Chapter 1

The base package

---

**base-package**  
*The R Base Package*

---

**Description**

Base R functions

**Details**

This package contains the basic functions which let R function as a language: arithmetic, input/output, basic programming support, etc. Its contents are available through inheritance from any environment.

For a complete list of functions, use `library(help="base")`.

---

**.Device**  
*Lists of Open/Active Graphics Devices*

---

**Description**

A pairlist of the names of open graphics devices is stored in `.Devices`. The name of the active device (see `dev.cur`) is stored in `.Device`. Both are symbols and so appear in the base name space.

**Value**

`.Device` is a length-one character vector.

`.Devices` is a pairlist of length-one character vectors. The first entry is always "null device", and there are as many entries as the maximal number of graphics devices which have been simultaneously active. If a device has been removed, its entry will be "" until the device number is reused.
.Machine

Numerical Characteristics of the Machine

Description

.

Machine is a variable holding information on the numerical characteristics of the machine \texttt{R} is running on, such as the largest double or integer and the machine’s precision.

Usage

.

Machine

Details

The algorithm is based on Cody’s (1988) subroutine MACHAR.

Note that on most platforms smaller positive values than \texttt{.Machine$double.xmin} can occur. On a typical \texttt{R} platform the smallest positive double is about 5e-324.

Value

A list with components (for simplicity, the prefix “double” is omitted in the explanations)

double.eps the smallest positive floating-point number \( x \) such that \( 1 + x \neq 1 \). It equals \( \text{base}^{\text{ulp.digits}} \) if either \( \text{base} \) is 2 or \text{rounding} is 0; otherwise, it is \( \text{base}^{\text{ulp.digits}} / 2 \).
double.neg.eps a small positive floating-point number \( x \) such that \( 1 - x \neq 1 \). It equals \( \text{base}^{\text{neg.ulp.digits}} \) if \( \text{base} \) is 2 or \text{round} is 0; otherwise, it is \( \text{base}^{\text{neg.ulp.digits}} / 2 \). As \text{neg.ulp.digits} is bounded below by \(-(\text{digits} + 3)\), \text{neg.eps} may not be the smallest number that can alter 1 by subtraction.
double.xmin the smallest non-vanishing normalized floating-point power of the radix, i.e., \( \text{base}^{\text{min.exp}} \).
double.xmax the largest finite floating-point number. Typically, it is equal to \((1 - \text{neg.eps}) \times \text{base}^{\text{max.exp}}\), but on some machines it is only the second, or perhaps third, largest number, being too small by 1 or 2 units in the last digit of the significand.
double.base the radix for the floating-point representation
double.digits the number of base digits in the floating-point significand
double.rounding the rounding action.
0 if floating-point addition chops;
1 if floating-point addition rounds, but not in the IEEE style;
2 if floating-point addition rounds in the IEEE style;
3 if floating-point addition chops, and there is partial underflow;
4 if floating-point addition rounds, but not in the IEEE style, and there is partial underflow;
5 if floating-point addition rounds in the IEEE style, and there is partial underflow.
double.guard  the number of guard digits for multiplication with truncating arithmetic. It is 1  
if floating-point arithmetic truncates and more than digits base base digits  
participate in the post-normalization shift of the floating-point significand in  
multiplication, and 0 otherwise.

double.ulp.digits  
the largest negative integer i such that 1 + base^i != 1, except that it is  
bounded below by -(digits + 3).

double.neg.ulp.digits  
the largest negative integer i such that 1 - base^i != 1, except that it is  
bounded below by -(digits + 3).

double.exponent  
the number of bits (decimal places if base is 10) reserved for the representation  
of the exponent (including the bias or sign) of a floating-point number

double.min.exp  
the largest in magnitude negative integer i such that base ^ i is positive and  
normalized.

double.max.exp  
the smallest positive power of base that overflows.

integer.max  the largest integer which can be represented.

sizeof.long  the number of bytes in a C long type.

sizeof.longlong  the number of bytes in a C long long type. Will be zero if there is no such  
type.

sizeof.longdouble  the number of bytes in a C long double type. Will be zero if there is no such  
type.

sizeof.pointer  the number of bytes in a C SEXP type.

See Also

.Platform for details of the platform.

Examples

.Machine  
## or for a neat printout
noquote(unlist(format(.Machine)))
.Platform Specific Variables

Description

$.Platform is a list with some details of the platform under which R was built. This provides means to write OS-portable R code.

Usage

$.Platform

Value

A list with at least the following components:

- **OS.type** character string, giving the Operating System (family) of the computer. One of "unix" or "windows".
- **file.sep** character string, giving the file separator used on your platform: "/" on both Unix-alikes and on Windows (but not on the now abandoned port to Classic MacOS).
- **dynlib.ext** character string, giving the file name extension of dynamically loadable libraries, e.g., ".dll" on Windows and ".so" or ".sl" on Unix-alikes. (Note for MacOS X users: these are shared objects as loaded by dyn.load and not dylibs.)
- **GUI** character string, giving the type of GUI in use, or "unknown" if no GUI can be assumed. Possible values are for Unix-alikes the values given via the `-g` command-line flag ("X11", "Tk", "none" and perhaps others under alternative front-ends or embedded R), "AQUA" (running under R.app on MacOS X), "RGui" and "RTerm" (Windows).
- **endian** character string, "big" or "little", giving the endianness of the processor in use. This is relevant when it is necessary to know the order to read/write bytes of e.g. an integer or double from/to a connection: see readBin.
- **pkgType** character string, the preferred setting for options("pkgType"). Values "source", "mac.binary" and "win.binary" are currently in use.
- **path.sep** character string, giving the path separator, used on your platform, e.g., ":" on Unix-alikes and ";" on Windows. Used to separate paths in variables such as PATH and TEXINPUTS.
- **r_arch** character string, possibly ".". The name of the architecture-specific directories used in this build of R.

See Also

R.version and Sys.info give more details about the OS. In particular, R.version$platform is the canonical name of the platform under which R was compiled.

.Machine for details of the arithmetic used, and system for invoking platform-specific system commands.
Examples

```r
## Note: this can be done in a system-independent way by file.info()$isdir
if(.Platform$OS.type == "unix") {
  system.test <- function(...) { system(paste("test", ...)) == 0 }
  dir.exists <- function(dir) sapply(dir, function(d)system.test("-d", d))
  dir.exists(c(R.home(), "/tmp", "/~", "/NO"))# > T T T F
}
```
Abbreviate Strings

Description
Abbreviate strings to at least `minlength` characters, such that they remain unique (if they were).

Usage
`abbreviate(names.arg, minlength = 4, use.classes = TRUE, dot = FALSE)`

Arguments
- `names.arg`: a character vector of names to be abbreviated, or an object to be coerced to a character vector by `as.character`.
- `minlength`: the minimum length of the abbreviations.
- `use.classes`: logical (currently ignored by R).
- `dot`: logical: should a dot (".") be appended?

Details
The algorithm used is similar to that of S. For a single string it works as follows. First all spaces at the beginning of the string are stripped. Then (if necessary) any other spaces are stripped. Next, lower case vowels are removed (starting at the right) followed by lower case consonants. Finally if the abbreviation is still longer than `minlength` upper case letters are stripped.

Characters are always stripped from the end of the word first. If an element of `names.arg` contains more than one word (words are separated by space) then at least one letter from each word will be retained.

Missing (NA) values are unaltered.

If `use.classes` is FALSE then the only distinction is to be between letters and space. This has NOT been implemented.

Value
A character vector containing abbreviations for the strings in its first argument. Duplicates in the original `names.arg` will be given identical abbreviations. If any non-duplicated elements have the same `minlength` abbreviations then `minlength` is incremented by one and new abbreviations are found for those elements only. This process is repeated until all unique elements of `names.arg` have unique abbreviations.

The character version of `names.arg` is attached to the returned value as a names argument: no other attributes are retained.

Warning
This is really only suitable for English, and does not work correctly with non-ASCII characters in multibyte locales. It will warn if used with non-ASCII characters.
agrep

See Also

substr.

Examples

```r
x <- c("abcd", "efgh", "abce")
abbreviate(x, 2)

(st.abb <- abbreviate(state.name, 2))
table(nchar(st.abb))# out of 50, 3 need 4 letters
```

agrep Approximate String Matching (Fuzzy Matching)

Description

Searches for approximate matches to `pattern` (the first argument) within the string `x` (the second argument) using the Levenshtein edit distance.

Usage

```r
agrep(pattern, x, ignore.case = FALSE, value = FALSE, max.distance = 0.1)
```

Arguments

- **pattern**: a non-empty character string to be matched (*not* a regular expression!). Coerced by `as.character` to a string if possible.
- **x**: character vector where matches are sought. Coerced by `as.character` to a character vector if possible.
- **ignore.case**: if FALSE, the pattern matching is case sensitive and if TRUE, case is ignored during matching.
- **value**: if FALSE, a vector containing the (integer) indices of the matches determined is returned and if TRUE, a vector containing the matching elements themselves is returned.
- **max.distance**: Maximum distance allowed for a match. Expressed either as integer, or as a fraction of the pattern length (will be replaced by the smallest integer not less than the corresponding fraction), or a list with possible components
  - **all**: maximal (overall) distance
  - **insertions**: maximum number/fraction of insertions
  - **deletions**: maximum number/fraction of deletions
  - **substitutions**: maximum number/fraction of substitutions
  If all is missing, it is set to 10%, the other components default to all. The component names can be abbreviated.

Details

The Levenshtein edit distance is used as measure of approximateness: it is the total number of insertions, deletions and substitutions required to transform one string into another.

The function is a simple interface to the `apse` library developed by Jarkko Hietaniemi (also used in the Perl String::Approx module).
**Value**

Either a vector giving the indices of the elements that yielded a match, or, if `value` is `TRUE`, the matched elements (after coercion, preserving names but no other attributes).

**Author(s)**

David Meyer (David.Meyer@wu-wien.ac.at) (based on C code by Jarkko Hietaniemi); modifications by Kurt Hornik.

agrep("lasy", "1 lazy 2")
agrep("lasy", "1 lazy 2", max = list(sub = 0))
agrep("laysy", c("1 lazy", "1", "1 LASY"), max = 2)
agrep("laysy", c("1 lazy", "1", "1 LASY"), max = 2, value = TRUE)
agrep("laysy", c("1 lazy", "1", "1 LAZY"), max = 2, ignore.case = TRUE)
```

---

**all**

**Are All Values True?**

**Description**

Given a set of logical vectors, are all of the values true?

**Usage**

```r
all(..., na.rm = FALSE)
```

**Arguments**

... one or more logical vectors. Other objects are coerced in a similar way as `as.logical.default`.

na.rm logical. If true NA values are removed before the result is computed.

**Details**

This is a generic function: methods can be defined for it directly or via the `Summary` group generic. For this to work properly, the arguments ... should be unnamed, and dispatch is on the first argument.

**Value**

Given a sequence of logical arguments, a logical value indicating whether or not all of the elements of `x` are `TRUE`.

The value returned is `TRUE` if all of the values in `x` are `TRUE`, and `FALSE` if any of the values in `x` are `FALSE`.

If `na.rm = FALSE` and `x` consists of a mix of `TRUE` and NA values, the value is NA.

any, the “complement” of all, and stopifnot(*) which is an all(*) “insurance”.

Examples

```r
range(x <- sort(round(rnorm(10) - 1.2, 1)))
if(all(x < 0)) cat("all x values are negative\n")
```

---

**all.equal**

Test if Two Objects are (Nearly) Equal

Description

`all.equal(x,y)` is a utility to compare R objects `x` and `y` testing “near equality”. If they are different, comparison is still made to some extent, and a report of the differences is returned. Don’t use `all.equal` directly in if expressions—either use `isTRUE(all.equal(...))` or `identical` if appropriate.

Usage

```r
all.equal(target, current, ...)
```

## S3 method for class 'numeric':
```r
all.equal(target, current, 
  tolerance = .Machine$double.eps ^ 0.5, 
  scale = NULL, check.attributes = TRUE, ...)
```

```r
attr.all.equal(target, current, 
  check.attributes = TRUE, check.names = TRUE, ...)
```

Arguments

- **target** R object.
- **current** other R object, to be compared with `target`.
- **...** Further arguments for different methods, notably the following two, for numerical comparison:
  - **tolerance** numeric ≥ 0. Differences smaller than `tolerance` are not considered.
  - **scale** numeric scalar > 0 (or `NULL`). See Details.
- **check.attributes** logical indicating if the attributes(.) of `target` and `current` should be compared as well.
- **check.names** logical indicating if the names(.) of `target` and `current` should be compared as well (and separately from the attributes).
Details

There are several methods available, most of which are dispatched by the default method, see methods("all.equal"). all.equal.list and all.equal.language provide comparison of recursive objects.

Numerical comparisons for scale = NULL (the default) are done by first computing the mean absolute difference of the two numerical vectors. If this is smaller than tolerance or not finite, absolute differences are used, otherwise relative differences scaled by the mean absolute difference.

If scale is positive, absolute comparisons are made after scaling (dividing) by scale.

For complex arguments, the modulus Mod of the difference is used: all.equal.numeric is called so arguments tolerance and scale are available.

attr.all.equal is used for comparing attributes, returning NULL or a character vector.

Value

Either TRUE or a vector of mode "character" describing the differences between target and current.

References

See Also

identical, isTRUE, ==, and all for exact equality testing.

Examples

all.equal(pi, 355/113) # not precise enough (default tol) > relative error

d45 <- pi*(1/4 + 1:10)
stopifnot(
  all.equal(tan(d45), rep(1,10))) # TRUE, but
  all.equal(tan(d45) -- rep(1,10)) # FALSE, since not exactly
  all.equal(tan(d45), rep(1,10), tol=0) # to see difference

all.names

Find All Names in an Expression

Description

Return a character vector containing all the names which occur in an expression or call.

Usage

all.names(expr, functions = TRUE, max.names = 200, unique = FALSE)

all.vars(expr, functions = FALSE, max.names = 200, unique = TRUE)
Arguments

- **expr**: an expression or call from which the names are to be extracted.
- **functions**: a logical value indicating whether function names should be included in the result.
- **max.names**: the maximum number of names to be returned.
- **unique**: a logical value which indicates whether duplicate names should be removed from the value.

Details

These functions differ only in the default values for their arguments.

Value

A character vector with the extracted names.

Examples

- `all.names(expression(sin(x+y)))`
- `all.vars(expression(sin(x+y)))`

---

**any**

Are Some Values True?

Description

Given a set of logical vectors, are any of the values true?

Usage

- `any(..., na.rm = FALSE)`

Arguments

- `...`: one or more logical vectors. Other objects are coerced in a similar way as `as.logical.default`.
- `na.rm`: logical. If true NA values are removed before the result is computed.

Details

This is a generic function: methods can be defined for it directly or via the `Summary` group generic. For this to work properly, the arguments `...` should be unnamed, and dispatch is on the first argument.

Value

Given a sequence of logical arguments, a logical value indicating whether or not any of the elements of `x` are TRUE.

The value returned is TRUE if any of the values in `x` are TRUE, and FALSE if all of the values in `x` are FALSE.

If `na.rm = FALSE` and `x` consists of a mix of FALSE and NA values, the value is NA.
aperm

Array Transposition

Description

Transpose an array by permuting its dimensions and optionally resizing it.

Usage

aperm(a, perm, resize = TRUE)

Arguments

a
the array to be transposed.

perm
the subscript permutation vector, which must be a permutation of the integers 1:n, where n is the number of dimensions of a. The default is to reverse the order of the dimensions.

resize
a flag indicating whether the vector should be resized as well as having its elements reordered (default TRUE).

Value

A transposed version of array a, with subscripts permuted as indicated by the array perm. If resize is TRUE, the array is reshaped as well as having its elements permuted, the dimnames are also permuted; if resize = FALSE then the returned object has the same dimensions as a, and the dimnames are dropped. In each case other attributes are copied from a.

The function t provides a faster and more convenient way of transposing matrices.

Author(s)

Jonathan Rougier, (J.C.Rougier@durham.ac.uk) did the faster C implementation.

References

See Also

t, to transpose matrices.

Examples

# interchange the first two subscripts on a 3-way array x
x <- array(1:24, 2:4)
x2 <- aperm(x, c(2,1,3))
stopifnot(t(x2[,,2]) == x[,,2],
        t(x2[,,3]) == x[,,3],
        t(x2[,,4]) == x[,,4])

Description

Add elements to a vector.

Usage

append(x, values, after = length(x))

Arguments

x the vector to be modified.
values to be included in the modified vector.
after a subscript, after which the values are to be appended.

Value

A vector containing the values in x with the elements of values appended after the specified element of x.

References

Examples

append(1:5, 0:1, after=3)
Apply Functions Over Array Margins

Description

Returns a vector or array or list of values obtained by applying a function to margins of an array.

Usage

`apply(X, MARGIN, FUN, ...)`

Arguments

- `X` the array to be used.
- `MARGIN` a vector giving the subscripts which the function will be applied over. 1 indicates rows, 2 indicates columns, c(1, 2) indicates rows and columns.
- `FUN` the function to be applied: see Details. In the case of functions like +, %*%, etc., the function name must be backquoted or quoted.
- `...` optional arguments to `FUN`.

Details

If `X` is not an array but has a dimension attribute, `apply` attempts to coerce it to an array via `as.matrix` if it is two-dimensional (e.g., data frames) or via `as.array`.

`FUN` is found by a call to `match.fun` and typically is either a function or a symbol (e.g. a backquoted name) or a character string specifying a function to be searched for from the environment of the call to `apply`.

Value

If each call to `FUN` returns a vector of length `n`, then `apply` returns an array of dimension `c(n, dim(X)[MARGIN])` if `n > 1`. If `n` equals 1, `apply` returns a vector if `MARGIN` has length 1 and an array of dimension `dim(X)[MARGIN]` otherwise. If `n` is 0, the result has length 0 but not necessarily the “correct” dimension.

If the calls to `FUN` return vectors of different lengths, `apply` returns a list of length `prod(dim(X)[MARGIN])` with `dim` set to `MARGIN` if this has length greater than one.

In all cases the result is coerced by `as.vector` to one of the basic vector types before the dimensions are set, so that (for example) factor results will be coerced to a character array.

apply
Examples

```r
## Compute row and column sums for a matrix:
x <- cbind(x1 = 3, x2 = c(4:1, 2:5))
dimnames(x)[[1]] <- letters[1:8]
apply(x, 2, mean, trim = .2)
col.sums <- apply(x, 2, sum)
row.sums <- apply(x, 1, sum)
rbind(cbind(x, Rtot = row.sums), Ctot = c(col.sums, sum(col.sums)))

stopifnot( apply(x, 2, is.vector)) # not ok in R <= 0.63.2

## Sort the columns of a matrix
apply(x, 2, sort)

##- function with extra args:
cave <- function(x, c1, c2) c(mean(x[c1]), mean(x[c2]))
apply(x,1, cave, c1="x1", c2=c("x1","x2"))

ma <- matrix(c(1:4, 1, 6:8), nr = 2)
ma
apply(ma, 1, table) #---> a list of length 2
apply(ma, 1, quantile)# 5 x n matrix with rownames

stopifnot(dim(ma) == dim(apply(ma, 1:2, sum)))## wasn't ok before R 0.63.1

## Example with different lengths for each call
z <- array(1:24, dim=2:4)
zseq <- apply(z, 1:2, function(x) seq(length=max(x)))
zseq ## a 2 x 3 matrix
typeof(zseq) ## list
dim(zseq) ## 2 3
zseq[1,]
apply(z, 3, function(x) seq(length=max(x))) ## a list without a dim attribute
```

### args

**Argument List of a Function**

**Description**

Displays the argument names and corresponding default values of a function or primitive.

**Usage**

```
args(name)
```

**Arguments**

- `name` a function (a closure or a primitive). If `name` is a character string then the function with that name is found and used.

**Details**

This function is mainly used interactively. For programming, use `formals` instead.
Value

A function with identical formal argument list but an empty body if given a closure.

A function with the documented usage for a primitive: note that in almost all cases primitives do not make use of named arguments and match by position rather than name. (rep and seq.int are exceptions.)

NULL in case of a non-function.

References

See Also

formals, help.

Examples

args(c)
args(graphics::plot.default)

Arithmetic

Description

These binary operators perform arithmetic on numeric or complex vectors (or objects which can be coerced to them).

Usage

\[
\begin{align*}
  x + y \\
  x - y \\
  x * y \\
  x / y \\
  x ^ y \\
  x % y \\
  x %/% y
\end{align*}
\]

Arguments

\[
\begin{align*}
  x, y
\end{align*}
\]

numeric or complex vectors or objects which can be coerced to such, or other objects for which methods have been written.
Details

The binary arithmetic operators are generic functions: methods can be written for them individually or via the Ops group generic function. (See Ops for how dispatch is computed.)

If applied to arrays the result will be an array if this is sensible (for example it will not if the recycling rule has been invoked).

Logical vectors will be coerced to numeric vectors, FALSE having value 0 and TRUE having value one.

1 ^ y and y ^ 0 are 1, always. x ^ y should also give the proper “limit” result when either argument is infinite (i.e., +-Inf).

Objects such as arrays or time-series can be operated on this way provided they are conformable.

For real arguments, % can be subject to catastrophic loss of accuracy if x is much larger than y, and a warning is given if this is detected.

Value

These operators return vectors containing the result of the element by element operations. The elements of shorter vectors are recycled as necessary (with a warning when they are recycled only fractionally). The operators are + for addition, - for subtraction, * for multiplication, / for division and ^ for exponentiation.

% is indicates x mod y and %/% indicates integer division. It is guaranteed that x == (x %% y) + y * (x %/% y) (up to rounding error) unless y == 0 where the result is NA or NaN (depending on the typeof of the arguments).

If either argument is complex the result will be complex, and if one or both arguments are numeric, the result will be numeric. If both arguments are integer, the result of / and ^ is numeric and of the other operators integer (with overflow returned as NA with a warning).

The rules for determining the attributes of the result are rather complicated. Most attributes are taken from the longer argument, the first if they are of the same length. Names will be copied from the first if it is the same length as the answer, otherwise from the second if that is. For time series, these operations are allowed only if the series are compatible, when the class and tsp attribute of whichever is a time series (the same, if both are) are used. For arrays (and an array result) the dimensions and dimnames are taken from first argument if it is an array, otherwise the second.

References

sqrt for miscellaneous and Special for special mathematical functions.

Syntax for operator precedence.

%% for matrix multiplication.

Examples

