning $F$, $1 - F, f'/f, f''/f$
- quantile(p,parms): Quantile function
- scale: Optional fixed value for scale parameter

and for transformations of the time variable

- name: name of distribution
- dist: name of transformed distribution
- trans: transformation (eg log)
- dtrans: derivative of transformation
- itrans: inverse of transformation
- scale: Optional fixed value for scale parameter

For transformations of user-defined families use

- name: name of distribution
- dist: transformed distribution in first format
- trans: transformation (eg log)
- dtrans: derivative of transformation
- itrans: inverse of transformation

See Also

survreg, coxph

Examples
scale: Optional fixed value for scale parameter

Details

There are four basic distributions: extreme, gaussian, logistic and t. The last three are parametrised in the same way as the distributions already present in R. The extreme value cdf is

\[ F = 1 - e^{-e^{-t}}. \]

When the logarithm of survival time has one of the first three distributions we obtain respectively weibull, lognormal, and loglogistic. The Weibull distribution is not parameterised the same way as in rweibull.

The other predefined distributions are defined in terms of these. The exponential and rayleigh distributions are Weibull distributions with fixed scale of 1 and 0.5 respectively, and loggaussian is a synonym for lognormal.

Parts of the built-in distributions are hardcoded in C, so the elements of survreg.distributions in the first format above must not be changed and new ones must not be added. The examples show how to specify user-defined distributions to survreg.

Examples

```r
## not a good fit, but a useful example
survreg(Surv(futime, fustat) ~ ecog.ps + rx, data=ovarian, dist='extreme')

## time transformation
survreg(Surv(futime, fustat) ~ ecog.ps + rx, data=ovarian, dist='weibull', scale=1)
my.weibull$trans<-function(y) log(y/365)
my.weibull$itrans<-function(y) exp(365*y)
survreg(Surv(futime, fustat) ~ ecog.ps + rx, data=ovarian, dist=my.weibull, scale=1)

## change the transformation to work in years
## intercept changes by log(365), other coefficients stay the same
my.weibull$trans<-function(y) log(y/365)
my.weibull$itrans<-function(y) exp(365*y)
survreg(Surv(futime, fustat) ~ ecog.ps + rx, data=ovarian, dist=my.weibull, scale=1)

## Weibull parametrisation
y<-rweibull(1000, shape=2, scale=5)
survreg(Surv(y) ~ 1, dist="weibull")
```

## survreg reports scale=1/2, intercept=log(5)
survreg.object  

**Parametric Survival Model Object**

**Description**

This class of objects is returned by the `survreg` function to represent a fitted parametric survival model. Objects of this class have methods for the functions `print`, `summary`, `predict`, and `residuals`.

**COMPONENTS**

The following components must be included in a legitimate `survreg` object.

- **coefficients** the coefficients of the `linear.predictors`, which multiply the columns of the model matrix. It does not include the estimate of error (sigma). The names of the coefficients are the names of the single-degree-of-freedom effects (the columns of the model matrix). If the model is over-determined there will be missing values in the coefficients corresponding to non-estimable coefficients.

- **icoef** coefficients of the baseline model, which will contain the intercept and log(scale), or multiple scale factors for a stratified model.

- **var** the variance-covariance matrix for the parameters, including the log(scale) parameter(s).

- **loglik** a vector of length 2, containing the log-likelihood for the baseline and full models.

- **iter** the number of iterations required

- **linear.predictors** the linear predictor for each subject.

- **df** the degrees of freedom for the final model. For a penalized model this will be a vector with one element per term.

- **scale** the scale factor(s), with length equal to the number of strata.

- **idf** degrees of freedom for the initial model.

- **means** a vector of the column means of the coefficient matrix.

- **dist** the distribution used in the fit.

  The object will also have the following components found in other model results (some are optional): `linear.predictors`, `weights`, `x`, `y`, `model`, `call`, `terms` and `formula`. See `lm`.

**See Also**

`survreg`, `lm`
**survreg.old**

*Old (survival4) Regression for a parametric survival model*

**Description**

This routine is a backwards-compatible interface to the improved `survreg` function, which is better.