```r
x <- -1:12
x + 1
2 * x + 3
x %% 2 #-- is periodic
x %/% 5
```
Description

Creates or tests for arrays.

Usage

array(data = NA, dim = length(data), dimnames = NULL)
as.array(x)
is.array(x)

Arguments

data    a vector (including a list) giving data to fill the array.
dim     the dim attribute for the array to be created, that is a vector of length one or more giving the maximal indices in each dimension.
dimnames the names for the dimensions. This is a list with one component for each dimension, either NULL or a character vector of the length given by dim for that dimension. The list can be names, and the names will be used as names for the dimensions.
x        an R object.

Value

array returns an array with the extents specified in dim and naming information in dimnames. The values in data are taken to be those in the array with the leftmost subscript moving fastest. If there are too few elements in data to fill the array, then the elements in data are recycled. If data has length zero, NA of an appropriate type is used for atomic vectors (0 for raw vectors) and NULL for lists.
as.array() coerces its argument to be an array by attaching a dim attribute to it. It also attaches dimnames if x has names. The sole purpose of this is to make it possible to access the dim[ names] attribute at a later time.
is.array returns TRUE or FALSE depending on whether its argument is an array (i.e., has a dim attribute of positive length) or not. It is generic: you can write methods to handle specific classes of objects, see InternalMethods.

as.data.frame

Examples

```r
dim(as.array(letters))
array(1:3, c(2,4)) # recycle 1:3 "2 2/3 times"
# [1,] 1 3 2 1
# [2,] 2 1 3 2
```

as.data.frame Coerce to a Data Frame

Description

Functions to check if an object is a data frame, or coerce it if possible.

Usage

```r
as.data.frame(x, row.names = NULL, optional = FALSE, ...)
## S3 method for class 'character':
as.data.frame(x, ..., stringsAsFactors = default.stringsAsFactors())
## S3 method for class 'matrix':
as.data.frame(x, row.names = NULL, optional = FALSE, ..., stringsAsFactors = default.stringsAsFactors())

is.data.frame(x)
```

Arguments

- **x**: any R object.
- **row.names**: NULL or a character vector giving the row names for the data frame. Missing values are not allowed.
- **optional**: logical. If TRUE, setting row names and converting column names (to syntactic names) is optional.
- **...**: additional arguments to be passed to or from methods.
- **stringsAsFactors**: logical: should the character vector be converted to a factor?

Details

as.data.frame is a generic function with many methods, and users and packages can supply further methods.

If a list is supplied, each element is converted to a column in the data frame. Similarly, each column of a matrix is converted separately. This can be overridden if the object has a class which has a method for as.data.frame: two examples are matrices of class "model.matrix" (which are included as a single column) and list objects of class "POSIXlt" which are coerced to class "POSIXct".

Arrays can be converted to data frames. One-dimensional arrays are treated like vectors and two-dimensional arrays like matrices. Arrays with more than two dimensions are converted to matrices by ‘flattening’ all dimensions after the first and creating suitable column labels.
Character variables are converted to factor columns unless protected by `I`.

If a data frame is supplied, all classes preceding "data.frame" are stripped, and the row names are changed if that argument is supplied.

If `row.names = NULL`, row names are constructed from the names or dimnames of `x`, otherwise are the integer sequence starting at one. Few of the methods check for duplicated row names. Names are removed from vector columns unless `I`.

Value

`as.data.frame` returns a data frame, normally with all row names "" if `optional = TRUE`. `is.data.frame` returns TRUE if its argument is a data frame (that is, has "data.frame" amongst its classes) and FALSE otherwise.

References

`data.frame`, `as.data.frame.table` for the `table` method (which has additional arguments if called directly).

---

### as.environment

**Coerce to an Environment Object**

Description

Converts a number or a character string to the corresponding environment on the search path.

Usage

`as.environment(object)`

Arguments

- `object` the object to convert. If it is already an environment, just return it. If it is a number, return the environment corresponding to that position on the search list. If it is a character string, match the string to the names on the search list.

Value

The corresponding environment object.

Author(s)

John Chambers

See Also

`environment` for creation and manipulation, `search`. 
as.function

Examples

as.environment(1) # the global environment
identical(globalenv(), as.environment(1)) # is TRUE
try(as.environment("package:stats")) # stats need not be loaded

as.function

Convert Object to Function

Description

as.function is a generic function which is used to convert objects to functions.
as.function.default works on a list x, which should contain the concatenation of a formal argument list and an expression or an object of mode "call" which will become the function body. The function will be defined in a specified environment, by default that of the caller.

Usage

as.function(x, 

## Default S3 method:
as.function(x, envir = parent.frame(), 

Arguments

x object to convert, a list for the default method.
... additional arguments, depending on object
envir environment in which the function should be defined

Value

The desired function.

Note

For ancient historical reasons, envir = NULL uses the global environment rather than the base environment. Please use envir = globalenv() instead if this is what you want, as the special handling of NULL may change in a future release.

Author(s)

Peter Dalgaard

as.function(alist(a=,b=2,a+b))(3)
### as.POSIX*

#### Date-time Conversion Functions

#### Description
Functions to manipulate objects of classes "POSIXlt" and "POSIXct" representing calendar dates and times.

#### Usage

```r
as.POSIXct(x, tz = "")
as.POSIXlt(x, tz = "")
```

```r
## S3 method for class 'POSIXlt':
as.numeric(x)
```

#### Arguments

- **x**: An object to be converted.
- **tz**: A timezone specification to be used for the conversion, if one is required. System-specific, but "" is the current timezone, and "GMT" is UTC (Coordinated Universal Time, in French).

#### Details

The `as.POSIX*` functions convert an object to one of the two classes used to represent date/times (calendar dates plus time to the nearest second). They can convert a wide variety of objects, including objects of the other class and of classes "Date", "date" (from package `date` or `survival`), "chron" and "dates" (from package `chron`) to these classes. Dates without times are treated as being at midnight UTC.

They can also convert character strings of the formats "2001-02-03" and "2001/02/03" optionally followed by white space and a time in the format "14:52" or "14:52:03". (Formats such as "01/02/03" are ambiguous but can be converted via a format specification by `strptime`.) (As from R 2.4.0 fractional seconds can be converted.)

Logical NAs can be converted to either of the classes, but no other logical vectors can be.

The `as.numeric` method converts "POSIXlt" objects to "POSIXct".

If you are given a numeric time as the number of seconds since an epoch, see the examples.

Where OSes describe their valid timezones can be obscure. The help for `tzset` (or `_tzset` on Windows) can be helpful, but it can also be inaccurate. There is a cumbersome POSIX specification, (listed under environment variable `TZ` at [http://www.opengroup.org/onlinetools/009695399/basedefs/xbd_chap08.html](http://www.opengroup.org/onlinetools/009695399/basedefs/xbd_chap08.html)), which is often at least partially supported, but there may be other more user-friendly ways to specify timezones. For most Unix-alikes (including MacOS X) this can be an optional colon prepended to the path to a file (by default under `/usr/share/zoneinfo` or `/usr/lib/zoneinfo` (or even `/usr/share/lib/zoneinfo` on Solaris)), for example ‘EST5EDT’ or ‘GB’ or ‘Europe/Paris’. See [http://www.twinsun.com/tz/tz-link.htm](http://www.twinsun.com/tz/tz-link.htm) for more details and references.
Value

as.POSIXct and as.POSIXlt return an object of the appropriate class. If tz was specified, as.POSIXlt will give an appropriate "tzone" attribute.

Note

If you want to extract specific aspects of a time (such as the day of the week) just convert it to class "POSIXlt" and extract the relevant component(s) of the list, or if you want a character representation (such as a named day of the week) use format.POSIXlt or format.POSIXct.

If a timezone is needed and that specified is invalid on your system, what happens is system-specific but it will probably be ignored.

See Also

DateTimeClasses for details of the classes; strftime for conversion to and from character representations.

Examples

(z <- Sys.time()) # the current datetime, as class "POSIXct"
unclass(z) # a large integer
floor(unclass(z)/86400) # the number of days since 1970-01-01
(z <- as.POSIXlt(Sys.time())) # the current datetime, as class "POSIXlt"
unlist(unclass(z)) # a list shown as a named vector

## suppose we have a time in seconds since 1960-01-01 00:00:00 GMT
z <- 1472562988
# two ways to convert this
ISOdatetime(1960,1,1,0,0,0) + z # late August 2006
strftime("1960-01-01", "%Y-%m-%d", tz="GMT") + z

as.POSIXlt(Sys.time(), "GMT") # the current time in GMT
## Not run:
## These may not be correct names on your system
as.POSIXlt(Sys.time(), "EST5EDT") # the current time in New York
as.POSIXlt(Sys.time(), "EST") # ditto, ignoring DST
as.POSIXlt(Sys.time(), "HST") # the current time in Hawaii
as.POSIXlt(Sys.time(), "Australia/Darwin")
## End(Not run)
Arguments

\(x\) an object

Details

Function \(I\) has two main uses.

- In function \(\text{data.frame}\). Protecting an object by enclosing it in \(I()\) in a call to \(\text{data.frame}\) inhibits the conversion of character vectors to factors, and the dropping of names. \(I\) can also be used to protect objects which are to be added to a data frame, or converted to a data frame via \(\text{as.data.frame}\).

  It achieves this by prepending the class "AsIs" to the object’s classes. Class "AsIs" has a few of its own methods, including for \([.\), \(\text{as.data.frame}\), \(\text{print}\) and \(\text{format}\).

- In function \(\text{formula}\). There it is used to inhibit the interpretation of operators such as "+", "-", "," and "^" as formula operators, so they are used as arithmetical operators. This is interpreted as a symbol by \(\text{terms.formula}\).

Value

A copy of the object with class "AsIs" prepended to the class(es).

\(\text{data.frame, formula}\)

---

\(\text{assign}\) Assign a Value to a Name

Description

Assign a value to a name in an environment.

Usage

\[
\text{assign}(x, \text{value}, \text{pos} = -1, \text{envir} = \text{as.environment}(\text{pos}), \\
\quad \text{inherits} = \text{FALSE}, \text{immediate} = \text{TRUE})
\]

Arguments

\(x\) a variable name (given as a quoted string in the function call).

\(\text{value}\) a value to be assigned to \(x\).

\(\text{pos}\) where to do the assignment. By default, assigns into the current environment. See the details for other possibilities.

\(\text{envir}\) the \text{environment} to use. See the details section.

\(\text{inherits}\) should the enclosing frames of the environment be inspected?

\(\text{immediate}\) an ignored compatibility feature.
assign

Details

The `pos` argument can specify the environment in which to assign the object in any of several ways: as an integer (the position in the search list); as the character string name of an element in the search list; or as an environment (including using `sys.frame` to access the currently active function calls). The `envir` argument is an alternative way to specify an environment, but is primarily there for back compatibility.

`assign` does not dispatch assignment methods, so it cannot be used to set elements of vectors, names, attributes, etc.

Note that assignment to an attached list or data frame changes the attached copy and not the original object: see `attach`.

Value

This function is invoked for its side effect, which is assigning value to the variable x. If no `envir` is specified, then the assignment takes place in the currently active environment.

If `inherits` is TRUE, enclosing environments of the supplied environment are searched until the variable x is encountered. The value is then assigned in the environment in which the variable is encountered (provided that the binding is not locked: see `lockBinding`: if it is, an error is signaled). If the symbol is not encountered then assignment takes place in the user’s workspace (the global environment).

If `inherits` is FALSE, assignment takes place in the initial frame of `envir`, unless an existing binding is locked or there is no existing binding and the environment is locked.

Note

Prior to R 2.4.0 the base environment was ignored in the search for a binding by `inherits = TRUE`.

`<-, get, exists, environment`.

Examples

```r
for(i in 1:6) { #-- Create objects 'r.1', 'r.2', ... 'r.6' --
  nam <- paste("r",i, sep=".")
  assign(nam, 1:i)
}
ls(pat="^r..$")

#-- Global assignment within a function:
myf <- function(x) {
  innerf <- function(x) assign("Global.res", x^2, env = .GlobalEnv)
  innerf(x+1)
}
myf(3)
Global.res # 16
```
assignOps

Assignment Operators

Description
Assign a value to a name.

Usage
\begin{verbatim}
x <- value
x <<- value
value -> x
value ->> x
\end{verbatim}

Arguments
\begin{itemize}
\item \texttt{x} \hspace{1cm} a variable name (possibly quoted).
\item \texttt{value} \hspace{1cm} a value to be assigned to \texttt{x}.
\end{itemize}

Details
There are three different assignment operators: two of them have leftwards and rightwards forms. The operators \texttt{<-} and \texttt{=} assign into the environment in which they are evaluated. The operator \texttt{<-} can be used anywhere, whereas the operator \texttt{=} is only allowed at the top level (e.g., in the complete expression typed at the command prompt) or as one of the subexpressions in a braced list of expressions.

The operators \texttt{<<-} and \texttt{->>} cause a search to made through the environment for an existing definition of the variable being assigned. If such a variable is found (and its binding is not locked) then its value is redefined, otherwise assignment takes place in the global environment. Note that their semantics differ from that in the S language, but are useful in conjunction with the scoping rules of \texttt{R}. See ‘The \texttt{R} Language Definition’ manual for further details and examples.

In all the assignment operator expressions, \texttt{x} can be a name or an expression defining a part of an object to be replaced (e.g., \texttt{z[[1]]}). A syntactic name does not need to be quoted, though it can be (preferably by backticks).

The leftwards forms of assignment \texttt{<-} = \texttt{<<-} group right to left, the other from left to right.

Value
\begin{verbatim}
value. Thus one can use a <- b <- c <- 6.
\end{verbatim}

Note
Prior to \texttt{R} 2.4.0 the base environment was ignored in the search for a binding by \texttt{<<-} and \texttt{->>}.
attach

References

See Also

assign, environment.

attach

Attach Set of R Objects to Search Path

Description

The database is attached to the R search path. This means that the database is searched by R when evaluating a variable, so objects in the database can be accessed by simply giving their names.

Usage

```r
attach(what, pos = 2, name = deparse(substitute(what)), warn.conflicts = TRUE)
```

Arguments

what

“database”. This may currently be a `data.frame` or a list or a R data file created with `save` or NULL or an environment. See also Details.

pos

integer specifying position in `search()` where to attach.

name

alternative way to specify the database to be attached.

warn.conflicts

logical. If `TRUE`, warnings are printed about `conflicts` from attaching the database, unless that database contains an object `.conflicts.OK`. A conflict is a function masking a function, or a non-function masking a non-function.

Details

When evaluating a variable or function name R searches for that name in the databases listed by `search`. The first name of the appropriate type is used.

By attaching a data frame (or list) to the search path it is possible to refer to the variables in the data frame by their names alone, rather than as components of the data frame (e.g. in the example below, `height` rather than `women$height`).

By default the database is attached in position 2 in the search path, immediately after the user’s workspace and before all previously loaded packages and previously attached databases. This can be altered to attach later in the search path with the `pos` option, but you cannot attach at `pos=1`.

The database is not actually attached. Rather, a new environment is created on the search path and the elements of a list (including columns of a data frame) or objects in a save file or an environment are `copied` into the new environment. If you use `<<-` or `assign` to assign to an attached database, you only alter the attached copy, not the original object. (Normal assignment will place a modified version in the user’s workspace: see the examples.) For this reason `attach` can lead to confusion.
One useful ‘trick’ is to use `what = NULL` (or equivalently a length-zero list) to create a new environment on the search path into which objects can be assigned by `assign` or `load` or `sys.source`.

There are hooks to attach user-defined table objects of class "UserDefinedDatabase", supported by the Omegahat package RObjectTables. See http://www.omegahat.org/RObjectTables/.

Value

The `environment` is returned invisibly with a "name" attribute.

References

See Also

`library`, `detach`, `search`, `objects`, `environment`, `with`.

Examples

```r
summary(women$height)  # refers to variable 'height' in the data frame
attach(women)
summary(height)         # The same variable now available by name
height <- height * 2.54 # Don't do this. It creates a new variable
                        # in the user's workspace
find("height")
summary(height)         # The new variable in the workspace
rm(height)
summary(height)         # The original variable.
height <= height * 25.4 # Change the copy in the attached environment
find("height")
summary(height)         # The changed copy
detach("women")
summary(women$height)   # unchanged
```

```r
## Not run:
## create an environment on the search path and populate it
sys.source("myfuns.R", envir=attach(NULL, name="myfuns"))
## End(Not run)
```

attr  Object Attributes

Description

Get or set specific attributes of an object.

Usage

```r
attr(x, which)
attr(x, which) <- value
```
attributes

Arguments

- `x`: an object whose attributes are to be accessed.
- `which`: a non-empty character string specifying which attribute is to be accessed.
- `value`: an object, the new value of the attribute, or NULL to remove the attribute.

Details

These functions provide access to a single attribute of an object. The replacement form causes the named attribute to take the value specified (or create a new attribute with the value given).

The extraction function first looks for an exact match to `which` amongst the attributes of `x`, then a unique partial match. The replacement function only uses exact matches.

Note that some attributes (namely class, comment, dim, dimnames, names, (from R 2.4.0) row.names and tsp) are treated specially and have restrictions on the values which can be set.

The extractor allows (and does not match) empty and missing values of which: the replacement function does not.

Value

For the extractor, the value of the attribute matched, or NULL if no exact match is found and no or more than one partial match is found.

References

See Also

- attributes

Examples

```r
# create a 2 by 5 matrix
x <- 1:10
attr(x,"dim") <- c(2, 5)
```

Description

These functions access an object’s attributes. The first form below returns the object’s attribute list. The replacement forms uses the list on the right-hand side of the assignment as the object’s attributes (if appropriate).

Usage

```r
attributes(obj)
attributes(obj) <- value
mostattributes(obj) <- value
```
Arguments

- **obj**: an object
- **value**: an appropriate named list of attributes, or NULL.

Details

Note that some attributes (namely `class`, `comment`, `dim`, `dimnames`, `names`, (from R 2.4.0) `row.names` and `tsp`) are treated specially and have restrictions on the values which can be set.

Attributes are not stored internally as a list and should be thought of as a set and not a vector. They must have unique names (and NA is taken as "NA", not a missing value).

The `mostattributes` assignment takes special care for the `dim`, `names` and `dimnames` attributes, and assigns them only when valid whereas an `attributes` assignment would give an error if any are not.

The names of a pairlist are not stored as attributes, but are reported as if they were (and can be set by the replacement method for attributes).

References

See Also

- **attr**

Examples

```r
x <- cbind(a=1:3, pi=pi) # simple matrix w/ dimnames
attributes(x)

## strip an object's attributes:
attributes(x) <- NULL
x # now just a vector of length 6

mostattributes(x) <- list(mycomment = "really special", dim = 3:2,
                          dimnames = list(letters[1:3], letters[1:5]), names = paste(1:6))
x # dim(), but not (dim)names
```

autoload

**On-demand Loading of Packages**

**Description**

`autoload` creates a promise-to-evaluate `autoloader` and stores it with name `name` in `.AutoloadEnv` environment. When R attempts to evaluate `name`, `autoloader` is run, the package is loaded and `name` is re-evaluated in the new package’s environment. The result is that R behaves as if file was loaded but it does not occupy memory.

`.Autoloaded` contains the “base names” of the packages for which autoloading has been promised.
Usage

autoload(name, package, reset = FALSE, ...)
autoloader(name, package, ...)

Arguments

name  string giving the name of an object.
package  string giving the name of a package containing the object.
reset  logical: for internal use by autoloader.
...  other arguments to library.

Value

This function is invoked for its side-effect. It has no return value.

See Also

delayedAssign, library

Examples

require(stats)
auto-load("interpSpline", "splines")
search()
ls("Autoloads")
.Autoloaded

x <- sort(rnorm(12))
y <- x^2
is <- interpSpline(x,y)
search() # now has splines
detach("package:splines")
search()
is2 <- interpSpline(x,y+x)
search() # and again
detach("package:splines")

backsolve

Solve an Upper or Lower Triangular System

Description

Solves a system of linear equations where the coefficient matrix is upper or lower triangular.

Usage

backsolve(r, x, k=ncol(r), upper.tri=TRUE, transpose=FALSE)
forwardsolve(l, x, k=ncol(l), upper.tri=FALSE, transpose=FALSE)

Arguments

- **r,l**
  
an upper (or lower) triangular matrix giving the coefficients for the system to be solved. Values below (above) the diagonal are ignored.

- **x**
  
a matrix whose columns give “right-hand sides” for the equations.

- **k**
  
The number of columns of r and rows of x to use.

- **upper.tri**
  
  logical; if TRUE (default), the upper triangular part of r is used. Otherwise, the lower one.

- **transpose**
  
  logical; if TRUE, solve \( r^\prime \ast y = x \) for \( y \), i.e., \( t(r) \ast y = x \).

Value

The solution of the triangular system. The result will be a vector if \( x \) is a vector and a matrix if \( x \) is a matrix.

References

See Also

- chol
- qr
- solve

Examples

```r
## upper triangular matrix 'r':
r <- rbind(c(1,2,3),
          c(0,1,1),
          c(0,0,2))
( y <- backsolve(r, x <- c(8,4,2)) ) # -1 3 1
r %*% y # == x = (8,4,2)
backsolve(r, x, transpose = TRUE) # 8 -12 -5
```

Description

These functions are provided for compatibility with older versions of R only, and may be defunct as soon as the next release.

Usage

```r
Sys.putenv(...)```

Arguments

- **...**
  
  named arguments with values coercible to a character string.
Basename

Details

The original help page for these functions is often available at help("oldName-deprecated") (note the quotes). Functions in packages other than the base package are listed in help("pkg-deprecated").