**Usage**

```r
survreg.old(formula, data=sys.frame(sys.parent()), ..., link=c("log", "identity"), dist=c("extreme", "logistic", "gaussian", "exponential", "rayleigh", "weibull"), fixed=list())
```

**Arguments**

- **formula**: a formula expression as for other regression models. See the documentation for `lm` and `formula` for details.
- **data**: optional data frame in which to interpret the variables occurring in the formula.
- **...**: other arguments to `survreg`
- **link**: transformation to be used on the y variable.
- **dist**: assumed distribution for the transformed y variable.
- **fixed**: a list of fixed parameters, most often just the scale.

**Value**

an object of class `survreg` is returned, which inherits from class `glm`.

**Examples**

```r
survreg.old(Surv(futime, fustat) ~ ecog.ps + rx, ovarian, dist='extreme', link='log', fixed=list(scale=1)) # Fit an exponential
```

---

**survSplit**

*Split a survival data set at specified times*

**Description**

Given a survival data set and a set of specified cut times, split each record into multiple subrecords at each cut time. The new data set will be in ‘counting process’ format, with a start time, stop time, and event status for each record.

**Usage**

```r
survSplit(data, cut, end, event, start, id = NULL, zero = 0, episode=NULL)
```
Arguments

- **data**: data frame
- **cut**: vector of timepoints to cut at
- **end**: character string with name of event time variable
- **event**: character string with name of censoring indicator
- **start**: character string with name of start time variable (will be created if it does not exist)
- **id**: character string with name of new id variable to create (optional)
- **zero**: If `start` doesn’t already exist, this is the time that the original records start. May be a vector or single value.
- **episode**: character string with name of new episode variable (optional)

Details

The function also works when the original data are in counting-process format, but the `id` and `episode` options are of little use in this context.

Value

New, longer, data frame.

See Also

`Surv, cut, reshape`

Examples

```r
aml3 <- survSplit(aml, cut = c(5, 10, 50), end = "time", start = "start",
                  event = "status", episode = "i")

summary(aml)
summary(aml3)

coxph(Surv(time, status) ~ x, data = aml)
# the same
coxph(Surv(start, time, status) ~ x, data = aml3)

aml4 <- survSplit(aml3, cut = 20, end = "time", start = "start", event = "status")
coxph(Surv(start, time, status) ~ x, data = aml4)
```

**tcut**

*Factors for person-year calculations*

Description

Attaches categories for person-year calculations to a variable without losing the underlying continuous representation.
Usage

tcut(x, breaks, labels, scale=1)

Arguments

x numeric/date variable
breaks breaks between categories, which are right-continuous
labels labels for categories
scale Multiply x and breaks by this.

Value

An object of class tcut

See Also

cut, pyears

Examples

```r
temp1 <- mdy.date(6,6,36)
temp2 <- mdy.date(6,6,55)# Now compare the results from person-years
#
temp.age <- tcut(temp2-temp1, floor(c(-1, (18:31 * 365.24))),
    labels=c('0-18', paste(18:30, 19:31, sep='-')))
temp.yr <- tcut(temp2, mdy.date(1,1,1954:1965), labels=1954:1964)
temp.time <- 3700  #total days of fu
py1 <- pyears(temp.time ~ temp.age + temp.yr, scale=1) #output in days
```

tobin  

Tobin’s Tobit data

Description

Economists fit a parametric censored data model called the ‘tobit’. These data are from Tobin’s original paper.

Usage

tobin

Format

A data frame with 20 observations on the following 3 variables.

durable Durable goods purchase
age Age in years
quant Liquidity ratio (x 1000)
untangle.specials  Help Process the ‘specials’ Argument of the ‘terms’ Function.

Description
Given a terms structure and a desired special name, this returns an index appropriate for subscripting the terms structure and another appropriate for the data frame.

Usage
untangle.specials(tt, special, order=1)

Arguments
tt  a terms object.
special  the name of a special function, presumably used in the terms object.
order  the order of the desired terms. If set to 2, interactions with the special function will be included.

Value
a list with two components:
vars  a vector of variable names, as would be found in the data frame, of the specials.
terms  a numeric vector, suitable for subscripting the terms structure, that indexes the terms in the expanded model formula which involve the special.