Sys.putenv is a deprecated synonym for Sys.setenv.

See Also

Deprecated, base-defunct

Basename: Manipulate File Paths

Description

basename removes all of the path up to the last path separator (if any).

dirname returns the part of the path up to (but excluding) the last path separator, or "." if there is no path separator.

Usage

basename(path)
dirname(path)

Arguments

path character vector, containing path names.

Details

For dirname tilde expansion is done: see the description of path.expand.

Trailing file separators are removed before dissecting the path, and for dirname any trailing file separators are removed from the result.

Value

A character vector of the same length as path. A zero-length input will give a zero-length output with no error.

See Also

file.path, path.expand.

Examples

basename(file.path("","p1","p2","p3", c("file1","file2")))
dirname(file.path("","p1","p2","p3","filename"))
Description

Bessel Functions of integer and fractional order, of first and second kind, $J_\nu$ and $Y_\nu$, and Modified Bessel functions (of first and third kind), $I_\nu$ and $K_\nu$.

gammaCody is the $(\Gamma)$ function as from the Specfun package and originally used in the Bessel code.

Usage

besselI(x, nu, expon.scaled = FALSE)
besselK(x, nu, expon.scaled = FALSE)
besselJ(x, nu)
besselY(x, nu)
gammaCody(x)

Arguments

x numeric, $\geq 0$.

nu numeric; The order (maybe fractional!) of the corresponding Bessel function.

expon.scaled logical; if TRUE, the results are exponentially scaled in order to avoid overflow ($I_\nu$) or underflow ($K_\nu$), respectively.

Details

If expon.scaled = TRUE, $e^{-x}I_\nu(x)$, or $e^xK_\nu(x)$ are returned.

gammaCody may be somewhat faster but less precise and/or robust than R’s standard gamma. It is here for experimental purpose mainly, and may be defunct very soon.

For $\nu < 0$, formulae 9.1.2 and 9.6.2 from the reference below are applied (which is probably suboptimal), unless for besselK which is symmetric in nu.

Value

Numeric vector of the same length of x with the (scaled, if expon.scale=TRUE) values of the corresponding Bessel function.

Author(s)

Original Fortran code: W. J. Cody, Argonne National Laboratory

```
Access to and Manipulation of the Body of a Function

Description

Get or set the body of a function.

Usage

body(fun = sys.function(sys.parent()))
body(fun, envir = environment(fun)) <- value

Arguments

fun a function object, or see Details.
envir environment in which the function should be defined.
value an expression or a list of R expressions.

Details

For the first form, fun can be a character string naming the function to be manipulated, which is searched for from the parent environment. If it is not specified, the function calling body is used.

Value

body returns the body of the function specified.

The replacement form sets the body of a function to the expression/list on the right hand side, and (potentially) resets the environment of the function.

See Also

alist, args, function.

Examples

body(body)
f <- function(x) x^5
body(f) <- expression(5^x)
## or equivalently  body(f) <- list(quote(5^x))
f(3) # = 125
body(f)
bquote

Partial substitution in expressions

Description

An analogue of the LISP backquote macro. bquote quotes its argument except that terms wrapped in .() are evaluated in the specified where environment.

Usage

bquote(expr, where = parent.frame())

Arguments

expr A language object.
where An environment.

Value

A language object.

See Also

quote, substitute

Examples

a <- 2

bquote(a == a)
quote(a == a)

bquote(a == .(a))
substitute(a == A, list(A = a))

plot(1:10, a*(1:10), main = bquote(a == .(a)))

browser

Environment Browser

Description

Interrupt the execution of an expression and allow the inspection of the environment where browser was called from.

Usage

browser()
Details

A call to browser can be included in the body of a function. When reached, this causes a pause in the execution of the current expression and allows access to the R interpreter.

At the browser prompt the user can enter commands or R expressions. The commands are

- **c** (or just return) exit the browser and continue execution at the next statement.
- **cont** synonym for c.
- **n** enter the step-through debugger. This changes the meaning of c: see the documentation for debug.
- **where** print a stack trace of all active function calls.
- **Q** exit the browser and the current evaluation and return to the top-level prompt.

(Leading and trailing whitespace is ignored, except for return).

Anything else entered at the browser prompt is interpreted as an R expression to be evaluated in the calling environment: in particular typing an object name will cause the object to be printed, and ls() lists the objects in the calling frame. (If you want to look at an object with a name such as n, print it explicitly.)

The number of lines printed for the deparsed call can be limited by setting options(deparse.max.lines).

References

See Also

debug, and traceback for the stack on error.

---

*builtins*  
*Returns the Names of All Built-in Objects*

Description

Return the names of all the built-in objects. These are fetched directly from the symbol table of the R interpreter.

Usage

```r
builtins(internal = FALSE)
```

Arguments

- **internal** a logical indicating whether only “internal” functions (which can be called via .Internal) should be returned.
by

Details

`builtins()` returns an unsorted list of the objects in the symbol table, that is all the objects in the base environment. These are the built-in objects plus any that have been added subsequently when the base package was loaded. It is less confusing to use `ls(baseenv(), all=TRUE).

`builtins(TRUE)` returns an unsorted list of the names of internal functions, that is those which can be accessed as `Internal(foo(args ...))` for `foo` in the list.

Value

A character vector.

by

Apply a Function to a Data Frame split by Factors

Description

Function `by` is an object-oriented wrapper for `tapply` applied to data frames.

Usage

`by(data, INDICES, FUN, ...)`

Arguments

data an R object, normally a data frame, possibly a matrix.

INDICES a factor or a list of factors, each of length `nrow(data)`.

FUN a function to be applied to data frame subsets of `data`.

... further arguments to `FUN`.

Details

A data frame is split by row into data frames subsetted by the values of one or more factors, and function `FUN` is applied to each subset in turn.

Object `data` will be coerced to a data frame by default.

Value

A list of class "by", giving the results for each subset.

See Also

tapply
Examples

```r
require(stats)
attach(warpbreaks)
by(warpbreaks[, 1:2], tension, summary)
by(warpbreaks[, 1], list(wool = wool, tension = tension), summary)
by(warpbreaks, tension, function(x) lm(breaks ~ wool, data = x))

## now suppose we want to extract the coefficients by group
tmp <- by(warpbreaks, tension, function(x) lm(breaks ~ wool, data = x))
sapply(tmp, coef)
detach("warpbreaks")
```

---

**c**

**Combine Values into a Vector or List**

**Description**

This is a generic function which combines its arguments.

The default method combines its arguments to form a vector. All arguments are coerced to a common type which is the type of the returned value, and all attributes except names are removed.

**Usage**

```r
c(..., recursive=FALSE)
```

**Arguments**

- `...` objects to be concatenated.
- `recursive` logical. If `recursive = TRUE`, the function recursively descends through lists (and pairlists) combining all their elements into a vector.

**Details**

The output type is determined from the highest type of the components in the hierarchy `NULL < raw < logical < integer < real < complex < character < list < expression`. Pairlists are treated as lists, but non-vector components (such names and calls) are treated as one-element lists which cannot be unlisted even if `recursive = TRUE`.

`c` is sometimes used for its side effect of removing attributes except names, for example to turn an array into a vector. `as.vector` is a more intuitive way to do this, but also drops names.

**Value**

NULL or an expression or a vector of an appropriate mode.

**References**

call

See Also

`unlist` and `as.vector` to produce attribute-free vectors.

Examples

```r
c(1,7:9)
c(1:5, 10.5, "next")
```

```r
## uses with a single argument to drop attributes
x <- 1:4
names(x) <- letters[1:4]
x
c(x) # has names
as.vector(x) # no names
dim(x) <- c(2,2)
x
c(x)
as.vector(x)
```

```r
## append to a list:
ll <- list(A = 1, c="C")
## do *not* use
## c(ll, d = 1:3) # which is == c(ll, as.list(c(d=1:3))
## but rather
## c(ll, d = list(1:3))# c() combining two lists

c(list(A=c(B=1)), recursive=TRUE)
c(options(), recursive=TRUE)
c(list(A=c(B=1,C=2), B=c(E=7)), recursive=TRUE)
```

---

call

**Function Calls**

Create or test for objects of mode "call".

**Description**

Create or test for objects of mode "call".

**Usage**

```r
call(name, ...)
is.call(x)
as.call(x)
```

**Arguments**

- name: a character string naming the function to be called.
- ...: arguments to be part of the call.
- x: an arbitrary R object.
call

Details

call returns an unevaluated function call, that is, an unevaluated expression which consists of the named function applied to the given arguments (name must be a quoted string which gives the name of a function to be called). Note that although the call is unevaluated, the arguments ... are evaluated.

call is a primitive, so the first argument (named or not) is taken as name and the remaining arguments as arguments for the constructed call: call(x="c", 1,3, name="foo") is a call to c and not to foo.
is.call is used to determine whether x is a call (i.e., of mode "call").

Objects of mode "list" can be coerced to mode "call". The first element of the list becomes the function part of the call, so should be a function or the name of one (as a symbol; a quoted string will not do).

References

do.call for calling a function by name and argument list; Recall for recursive calling of functions; further is.language, expression, function.

Examples

is.call(call) #-> FALSE: Functions are NOT calls

## set up a function call to round with argument 10.5
cl <- call("round", 10.5)
is.call(cl)# TRUE
cl

## such a call can also be evaluated.
eval(cl)# [1] 10

A <- 10.5
call("round", A) # round(10.5)
call("round", quote(A)) # round(A)
f <- "round"
call(f, quote(A)) # round(A)

## if we want to supply a function we need to use as.call or similar
f <- round

## Not run: call(f, quote(A)) # error: first arg must be character
g <- as.call(list(f, quote(A)))
eval(g)

## alternatively but less transparently
g <- list(f, quote(A))
mode(g) <- "call"
g
eval(g)

## see also the examples in the help for do.call
callCC      

*Call With Current Continuation*

**Description**

A downward-only version of Scheme’s call with current continuation.

**Usage**

`callCC(fun)`

**Arguments**

`fun` function of one argument, the exit procedure.

**Details**

`callCC` provides a non-local exit mechanism that can be useful for early termination of a computation. `callCC` calls `fun` with one argument, an exit function. The exit function takes a single argument, the intended return value. If the body of `fun` calls the exit function then the call to `callCC` immediately returns, with the value supplied to the exit function as the value returned by `callCC`.

**Author(s)**

Luke Tierney

**Examples**

```r
# The following all return the value 1
callCC(function(k) 1)
callCC(function(k) k(1))
callCC(function(k) {k(1); 2})
callCC(function(k) repeat k(1))
```

---

capabilities      

*Report Capabilities of this Build of R*

**Description**

Report on the optional features which have been compiled into this build of R.

**Usage**

`capabilities(what = NULL)`

**Arguments**

`what` character vector or `NULL`, specifying required components. `NULL` implies that all are required.
Value

A named logical vector. Current components are

- `jpeg`  Is the `jpeg` function operational?
- `png`  Is the `png` function operational?
- `tcltk`  Is the `tcltk` package operational?
- `X11` (Unix) Are the `X11` graphics device and the `X11`-based data editor available? This loads the `X11` module if not already loaded, and checks that the default display can be contacted unless a `X11` device has already been used.
- `http/ftp`  Are `url` and the internal method for `download.file` available?
- `sockets`  Are `make.socket` and related functions available?
- `libxml`  Is there support for integrating `libxml` with the `R` event loop?
- `fifo`  are FIFO connections supported?
- `cledit`  Is command-line editing available in the current `R` session? This is false in non-interactive sessions. It will be true for the command-line interface if `readline` support has been compiled in and `--no-readline` was not invoked.
- `iconv`  is internationalization conversion via `iconv` supported?
- `NLS`  is there Natural Language Support (for message translations)?
- `profmem`  is there support for memory profiling?

`.Platform`

Examples

capabilities()

if(!capabilities("http/ftp"))
  warning("internal download.file() is not available")

## See also the examples for 'connections'.

---

**cat**

*Concatenate and Print*

**Description**

Outputs the objects, concatenating the representations. `cat` performs much less conversion than `print`.

**Usage**

cat(... , file = "", sep = " ", fill = FALSE, labels = NULL, append = FALSE)
Arguments

- **...**: R objects (see Details for the types of objects allowed).
- **file**: A connection, or a character string naming the file to print to. If "" (the default), `cat` prints to the standard output connection, the console unless redirected by `sink`. If it is "|cmd", the output is piped to the command given by `cmd`, by opening a pipe connection.
- **sep**: a character vector of strings to append after each element.
- **fill**: a logical or (positive) numeric controlling how the output is broken into successive lines. If FALSE (default), only newlines created explicitly by `"\n"` are printed. Otherwise, the output is broken into lines with print width equal to the option `width` if `fill` is TRUE, or the value of `fill` if this is numeric. Non-positive `fill` values are ignored, with a warning.
- **labels**: character vector of labels for the lines printed. Ignored if `fill` is FALSE.
- **append**: logical. Only used if the argument `file` is the name of file (and not a connection or "|cmd"). If TRUE output will be appended to `file`; otherwise, it will overwrite the contents of `file`.

Details

cat is useful for producing output in user-defined functions. It converts its arguments to character vectors, concatenates them to a single character vector, appends the given `sep=` string(s) to each element and then outputs them.

No linefeeds are output unless explicitly requested by `"\n"` or if generated by filling (if argument `fill` is TRUE or numeric.)

Currently only atomic vectors (and so not lists) and names are handled. Character strings are output 'as is' (unlike `print.default` which escapes non-printable characters and backslash — use `encodeString` if you want to output encoded strings using cat). Other types of R object should be converted (e.g. by `as.character` or `format`) before being passed to cat.

cat converts numeric/complex elements in the same way as `print` (and not in the same way as `as.character` which is used by the S equivalent), so `options "digits"` and `"scipen"` are relevant. However, it uses the minimum field width necessary for each element, rather than the same field width for all elements.

Value

None (invisible NULL).

Note

Despite its name and earlier documentation, `sep` is a vector of terminators rather than separators, being output after every vector element (including the last). Entries are recycled as needed.

References

See Also

`print`, `format`, and `paste` which concatenates into a string.
Examples

```r
iter <- rpois(1, lambda=10)
## print an informative message
cat("iteration = ", iter <- iter + 1, \\
"
## 'fill' and label lines:
\ 
cat(paste(letters, 100* 1:26), fill = TRUE,
  labels = paste("("1:10,"":*,sep=""))
```

```r
cbind
```

Combine R Objects by Rows or Columns

Description

Take a sequence of vector, matrix or data frames arguments and combine by columns or rows, respectively. These are generic functions with methods for other R classes.

Usage

```r
cbind(..., deparse.level = 1)
rbind(..., deparse.level = 1)
```

Arguments

... vectors or matrices. These can be given as named arguments. Other R objects will be coerced as appropriate: see section Details and Value. (For the "data.frame" method of `cbind` these can be further arguments to `data.frame` such as `stringsAsFactors` and `check.names`.)

deparse.level integer controlling the construction of labels in the case of "non-matrix-like" arguments (i.e., for the default method):
deparse.level = 0 constructs no labels; the default, deparse.level = 1 or 2 constructs labels from the argument names, see the 'Value' section below.

Details

The functions `cbind` and `rbind` are S3 generic, with methods for data frames. The data frame method will be used if at least one argument is a data frame and the rest are vectors or matrices. There can be other methods; in particular, there is one for time series objects.

In the default method, all the vectors/matrices must be atomic (see `vector`) or lists. Expressions are not allowed. Language objects (such as formulae and calls) and pairlists will be coerced to lists: other objects (such as names and external pointers) will be included as elements in a list result.

If there are several matrix arguments, they must all have the same number of columns (or rows) and this will be the number of columns (or rows) of the result. If all the arguments are vectors, the number of columns (rows) in the result is equal to the length of the longest vector. Values in shorter arguments are recycled to achieve this length (with a `warning` if they are recycled only fractionally).

When the arguments consist of a mix of matrices and vectors the number of columns (rows) of the result is determined by the number of columns (rows) of the matrix arguments. Any vectors have their values recycled or subsetted to achieve this length.
For `cbind(rbind)`, vectors of zero length (including `NULL`) are ignored unless the result would have zero rows (columns), for S compatibility. (Zero-extent matrices do not occur in S3 and are not ignored in R.)

The `rbind` data frame method first drops all zero-column and zero-row arguments. (If that leaves none, it returns the first argument with columns otherwise a zero-column zero-row data frame.) It then takes the classes of the columns from the first data frame, and matches columns by name (rather than by position). Factors have their levels expanded as necessary (in the order of the levels of the levelsets of the factors encountered) and the result is an ordered factor if and only if all the components were ordered factors. (The last point differs from S-PLUS.) Categories (integer vectors with levels) are promoted to factors.

**Value**

A matrix or data frame combining the... arguments column-wise or row-wise. (Exception: if all the inputs are `NULL`, the value is `NULL`.)

For `cbind(rbind)` the column (row) names are taken from the `colnames(rownames)` of the arguments if these are matrix-like. Otherwise from the names of the arguments or where those are not supplied and `deparse.level > 0`, by deparsing the expressions given, for `deparse.level = 1` only if that gives a sensible name (a ‘symbol’, see `is.symbol`).

The names will depend on whether data frames are included: see the examples.

If a matrix is created, it will be a list if any of the inputs is not `NULL` nor an atomic vector. Otherwise its type is determined from the highest type of the inputs in the hierarchy `NULL < raw < logical < integer < real < complex < character < list`.

**Note**

The method dispatching is not done via `UseMethod()`, but by C-internal dispatching. Therefore, there is no need for, e.g., `rbind.default`.

The dispatch algorithm is described in the source file (`'.../src/main/bind.c'`) as

1. For each argument we get the list of possible class memberships from the class attribute.
2. We inspect each class in turn to see if there is an an applicable method.
3. If we find an applicable method we make sure that it is identical to any method determined for prior arguments. If it is identical, we proceed, otherwise we immediately drop through to the default code.

If you want to combine other objects with data frames, it may be necessary to coerce them to data frames first. (Note that this algorithm can result in calling the data frame method if the arguments are all either data frames or vectors, and this will result in the coercion of character vectors to factors.)

**References**

**See Also**

`c` to combine vectors (and lists) as vectors, `data.frame` to combine vectors and matrices as a data frame.
Examples

m <- cbind(1, 1:7) # the '1' (= shorter vector) is recycled
m
m <- cbind(m, 8:14)[, c(1, 3, 2)] # insert a column
m
cbind(1:7, diag(3)) # vector is subset -> warning

cbind(0, rbind(1, 1:3))
cbind(I=0, X=rbind(a=1, b=1:3)) # use some names
xx <- data.frame(I=rep(0,2))
cbind(xx, X=rbind(a=1, b=1:3)) # named differently

cbind(0, matrix(1, nrow=0, ncol=4)) # Warning (making sense)
dim(cbind(0, matrix(1, nrow=2, ncol=0))) #-> 2 x 1

## deparse.level
dd <- 10
rbind(1:4, c=2, "a++" = 10, dd, deparse.level=0)# middle 2 rownames
rbind(1:4, c=2, "a++" = 10, dd, deparse.level=1)# 3 rownames (default)
rbind(1:4, c=2, "a++" = 10, dd, deparse.level=2)# 4 rownames

char.expand

Expand a String with Respect to a Target Table

Description

Seeks a unique match of its first argument among the elements of its second. If successful, it returns this element; otherwise, it performs an action specified by the third argument.

Usage

char.expand(input, target, nomatch = stop("no match"))

Arguments

input a character string to be expanded.
target a character vector with the values to be matched against.
nomatch an R expression to be evaluated in case expansion was not possible.

Details

This function is particularly useful when abbreviations are allowed in function arguments, and need to be uniquely expanded with respect to a target table of possible values.

See Also

charmatch and pmatch for performing partial string matching.

Examples

locPars <- c("mean", "median", "mode")
char.expand("me", locPars, warning("Could not expand!"))
char.expand("mo", locPars)
**character**

*Character Vectors*

**Description**

Create or test for objects of type "character".

**Usage**

```r
character(length = 0)
as.character(x, ...)
is.character(x)
```

**Arguments**

- `length` desired length.
- `x` object to be coerced or tested.
- `...` further arguments passed to or from other methods.

**Details**

`as.character` and `is.character` are generic; you can write methods to handle specific classes of objects, see `InternalMethods`. Further, for `as.character` the default method calls `as.vector`, so dispatch is first on methods for `as.character` and then for methods for `as.vector`.

`as.character` represents real and complex numbers to 15 significant digits (technically the compiler’s setting of the ISO C constant `DBL_DIG`, which will be 15 on machines supporting IEC60559 arithmetic according to the C99 standard). This ensures that all the digits in the result will be reliable (and not the result of representation error), but does mean that conversion to character and back to numeric may change the number. If you want to convert numbers to character with the maximum possible precision, use `format`.

**Value**

- `character` creates a character vector of the specified length. The elements of the vector are all equal to "".
- `as.character` attempts to coerce its argument to character type; like `as.vector` it strips attributes including names. For lists it deparses the elements individually, except that it extracts the first element of length-one character vectors.
- `is.character` returns `TRUE` or `FALSE` depending on whether its argument is of character type or not.

**Note**

`as.character` truncates components of language objects to 500 characters (was about 70 before 1.3.1).

**References**

charmatch

See Also

paste, substr and strsplit for character concatenation and splitting, chartr for character translation and casefolding (e.g., upper to lower case) and sub, grep etc for string matching and substitutions. Note that help.search(keyword = "character") gives even more links. deparse, which is normally preferable to as.character for language objects.

Examples

form <- y ~ a + b + c
as.character(form)  ## length 3
deparse(form)      ## like the input

a0 <- 11/999       # has a repeating decimal representation
(a1 <- as.character(a0))
format(a0, digits=16) # shows one more digit
a2 <- as.numeric(a1)
a2 - a0            # normally around -1e-17
as.character(a2)   # normally different from a1
print(c(a0, a2), digits = 16)

charmatch

Partial String Matching

Description

charmatch seeks matches for the elements of its first argument among those of its second.

Usage

charmatch(x, table, nomatch = NA)

Arguments

x       the values to be matched: converted to a character vector by as.character.
table   the values to be matched against: converted to a character vector.
nomatch the value to be returned at non-matching positions.

Details

Exact matches are preferred to partial matches (those where the value to be matched has an exact match to the initial part of the target, but the target is longer).

If there is a single exact match or no exact match and a unique partial match then the index of the matching value is returned; if multiple exact or multiple partial matches are found then 0 is returned and if no match is found then nomatch is returned.

NA values are treated as the string constant "NA".

Author(s)

This function is based on a C function written by Terry Therneau.
chartr

See Also

pmatch, match.
grep or regexpr for more general (regexp) matching of strings.

Examples

charmatch("", ") # returns 1
caratter("m", c("mean", "median", "mode")) # returns 0
caratter("med", c("mean", "median", "mode")) # returns 2

chartr

Character Translation and Casefolding

Description

Translate characters in character vectors, in particular from upper to lower case or vice versa.

Usage

chartr(old, new, x)
tolower(x)
toupper(x)
casefold(x, upper = FALSE)

Arguments

x a character vector, or an object that can be coerced to character by as.character.
old a character string specifying the characters to be translated.
new a character string specifying the translations.
upper logical: translate to upper or lower case?

Details

chartr translates each character in x that is specified in old to the corresponding character specified in new. Ranges are supported in the specifications, but character classes and repeated characters are not. If old contains more characters than new, an error is signaled; if it contains fewer characters, the extra characters at the end of new are ignored.
tolower and toupper convert upper-case characters in a character vector to lower-case, or vice versa. Non-alphabetic characters are left unchanged.
casefold is a wrapper for tolower and toupper provided for compatibility with S-PLUS.

Value

A character vector of the same length and with the same attributes as x (after possible coercion).

See Also

sub and gsub for other substitutions in strings.
Examples