Examples
formula<-Surv(tt,ss)-x+z*strata(id)
tms<-terms(formula,specials="strata")
## the specials attribute
attr(tms,"specials")
## main effects
untangle.specials(tms,"strata")
## and interactions
untangle.specials(tms,"strata",order=1:2)

Source

Examples
tfit <- survreg(Surv(durable, durable>0, type='left') ~age + quant,
data=tobin, dist='gaussian')
predict(tfit,type="response")
Veterans’ Administration Lung Cancer study

Description

Randomised trial of two treatment regimens for lung cancer. This is a standard survival analysis data set.

Usage

veteran

Chapter 27

The tcltk package

description

Interface and language bindings to Tcl/Tk GUI elements.

details

This package provides access to the platform-independent Tcl scripting language and Tk GUI elements. See TkWidgets for a list of supported widgets, TkWidgetcmds for commands to work with them, and references in those files for more.

The Tcl/Tk documentation is in the system man pages.

For a complete list of functions, use ls("package:tcltk").

Note that Tk will not be initialized if there is no DISPLAY variable set, but Tcl can still be used. This is most useful to allow the loading of a package which depends on tcltk in a session that does not actually use it (e.g. during installation).

author(s)

R Development Core Team

Maintainer: R Core Team (R-core@r-project.org)

description

These functions and variables provide the basic glue between R and the Tcl interpreter and Tk GUI toolkit. Tk windows may be represented via R objects. Tcl variables can be accessed via objects of class tclVar and the C level interface to Tcl objects is accessed via objects of class tclObj.
Usage

`.Tcl(...)
.Tcl.objv(objv)
.Tcl.args(...)
.Tcl.args.objv(...)
.Tcl.callback(...)
.Tk.ID(win)
.Tk.newwin(ID)
.Tk.subwin(parent)
.TkRoot

tkdestroy(win)
is.tkwin(x)

tclvalue(x)
tclvalue(x) <- value

tclVar(init="")
## S3 method for class 'tclVar':
as.character(x, ...)
## S3 method for class 'tclVar':
tclvalue(x)
## S3 replacement method for class 'tclVar':
tclvalue(x) <- value

tclArray()
## S3 method for class 'tclArray':
x[[...]]
## S3 replacement method for class 'tclArray':
x[[...]] <- value
## S3 method for class 'tclArray':
x$i
## S3 replacement method for class 'tclArray':

## S3 method for class 'tclObj':
tclvalue(x)

## Default S3 method:
tclvalue(x)
## S3 replacement method for class 'default':
tclvalue(x) <- value

addTclPath(path = ".")
tclRequire(package, warn = TRUE)

### Arguments

- **objv**: a named vector of Tcl objects
- **win**: a window structure
- **x**: an object
- **i**: character or (unquoted) name
- **drop**: logical. Indicates whether a single-element vector should be made into a simple Tcl object or a list of length one
- **value**: For tclvalue assignments, a character string. For tclObj assignments, an object of class tclObj
- **ID**: a window ID
- **parent**: a window which becomes the parent of the resulting window
- **path**: path to a directory containing Tcl packages
- **package**: a Tcl package name
- **warn**: logical. Warn if not found?
- **...**: Additional arguments. See below.
- **init**: initialization value

### Details

Many of these functions are not intended for general use but are used internally by the commands that create and manipulate Tk widgets and Tcl objects. At the lowest level .Tcl sends a command as a text string to the Tcl interpreter and returns the result as an object of class tclObj (see below). A newer variant .Tcl.objv accepts arguments in the form of a named list of tclObj objects.

.Tcl.args converts an R argument list of tag=value pairs to the Tcl -option value style, thus enabling a simple translation between the two languages. To send a value with no preceding option flag to Tcl, just use an untagged argument. In the rare case one needs an option with no subsequent value tag=NULL can be used. Most values are just converted to character mode and inserted in the command string, but window objects are passed using their ID string, and callbacks are passed via the result of .Tcl.callback. Tags are converted to option flags simply by prepending a -

.Tcl.args.objv serves a similar purpose as .Tcl.args but produces a list of tclObj objects suitable for passing to .Tcl.objv. The names of the list are converted to Tcl option style internally by .Tcl.objv.
Callbacks can be either atomic callbacks handled by \texttt{Tcl.callback} or expressions. An expression is treated as a list of atomic callbacks, with the following exceptions: if an element is a name, it is first evaluated in the callers frame, and likewise if it is an explicit function definition; the \texttt{break} expression is translated directly to the Tcl counterpart. \texttt{Tcl.callback} converts \texttt{R} functions and unevaluated calls to Tcl command strings. The argument must be either a function closure or an object of mode "call" followed by an environment. The return value in the first case is of the form \texttt{R\_call 0x408b94d4} in which the hexadecimal number is the memory address of the function. In the second case it will be of the form \texttt{R\_call\_lang 0x8a95904 0x819bfd0}. For expressions, a sequence of similar items is generated, separated by semicolons.