```r
x <- "MiXeD cAsE 123"
chartr("ixs", "why", x)
chartr("a-cX", "D-Fw", x)
tolower(x)
toupper(x)

## "Mixed Case" Capitalizing - toupper( every first letter of a word ) :

.simpleCap <- function(x) {
  s <- strsplit(x, " ")[[1]]
  paste(toupper(substring(s, 1,1)), substring(s, 2), sep="", collapse=" ")
}

.simpleCap("the quick red fox jumps over the lazy brown dog")
## [1] "The Quick Red Fox Jumps Over The Lazy Brown Dog"

## and the better, more sophisticated version:
.capwords <- function(s, strict = FALSE) {
  cap <- function(s) paste(toupper(substring(s,1,1)),
                           {s <- substring(s,2); if(strict) tolower(s) else s},
                           sep = "", collapse = " ")
  sapply(strsplit(s, split = " "), cap, USE.NAMES = !is.null(names(s)))
}

capwords(c("using AIC for model selection"))
## [1] "Using AIC For Model Selection"

capwords(c("using AIC", "for MODEL selection"), strict=TRUE)
## [1] "Using Aic" "For Model Selection"

## ^^^ ^^^^^
## 'bad' 'good'

## -- Very simple insecure crypto --
.rot <- function(ch, k = 13) {
  p0 <- function(...) paste(c(...), collapse="")
  A <- c(letters, LETTERS, " '")
  I <- seq_len(k); chartr(p0(A), p0(c(A[-I], A[I])), ch)
}

pw <- "my secret pass phrase"
(crypw <- rot(pw, 13)) #=> you can send this off

## now `\`decrypt' :
rot(crypw, 54 - 13)# -> the original:
stopifnot(identical(pw, rot(crypw, 54 - 13)))
```

---

**chol**

*The Choleski Decomposition*

Description

Compute the Choleski factorization of a real symmetric positive-definite square matrix.

Usage

```r
chol(x, pivot = FALSE, LINPACK = pivot)
```
Arguments

- **x**: a real symmetric, positive-definite matrix
- **pivot**: Should pivoting be used?
- **LINPACK**: logical. Should LINPACK be used in the non-pivoting case (for compatibility with R < 1.7.0)?

Details

This is an interface to the LAPACK routine DPOTRF and the LINPACK routines DPOFA and DCHDC.

Note that only the upper triangular part of `x` is used, so that $R' R = x$ when `x` is symmetric.

If `pivot = FALSE` and `x` is not non-negative definite an error occurs. If `x` is positive semi-definite (i.e., some zero eigenvalues) an error will also occur, as a numerical tolerance is used.

If `pivot = TRUE`, then the Choleski decomposition of a positive semi-definite `x` can be computed. The rank of `x` is returned as `attr(Q, "rank")`, subject to numerical errors. The pivot is returned as `attr(Q, "pivot")`. It is no longer the case that `t(Q) %*% Q` equals `x`. However, setting `pivot <- attr(Q, "pivot")` and `oo <- order(pivot)`, it is true that `t(Q[, oo]) %*% Q[, oo]` equals `x`, or, alternatively, `t(Q) %*% Q equals x[pivot, pivot]`. See the examples.

Value

The upper triangular factor of the Choleski decomposition, i.e., the matrix `R` such that $R' R = x` (see example).

If pivoting is used, then two additional attributes "pivot" and "rank" are also returned.

Warning

The code does not check for symmetry.

If `pivot = TRUE` and `x` is not non-negative definite then there will be a warning message but a meaningless result will occur. So only use `pivot = TRUE` when `x` is non-negative definite by construction.

References

See Also

- `chol2inv` for its inverse (without pivoting), `backsolve` for solving linear systems with upper triangular left sides.
- `qr`, `svd` for related matrix factorizations.
Examples

```r
(m <- matrix(c(5,1,1,3),2,2))
(cm <- chol(m))
t(cm) %*% cm #-- = 'm'
crossprod(cm) #-- = 'm'

# now for something positive semi-definite
x <- matrix(c(1:5, (1:5)^2), 5, 2)
x <- cbind(x, x[, 1] + 3*x[, 2])
m <- crossprod(x)
qr(m)$rank # is 2, as it should be

# chol() may fail, depending on numerical rounding:
# chol() unlike qr() does not use a tolerance.
try(chol(m))

(Q <- chol(m, pivot = TRUE)) # NB wrong rank here ... see Warning section.
## we can use this by
pivot <- attr(Q, "pivot")
oo <- order(pivot)
t(Q[, oo]) %*% Q[, oo] # recover m

## now for a non-positive-definite matrix
(m <- matrix(c(5,-5,-5,3),2,2))
try(chol(m)) # fails
try(chol(m, LINPACK=TRUE)) # fails
(Q <- chol(m, pivot = TRUE)) # warning
crossprod(Q) # not equal to m
```

chol2inv

**Inverse from Choleski Decomposition**

Description

Invert a symmetric, positive definite square matrix from its Choleski decomposition.

Usage

```r
chol2inv(x, size = NCOL(x), LINPACK = FALSE)
```

Arguments

- **x**
  
  a matrix. The first size columns of the upper triangle contain the Choleski decomposition of the matrix to be inverted.

- **size**
  
  the number of columns of x containing the Choleski decomposition.

- **LINPACK**

  logical. Should LINPACK be used (for compatibility with R < 1.7.0)?

Details

This is an interface to the LAPACK routine DPOTRI and the LINPACK routine DPODI.
Value

The inverse of the matrix whose Choleski decomposition was given.

References

See Also

chol, solve.

Examples

cma <- chol(ma <- cbind(1, 1:3, c(1,3,7)))
ma %*% chol2inv(cma)

Description

R possesses a simple generic function mechanism which can be used for an object-oriented style of programming. Method dispatch takes place based on the class of the first argument to the generic function.

Usage

class(x)
class(x) <- value
unclass(x)
inherits(x, what, which = FALSE)

oldClass(x)
oldClass(x) <- value

Arguments

x a R object
what, value a character vector naming classes. value can also be NULL.
which logical affecting return value: see Details.
Details

Many R objects have a `class` attribute, a character vector giving the names of the classes which the object "inherits" from. If the object does not have a class attribute, it has an implicit class, "matrix", "array" or the result of `mode(x)`. (Functions `oldClass` and `oldClass<-` get and set the attribute, which can also be done directly.)

When a generic function `fun` is applied to an object with class attribute `c("first", "second")`, the system searches for a function called `fun.first` and, if it finds it, applies it to the object. If no such function is found, a function called `fun.second` is tried. If no class name produces a suitable function, the function `fun.default` is used (if it exists). If there is no class attribute, the implicit class is tried, then the default method.

The function `class` prints the vector of names of classes an object inherits from. Correspondingly, `class<-` sets the classes an object inherits from. Assigning a zero-length vector or `NULL` removes the class attribute.

`unclass` returns (a copy of) its argument with its class attribute removed. (It is not allowed for objects which cannot be copied, namely environments and external pointers.)

`inherits` indicates whether its first argument inherits from any of the classes specified in the `what` argument. If `which` is `TRUE` then an integer vector of the same length as `what` is returned. Each element indicates the position in the `class(x)` matched by the element of `what`; zero indicates no match. If `which` is `FALSE` then `TRUE` is returned by `inherits` if any of the names in `what` match with any class.

Formal classes

An additional mechanism of formal classes is available in packages `methods` which is attached by default. For objects which have a formal class, its name is returned by `class` as a character vector of length one.

The replacement version of the function sets the class to the value provided. For classes that have a formal definition, directly replacing the class this way is strongly deprecated. The expression `as(object, value)` is the way to coerce an object to a particular class.

Note

Functions `oldClass` and `oldClass<-` behave in the same way as functions of those names in S-PLUS 5/6, but in R `UseMethod` dispatches on the class as returned by `class` (with some interpolated classes: see the link) rather than `oldClass`. However, `group generics` dispatch on the `oldClass` for efficiency, and `internal generics` only dispatch on objects for which `is.object` is true.

See Also

`UseMethod`, `NextMethod`, `group generic`.

Examples

```r
x <- 10
inherits(x, "a") #FALSE
class(x) <- c("a", "b")
inherits(x, "a") #TRUE
inherits(x, "a", TRUE) # 1
inherits(x, c("a", "b", "c"), TRUE) # 1 2 0
```
**col**  
*Column Indexes*

**Description**

Returns a matrix of integers indicating their column number in the matrix.

**Usage**

\[
\text{col}(x, \text{as.factor} = \text{FALSE})
\]

**Arguments**

- **x**: a matrix.
- **as.factor**: a logical value indicating whether the value should be returned as a factor rather than as numeric.

**Value**

An integer matrix with the same dimensions as \(x\) and whose \(ij\)-th element is equal to \(j\).

**References**

**See Also**

`row` to get rows.

**Examples**

```r
# extract an off-diagonal of a matrix
ma <- matrix(1:12, 3, 4)
ma[row(ma) == col(ma) + 1]

# create an identity 5-by-5 matrix
x <- matrix(0, nr = 5, nc = 5)
x[row(x) == col(x)] <- 1
```

---

**Colon**  
*Colon Operator*

**Description**

Generate regular sequences.

**Usage**

```
from:to
a:b
```
Arguments

from          starting value of sequence.
to            (maximal) end value of the sequence.
a, b          factors of same length.

Details

The binary operator `:` has two meanings: for factors `a:b` is equivalent to `interaction(a, b)` (but the levels are ordered and labelled differently).

For numeric arguments `from:to` is equivalent to `seq(from, to)`, and generates a sequence from `from` to `to` in steps of 1 or 1-. Value `to` will be included if it differs from `from` by an integer up to a numeric fuzz of about `1e-7`.

Value

For numeric arguments, a numeric vector. This will be of type `integer` if `from` and `to` are both integers and representable in the integer type, otherwise of type `numeric`.

For factors, an unordered factor with levels labelled as `la:lb` and ordered lexicographically (that is, `lb` varies fastest).

References

(for numeric arguments: S does not have : for factors.)

See Also

`seq`.

As an alternative to using : for factors, `interaction`.

For : used in the formal representation of an interaction, see `formula`.

Examples

```r
1:4
pi:6 # real
6:pi # integer

f1 <- gl(2,3); f1
f2 <- gl(3,2); f2
f1:f2 # a factor, the "cross" f1 x f2
```
Form Row and Column Sums and Means

Description

Form row and column sums and means for numeric arrays.

Usage

```r
colSums(x, na.rm = FALSE, dims = 1)
rowSums(x, na.rm = FALSE, dims = 1)
colMeans(x, na.rm = FALSE, dims = 1)
rowMeans(x, na.rm = FALSE, dims = 1)
```

Arguments

- `x`: an array of two or more dimensions, containing numeric, complex, integer or logical values, or a numeric data frame.
- `na.rm`: logical. Should missing values (including NaN) be omitted from the calculations?
- `dims`: Which dimensions are regarded as “rows” or “columns” to sum over. For `row*`, the sum or mean is over dimensions `dims+1, ...,` for `col*` it is over dimensions `1:dims`.

Details

These functions are equivalent to use of `apply` with `FUN = mean` or `FUN = sum` with appropriate margins, but are a lot faster. As they are written for speed, they blur over some of the subtleties of NaN and NA. If `na.rm = FALSE` and either NaN or NA appears in a sum, the result will be one of NaN or NA, but which might be platform-dependent.

Value

A numeric or complex array of suitable size, or a vector if the result is one-dimensional. The `dimnames` (or `names` for a vector result) are taken from the original array.

If there are no values in a range to be summed over (after removing missing values with `na.rm = TRUE`), that component of the output is set to 0 (Sums) or NA (Means), consistent with `sum` and `mean`.

See Also

`apply`, `rowsum`

Examples

```r
## Compute row and column sums for a matrix:
x <- cbind(x1 = 3, x2 = c(4:1, 2:5))
rowSums(x); colSums(x)
dimnames(x)[[1]] <- letters[1:8]
rowSums(x); colSums(x); rowMeans(x); colMeans(x)
x[] <- as.integer(x)
rowSums(x); colSums(x)
```
commandArgs

Extract Command Line Arguments

Description

Provides access to a copy of the command line arguments supplied when this R session was invoked.

Usage

commandArgs(trailingOnly = FALSE)

Arguments

trailingOnly logical. Should only arguments after --args be returned?

Details

These arguments are captured before the standard R command line processing takes place. This means that they are the unmodified values. If it were useful, we could provide support for an argument which indicated whether we want the unprocessed or processed values.

This is especially useful with the --args command-line flag to R, as all of the command line after that flag is skipped.

Value

A character vector containing the name of the executable and the user-supplied command line arguments. The first element is the name of the executable by which R was invoked. As far as I am aware, the exact form of this element is platform dependent. It may be the fully qualified name, or simply the last component (or basename) of the application.

If trailingOnly = TRUE, a character vector of those arguments (if any) supplied after --args.

Comparison

Relational Operators

Description

Binary operators which allow the comparison of values in atomic vectors.

Usage

\[
\begin{align*}
& x < y \\
& x > y \\
& x <= y \\
& x >= y \\
& x == y \\
& x != y
\end{align*}
\]

Arguments

\[x, y\]

atomic vectors, symbols, calls, or other objects for which methods have been written.

Details

The binary comparison operators are generic functions: methods can be written for them individually or via the `Ops` group generic function. (See `Ops` for how dispatch is computed.)

Comparison of strings in character vectors is lexicographic within the strings using the collating sequence of the locale in use: see `locales`. The collating sequence of locales such as ‘en_US’ is normally different from ‘C’ (which should use ASCII) and can be surprising.

At least one of \(x\) and \(y\) must be an atomic vector, but if the other is a list \(R\) attempts to coerce it to the type of the atomic vector: this will succeed if the list is made up of elements of length one that can be coerced to the correct type.

If the two arguments are atomic vectors of different types, one is coerced to the type of the other, the (decreasing) order of precedence being character, complex, numeric, integer, logical and raw.

When comparisons are made between character strings, parts of the strings after embedded \(nul\) characters are ignored. (This is necessary as the position of \(nul\) in the collation sequence is undefined, and we want one of \(<, ==\) and \(>\) to be true for any comparison.)

Missing values (NA) and NaN values are regarded as non-comparable even to themselves, so comparisons involving them will always result in NA. Missing values can also result when character strings are compared and one is not valid in the current collation locale.

Language objects such as symbols and calls are deparsed to character strings before comparison.

Value

A vector of logicals indicating the result of the element by element comparison. The elements of shorter vectors are recycled as necessary.

Objects such as arrays or time-series can be compared this way provided they are conformable.
Note

Do not use == and != for tests, such as in if expressions, where you must get a single TRUE or FALSE. Unless you are absolutely sure that nothing unusual can happen, you should use the identical function instead.

For numerical and complex values, remember == and != do not allow for the finite representation of fractions, nor for rounding error. Using all.equal with identical is almost always preferable. See the examples.

References

See Also

factor for the behaviour with factor arguments.

Syntax for operator precedence.

Examples

x <- rnorm(20)
x < 1
x[x > 0]

x1 <- 0.5 - 0.3
x2 <- 0.3 - 0.1
x1 == x2  # FALSE on most machines
identical(all.equal(x1, x2), TRUE)  # TRUE everywhere

complex

Complex Vectors

Description

Basic functions which support complex arithmetic in R.

Usage

complex(length.out = 0, real = numeric(), imaginary = numeric(), modulus = 1, argument = 0)
as.complex(x, ...)
is.complex(x)

Re(z)
Im(z)
Mod(z)
Arg(z)
Conj(z)
Arguments

- `length.out` numeric. Desired length of the output vector, inputs being recycled as needed.
- `real` numeric vector.
- `imaginary` numeric vector.
- `modulus` numeric vector.
- `argument` numeric vector.
- `x` an object, probably of mode `complex`.
- `z` an object of mode `complex`, or one of a class for which a methods has been defined.
- ... further arguments passed to or from other methods.

Details

Complex vectors can be created with `complex`. The vector can be specified either by giving its length, its real and imaginary parts, or modulus and argument. (Giving just the length generates a vector of complex zeroes.)

`as.complex` attempts to coerce its argument to be of complex type: like `as.vector` it strips attributes including names. All forms of `NA` and `NaN` are coerced to a complex `NA`, for which both the real and imaginary parts are `NA`.

Note that `is.complex` and `is.numeric` are never both TRUE.

The functions `Re`, `Im`, `Mod`, `Arg` and `Conj` have their usual interpretation as returning the real part, imaginary part, modulus, argument and complex conjugate for complex values. Modulus and argument are also called the polar coordinates. If \( z = x + iy \) with real \( x \) and \( y \), for \( r = \text{Mod}(z) = \sqrt{x^2 + y^2} \), and \( \phi = \text{Arg}(z) \), \( x = r \cos(\phi) \) and \( y = r \sin(\phi) \). They are all generic functions: methods can be defined for them individually or via the `Complex` group generic.

In addition, the elementary trigonometric, logarithmic and exponential functions are available for complex values.

References

Examples

```r
go
0i ^ (-3:3)
matrix(li^ (-6:5), nr=4)#- all columns are the same
0 ^ li # a complex NaN

## create a complex normal vector
z <- complex(real = rnorm(100), imag = rnorm(100))
## or also (less efficiently):
z2 <- 1:2 + li*(8:9)

## The Arg(.) is an angle:
zz <- (rep(1:4,len=9) + li*(9:1))/10
zz.shift <- complex(modulus = Mod(zz), argument= Arg(zz) + pi)
plot(zz, xlim=c(-1,1), ylim=c(-1,1), col="red", asp = 1,
     main = expression(paste("Rotation by ", "pi == 180^o")))
```
### Description

These functions provide a mechanism for handling unusual conditions, including errors and warnings.

### Usage

```r
tryCatch(expr, ..., finally)
withCallingHandlers(expr, ...)
signalCondition(cond)

simpleCondition(message, call = NULL)
simpleError (message, call = NULL)
simpleWarning (message, call = NULL)
simpleMessage (message, call = NULL)
```

```r
## S3 method for class 'condition':
as.character(x, ...)
## S3 method for class 'error':
as.character(x, ...)
## S3 method for class 'condition':
print(x, ...)
## S3 method for class 'restart':
print(x, ...)

conditionCall(c)
## S3 method for class 'condition':
conditionCall(c)
conditionMessage(c)
## S3 method for class 'condition':
conditionMessage(c)

withRestarts(expr, ...)

computeRestarts(cond = NULL)
findRestart(name, cond = NULL)
invokeRestart(r, ...)
invokeRestartInteractively(r)

isRestart(x)
restartDescription(r)
restartFormals(r)