\texttt{Tcl.callback} converts \texttt{R} functions and unevaluated calls to Tcl command strings. The argument must be either a function closure or an object of mode "call" followed by an environment. The return value in the first case is of the form \texttt{R\_call 0x408b94d4} in which the hexadecimal number is the memory address of the function. In the second case it will be of the form \texttt{R\_call\_lang 0x8a95904 0x819bfd0}. For expressions, a sequence of similar items is generated, separated by semicolons.

\texttt{Tcl.callback} converts \texttt{R} functions and unevaluated calls to Tcl command strings. The argument must be either a function closure or an object of mode "call" followed by an environment. The return value in the first case is of the form \texttt{R\_call 0x408b94d4} in which the hexadecimal number is the memory address of the function. In the second case it will be of the form \texttt{R\_call\_lang 0x8a95904 0x819bfd0}. For expressions, a sequence of similar items is generated, separated by semicolons.

Tk windows are represented as objects of class \texttt{tkwin} which are lists containing a \texttt{ID} field and an \texttt{env} field which is an \texttt{R} environments, enclosed in the global environment. The value of the \texttt{ID} field is identical to the Tk window name. The \texttt{env} environment contains a \texttt{parent} variable and a \texttt{num.subwin} variable. If the window obtains sub-windows and callbacks, they are added as variables to the environment. \texttt{Tk\_Root} is the top window with ID "."; this window is not displayed in order to avoid ill effects of closing it via window manager controls. The \texttt{parent} variable is undefined for \texttt{Tk\_Root}.

\texttt{Tk\_ID} extracts the \texttt{ID} of a window, \texttt{Tk\_newwin} creates a new window environment with a given \texttt{ID} and \texttt{Tk\_subwin} creates a new window which is a sub-window of a given parent window.

\texttt{tk\_destroy} destroys a window and also removes the reference to a window from its parent.

\texttt{is\_tkwin} can be used to test whether a given object is a window environment.

\texttt{tcl\_Var} creates a new Tcl variable and initializes it to \texttt{init}. An \texttt{R} object of class \texttt{tcl\_Var} is created to represent it. Using \texttt{as\_character} on the object returns the Tcl variable name. Accessing the Tcl variable from \texttt{R} is done using the \texttt{tcl\_value} function, which can also occur on the left-hand side of assignments. If \texttt{tcl\_value} is passed an argument which is not a \texttt{tcl\_Var} object, then it will assume that it is a character string explicitly naming global Tcl variable. Tcl variables created by \texttt{tcl\_Var} are uniquely named and automatically unset by the garbage collector when the representing object is no longer in use.

\texttt{tcl\_Array} creates a new Tcl array and initializes it to the empty array. An \texttt{R} object of class \texttt{tcl\_Array} and inheriting from class \texttt{tcl\_Var} is created to represent it. You can access elements of the Tcl array using indexing with \texttt{[} \texttt{i} \texttt{]} or \texttt{\$} \texttt{i}, which also allow replacement forms. Notice that Tcl arrays are associative by nature and hence unordered; indexing with a numeric index \texttt{i} refers to the element with the \texttt{name as.character(i)}. Multiple indices are pasted together separated by commas to form a single name. You can query the length and the set of names in an array using methods for \texttt{length} and \texttt{names}, respectively; these cannot meaningfully be set so assignment forms exist only to print an error message.

It is possible to access Tcl’s ‘dual-ported’ objects directly, thus avoiding parsing and deparsing of their string representation. This works by using objects of class \texttt{tcl\_Obj}. The string representation of such objects can be extracted (but not set) using \texttt{tcl\_value} and conversion to vectors of mode "character", "double", or "integer". Conversely, such vectors can be converted using \texttt{as\_tcl\_Obj}. There is an ambiguity as to what should happen for length one vectors, controlled by the \texttt{drop} argument; there are cases where the distinction matters to Tcl, although mostly it treats them equivalently. Notice that \texttt{tcl\_value} and \texttt{as\_character} differ on an object whose string representation has embedded spaces, the former is sometimes to be preferred, in particular when applied to the result of \texttt{tcl\_read}, \texttt{tk\_getOpenFile}, and similar functions.