.signalSimpleWarning(msg, call)
.handleSimpleError(h, msg, call)
```
Arguments

- `c` a condition object.
- `call` call expression.
- `cond` a condition object.
- `expr` expression to be evaluated.
- `finally` expression to be evaluated before returning or exiting.
- `h` function.
- `message` character string.
- `msg` character string.
- `name` character string naming a restart.
- `r` restart object.
- `x` object.
- `...` additional arguments; see details below.

Details

The condition system provides a mechanism for signaling and handling unusual conditions, including errors and warnings. Conditions are represented as objects that contain information about the condition that occurred, such as a message and the call in which the condition occurred. Currently conditions are S3-style objects, though this may eventually change.

Conditions are objects inheriting from the abstract class `condition`. Errors and warnings are objects inheriting from the abstract subclasses `error` and `warning`. The class `simpleError` is the class used by `stop` and all internal error signals. Similarly, `simpleWarning` is used by `warning`, and `simpleMessage` is used by `message`. The constructors by the same names take a string describing the condition as argument and an optional call. The functions `conditionMessage` and `conditionCall` are generic functions that return the message and call of a condition.

Conditions are signaled by `signalCondition`. In addition, the `stop` and `warning` functions have been modified to also accept condition arguments.

The function `tryCatch` evaluates its expression argument in a context where the handlers provided in the `...` argument are available. The `finally` expression is then evaluated in the context in which `tryCatch` was called; that is, the handlers supplied to the current `tryCatch` call are not active when the `finally` expression is evaluated.

Handlers provided in the `...` argument to `tryCatch` are established for the duration of the evaluation of `expr`. If no condition is signaled when evaluating `expr` then `tryCatch` returns the value of the expression.

If a condition is signaled while evaluating `expr` then established handlers are checked, starting with the most recently established ones, for one matching the class of the condition. When several handlers are supplied in a single `tryCatch` then the first one is considered more recent than the second. If a handler is found then control is transferred to the `tryCatch` call that established the handler, the handler found and all more recent handlers are disestablished, the handler is called with the condition as its argument, and the result returned by the handler is returned as the value of the `tryCatch` call.

Calling handlers are established by `withCallingHandlers`. If a condition is signaled and the applicable handler is a calling handler, then the handler is called by `signalCondition` in the context where the condition was signaled but with the available handlers restricted to those below
the handler called in the handler stack. If the handler returns, then the next handler is tried; once
the last handler has been tried, signalCondition returns NULL.

User interrupts signal a condition of class interrupt that inherits directly from class
 condition before executing the default interrupt action.

Restarts are used for establishing recovery protocols. They can be established using
withRestarts. One pre-established restart is an abort restart that represents a jump to top
level.

findRestart and computeRestarts find the available restarts. findRestart returns the
most recently established restart of the specified name. computeRestarts returns a list of all
restarts. Both can be given a condition argument and will then ignore restarts that do not apply to
the condition.

invokeRestart transfers control to the point where the specified restart was established
and calls the restart’s handler with the arguments, if any, given as additional arguments to
invokeRestart. The restart argument to invokeRestart can be a character string, in which
case findRestart is used to find the restart.

New restarts for withRestarts can be specified in several ways. The simplest is in
name=function form where the function is the handler to call when the restart is invoked. An-
other simple variant is as name=string where the string is stored in the description field of
the restart object returned by findRestart; in this case the handler ignores its arguments and
returns NULL. The most flexible form of a restart specification is as a list that can include several
fields, including handler, description, and test. The test field should contain a function
of one argument, a condition, that returns TRUE if the restart applies to the condition and FALSE if
it does not; the default function returns TRUE for all conditions.

One additional field that can be specified for a restart is interactive. This should
be a function of no arguments that returns a list of arguments to pass to the restart han-
der. The list could be obtained by interacting with the user if necessary. The function
invokeRestartInteractively calls this function to obtain the arguments to use when in-
voking the restart. The default interactive method queries the user for values for the formal
arguments of the handler function.

.signalSimpleWarning and .handleSimpleError are used internally and should not be
called directly.

References

The tryCatch mechanism is similar to Java error handling. Calling handlers are based on Com-
mon Lisp and Dylan. Restarts are based on the Common Lisp restart mechanism.

See Also

stop and warning signal conditions, and try is essentially a simplified version of tryCatch.

Examples

tryCatch(1, finally=print("Hello"))
e <- simpleError("test error")
  ## Not run:
  stop(e)
tryCatch(stop(e), finally=print("Hello"))
tryCatch(stop("fred"), finally=print("Hello"))
  ## End(Not run)
tryCatch(stop(e), error = function(e) e, finally=print("Hello"))
tryCatch(stop("fred"), error = function(e) e, finally=print("Hello"))
withCallingHandlers({ warning("A"); 1+2 }, warning = function(w) { })
  ## Not run:
  { withRestarts(stop("A"), abort = function() {}); 1 }
  ## End(Not run)
withRestarts(invokeRestart("foo", 1, 2), foo = function(x, y) {x + y})

conflicts

Search for Masked Objects on the Search Path

Description

conflicts reports on objects that exist with the same name in two or more places on the search path, usually because an object in the user’s workspace or a package is masking a system object of the same name. This helps discover unintentional masking.

Usage

conflicts(where = search(), detail = FALSE)

Arguments

where A subset of the search path, by default the whole search path.
detail If TRUE, give the masked or masking functions for all members of the search path.

Value

If detail=FALSE, a character vector of masked objects. If detail=TRUE, a list of character vectors giving the masked or masking objects in that member of the search path. Empty vectors are omitted.

Examples

lm <- 1:3
conflicts(), TRUE)
  ## gives something like
  # $\.GlobalEnv
  # [1] "lm"
  # # $package:base
  # [1] "lm"
  
  ## Remove things from your "workspace" that mask others:
  remove(list = conflicts(detail=TRUE)$\.GlobalEnv)
Connections

Functions to Manipulate Connections

Description

Functions to create, open and close connections.

Usage

file(description = "", open = "", blocking = TRUE,
      encoding = getOption("encoding"))

pipe(description, open = "", encoding = getOption("encoding"))

fifo(description = "", open = "", blocking = FALSE,
      encoding = getOption("encoding"))

gzfile(description, open = "", encoding = getOption("encoding"),
        compression = 6)

unz(description, filename, open = "",  
     encoding = getOption("encoding"))

bzfile(description, open = "", encoding = getOption("encoding"))

url(description, open = "", blocking = TRUE,
     encoding = getOption("encoding"))

socketConnection(host = "localhost", port, server = FALSE,
                  blocking = FALSE, open = "a+",  
                  encoding = getOption("encoding"))

open(con, ...)

## S3 method for class 'connection':
open(con, open = "r", blocking = TRUE, ...)

close(con, ...)

## S3 method for class 'connection':
close(con, type = "rw", ...)

flush(con)

isOpen(con, rw = "")
isIncomplete(con)

Arguments

description character. A description of the connection. For file and pipe this is a path to the file to be opened. For url it is a complete URL, including schemes (http://, ftp:// or file:// – see Details). file also accepts complete URLs.
connections

filename | a filename within a zip file.
con | a connection.
host | character. Host name for port.
port | integer. The TCP port number.
server | logical. Should the socket be a client or a server?
open | character. A description of how to open the connection (if at all). See Details for possible values.
blocking | logical. See the ‘Blocking’ section below.
encoding | The name of the encoding to be used. See the ‘Encoding’ section below.
compression | integer in 0–9. The amount of compression to be applied when writing, from none to maximal. The default is a good space/time compromise.
type | character. Currently ignored.
rw | character. Empty or "read" or "write", partial matches allowed.
... | arguments passed to or from other methods.

Details

The first eight functions create connections. By default the connection is not opened (except for socketConnection), but may be opened by setting a non-empty value of argument open.

c file allows description="stdin" to refer to the C-level stdin of the process (which need not be connected to anything in a console version or embedded version of R), provided the C99 function fdopen is supported on the platform.
gzfile applies to files compressed by ‘gzip’, and bzfile to those compressed by ‘bzip2’.
gzfile can also open uncompressed files. In each case the actual file is opened in binary mode and so no translations are done if the original file was a text file. (See gzcon for a way to add compression to non-file connections.)

unz reads (only) single files within zip files, in binary mode. The description is the full path, with ‘.zip’ extension if required.

All platforms support file, gzfile, bzfile, unz and url("file://") connections. The other types may be partially implemented or not implemented at all. (They do work on most Unix platforms, and all but fifo on Windows.)

Proxies can be specified for url connections: see download.file.

open, close and seek are generic functions: the following applies to the methods relevant to connections.

open opens a connection. In general functions using connections will open them if they are not open, but then close them again, so to leave a connection open call open explicitly.

Possible values for the mode open to open a connection are

"r" or "rt" Open for reading in text mode.
"w" or "wt" Open for writing in text mode.
"a" or "at" Open for appending in text mode.
"rb" Open for reading in binary mode.
"wb" Open for writing in binary mode.
"ab" Open for appending in binary mode.
"z+", "z+b" Open for reading and writing.
"w+", "w+b" Open for reading and writing, truncating file initially.
"a+", "a+b" Open for reading and appending.

Not all modes are applicable to all connections: for example URLs can only be opened for reading. Only file and socket connections can be opened for reading and writing/appending. For many connections there is little or no difference between text and binary modes, but there is for file-like connections on Windows, and `pushBack` is text-oriented and is only allowed on connections open for reading in text mode.

`close` closes and destroys a connection.

`flush` flushes the output stream of a connection open for write/append (where implemented).

If for a file connection the description is "", the file is immediately opened (in "w+" mode unless `open="w+b"` is specified) and unlinked from the file system. This provides a temporary file to write to and then read from.

A note on file:// URLs. The most general form (from RFC1738) is `file://host/path/to/file`, but R only accepts the form with an empty `host` field referring to the local machine. This is then `file:///path/to/file`, where `path/to/file` is relative to / . So although the third slash is strictly part of the specification not part of the path, this can be regarded as a way to specify the file ‘/path/to/file’. It is not possible to specify a relative path using a file URL. Also, no attempt is made to decode an encoded URL: call `URLdecode` if necessary.

Note that https:// connections are not supported.

Value

`file`, `pipe`, `fifo`, `url`, `gzfile`, `bzfile`, `unz` and `socketConnection` return a connection object which inherits from class "connection" and has a first more specific class.

`isOpen` returns a logical value, whether the connection is currently open.

`isIncomplete` returns a logical value, whether last read attempt was blocked, or for an output text connection whether there is unflushed output.

Encoding

The encoding of the input/output stream of a connection in text mode can be specified by name, in the same way as it would be given to `iconv`: see that help page for how to find out what names are recognized on your platform. Additionally, "" and "native.enc" both mean the ‘native’ encoding, that is the internal encoding of the current locale and hence no translation is done. Not all builds of R support this, and if yours does not, specifying a non-default encoding will give an error when the connection is opened.

Re-encoding only works for connections in text mode.

The encoding "UCS-2LE" is treated specially, as it is the appropriate value for Windows ‘Unicode’ text files. If the first two bytes are the Byte Order Mark 0xFFFE then these are removed as most implementations of `iconv` do not accept BOMs. Note that some implementations will handle BOMs using encoding "UCS2" but many will not.

Exactly what happens when the requested translation cannot be done is in general undocumented. Requesting a conversion that is not supported is an error, reported when the connection is opened. On output the result is likely to be that up to the error, with a warning. On input, it will most likely be all or some of the input up to the error.
connections

Blocking

The default condition for all but fifo and socket connections is to be in blocking mode. In that
mode, functions do not return to the R evaluator until they are complete. In non-blocking mode,
operations return as soon as possible, so on input they will return with whatever input is available
(possibly none) and for output they will return whether or not the write succeeded.

The function `readLines` behaves differently in respect of incomplete last lines in the two modes: see its help page.

Even when a connection is in blocking mode, attempts are made to ensure that it does not block the
event loop and hence the operation of GUI parts of R. These do not always succeed, and the whole
process will be blocked during a DNS lookup on Unix, for example.

Most blocking operations on URLs and sockets are subject to the timeout set by `options("timeout")`. Note that this is a timeout for no response at all, not for the whole operation.

Fifos

Fifos default to non-blocking. That follows Svr4 and is probably most natural, but it does have
some implications. In particular, opening a non-blocking fifo connection for writing (only) will fail
unless some other process is reading on the fifo.

Opening a fifo for both reading and writing (in any mode: one can only append to fifos) connects
both sides of the fifo to the R process, and provides an similar facility to `file()`.

Clipboard

`file` can also be used with `description = "clipboard"` in mode "r" only. This
reads the X11 primary selection (see http://standards.freedesktop.org/
clipboards-spec/clipboards-latest.txt), which can also be specified as
"X11_primary" and the secondary selection as "X11_secondary". On most sys-
tems the clipboard selection (that used by ‘Copy’ from an ‘Edit’ menu) can be specified as
"X11_clipboard".

When a clipboard is opened for reading, the contents are immediately copied to internal storage in
the connection.

Unix users wishing to `write` to one of the selections may be able to do so via `xclip` (http://people.debian.org/~kims/xclip/), for example by `pipe("xclip -i", "w")`
for the primary selection.

MacOS X users can use `pipe("pbpaste")` and `pipe("pbcopy", "w")` to read from and
write to that system’s clipboard.

Note

R’s connections are modelled on those in S version 4 (see Chambers, 1998). However R goes well
beyond the Svr4 model, for example in output text connections and URL, `gzfile`, `bzfile` and
socket connections.

The default mode in R is "r" except for socket connections. This differs from Svr4, where it is the
equivalent of "r+", known as "*".

On platforms where `vsnprintf` does not return the needed length of output there is a 100,000
character output limit on the length of line for fifo, `gzfile` and `bzfile` connections: longer
lines will be truncated with a warning.
Connections

gzcon to wrap gzip (de)compression around a connection.

Examples

zz <- file("ex.data", "w") # open an output file connection
cat("TITLE extra line", "2 3 5 7", "", "11 13 17", file = zz, sep = "\n")
cat("One more line\n", file = zz)
close(zz)
readLines("ex.data")
unlink("ex.data")

zz <- gzfile("ex.gz", "w") # compressed file
cat("TITLE extra line", "2 3 5 7", "", "11 13 17", file = zz, sep = "\n")
close(zz)
readLines(zz <- gzfile("ex.gz"))
close(zz)
unlink("ex.gz")

zz <- bzfile("ex.bz2", "w") # bzip2-ed file
cat("TITLE extra line", "2 3 5 7", "", "11 13 17", file = zz, sep = "\n")
close(zz)
print(readLines(zz <- bzfile("ex.bz2")))
close(zz)
unlink("ex.bz2")

## An example of a file open for reading and writing
Tfile <- file("test1", "w+")
c(isOpen(Tfile, "r"), isOpen(Tfile, "w")) # both TRUE
cat("abc\n\ndef\n", file=Tfile)
readLines(Tfile)
seek(Tfile, 0, rw="r") # reset to beginning
readLines(Tfile)
cat("ghi\n", file=Tfile)
readLines(Tfile)
close(Tfile)
unlink("test1")

## We can do the same thing with an anonymous file.
Tfile <- file()
cat("abc\n\ndef\n", file=Tfile)
readLines(Tfile)
close(Tfile)

if(capabilities("fifo")) {
  zz <- fifo("foo", "w+")
  writeLines("abc", zz)
}
76

Constants
print(readLines(zz))
close(zz)
unlink("foo")
}
## Not run: ## Unix examples of use of pipes
# read listing of current directory
readLines(pipe("ls -1"))
# remove trailing commas. Suppose
% cat data2
450, 390, 467, 654, 30, 542, 334, 432, 421,
357, 497, 493, 550, 549, 467, 575, 578, 342,
446, 547, 534, 495, 979, 479
# Then read this by
scan(pipe("sed -e s/,$// data2"), sep=",")
# convert decimal point to comma in output
# both R strings and (probably) the shell need \ doubled
zz <- pipe(paste("sed s/\\\\./,/ >", "outfile"), "w")

## End(Not run)

Constants

Built-in Constants


### Constants

**Description**

Constants built into R.

**Usage**

```r
LETTERS
letters
month.abb
month.name
pi
```

**Details**

R has a limited number of built-in constants (there is also a rather larger library of data sets which can be loaded with the function `data`).

The following constants are available:

- `LETTERS`: the 26 upper-case letters of the Roman alphabet;
- `letters`: the 26 lower-case letters of the Roman alphabet;
- `month.abb`: the three-letter abbreviations for the English month names;
- `month.name`: the English names for the months of the year;
- `pi`: the ratio of the circumference of a circle to its diameter.

**References**

**See Also**

`data`, `DateTimeClasses`.

Quotes for the parsing of character constants, `NumericConstants` for numeric constants.

**Examples**

# John Machin (1705) computed 100 decimals of pi :
pi - 4*(4.atan(1/5) - atan(1/239))

## months in English

```r
month.name
```

## months in your current locale

```r
format(ISOdate(2000, 1:12, 1), "%B")
format(ISOdate(2000, 1:12, 1), "%b")
```
contributors  

**R Project Contributors**

**Description**

The R Who-is-who, describing who made significant contributions to the development of R.

**Usage**

```r
contributors()
```

---

**Control**  

**Control Flow**

**Description**

These are the basic control-flow constructs of the R language. They function in much the same way as control statements in any Algol-like language.

**Usage**

```r
if(cond) expr
if(cond) cons.expr else alt.expr

for(var in seq) expr
while(cond) expr
repeat expr
break
next
```

**Arguments**

- **cond**: A length-one logical vector that is not NA. Conditions of length greater than one are accepted with a warning, but only the first element is used.
- **var**: A syntactical name for a variable.
- **seq**: An expression evaluating to a vector (including a list and an expression) or to a pairlist or NULL.
- **expr, cons.expr, alt.expr**: An expression in a formal sense. This is either a simple expression or a so called compound expression, usually of the form `{ expr1 ; expr2 }`.

**Details**

- **break**: breaks out of a `for, while` or `repeat` loop; control is transferred to the first statement outside the inner-most loop. `next` halts the processing of the current iteration and advances the looping index. Both `break` and `next` apply only to the innermost of nested loops.
- Note that it is a common mistake to forget to put braces (`{ ... }`) around your statements, e.g., after `if(...)` or `for(...). In particular, you should not have a newline between `}` and `else` to avoid a syntax error in entering a `if ... else` construct at the keyboard or via `source`.
For that reason, one (somewhat extreme) attitude of defensive programming is to always use braces, e.g., for if clauses.

The index seq in a for loop is evaluated at the start of the loop; changing it subsequently does not affect the loop. The variable var has the same type as seq, and is read-only: assigning to it does not alter seq. If seq is a factor (which is not strictly allowed) then its internal codes are used: the effect is that of as.integer not as.vector.

Value

if returns the value of the expression evaluated, or NULL if none was (which may happen if there is no else).

for, while and repeat return the value of the last expression evaluated (or NULL if none was), invisibly. for sets var to the last used element of seq, or to NULL if it was of length zero.

break and next have value NULL, although it would be strange to look for a return value.

References

See Also

Syntax for the basic R syntax and operators, Paren for parentheses and braces; further, ifelse, switch.

Examples

for(i in 1:5) print(1:i)
for(n in c(2,5,10,20,50)) {
  x <- rnorm(n)
  cat(n,"\t", sum(x^2),"\n")
}

copyright  Copyrights of Files Used to Build R

Description

R is released under the 'GNU Public License': see license for details. The license describes your right to use R. Copyright is concerned with ownership of intellectual rights, and some of the software used has conditions that the copyright must be explicitly stated: see the Details section. We are grateful to these people and other contributors (see contributors) for the ability to use their work.

Details

The file `$R_HOME/COPYRIGHTS` lists the copyrights in full detail.
**crossprod**  

*Matrix Crossproduct*

**Description**

Given matrices \( x \) and \( y \) as arguments, return a matrix cross-product. This is formally equivalent to (but faster than) the call \( t(x) \ %*% y \) (crossprod) or \( x \ %*% t(y) \) (tcrossprod).

**Usage**

```r
crossprod(x, y = NULL)
tcrossprod(x, y = NULL)
```

**Arguments**

- \( x, y \) matrices: \( y = \) NULL is taken to be the same matrix as \( x \). Vectors are promoted to single-column matrices.

**Note**

When \( x \) or \( y \) are not matrices, they are treated as column or row matrices, but their names are usually not promoted to dimnames. Hence, currently, the last example has empty dimnames.

**References**

**See Also**

\%\% and outer product \%o\%.

**Examples**

```r
(z <- crossprod(1:4)) # = sum(1 + 2^2 + 3^2 + 4^2)
drop(z) # scalar
x <- 1:4; names(x) <- letters[1:4]; x
tcrossprod(as.matrix(x)) # is identical(tcrossprod(as.matrix(x)),
                         crossprod(t(x)))
tcrossprod(x) # no dimnames
```
Cstack_info

Report Information on C Stack Size and Usage

Description

Report information on the C stack size and usage (if available).

Usage

Cstack_info()

Details

On most platforms, C stack information is recorded when R is initialized and used for stack-checking. If this information is unavailable, the size will be returned as NA, and stack-checking is not performed.

The information on the stack base address is thought to be accurate on Windows, Linux and FreeBSD (including MacOS X), but a heuristic is used on other platforms. Because this might be slightly inaccurate, the current usage could be estimated as negative. (The heuristic is not used on embedded uses of R on platforms where the stack base is not thought to be accurate.)

Value

An integer vector. This has named elements

- size: The size of the stack (in bytes), or NA if unknown.
- current: The estimated current usage (in bytes), possibly NA.
- direction: 1 (stack grows down, the usual case) or -1 (stack grows up).
- eval_depth: The current evaluation depth (including two calls for the call to Cstack_info).

Examples

Cstack_info()

---

cumsum

Cumulative Sums, Products, and Extremes

Description

Returns a vector whose elements are the cumulative sums, products, minima or maxima of the elements of the argument.

Usage

cumsum(x)
cumprod(x)
cummax(x)
cummin(x)
Arguments

x  
   a numeric or complex (not cummin or cummax) object, or an object that can be coerced to one of these.

Details

These are generic functions: methods can be defined for them individually or via the Math group generic.

Value

A vector of the same length and type as x (after coercion), except that cumprod returns a numeric vector for integer input (for consistency with *). Names are preserved.

An NA value in x causes the corresponding and following elements of the return value to be NA, as does integer overflow in cumsum (with a warning).

References

Examples

cumsum(1:10)
cumprod(1:10)
cummin(c(3:1, 2:0, 4:2))
cummax(c(3:1, 2:0, 4:2))

---

**cut**  
*Convert Numeric to Factor*

Description

cut divides the range of x into intervals and codes the values in x according to which interval they fall. The leftmost interval corresponds to level one, the next leftmost to level two and so on.

Usage

cut(x, ...)

## Default S3 method:
cut(x, breaks, labels = NULL,  
include.lowest = FALSE, right = TRUE, dig.lab = 3,  
ordered_result = FALSE, ...)

Arguments

- `x`: a numeric vector which is to be converted to a factor by cutting.
- `breaks`: either a numeric vector of cut points or number giving the number of intervals which `x` is to be cut into.
- `labels`: labels for the levels of the resulting category. By default, labels are constructed using "(a,b]" interval notation. If `labels = FALSE`, simple integer codes are returned instead of a factor.
- `include.lowest`: logical, indicating if an `x[i]` equal to the lowest (or highest, for `right = FALSE`) `breaks` value should be included.
- `right`: logical, indicating if the intervals should be closed on the right (and open on the left) or vice versa.
- `dig.lab`: integer which is used when labels are not given. It determines the number of digits used in formatting the break numbers.
- `ordered_result`: logical: should the result be an ordered factor?
- `...`: further arguments passed to or from other methods.

Details

If a `labels` parameter is specified, its values are used to name the factor levels. If none is specified, the factor level labels are constructed as "(a1, b2)", "(b2, b3]" etc. for `right = TRUE` and as "[a1, b2)",... if `right = FALSE`. In this case, `dig.lab` indicates the minimum number of digits should be used in formatting the numbers a1, b2, ... A larger value (up to 12) will be used if needed to distinguish between any pair of endpoints: if this fails labels such as "Range3" will be used.

Value

A factor is returned, unless `labels = FALSE` which results in the mere integer level codes.

Note

Instead of `table(cut(x, br))`, `hist(x, br, plot = FALSE)` is more efficient and less memory hungry. Instead of `cut(*, labels = FALSE)`, `findInterval()` is more efficient.

References

See Also

`split` for splitting a variable according to a group factor; `factor`, `tabulate`, `table`, `findInterval()`.
**Examples**

```r
Z <- rnorm(10000)
table(cut(Z, br = -6:6))
sum(table(cut(Z, br = -6:6, labels=FALSE)))
sum(hist(Z, br = -6:6, plot=FALSE)$counts)
cut(rep(1,5),4)#-- dummy

tx0 <- c(9, 4, 6, 5, 3, 10, 5, 3, 5)
x <- rep(0:8, tx0)
stopifnot(table(x) == tx0)

table( cut(x, b = 8))
table( cut(x, br = 3*(-2:5)))
table( cut(x, br = 3*(-2:5), right = FALSE))

##--- some values OUTSIDE the breaks :
table(cx <- cut(x, br = 2*(0:4)))
table(cxl <- cut(x, br = 2*(0:4), right = FALSE))
which(is.na(cx)); x[is.na(cx)] #-- the first 9 values 0
which(is.na(cxl)); x[is.na(cxl)] #-- the last 5 values 8

## Label construction:
y <- rnorm(100)
table(cut(y, breaks = pi/3*(-3:3)))
table(cut(y, breaks = pi/3*(-3:3), dig.lab=4))
table(cut(y, breaks = 1*(-3:3), dig.lab=4))
# extra digits don't "harm" here
table(cut(y, breaks = 1*(-3:3), right = FALSE))
#-- the same, since no exact INT!

## sometimes the default dig.lab is not enough to be avoid confusion:

aaa <- c(1,2,3,4,5,2,3,4,5,6,7)
cut(aaa, 3)
cut(aaa, 3, dig.lab=4, ordered = TRUE)
```

---

**cut.POSIXt**

*Convert a Date or Date-Time Object to a Factor*

**Description**

Method for `cut` applied to date-time objects.

**Usage**

```r
## S3 method for class 'POSIXt':
cut(x, breaks, labels = NULL, start.on.monday = TRUE, 
    right = FALSE, ...)

## S3 method for class 'Date':
cut(x, breaks, labels = NULL, start.on.monday = TRUE, 
    right = FALSE, ...)
```
Arguments

x an object inheriting from class "POSIXt" or "Date".

breaks a vector of cut points or number giving the number of intervals which x is to be cut into or an interval specification, one of "sec", "min", "hour", "day", "DSTday", "week", "month" or "year", optionally preceded by an integer and a space, or followed by "s". For "Date" objects only "day", "week", "month" and "year" are allowed.

labels labels for the levels of the resulting category. By default, labels are constructed from the left-hand end of the intervals (which are include for the default value of right). If labels = FALSE, simple integer codes are returned instead of a factor.

start.on.monday logical. If breaks = "weeks", should the week start on Mondays or Sundays?

right, ... arguments to be passed to or from other methods.

Details

Using both right = TRUE and include.lowest = TRUE will include both ends of the range of dates.

Value

A factor is returned, unless labels = FALSE which returns the integer level codes.

See Also

seq.POSIXt, seq.Date, cut

Examples

```r
## random dates in a 10-week period
cut(ISOdate(2001, 1, 1) + 70*86400*runif(100), "weeks")
cut(as.Date("2001/1/1") + 70*runif(100), "weeks")
```

---

data.class Object Classes

Description

Determine the class of an arbitrary R object.

Usage

data.class(x)

Arguments

x an R object.
Value

class character string giving the “class” of x.
The “class” is the (first element) of the \texttt{class} attribute if this is non-NULL, or inferred from the object’s \texttt{dim} attribute if this is non-NULL, or \texttt{mode(x)}.

Simply speaking, \texttt{data.class(x)} returns what is typically useful for method dispatching. (Or, what the basic creator functions already and maybe eventually all will attach as a class attribute.)

Note

For compatibility reasons, there is one exception to the rule above: When \( x \) is \texttt{integer}, the result of \texttt{data.class(x)} is "numeric" even when \( x \) is classed.

See Also

class

Examples

\begin{verbatim}
x <- LETTERS
data.class(factor(x)) # has a class attribute
data.class(matrix(x, nc = 13)) # has a dim attribute
data.class(list(x)) # the same as mode(x)
data.class(x) # the same as mode(x)

stopifnot(data.class(1:2) == "numeric")# compatibility "rule"
\end{verbatim}

\texttt{data.frame} \hfill \textit{Data Frames}

Description

This function creates data frames, tightly coupled collections of variables which share many of the properties of matrices and of lists, used as the fundamental data structure by most of R’s modeling software.

Usage

\begin{verbatim}
data.frame(..., row.names = NULL, check.rows = FALSE, check.names = TRUE, stringsAsFactors = default.stringsAsFactors())

default.stringsAsFactors()
\end{verbatim}

Arguments

... these arguments are of either the form \texttt{value} or \texttt{tag = value}. Component names are created based on the tag (if present) or the deparsed argument itself.

\texttt{row.names} NULL or a single integer or character string specifying a column to be used as row names, or a character or integer vector giving the row names for the data frame.

\texttt{check.rows} if \texttt{TRUE} then the rows are checked for consistency of length and names.
check.names  logical. If TRUE then the names of the variables in the data frame are checked
to ensure that they are syntactically valid variable names and are not duplicated.
If necessary they are adjusted (by make.names) so that they are.

stringsAsFactors  logical: should character vectors be converted to factors?

Details

A data frame is a list of variables of the same length with unique row names, given class
"data.frame". If there are zero variables, the row names determine the number of rows.
data.frame converts each of its arguments to a data frame by calling
as.data.frame(optional=TRUE). As that is a generic function, methods can be written to
change the behaviour of arguments according to their classes: R comes with many such methods.
Character variables passed to data.frame are converted to factor columns unless protected by
I. If a list or data frame or matrix is passed to data.frame it is as if each component or column
had been passed as a separate argument.

Objects passed to data.frame should have the same number of rows, but atomic vectors, factors
and character vectors protected by I will be recycled a whole number of times if necessary.

If row names are not supplied in the call to data.frame, the row names are taken from the first
component that has suitable names, for example a named vector or a matrix with rownames or a
data frame. (If that component is subsequently recycled, the names are discarded with a warning.)
If row.names was supplied as NULL or no suitable component was found the row names are the
integer sequence starting at one (and such row names are considered to be ‘automatic’, and not
preserved by as.matrix).

If row names are supplied of length one and the data frame has a single row, the row.names is
taken to specify the row names and not a column (by name or number).

Names are removed from vector inputs not protected by I.
default.stringsAsFactors is a utility that takesgetOption("stringsAsFactors")
and ensures the result is TRUE or FALSE.

Value

A data frame, a matrix-like structure whose columns may be of differing types (numeric, logical,
factor and character and so on).

Note

In versions of R prior to 2.4.0 row.names had to be character: to ensure compatibility with earlier
versions of R, supply a character vector as the row.names argument.

References

See Also

I.plot.data.frame, print.data.frame, row.names, names (for the column names),
[,data.frame for subsetting methods, Math.data.frame etc, about Group methods for
data.frames; read.table, make.names.
Examples

```r
L3 <- LETTERS[1:3]
(d <- data.frame(cbind(x=1, y=1:10), fac=sample(L3, 10, repl=TRUE)))
```

```r
## The same with automatic column names:
data.frame(cbind( 1, 1:10), sample(L3, 10, repl=TRUE))
```

```r
is.data.frame(d)
```

```r
## do not convert to factor, using I() :
(dd <- cbind(d, char = I(letters[1:10])))
rbind(class=sapply(dd, class), mode=sapply(dd, mode))
```

```r
stopifnot(1:10 == row.names(d))# {coercion}
```

```r
(d0  <- d[, FALSE]) # NULL data frame with 10 rows
(d.0 <- d[FALSE, ]) # <0 rows> data frame (3 cols)
(d00 <- d0[FALSE,]) # NULL data frame with 0 rows
```

---

**data.matrix**  
*Convert a Data Frame to a Numeric Matrix*

**Description**

Return the matrix obtained by converting all the variables in a data frame to numeric mode and then binding them together as the columns of a matrix. Factors and ordered factors are replaced by their internal codes.

**Usage**

```r
data.matrix(frame, rownames.force = NA)
```

**Arguments**

- `frame`: a data frame whose components are logical vectors, factors or numeric vectors.
- `rownames.force`: logical indicating if the resulting matrix should have character (rather than NULL) rownames. The default, NA, uses NULL rownames if the data frame has `automatic` row.names or for a zero-row data frame.

**Details**

Supplying a data frame with columns which are not numeric, factor or logical is an error. A warning is given if any non-factor column has a class, as then information can be lost.

**Value**

If `frame` inherits from class "data.frame", an integer or numeric matrix of the same dimensions as `frame`, with dimnames taken from the `row.names` (or NULL, depending on `rownames.force`) and names. Otherwise, the result of `as.matrix`. 
Note

The default behaviour for data frames differs from R < 2.5.0 which always gave the result character rownames.

References

See Also

`as.matrix`, `data.frame`, `matrix`.

Examples

```r
DF <- data.frame(a=1:3, b=letters[10:12],
                 c=seq(as.Date("2004-01-01"), by = "week", len = 3),
                 stringsAsFactors = TRUE)
data.matrix(DF[1:2])
data.matrix(DF) # gives a warning and quotes dates as #days since 1970.
```

---

date

**System Date and Time**

Description

Returns a character string of the current system date and time.

Usage

`date()`

Value

The string has the form "Fri Aug 20 11:11:00 1999", i.e., length 24, since it relies on POSIX’s `ctime` ensuring the above fixed format. Timezone and Daylight Saving Time are taken account of, but *not* indicated in the result.

The day and month abbreviations are always in English, irrespective of locale.

References

See Also

`Sys.Date` and `Sys.time`; `Date` and `DateTimeClasses` for objects representing date and time.
Examples

(d <- date())
nchar(d) == 24

## something similar in the current locale
format(Sys.time(), "%a %b %d %H:%M:%S %Y")

### Dates

**Date Class**

**Description**

Description of the class "Date" representing calendar dates.

**Usage**

```r
## S3 method for class 'Date':
summary(object, digits = 12, ...)
```

**Arguments**

- **object**: An object summarized.
- **digits**: Number of significant digits for the computations.
- **...**: Further arguments to be passed from or to other methods.

**Details**

Dates are represented as the number of days since 1970-01-01, with negative values for earlier dates. They are always printed following the rules of the current Gregorian calendar, even though that calendar was not in use long ago (it was adopted in 1752 in Great Britain and its colonies).

It is intended that the date should be an integer, but this is not enforced in the internal representation. Fractional days will be ignored when printing. It is possible to produce fractional days via the `mean` method or by adding or subtracting (see `Ops.Date`).

**See Also**

- `Sys.Date` for the current date.
- `Ops.Date` for operators on "Date" objects.
- `format.Date` for conversion to and from character strings.
- `plot.Date` and `hist.Date` for plotting.
- `weekdays` for convenience extraction functions.
- `seq.Date`, `cut.Date`, `round.Date` for utility operations.
- `DateTimeClasses` for date-time classes.
Examples

```r
(today <- Sys.Date())
format(today, "%d %b %Y") # with month as a word
(tenweeks <- seq(today, len=10, by="1 week")) # next ten weeks
weekdays(today)
months(tenweeks)
as.Date(.leap.seconds)
```

Description

Description of the classes "POSIXlt" and "POSIXct" representing calendar dates and times (to the nearest second).

Usage

```r
## S3 method for class 'POSIXct':
print(x, ...)
## S3 method for class 'POSIXct':
summary(object, digits = 15, ...)

time + z

time - z
time1 lop time2
```

Arguments

- `x, object` An object to be printed or summarized from one of the date-time classes.
- `digits` Number of significant digits for the computations: should be high enough to represent the least important time unit exactly.
- `...` Further arguments to be passed from or to other methods.
- `time` date-time objects
- `time1, time2` date-time objects or character vectors. (Character vectors are converted by `as.POSIXct`.)
- `z` a numeric vector (in seconds) or an object of class "difftime".
- `lop` One of `==, !=, <, <=, >, >=`.

Details

There are two basic classes of date/times. Class "POSIXct" represents the (signed) number of seconds since the beginning of 1970 as a numeric vector. Class "POSIXlt" is a named list of vectors representing

- `sec` 0–61: seconds
- `min` 0–59: minutes
- `hour` 0–23: hours
DateTimeClasses

mday  1–31: day of the month
mon   0–11: months after the first of the year.
year  Years since 1900.
wday  0–6 day of the week, starting on Sunday.
yday  0–365: day of the year.
isdst Daylight savings time flag. Positive if in force, zero if not, negative if unknown.

The classes correspond to the ANSI C constructs of “calendar time” (the time_t data type) and “local time” (or broken-down time, the struct tm data type), from which they also inherit their names.

"POSIXct" is more convenient for including in data frames, and "POSIXlt" is closer to human-readable forms. A virtual class "POSIXt" inherits from both of the classes: it is used to allow operations such as subtraction to mix the two classes.

Logical comparisons and limited arithmetic are available for both classes. One can add or subtract a number of seconds from a date-time object, but not add two date-time objects. Subtraction of two date-time objects is equivalent to using difftime. Be aware that "POSIXlt" objects will be interpreted as being in the current timezone for these operations, unless a timezone has been specified.

"POSIXlt" objects will often have an attribute "tzone", a character vector of length 3 giving the timezone name from the TZ environment variable and the names of the base timezone and the alternate (daylight-saving) timezone. Sometimes this may just be of length one, giving the timezone name.

"POSIXct" objects may also have an attribute "tzone", a character vector of length one. If set, it will determine how the object is converted to class "POSIXlt" and in particular how it is printed. This is usually desirable, but if you want to specify an object in a particular timezone but to be printed in the current timezone you may want to remove the "tzone" attribute (e.g. by c(x)).

Unfortunately, the conversion is complicated by the operation of time zones and leap seconds (23 days have been 86401 seconds long so far: the times of the extra seconds are in the object .leap.seconds). The details of this are entrusted to the OS services where possible. This will usually cover the period 1970–2037, and on Unix machines back to 1902 (when time zones were in their infancy). Outside those ranges we use our own C code. This uses the offset from GMT in use in the timezone in one of 1970 to 1978 (chosen so that the likely DST transition days are Sundays), and uses the alternate (daylight-saving) timezone only if isdst is positive. (There is no reason to suppose that the DST rules will remain the same in the future, and indeed the US legislated in 2005 to change its rules as from 2007, with a possible future reversion.)

It seems that some systems use leap seconds but most do not. This is detected and corrected for at build time, so all "POSIXct" times used by R do not include leap seconds. (Conceivably this could be wrong if the system has changed since build time, just possibly by changing locales.)

Using c on "POSIXlt" objects converts them to the current time zone.

Sub-section Accuracy

Classes "POSIXct" and "POSIXlt" are able to express fractions of a second. (Conversion of fractions between the two forms may not be exact, but will have better than microsecond accuracy.)

Fractional seconds are printed only if options("digitssecs") is set: see strftime.
Warning

Some Unix-like systems (especially Linux ones) do not have "TZ" set, yet have internal code that expects it (as does POSIX). We have tried to work around this, but if you get unexpected results try setting "TZ". See \texttt{as.POSIXlt} for valid settings.

See Also

\texttt{Dates} for dates without times.  
\texttt{as.POSIXct} and \texttt{as.POSIXlt} for conversion between the classes.  
\texttt{strptime} for conversion to and from character representations.  
\texttt{Sys.time} for clock time as a "POSIXct" object.  
\texttt{difftime} for time intervals.  
\texttt{cut.POSIXt, seq.POSIXt, round.POSIXt} and \texttt{trunc.POSIXt} for methods for these classes.  
\texttt{weekdays.POSIXt} for convenience extraction functions.

Examples

\begin{verbatim}
(z <- Sys.time()) # the current date, as class "POSIXct"
Sys.time() - 3600 # an hour ago
as.POSIXlt(Sys.time(), "GMT") # the current time in GMT
format(.leap.seconds) # all 23 leapseconds in your timezone
print(.leap.seconds, tz="PST8PDT") # and in Seattle's
\end{verbatim}

\texttt{dcf} \hspace{1cm} \textit{Read and Write Data in DCF Format}

Description

Reads or writes an \texttt{R} object from/to a file in Debian Control File format.

Usage

\begin{verbatim}
read.dcf(file, fields=NULL)
write.dcf(x, file = "", append = FALSE,
         indent = 0.1 * getOption("width"),
         width = 0.9 * getOption("width"))
\end{verbatim}

Arguments

\begin{verbatim}
file \hspace{1cm} \texttt{either a character string naming a file or a connection. "}\"\texttt{ indicates output to the console. For \texttt{read.dcf} this can name a gzip-compressed file.}
fields \hspace{1cm} \texttt{Fields to read from the DCF file. Default is to read all fields.}
x \hspace{1cm} \texttt{the object to be written, typically a data frame. If not, it is attempted to coerce x to a data frame.}
append \hspace{1cm} \texttt{logical. If \texttt{TRUE}, the output is appended to the file. If \texttt{FALSE}, any existing file of the name is destroyed.}
\end{verbatim}
indent  a positive integer specifying the indentation for continuation lines in output entries.
width  a positive integer giving the target column for wrapping lines in the output.

Details

DCF is a simple format for storing databases in plain text files that can easily be directly read and written by humans. DCF is used in various places to store R system information, like descriptions and contents of packages.

The DCF rules as implemented in R are:

1. A database consists of one or more records, each with one or more named fields. Not every record must contain each field, a field may appear only once in a record.
2. Regular lines start with a non-whitespace character.
3. Regular lines are of form tag:value, i.e., have a name tag and a value for the field, separated by : (only the first : counts). The value can be empty (=whitespace only).
4. Lines starting with whitespace are continuation lines (to the preceding field) if at least one character in the line is non-whitespace.
5. Records are separated by one or more empty (=whitespace only) lines.

read.dcf returns a character matrix with one line per record and one column per field. Leading and trailing whitespace of field values is ignored. If a tag name is specified, but the corresponding value is empty, then an empty string of length 0 is returned. If the tag name of a fields is never used in a record, then \texttt{NA} is returned. If there are multiple records with the same tag name, the last one encountered is returned. Malformed lines are ignored (with a warning).

See Also
write.table.

Examples

```r
## Create a reduced version of the 'CONTENTS' file in package 'splines'
x <- read.dcf(file = system.file("CONTENTS", package = "splines"),
              fields = c("Entry", "Description"))
write.dcf(x)
```

---

### debug

**Debug a Function**

**Description**

Set or unset the debugging flag on a function.

**Usage**

```r
download(fun)
undownload(fun)
```

**Arguments**

fun any interpreted R function.
Details

When a function flagged for debugging is entered, normal execution is suspended and the body of function is executed one statement at a time. A new browser context is initiated for each step (and the previous one destroyed).

At the debug prompt the user can enter commands or \texttt{R} expressions. The commands are

- \texttt{n} (or just return). Advance to the next step.
- \texttt{c} continue to the end of the current context: e.g. to the end of the loop if within a loop or to the end of the function.
- \texttt{cont} synonym for \texttt{c}.
- \texttt{where} print a stack trace of all active function calls.
- \texttt{Q} exit the browser and the current evaluation and return to the top-level prompt.

(Leading and trailing whitespace is ignored, except for return).

Anything else entered at the debug prompt is interpreted as an \texttt{R} expression to be evaluated in the calling environment: in particular typing an object name will cause the object to be printed, and \texttt{ls()} lists the objects in the calling frame. (If you want to look at an object with a name such as \texttt{n}, print it explicitly.)

If a function is defined inside a function, single-step though to the end of its definition, and then call \texttt{debug} on its name.

In order to debug S4 methods (see \texttt{Methods}), you need to use \texttt{trace}, typically calling \texttt{browser}, e.g., as

\texttt{trace("plot", browser, exit=browser, signature = c("track", "missing"))}

See Also

- \texttt{browser}, \texttt{trace}, \texttt{traceback} to see the stack after an \texttt{Error}: \ldots message; \texttt{recover} for another debugging approach.

---

\texttt{Defunct} \hspace{1cm} \textit{Marking Objects as Defunct}

Description

When a function is removed from \texttt{R} it should be replaced by a function which calls \texttt{.Defunct}.

Usage

\texttt{.Defunct(new, package = NULL, msg)}

Arguments

- \texttt{new} character string: A suggestion for a replacement function.
- \texttt{package} character string: The package to be used when suggesting where the defunct function might be listed.
- \texttt{msg} character string: A message to be printed, if missing a default message is used.
delayedAssign

Details

`.Defunct` is called from `defunct` functions. Functions should be listed in `help("pkg-defunct")` for an appropriate `pkg`, including `base`.

See Also

- `Deprecated`.
- `base-defunct` and so on which list the defunct functions in the packages.

Description

delayedAssign creates a promise to evaluate the given expression if its value is requested. This provides direct access to the lazy evaluation mechanism used by R for the evaluation of (interpreted) functions.

Usage

delayedAssign(x, value, eval.env = parent.frame(1), assign.env = parent.frame(1))

Arguments

- **x**: a variable name (given as a quoted string in the function call)
- **value**: an expression to be assigned to x
- **eval.env**: an environment in which to evaluate value
- **assign.env**: an environment in which to assign x

Details

Both `eval.env` and `assign.env` default to the currently active environment.

The expression assigned to a promise by `delayedAssign` will not be evaluated until it is eventually “forced”. This happens when the variable is first accessed.

When the promise is eventually forced, it is evaluated within the environment specified by `eval.env` (whose contents may have changed in the meantime). After that, the value is fixed and the expression will not be evaluated again.

This function is meant to replace the `delay()` function, to make it more difficult for R code to see “naked” promises.

Value

This function is invoked for its side effect, which is assigning a promise to evaluate `value` to the variable `x`.

See Also

- `substitute`, to see the expression associated with a promise.
**Examples**