The object behind a \texttt{tcl\_Var} object is extracted using \texttt{tcl\_Obj(x)} which also allows an assignment form, in which the right hand side of the assignment is automatically converted using \texttt{as\_tcl\_Obj}. There is a print method for \texttt{tcl\_Obj} objects; it prints \texttt{<Tcl>} followed by the string
representation of the object. Notice that `as.character` on a `tclVar` object is the name of the corresponding Tcl variable and not the value.

Tcl packages can be loaded with `tclRequire`; it may be necessary to add the directory where they are found to the Tcl search path with `addTclPath`.

**Note**

Strings containing unbalanced braces are currently not handled well in many circumstances.

**See Also**

`TkWidgets`, `TkCommands`, `TkWidgetcmds`. `capabilities("tcltk")` to see if Tcl/Tk support was compiled into this build of R.

**Examples**

```r
## Not run:
## These cannot be run by example() but should be OK when pasted
## into an interactive R session with the tcltk package loaded
.Tcl("format \"%s\n\" \"Hello, World!\"")
f <- function()cat("HI!\n")
.Tcl.callback(f)
.Tcl.args(text="Push!", command=f)  # NB: Different address

xyzzy <- tclVar(7913)
tclvalue(xyzzy)
tclvalue(xyzzy) <- "foo"
as.character(xyzzy)
tcl("set", as.character(xyzzy))

top <- tktoplevel()  # a Tk widget, see Tk-widgets
s(envir=top$env, all=TRUE)
ls(envir=.TkRoot$env, all=TRUE)# .Tcl.args put a callback ref in here
## End(Not run)
```

---

**tclServiceMode**

Allow Tcl events to be serviced or not

**Description**

This function controls or reports on the Tcl service mode, i.e. whether Tcl will respond to events.

**Usage**

`tclServiceMode(on = NULL)`

**Arguments**

- `on` (logical) Whether event servicing is turned on.

**Details**

If called with `on == NULL` (the default), no change is made.
Value

The value of the Tcl service mode before the call.

Examples

## Not run:

```r
oldmode <- tclServiceMode(FALSE)
# Do some work to create a nice picture. Nothing will be displayed until...
tclServiceMode(oldmode)
## End(Not run)
```

---

TkCommands

**Tk non-widget commands**

Description

These functions interface to Tk non-widget commands, such as the window manager interface commands and the geometry managers.

Usage

```r
tcl(...) 
tktitle(x)

# value

tktitle(x) <- value

tkbell(...) 
tkbind(...) 
tkbindtags(...) 
tkfocus(...) 
tklower(...) 
tkraise(...)

tkclipboard.append(...) 
tkclipboard.clear(...)

tkevent.add(...) 
tkevent.delete(...) 
tkevent.generate(...) 
tkevent.info(...)

tkfont.actual(...) 
tkfont.configure(...) 
tkfont.create(...) 
tkfont.delete(...) 
tkfont.families(...) 
tkfont.measure(...) 
tkfont.metrics(...) 
tkfont.names(...)
```
TkCommands

Tkgrab(...)  
tkgrab.current(...)  
tkgrab.release(...)  
tkgrab.set(...)  
tkgrab.status(...)  

tkimage.cget(...)  
tkimage.configure(...)

**Arguments**

- `x`  
  A window object
tkpager

value For tktitle assignments, a character string.
...
Handled via .Tcl.args

Details
tcl provides a generic interface to calling any Tk or Tcl command by simply running .Tcl.args.objv on the argument list and passing the result to .Tcl.objv. Most of the other commands simply call tcl with a particular first argument and sometimes also a second argument giving the subcommand.
tktitle and its assignment form provides an alternate interface to Tk's wm title

There are far too many of these commands to describe them and their arguments in full. Please refer to the Tcl/Tk documentation for details. With a few exceptions, the pattern is that Tk subcommands like pack configure are converted to function names like tkpack.configure, and Tcl subcommands are like tclfile.dir.