```r
msg <- "old"
delayedAssign("x", msg)
msg <- "new!"
x  #= new!
substitute(x)  #= msg

delayedAssign("x", {
  for(i in 1:3)
    cat("yippee!\n")
  10
})
x^2  #= yippee
x^2  #= simple number

e <- (function(x, y = 1, z) environment())(1+2, "y", {cat(" HO! "); pi+2})
(le <- as.list(e))  # evaluates the promises
```

---

**deparse**  
*Expression Deparsing*

**Description**

Turn unevaluated expressions into character strings.

**Usage**

```r
deparse(expr, width.cutoff = 60,
    backtick = mode(expr) %in% c("call", "expression", "("),
    control = c("keepInteger", "showAttributes", "keepNA") )
```

**Arguments**

- **expr**  
  any R expression.
- **width.cutoff**  
  integer in [20, 500] determining the cutoff at which line-breaking is tried.
- **backtick**  
  logical indicating whether symbolic names should be enclosed in backticks if they do not follow the standard syntax.
- **control**  
  character vector of deparsing options. See `.deparseOpts`.

**Details**

This function turns unevaluated expressions (where “expression” is taken in a wider sense than the strict concept of a vector of mode "expression" used in `expression`) into character strings (a kind of inverse `parse`).

A typical use of this is to create informative labels for data sets and plots. The example shows a simple use of this facility. It uses the functions `deparse` and `substitute` to create labels for a plot which are character string versions of the actual arguments to the function `myplot`.

The default for the `backtick` option is not to quote single symbols but only composite expressions. This is a compromise to avoid breaking existing code.
Using control = "all" comes closest to making `deparse()` an inverse of `parse()`. However, not all objects are deparse-able even with this option and a warning will be issued if the function recognizes that it is being asked to do the impossible.

Numeric and complex vectors are converted using 15 significant digits: see `as.character` for more details.

**Note**

To avoid the risk of a source attribute out of sync with the actual function definition, the source attribute of a function will never be deparsed as an attribute.

**References**

**See Also**

`substitute`, `parse`, `expression`.

Quotes for quoting conventions, including backticks.

**Examples**

```r
require(stats)
deparse(args(lm))
deparse(args(lm), width = 500)
myplot <- function(x, y) {
  plot(x, y, xlab=deparse(substitute(x)),
       ylab=deparse(substitute(y)))
}
e <- quote(`foo bar``)
deparse(e)
deparse(e, backtick=TRUE)
e <- quote(`foo bar`+1)
deparse(e)
deparse(e, control = "all")
```

---

**deparseOpts**

*Options for Expression Deparsing*

**Description**

Process the deparsing options for `deparse`, `dput` and `dump`.

**Usage**

`.deparseOpts(control)`

**Arguments**

`control` character vector of deparsing options.
Details

This is called by `deparse`, `dput` and `dump` to process their `control` argument. The `control` argument is a vector containing zero or more of the following strings. Partial string matching is used.

**keepInteger** Either surround integer vectors by `as.integer()` or use suffix `L`, so they are not converted to type double when parsed. This includes making sure that integer NAs are preserved (via `NA_integer_` if there are no non-NA values in the vector, unless "S_compatible" is set).

**quoteExpressions** Surround expressions with `quote()`, so they are not evaluated when re-parsed.

**showAttributes** If the object has attributes (other than a `source` attribute), use `structure()` to display them as well as the object value. This is the default for `deparse` and `dput`.

**useSource** If the object has a `source` attribute, display that instead of deparsing the object. Currently only applies to function definitions.

**warnIncomplete** Some exotic objects such as `environment`s, external pointers, etc. can not be deparsed properly. This option causes a warning to be issued if any of those may give problems.

**keepNA** Integer, real and character NAs are surrounded by coercion where necessary to ensure that they are parsed to the same type.

**all** An abbreviated way to specify all of the options listed above. This is the default for `dump`.

**delayPromises** Deparse promises in the form `<promise: expression>` rather than evaluating them. The value and the environment of the promise will not be shown and the deparsed code cannot be sourced.

**S_compatible** Make deparsing as far as possible compatible with S and R < 2.5.0. For compatibility with S, integer values of double vectors are deparsed with a trailing decimal point.

For the most readable (but perhaps incomplete) display, use `control = NULL`. This displays the object’s value, but not its attributes. The default in `deparse` is to display the attributes as well, but not to use any of the other options to make the result parseable. (`dput` and `dump` do use more default options, and printing of functions without sources uses c("keepInteger", "keepNA").)

Using `control = "all"` comes closest to making `deparse()` an inverse of `parse()`. However, not all objects are deparse-able even with this option. A warning will be issued if the function recognizes that it is being asked to do the impossible.

Value

A numerical value corresponding to the options selected.
Usage

```r
.deprecated(new, package=NULL, msg)
```

Arguments

- `new` character string: A suggestion for a replacement function.
- `package` character string: The package to be used when suggesting where the deprecated function might be listed.
- `msg` character string: A message to be printed, if missing a default message is used.

Details

`.Deprecated("<new name>")` is called from deprecated functions. The original help page for these functions is often available at `help("oldName-deprecated")` (note the quotes). Functions should be listed in `help("pkg-deprecated")` for an appropriate `pkg`, including `base`.

See Also

- `Defunct`
- `base-deprecated`
- and so on which list the deprecated functions in the packages.

---

### det

**Calculate the Determinant of a Matrix**

**Description**

det calculates the determinant of a matrix. determinant is a generic function that returns separately the modulus of the determinant, optionally on the logarithm scale, and the sign of the determinant.

**Usage**

det(x, ...)
determinant(x, logarithm = TRUE, ...)

Arguments

- `x` numeric matrix.
- `logarithm` logical; if TRUE (default) return the logarithm of the modulus of the determinant.
- `...` Optional arguments. At present none are used. Previous versions of det allowed an optional method argument. This argument will be ignored but will not produce an error.

**Details**

The determinant function uses an LU decomposition and the det function is simply a wrapper around a call to determinant.

Often, computing the determinant is *not* what you should be doing to solve a given problem.
Value

For det, the determinant of x. For determinant, a list with components

- **modulus**: a numeric value. The modulus (absolute value) of the determinant if logarithm is FALSE; otherwise the logarithm of the modulus.

- **sign**: integer; either +1 or −1 according to whether the determinant is positive or negative.

Examples

```r
(x <- matrix(1:4, ncol=2))
unlist(determinant(x))
det(x)
det(print(cbind(1,1:3,c(2,0,1))))
```

---

**detach**

*Detach Objects from the Search Path*

Description

Detach a database, i.e., remove it from the search() path of available R objects. Usually, this is either a data.frame which has been attached or a package which was required previously.

Usage

```r
detach(name, pos = 2, version, unload = FALSE)
```

Arguments

- **name**: The object to detach. Defaults to search()[pos]. This can be an unquoted name or a character string but not a character vector. If a number is supplied this is taken as pos.

- **pos**: Index position in search() of database to detach. When name is a number, pos = name is used.

- **version**: A character string denoting a version number of the package to be removed. This should be used only with a versioned installation of the package: see library.

- **unload**: A logical value indicating whether or not to attempt to unload the namespace and S4 methods when a package is being detached. If the package has a namespace and unload is TRUE, then detach will attempt to unload the namespace and remove any S4 methods defined by the package. If the namespace is in use or unload is FALSE, no unloading will occur.

Details

This most commonly used with a single number argument referring to a position on the search list, and can also be used with a unquoted or quoted name of an item on the search list such as package:tools.

When a package have been loaded with an explicit version number it can be detached using the name shown by search or by supplying name and version: see the examples.
If a package has a namespace, detaching it does not by default unload the namespace (and may not even with `unload=TRUE`), and detaching will not in general unload any dynamically loaded compiled code. Further, registered S3 methods from the namespace will not be removed. If you use `library` on a package whose name space is loaded, it attaches the exports of the loaded name space. So detaching and re-attaching a package may not refresh some or all components of the package, and is inadvisable.

**Value**

The attached database is returned invisibly, either as `data.frame` or as `list`.

**Note**

You cannot detach either the workspace (position 1) or the `base` package (the last item in the search list).

**References**

**See Also**

`attach`, `library`, `search`, `objects`, `unloadNamespace`, `library.dynam.unload`.

**Examples**

```r
require(splines) # package
detach(package:splines)
## could equally well use detach("package:splines")
## but NOT pkg <- "package:splines"; detach(pkg)
## Instead, use library(splines)
pkg <- "package:splines"
detach(pos = match(pkg, search()))
## careful: do not do this unless 'splines' is not already loaded.
library(splines)
detach(2) # 'pos' used for 'name'
## an example of the name argument to attach
## and of detaching a database named by a character vector
attach_and_detach <- function(db, pos=2)
{
  name <- deparse(substitute(db))
  attach(db, pos=pos, name=name)
  print(search()[pos])
  eval(substitute(detach(n), list(n=name)))
}
attach_and_detach(women, pos=3)
## Not run:
## Using a versioned install
library(ash, version="1.0-9") # or perhaps just library(ash)
# then one of
detach("package:ash", version="1.0-9")
```
diag

# or
detach("package:ash_1.0-9")
## End(Not run)

### Matrix Diagonals

**Description**

Extract or replace the diagonal of a matrix, or construct a diagonal matrix.

**Usage**

```r
diag(x = 1, nrow, ncol = n)
diag(x) <- value
```

**Arguments**

- **x**: a matrix, vector or 1D array.
- **nrow, ncol**: Optional dimensions for the result.
- **value**: either a single value or a vector of length equal to that of the current diagonal. Should be of a mode which can be coerced to that of `x`.

**Value**

If `x` is a matrix then `diag(x)` returns the diagonal of `x`. The resulting vector will have names if the matrix `x` has matching column and row names.

If `x` is a vector (or 1D array) of length two or more, then `diag(x)` returns a diagonal matrix whose diagonal is `x`.

If `x` is a vector of length one then `diag(x)` returns an identity matrix of order the nearest integer to `x`. The dimension of the returned matrix can be specified by `nrow` and `ncol` (the default is square).

The replacement form sets the diagonal of the matrix `x` to the given value(s).

**Note**

Using `diag(x)` can have unexpected effects if `x` is a vector that could be of length one. Use `diag(x, nrow = length(x))` for consistent behaviour.

**References**

**See Also**

`upper.tri, lower.tri, matrix`
Examples

```r
require(stats)
dim(diag(3))
diag(10,3,4) # guess what?
all(diag(1:3) == {m <- matrix(0,3,3); diag(m) <- 1:3; m})

diag(var(M <- cbind(X=1:5, Y=rnorm(5)))) #-> vector with names "X" and "Y"
rownames(M) <- c(colnames(M), rep("",3));
M; diag(M) # named as well
```

### diff

#### Lagged Differences

**Description**

Returns suitably lagged and iterated differences.

**Usage**

```r
diff(x, ...)
```

#### Default S3 method:

```r
diff(x, lag = 1, differences = 1, ...)
```

#### S3 method for class 'POSIXt':

```r
diff(x, lag = 1, differences = 1, ...)
```

#### S3 method for class 'Date':

```r
diff(x, lag = 1, differences = 1, ...)
```

**Arguments**

- `x`: a numeric vector or matrix containing the values to be differenced.
- `lag`: an integer indicating which lag to use.
- `differences`: an integer indicating the order of the difference.
- `...`: further arguments to be passed to or from methods.

**Details**

`diff` is a generic function with a default method and ones for classes "ts", "POSIXt" and "Date".

NA's propagate.

**Value**

If `x` is a vector of length `n` and `differences=1`, then the computed result is equal to the successive differences `x[(1+lag):n] - x[1:(n-lag)]`.

If difference is larger than one this algorithm is applied recursively to `x`. Note that the returned value is a vector which is shorter than `x`.

If `x` is a matrix then the difference operations are carried out on each column separately.
**References**

**See Also**

`diff.ts`, `diffinv`.

**Examples**

```r
diff(1:10, 2)
diff(1:10, 2, 2)
x <- cumsum(cumsum(1:10))
diff(x, lag = 2)
diff(x, differences = 2)
diff(.leap.seconds)
```

---

**Description**

Create, print and round time intervals.

**Usage**

```r
time1 - time2
difftime(time1, time2, tz = "", units = c("auto", "secs", "mins", "hours", "days", "weeks"))
as.difftime(tim, format = "%X", units="auto")
```

## S3 method for class 'difftime':

```r
round(x, digits = 0, ...)
format(x, ...)
units(x)
units(x) <- value
as.double(x, units="auto", ...)
```

**Arguments**

- `time1, time2`: date-time or date objects.
- `tz`: a timezone specification to be used for the conversion. System-specific, but "" is the current time zone, and "GMT" is UTC.
- `units`: character. Units in which the results are desired. Can be abbreviated.
value character. Like units above, except that abbreviations are not allowed.
tim character string or numeric value specifying a time interval.
format character specifying the format of tim: see strptime. The default is a locale-specific time format.
x an object inheriting from class "difftime".
digits integer. Number of significant digits to retain.
... arguments to be passed to or from other methods.

Details
Function difftime calculates a difference of two date/time objects and returns an object of class "difftime" with an attribute indicating the units. There is a round method for objects of this class, as well as methods for the group-generic (see Ops) logical and arithmetic operations.

If units = "auto", a suitable set of units is chosen, the largest possible (excluding "weeks") in which all the absolute differences are greater than one.

Subtraction of date-time objects gives an object of this class, by calling difftime with units="auto". Alternatively, as.difftime() works on character-coded or numeric time intervals; in the latter case, units must be specified, and format has no effect.

Limited arithmetic is available on "difftime" objects: they can be added or subtracted, and multiplied or divided by a numeric vector. In addition, adding or subtracting a numeric vector implicitly converts the numeric vector to a "difftime" object with the same units as the "difftime" object.

The units of a "difftime" object can be extracted by the units function, which also has an assignment form. If the units are changed, the numerical value is scaled accordingly.

The as.double method returns the numeric value expressed in the specified units. Using units="auto" means the units of the object.

The format method simply formats the numeric value and appends the units as a text string.

See Also
DateTimeClasses.

Examples
(z <- Sys.time() - 3600)
Sys.time() - z # just over 3600 seconds.

## time interval between releases of 1.2.2 and 1.2.3.

as.difftime(c("0:3:20", "11:23:15"))
as.difftime(c("3:20", "23:15", "2:"), format="%H:%M") # 3rd gives NA
(z <- as.difftime(c(0,30,60), units="mins"))
as.numeric(z, units="secs")
as.numeric(z, units="hours")
format(z)
**dim**

*Dimensions of an Object*

**Description**

Retrieve or set the dimension of an object.

**Usage**

```r
dim(x)
dim(x) <- value
```

**Arguments**

- `x` an R object, for example a matrix, array or data frame.
- `value` For the default method, either `NULL` or a numeric vector which coerced to integer (by truncation).

**Details**

The functions `dim` and `dim<-` are generic.

- `dim` has a method for `data.frames`, which returns the length of the `row.names` attribute of `x` and the length of `x` (the numbers of “rows” and “columns”).

**Value**

For an array (and hence in particular, for a matrix) `dim` retrieves the `dim` attribute of the object. It is `NULL` or a vector of mode `integer`.

The replacement method changes the "dim" attribute (provided the new value is compatible) and removes any "dimnames" and "names" attributes.

**References**

**See Also**

- `ncol`, `nrow` and `dimnames`.

**Examples**

```r
x <- 1:12 ; dim(x) <- c(3,4)
x

# simple versions of nrow and ncol could be defined as follows
nrow0 <- function(x) dim(x)[1]
col0 <- function(x) dim(x)[2]
```
Description

Retrieve or set the dimnames of an object.

Usage

```r
dimnames(x)
dimnames(x) <- value
```

Arguments

- `x` an R object, for example a matrix, array or data frame.
- `value` a possible value for `dimnames(x)`: see “Value”.

Details

The functions `dimnames` and `dimnames<-` are generic.

For an array (and hence in particular, for a matrix), they retrieve or set the `dimnames` attribute (see `attributes`) of the object. A list `value` can have names, and these will be used to label the dimensions of the array where appropriate.

The replacement method for arrays/matrices coerces vector and factor elements of `value` to character, but does not dispatch methods for `as.character`. It coerces zero-length elements to `NULL`.

Both have methods for data frames. The dimnames of a data frame are its `row.names` and its `names`. For the replacement method each component of `value` will be coerced by `as.character`.

For a 1D matrix the `names` are the same thing as the (only) component of the `dimnames`.

Value

The dimnames of a matrix or array can be `NULL` or a list of the same length as `dim(x)`. If a list, its components are either `NULL` or a character vector with positive length of the appropriate dimension of `x`.

For the "data.frame" method both `dimnames` are character vectors, and the rownames must contain no duplicates nor missing values.

Note

Setting components of the dimnames, e.g. `dimnames(A)[[1]] <- value` is a common paradigm, but note that it will not work if the value assigned is `NULL`. Use `rownames` instead, or (as it does) manipulate the whole `dimnames` list.

### Execute a Function Call

**Description**

do.call constructs and executes a function call from a name or a function and a list of arguments to be passed to it.

**Usage**

do.call(what, args, quote = FALSE, envir = parent.frame())

**Arguments**

- `what` either a function or a character string naming the function to be called.
- `args` a list of arguments to the function call. The names attribute of args gives the argument names.
- `quote` a logical value indicating whether to quote the arguments.
- `envir` an environment within which to evaluate the call. This will be most useful if what is a character string and the arguments are symbols or quoted expressions.

**Details**

If `quote` is FALSE, the default, then the arguments are evaluated (in the calling environment, not envir). If `quote` is TRUE then each argument is quoted (see `quote`) so that the effect of argument evaluation is to remove the quote – leaving the original argument unevaluated when the call is constructed.

The behavior of some functions, such as `substitute`, will not be the same for functions evaluated using `do.call` as if they were evaluated from the interpreter. The precise semantics are currently undefined and subject to change.

**Value**

The result of the (evaluated) function call.

**References**

See Also

call which creates an unevaluated call.

Examples

do.call("complex", list(imag = 1:3))

## if we already have a list (e.g. a data frame)
## we need c() to add further arguments
tmp <- expand.grid(letters[1:2], 1:3, c("+", "-"))
do.call("paste", c(tmp, sep=""))

do.call(paste, list(as.name("A"), as.name("B")), quote=TRUE)

## examples of where objects will be found.
A <- 2
f <- function(x) print(x^2)
env <- new.env()
assign("A", 10, envir = env)
assign("f", f, envir = env)
f <- function(x) print(x)

f(A) # 2
do.call("f", list(A)) # 2
do.call("f", list(A), envir=env) # 4
do.call(f, list(A), envir=env) # 2
do.call("f", list(quote(A)), envir=env) # 100
do.call(f, list(quote(A)), envir=env) # 10
do.call("f", list(as.name("A")), envir=env) # 100
eval(call("f", A)) # 2
eval(call("f", quote(A))) # 2
eval(call("f", A), envir=env) # 4
eval(call("f", quote(A)), envir=env) # 100

double Double Precision Vectors

Description

Create, coerce to or test for a double-precision vector.

Usage

double(length = 0)
as.double(x, ...)
is.double(x)

single(length = 0)
as.single(x, ...)
Arguments

length  desired length.
\( x \)  object to be coerced or tested.
\[ ... \]  further arguments passed to or from other methods.

Value

double creates a double precision vector of the specified length. The elements of the vector are all equal to 0.

as.double attempts to coerce its argument to be of double type: like as.vector it strips attributes including names. (To ensure that an object is of double type without stripping attributes, use storage.mode.) Character strings containing either a decimal representation or a hexadecimal representation (starting with 0x or 0X) can be converted.

is.double returns TRUE or FALSE depending on whether its argument is of double type or not.

Note

R has no single precision data type. All real numbers are stored in double precision format. The functions as.single and single are identical to as.double and double except they set the attribute Csingle that is used in the .C and .Fortran interface, and they are intended only to be used in that context.

References

Arguments

x an object.

file either a character string naming a file or a connection. "" indicates output to the console.

control character vector indicating deparsing options. See .deparseOpts for their description.

Details
dput opens file and deparses the object x into that file. The object name is not written (unlike dump). If x is a function the associated environment is stripped. Hence scoping information can be lost.

Deparsing an object is difficult, and not always possible. With the default control, dput() attempts to deparse in a way that is readable, but for more complex or unusual objects, not likely to be parsed as identical to the original. Use control = "all" for the most complete deparsing; use control = NULL for the simplest deparsing, not even including attributes.

dput will warn if fewer characters were written to a file than expected, which may indicate a full or corrupt file system.

To display saved source rather than deparsing the internal representation include "useSource" in control. R currently saves source only for function definitions.

Value

For dput, the first argument invisibly.

For dget, the object created.

Note

To avoid the risk of a source attribute out of sync with the actual function definition, the source attribute of a function will never be written as an attribute.

References

See Also
deparse, dump, write.

Examples

## Write an ASCII version of mean to the file "foo"
dput(mean, "foo")
## And read it back into 'bar'
bar <- dget("foo")
unlink("foo")
## Create a function with comments
baz <- function(x) {
  # Subtract from one
  1-x
}
## and display it
dput(baz)
## and now display the saved source
dput(baz, control = "useSource")

---

### drop

**Drop Redundant Extent Information**

**Description**

Delete the dimensions of an array which have only one level.

**Usage**

drop(x)

**Arguments**

- **x**: an array (including a matrix).

**Value**

If x is an object with a dim attribute (e.g., a matrix or array), then drop returns an object like x, but with any extents of length one removed. Any accompanying dimnames attribute is adjusted and returned with x.

Array subsetting ([]) performs this reduction unless used with drop = FALSE, but sometimes it is useful to invoke drop directly.

**See Also**

drop1 which is used for dropping terms in models.

**Examples**

dim(drop(array(1:12, dim=c(1,3,1,1,2,1,2)))) # = 3 2 2
drop(1:3 %*% 2:4)# scalar product

---

### dump

**Text Representations of R Objects**

**Description**

This function takes a vector of names of R objects and produces text representations of the objects on a file or connection. A dump file can usually be sourced into another R (or S) session.

**Usage**

dump(list, file = "dumpdata.R", append = FALSE,
         control = "all", envir = parent.frame(), evaluate = TRUE)
dump

Arguments

- **list**: character. The names of one or more R objects to be dumped.
- **file**: either a character string naming a file or a connection. """ indicates output to the console.
- **append**: if TRUE, output will be appended to file; otherwise, it will overwrite the contents of file.
- **control**: character vector indicating deparsing options. See .deparseOpts for their description.
- **envir**: the environment to search for objects.
- **evaluate**: logical. Should promises be evaluated?

Details

If some of the objects named do not exist (in scope), they are omitted, with a warning. If file is a file and no objects exist then no file is created.

At present sourcing may not produce an identical copy of dumped objects. A warning is issued if it is likely that problems will arise, for example when dumping exotic objects such as environments and external pointers.

dump will also warn if fewer characters were written to a file than expected, which may indicate a full or corrupt file system.

A dump file can be sourced into another R (or perhaps S) session, but the function save is designed to be used for transporting R data, and will work with R objects that dump does not handle.

To produce a more readable representation of an object, use control = NULL. This will skip attributes, and will make other simplifications that make source less likely to produce an identical copy. See deparse for details.

To deparse the internal representation of a function rather than displaying the saved source, use control = c("keepInteger", "warnIncomplete", "keepNA"). This will lose all formatting and comments, but may be useful in those cases where the saved source is no longer correct.

Promises will normally only be encountered by users as a result of lazy-loading (when the default evaluate = TRUE is essential) and after the use of delayedAssign, when evaluate = FALSE might be intended.

Value

An invisible character vector containing the names of the objects which were dumped.

Note

As dump is defined in the base name space, the base package will be searched before the global environment unless dump is called from the top level or the envir argument is given explicitly.

To avoid the risk of a source attribute out of sync with the actual function definition, the source attribute of a function will never be dumped as an attribute.

References

duplicated

See Also
dput, dget, write.
save for a more reliable way to save R objects.

Examples