TclInterface, TkWidgets, TkWidgetcmds

Examples
## Not run:
## These cannot be run by examples() but should be OK when pasted
## into an interactive R session with the tcltk package loaded

tt <- tktoplevel()
tkpack(l1<-tklabel(tt,text="Heave"), l2<-tklabel(tt,text="Ho"))
tkpack.configure(l1, side="left")

## Try stretching the window and then
tkdestroy(tt)
## End(Not run)

tkpager

Page file using Tk text widget

Description
This plugs into file.show, showing files in separate windows.

Usage
tkpager(file, header, title, delete.file)

Arguments
file character vector containing the names of the files to be displayed
header headers to use for each file
title common title to use for the window(s). Pasted together with the header to form actual window title.
delete.file logical. Should file(s) be deleted after display?
Note

The "_" string used for underlining is currently quietly removed. The font and background colour are currently hardcoded to Courier and gray90.

file.show

tkStartGUI

Tk/Tk GUI startup

Description

Starts up the Tcl/Tk GUI

Usage

tkStartGUI()

Details

Starts a GUI console implemented via a Tk text widget. This should probably be called at most once per session. Also redefines the file pager (as used by help()) to be the Tk pager.

Note

tkStartGUI() saves its evaluation environment as .GUIenv. This means that the user interface elements can be accessed in order to extend the interface. The three main objects are named Term, Menu, and Toolbar, and the various submenus and callback functions can be seen with ls(envir=.GUIenv).

TkWidgetcmds

Tk widget commands

Description

These functions interface to Tk widget commands.
Usage

- tkactivate(widget, ...)
- tkadd(widget, ...)
- tkaddtag(widget, ...)
- tkbbox(widget, ...)
- tkcanvasx(widget, ...)
- tkcanvasy(widget, ...)
- tkcget(widget, ...)
- tkcompare(widget, ...)
- tkconfigure(widget, ...)
- tkcoords(widget, ...)
- tkcreate(widget, ...)
- tkcurselection(widget, ...)
- tkdchars(widget, ...)
- tkdebug(widget, ...)
- tkdelete(widget, ...)
- tkdelta(widget, ...)
- tkdeselect(widget, ...)
- tkdlineinfo(widget, ...)
- tkdtag(widget, ...)
- tkdump(widget, ...)
- tkentrycget(widget, ...)
- tkentryconfigure(widget, ...)
- tkfind(widget, ...)
- tkflash(widget, ...)
- tkfraction(widget, ...)
- tkget(widget, ...)
- tkgettags(widget, ...)
- tkicursor(widget, ...)
- tkidentify(widget, ...)
- tkindex(widget, ...)
- tkinsert(widget, ...)
- tkinvoke(widget, ...)
- tkitembind(widget, ...)
- tkitemcget(widget, ...)
- tkitemconfigure(widget, ...)
- tkitemfocus(widget, ...)
- tkitemlower(widget, ...)
- tkitemraise(widget, ...)
- tkitemscale(widget, ...)
- tkmark.gravity(widget, ...)
- tkmark.names(widget, ...)
- tkmark.next(widget, ...)
- tkmark.previous(widget, ...)
- tkmark.set(widget, ...)
- tkmark.unset(widget, ...)
- tkmove(widget, ...)
- tknearest(widget, ...)
- tkpost(widget, ...)
- tkpostcascade(widget, ...)
- tkpostsnapshot(widget, ...)
- tkscan.mark(widget, ...)
tkscan.dragto(widget, ...)
tksearch(widget, ...)
tksee(widget, ...)
tkselect(widget, ...)
tkselection.adjust(widget, ...)
tkselection.anchor(widget, ...)
tkselection.clear(widget, ...)
tkselection.from(widget, ...)
tkselection.includes(widget, ...)
tkselection.present(widget, ...)
tkselection.range(widget, ...)
tkselection.set(widget, ...)
tkselection.to(widget, ...)
tkset(widget, ...)
tksize(widget, ...)
tktoggle(widget, ...)
tktag.add(widget, ...)
tktag.bind(widget, ...)
tktag.cget(widget, ...)
tktag.configure(widget, ...)
tktag.delete(widget, ...)
tktag.lower(widget, ...)
tktag.names(widget, ...)
tktag.nextrange(widget, ...)
tktag.prevrange(widget, ...)
tktag.raise(widget, ...)
tktag.ranges(widget, ...)
tktag.remove(widget, ...)
tktype(widget, ...)
tkunpost(widget, ...)
tkwindow.cget(widget, ...)
tkwindow.configure(widget, ...)
tkwindow.create(widget, ...)
tkwindow.names(widget, ...)
tkxview(widget, ...)
tkxview.moveto(widget, ...)
tkxview.scroll(widget, ...)
tkyposition(widget, ...)
tkyview(widget, ...)
tkyview.moveto(widget, ...)
tkyview.scroll(widget, ...)

Arguments

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>widget</td>
<td>The widget this applies to</td>
</tr>
<tr>
<td>...</td>
<td>Handled via .Tcl.args</td>
</tr>
</tbody>
</table>

Details

There are far too many of these commands to describe them and their arguments in full. Please refer to the Tcl/Tk documentation for details. Except for a few exceptions, the pattern is that Tcl widget commands possibly with subcommands like .a.b selection clear are converted to function names like tkselection.clear and the widget is given as the first argument.
TkWidgets

Examples

## Not run:
## These cannot be run by examples() but should be OK when pasted
## into an interactive R session with the tcltk package loaded

```r
tt <- tktoplevel()
tkpack(txt.w <- tktext(tt))
tkinsert(txt.w, "0.0", "plot(1:10)")

# callback function
eval.txt <- function()
  eval(parse(text=tclvalue(tkget(txt.w, "0.0", "end"))))
tkpack(but.w <- tkbutton(tt, text="Submit", command=eval.txt))

## Try pressing the button, edit the text and when finished:

tkdestroy(tt)
## End(Not run)
```

TkWidgets

**Tk widgets**

Create Tk widgets and associated R objects.

Usage

- `tkwidget(parent, type, ...)`
- `tkbutton(parent, ...)`
- `tkcanvas(parent, ...)`
- `tkcheckbutton(parent, ...)`
- `tkentry(parent, ...)`
- `tkframe(parent, ...)`
- `tklabel(parent, ...)`
- `tklistbox(parent, ...)`
- `tkmenu(parent, ...)`
- `tkmenubutton(parent, ...)`
- `tkmessage(parent, ...)`
- `tkradiobutton(parent, ...)`
- `tkscale(parent, ...)`
- `tkscrollbar(parent, ...)`
- `tktext(parent, ...)`
- `tktoplevel(parent=.TkRoot, ...)`
Arguments

parent  Parent of widget window

type  string describing the type of widget desired

Details

These functions create Tk widgets. `tkwidget` creates a widget of a given type, the others simply call `tkwidget` with the respective `type` argument.

It is not possible to describe the widgets and their arguments in full. Please refer to the Tcl/Tk documentation.

`TclInterface`, `TkCommands`, `TkWidgetcmds`

Examples

```r
## Not run:
## These cannot be run by examples() but should be OK when pasted
## into an interactive R session with the tcltk package loaded

tt <- tktoplevel()
lbl <- tklabel(tt, text="Hello, World!")
bt <- tkbutton(tt, text="Push",
               command=function()cat("OW!\n"))
tkpack(lbl, bt) # geometry manager
               # see Tk-commands

## Push the button and then...

tkdestroy(tt)
## End(Not run)
```

---

**tk_select.list**  Select Items from a List

Description

Select item(s) from a character vector using a Tk listbox.

Usage

```r
tk_select.list(list, preselect = NULL, multiple = FALSE, title = NULL)
```

Arguments

- **list**: character. A list of items.
- **preselect**: a character vector, or `NULL`. If non-null and if the string(s) appear in the list, the item(s) are selected initially.
- **multiple**: logical: can more than one item be selected?
- **title**: optional character string for window title.
Details

This is a version of `select.list` implemented as a Tk list box plus OK and Cancel buttons. There will be a scrollbar if the list is too long to fit comfortably on the screen.

The dialog box is modal, so a selection must be made or cancelled before the R session can proceed.

Value

A character vector of selected items. If `multiple` is false and no item was selected (or Cancel was used), "" is returned. If `multiple` is true and no item was selected (or Cancel was used) then a character vector of length 0 is returned.

See Also

`select.list` (a text version except on Windows), `menu` (whose graphics=TRUE mode uses this on most Unix-alikes).