```r
x <- 1; y <- 1:10
dump(ls(patt='^[xyz]$'), "xyz.Rdmped")
print(.Last.value)
unlink("xyz.Rdmped")
```

---

**duplicated**  
*Determine Duplicate Elements*

**Description**

Determines which elements of a vector or data frame are duplicates of elements with smaller subscripts, and returns a logical vector indicating which elements (rows) are duplicates.

**Usage**

duplicated(x, incomparables = FALSE, ...)

### S3 method for class 'array':
duplicated(x, incomparables = FALSE, MARGIN = 1, ...)

**Arguments**

- `x`: a vector or a data frame or an array or NULL.
- `incomparables`: a vector of values that cannot be compared. Currently, FALSE is the only possible value, meaning that all values can be compared.
- `...`: arguments for particular methods.
- `MARGIN`: the array margin to be held fixed: see `apply`.

**Details**

This is a generic function with methods for vectors (including lists), data frames and arrays (including matrices).

The data frame method works by pasting together a character representation of the rows separated by \r, so may be imperfect if the data frame has characters with embedded carriage returns or columns which do not reliably map to characters.

The array method calculates for each element of the sub-array specified by `MARGIN` if the remaining dimensions are identical to those for an earlier element (in row-major order). This would most commonly be used to find duplicated rows (the default) or columns (with `MARGIN` = 2).

**Warning**

Using this for lists is potentially slow, especially if the elements are not atomic vectors (see `vector`) or differ only in their attributes. In the worst case it is $O(n^2)$.

See Also
unique.
Examples
x <- c(9:20, 1:5, 3:7, 0:8)
## extract unique elements
(xu <- x[!duplicated(x)])
## xu == unique(x) but unique(x) is more efficient
duplicated(iris)[140:143]
duplicated(iris3, MARGIN = c(1, 3))

dyn.load

Foreign Function Interface

Description
Load or unload shared libraries, and test whether a C function or Fortran subroutine is available.
Usage
dyn.load(x, local = TRUE, now = TRUE)
dyn.unload(x)
is.loaded(symbol, PACKAGE = "", type = "")
Arguments
x

a character string giving the pathname to a shared library or DLL.

local

a logical value controlling whether the symbols in the shared library are stored
in their own local table and not shared across shared libraries, or added to the
global symbol table. Whether this has any effect is system-dependent.

now

a logical controlling whether all symbols are resolved (and relocated) immediately the library is loaded or deferred until they are used. This control is useful
for developers testing whether a library is complete and has all the necessary
symbols, and for users to ignore missing symbols. Whether this has any effect
is system-dependent.

symbol

a character string giving a symbol name.

PACKAGE

if supplied, confine the search for the name to the DLL given by this argument
(plus the conventional extension, .so, .sl, .dll, . . . ). This is intended to
add safety for packages, which can ensure by using this argument that no other
package can override their external symbols. Use PACKAGE="base" for symbols linked in to R. This is used in the same way as in .C, .Call, .Fortran
and .External functions


The type of symbol to look for: can be any ("", the default), "Fortran", "Call" or "External".

Details

See ‘See Also’ and the Writing R Extensions and R Installation and Administration manuals for how to create and install a suitable shared library. Note that unlike some versions of S-PLUS, dyn.load does not load an object (`.o`) file but a shared library or DLL.

Unfortunately a very few platforms (Compaq Tru64) do not handle the PACKAGE argument correctly, and may incorrectly find symbols linked into R.

The additional arguments to dyn.load mirror the different aspects of the mode argument to the dlopen() routine on UNIX systems. They are available so that users can exercise greater control over the loading process for an individual library. In general, the defaults values are appropriate and you should override them only if there is good reason and you understand the implications.

The local argument allows one to control whether the symbols in the DLL being attached are visible to other DLLs. While maintaining the symbols in their own name space is good practice, the ability to share symbols across related “chapters” is useful in many cases. Additionally, on certain platforms and versions of an operating system, certain libraries must have their symbols loaded globally to successfully resolve all symbols.

One should be careful of the potential side-effect of using lazy loading via the now argument as FALSE. If a routine is called that has a missing symbol, the process will terminate immediately and unsaved session variables will be lost. The intended use is for library developers to call specify a value TRUE to check that all symbols are actually resolved and for regular users to all with FALSE so that missing symbols can be ignored and the available ones can be called.

The initial motivation for adding these was to avoid such termination in the _init() routines of the Java virtual machine library. However, symbols loaded locally may not be (read probably) available to other DLLs. Those added to the global table are available to all other elements of the application and so can be shared across two different DLLs.

Some systems do not provide (explicit) support for local/global and lazy/eager symbol resolution. This can be the source of subtle bugs. One can arrange to have warning messages emitted when unsupported options are used. This is done by setting either of the options verbose or warn to be non-zero via the options function. Currently, we know of only 2 platforms that do not provide a value for local load (RTLD_LOCAL). These are IRIX6.4 and unpatched versions of Solaris 2.5.1.

There is a short discussion of these additional arguments with some example code available at http://cm.bell-labs.com/stat/duncan/R/dynload.

Value

The function dyn.load is used for its side effect which links the specified shared library to the executing R image. Calls to .C, .Call, .Fortran and .External can then be used to execute compiled C functions or Fortran subroutines contained in the library. The return value of dyn.load is an object of class DLLInfo. See getLoadedDLLs for information about this class.

The function dyn.unload unlinks the shared library.

is.loaded checks if the symbol name is loaded and hence available for use in .C or .Fortran or .Call or .External: it requires the name you would give to .C etc and not (as in S) that remapped by defunct functions symbol.C or symbol.For. It will succeed if any one of the four calling functions would succeed in using the entry point unless type is specified. (See .Fortran for how Fortran symbols are mapped.)
**Warning**

Do not use `dyn.unload` on a shared object loaded by `library.dynam`: use `library.dynam.unload`.

**Note**

The creation of shared libraries and the runtime linking of them into executing programs is very platform dependent. In recent years there has been some simplification in the process because the C subroutine call `dlopen` has become the standard for doing this under UNIX. Under UNIX `dyn.load` uses the `dlopen` mechanism and should work on all platforms which support it. On Windows it uses the standard mechanisms for loading 32-bit DLLs.

The original code for loading DLLs in UNIX was provided by Heiner Schwarte. The compatibility code for HP-UX was provided by Luke Tierney.

**References**

**See Also**

`library.dynam` to be used inside a package’s `.First.lib` initialization.

`SHLIB` for how to create suitable shared objects.

**Examples**

```r
is.loaded("hcass2") #-> probably TRUE, as stats is loaded
is.loaded("supsmu") # Fortran entry point in stats
is.loaded("supsmu", "stats", "Fortran")
is.loaded("PDF", type = "External")
```

---

**eapply**

*Apply a Function over values in an environment*

**Description**

`eapply` applies `FUN` to the named values from an environment and returns the results as a list. The user can request that all named objects are used (normally names that begin with a dot are not). The output is not sorted and no parent environments are searched.

**Usage**

```r
eapply(env, FUN, ..., all.names = FALSE)
```

**Arguments**

- `env` environment to be used.
- `FUN` the function to be applied, found via `match.fun`. In the case of functions like `+`, `%*%`, etc., the function name must be backquoted or quoted.
- `...` optional arguments to `FUN`.
- `all.names` a logical indicating whether to apply the function to all values
eigen

Spectral Decomposition of a Matrix

Description
Computes eigenvalues and eigenvectors of real or complex matrices.

Usage

```r
eigen(x, symmetric, only.values = FALSE, EISPACK = FALSE)
```

Arguments

- `x`: a matrix whose spectral decomposition is to be computed.
- `symmetric`: if TRUE, the matrix is assumed to be symmetric (or Hermitian if complex) and only its lower triangle is used. If `symmetric` is not specified, the matrix is inspected for symmetry.
- `only.values`: if TRUE, only the eigenvalues are computed and returned, otherwise both eigenvalues and eigenvectors are returned.
- `EISPACK`: logical. Should EISPACK be used (for compatibility with R < 1.7.0)?

Details

By default `eigen` uses the LAPACK routines DSYEVR, DGEEV, ZHEEV and ZGEEV whereas `eigen(EISPACK=TRUE)` provides an interface to the EISPACK routines RS, RG, CH and CG.

If `symmetric` is unspecified, the code attempts to determine if the matrix is symmetric up to plausible numerical inaccuracies. It is faster and surer to set the value yourself.

`eigen` is preferred to `eigen(EISPACK = TRUE)` for new projects, but its eigenvectors may differ in sign and (in the asymmetric case) in normalization. (They may also differ between methods and between platforms.)

Computing the eigenvectors is the slow part for large matrices.

Examples

```r
env <- new.env()
env$a <- 1:10
env$beta <- exp(-3:3)
env$logic <- c(TRUE, FALSE, FALSE, TRUE)
# what have we there?
eapply(env, str)

# compute the mean for each list element
eapply(env, mean)
# median and quartiles for each list element
eapply(env, quantile, probs = 1:3/4)
```
Computing the eigendecomposition of a matrix is subject to errors on a real-world computer: the definitive analysis is Wilkinson (1965). All you can hope for is a solution to a problem suitably close to \( x \). So even though a real asymmetric \( x \) may have an algebraic solution with repeated real eigenvalues, the computed solution may be of a similar matrix with complex conjugate pairs of eigenvalues.

**Value**

The spectral decomposition of \( x \) is returned as components of a list with components

- **values**: a vector containing the \( p \) eigenvalues of \( x \), sorted in decreasing order, according to \( \text{Mod(values)} \) in the asymmetric case when they might be complex (even for real matrices). For real asymmetric matrices the vector will be complex only if complex conjugate pairs of eigenvalues are detected.
- **vectors**: either a \( p \times p \) matrix whose columns contain the eigenvectors of \( x \), or NULL if only.values is TRUE.

For `eigen(, symmetric = FALSE, EISPACK = TRUE)` the choice of length of the eigenvectors is not defined by EISPACK. In all other cases the vectors are normalized to unit length.

Recall that the eigenvectors are only defined up to a constant: even when the length is specified they are still only defined up to a scalar of modulus one (the sign for real matrices).

**References**

**See Also**

`svd`, a generalization of `eigen`; `qr`, and `chol` for related decompositions.

To compute the determinant of a matrix, the `qr` decomposition is much more efficient: `det`.

`capabilities` to test for IEEE 754 arithmetic.

**Examples**

```r
eigen(cbind(c(1,-1),c(-1,1)))
eigen(cbind(c(1,-1),c(-1,1)), symmetric = FALSE) # same (different algorithm).

eigen(cbind(1,c(1,-1)), only.values = TRUE)
eigen(cbind(-1,2:1)) # complex values
eigen(print(cbind(c(0,1i), c(-1i,0))))# Hermite ==> real Eigen values
## 3 x 3:
eigen(cbind( 1,3:1,1:3))
eigen(cbind(-1,c(1:2,0),0:2)) # complex values
```
encodeString

Description

encodeString escapes the strings in a character vector in the same way print.default does, and optionally fits the encoded strings within a field width.

Usage

```
encodeString(x, width = 0, quote = "", na.encode = TRUE,
             justify = c("left", "right", "centre", "none"))
```

Arguments

- `x`: A character vector, or an object that can be coerced to one by `as.character`.
- `width`: integer: the minimum field width. If NULL or NA, this is taken to be the largest field width needed for any element of `x`.
- `quote`: character: quoting character, if any.
- `na.encode`: logical: should NA strings be encoded?
- `justify`: character: partial matches are allowed. If padding to the minimum field width is needed, how should spaces be inserted? `justify == "none"` is equivalent to `width = 0`, for consistency with `format.default`.

Details

This escapes backslash and the control characters
a (bell),
b (backspace),
f (formfeed),
n (line feed),
r (carriage return),
t (tab),
v (vertical tab) and
0 (null) as well as any non-printable characters in a single-byte locale, which are printed in octal notation (xyz with leading zeroes). (Which characters are non-printable depends on the current locale.) See `print.default` for how non-printable characters are handled in multi-byte locales.

If `quote` is a single or double quote any embedded quote of the same type is escaped. Note that justification is of the quoted string, hence spaces are added outside the quotes.

Value

A character vector of the same length as `x`, with the same attributes (including names and dimensions) but with no class set.

Note

The default for `width` is different from `format.default`, which does similar things for character vectors but without encoding using escapes.
Encoding

See Also

print.default

Examples

x <- "ab\bc\ndef"
print(x)
cat(x) # interprets escapes
cat(encodeString(x), "\n", sep="") # similar to print()

factor(x) # makes use of this to print the levels

x <- c("a", "ab", "abcode")
encodeString(x, w = NA) # left justification
encodeString(x, w = NA, justify = "c")
encodeString(x, w = NA, justify = "r")
encodeString(x, w = NA, quote = ",", justify = "r")

Encoding

Read or Set the Declared Encodings for a Character Vector

Description

Read or set the declared encodings for a character vector.

Usage

Encoding(x)

Encoding(x) <- value

Arguments

x A character vector.
value A character vector of positive length.

Details

As from R 2.5.0, character strings in R can be declared to be in "latin1" or "UTF-8". These declarations can be read by Encoding, which will return a character vector of values "latin1", "UTF-8" or "unknown", or set, when value is recycled as needed and other values are silently treated as "unknown".

There are other ways for character strings to acquire a declared encoding apart from explicitly setting it. Functions scan, read.table, readLines, parse and source have an encoding argument that is used to declare encodings, iconv declares encodings from its from argument, and console input in suitable locales is also declared.

Value

A character vector.
Examples

```r
## x is intended to be in latin1
x <- "fa\xE7ile"
Encoding(x)
Encoding(x) <- "latin1"
x
xx <- iconv(x, "latin1", "UTF-8")
Encoding(c(x, xx))
c(x, xx)
```

environment

### Environment Access

Get, set, test for and create environments.

#### Usage

```r
environment(fun = NULL)
environment(fun) <- value

is.environment(x)

.GlobalEnv
globalenv()
/BaseNamespaceEnv

emptyenv()
baseenv()

new.env(hash = FALSE, parent = parent.frame(), size = 29L)

parent.env(env)
parent.env(env) <- value

environmentName(env)

env.profile(env)
```

#### Arguments

- `fun` a function, a formula, or NULL, which is the default.
- `value` an environment to associate with the function
- `x` an arbitrary R object
- `hash` a logical, if TRUE the environment will be hashed
- `parent` an environment to be used as the enclosure of the environment created.
- `env` an environment
- `size` an integer specifying the initial size for a hashed environment. An internal default value will be used if size is NA or zero. This argument is ignored if hash is FALSE.
Details

Environments consist of a frame, or collection of named objects, and a pointer to an enclosing environment. The most common example is the frame of variables local to a function call; its enclosure is the environment where the function was defined. The enclosing environment is distinguished from the parent frame: the latter (returned by `parent.frame`) refers to the environment of the caller of a function.

When `get` or `exists` search an environment with the default `inherits = TRUE`, they look for the variable in the frame, then in the enclosing frame, and so on.

The global environment `.GlobalEnv`, more often known as the user’s workspace, is the first item on the search path. It can also be accessed by `globalenv()`. On the search path, each item’s enclosure is the next item.

The object `.BaseNamespaceEnv` is the name space environment for the base package. The environment of the base package itself is available as `baseenv()`. The ultimate enclosure of any environment is the empty environment `emptyenv()`, to which nothing may be assigned. If one follows the `parent.env()` chain of enclosures back far enough from any environment, eventually one reaches the empty environment.

The replacement function `parent.env<-` is extremely dangerous as it can be used to destructively change environments in ways that violate assumptions made by the internal C code. It may be removed in the near future.

Value

If `fun` is a function or a formula then `environment(fun)` returns the environment associated with that function or formula. If `fun` is `NULL` then the current evaluation environment is returned.

The replacement form sets the environment of the function or formula `fun` to the value given.

`is.environment(obj)` returns TRUE if and only if `obj` is an environment.

`new.env` returns a new (empty) environment enclosed in the parent’s environment, by default.

`parent.env` returns the parent environment of its argument.

`parent.env<-` sets the enclosing environment of its first argument.

`environmentName` returns a character string, that given when the environment is printed or "" if it is not a named environment.

`env.profile` returns a list with the following components: `size` the number of chains that can be stored in the hash table, `nchains` the number of non-empty chains in the table (as reported by `HASHPRI`), and `counts` an integer vector giving the length of each chain (zero for empty chains). This function is intended to assess the performance of hashed environments. When `env` is a non-hashed environment, `NULL` is returned.

See Also

The `envir` argument of `eval`, `get`, and `exists`.

`ls` may be used to view the objects in an environment, and hence `ls.str` may be useful for an overview.

`sys.source` can be used to “fill” an environment.

Examples

```r
f <- function() "top level function"
```

### all three give the same:
eval

Evaluate an (Unevaluated) Expression

Description

Evaluate an R expression in a specified environment.

Usage

\[
\text{eval}(\text{expr}, \text{envir} = \text{parent.frame}(), \text{enclos} = \text{if(is.list(envir) || is.pairlist(envir)) parent.frame() else baseenv()})
\]

\[
\text{evalq}(\text{expr}, \text{envir}, \text{enclos})
\]

\[
\text{eval.parent}(\text{expr}, n = 1)
\]

\[
\text{local}(\text{expr}, \text{envir} = \text{new.env}())
\]

Arguments

- **expr**: an object to be evaluated. See Details.
- **envir**: the environment in which expr is to be evaluated. May also be NULL, a list, a data frame, a pairlist or an integer as specified to sys.call.
- **enclos**: Relevant when envir is a (pair)list or a data frame. Specifies the enclosure, i.e., where R looks for objects not found in envir. This can be NULL (interpreted as the base package environment) or an environment.
- **n**: number of parent generations to go back

Details

eval evaluates the expr argument in the environment specified by envir and returns the computed value. If envir is not specified, then the default is parent.frame() (the environment where the call to eval was made).

Objects to be evaluated can be of types call or expression or symbol (when the symbol is looked up in the current scope and its binding is evaluated), a promise or any of the basic types such as vectors, functions and environments (which are returned unchanged).
The `evalq` form is equivalent to `eval(quote(expr), ...)`.
`eval` evaluates its first argument in the current scope before passing it to the evaluator: `evalq` avoids this.

`eval.parent(expr, n)` is a shorthand for `eval(expr, parent.frame(n))`.

If `envir` is a list (such as a data frame) or pairlist, it is copied into a temporary environment (with enclosure `enclos`), and the temporary environment is used for evaluation. So if `expr` changes any of the components named in the (pair)list, the changes are lost.

If `envir` is `NULL` it is interpreted as an empty list so no values could be found in `envir` and look-up goes directly to `enclos`.

`local` evaluates an expression in a local environment. It is equivalent to `evalq` except that its default argument creates a new, empty environment. This is useful to create anonymous recursive functions and as a kind of limited name space feature since variables defined in the environment are not visible from the outside.

**Value**

The result of evaluating the object: for an expression vector this it the result of evaluating the last elements.

**Note**

Due to the difference in scoping rules, there are some differences between R and S in this area. In particular, the default enclosure in S is the global environment.

When evaluating expressions in data frames that has been passed as argument to a function, the relevant enclosure is often the caller’s environment, i.e., one needs `eval(x, data, parent.frame())`.

**References**

**See Also**

`expression`, `quote`, `sys.frame`, `parent.frame`, `environment`.

Further, `force` to force evaluation, typically of function arguments.

**Examples**

```r
eval(2 ^ 2 ^ 3)
mEx <- expression(2^2^3); mEx; 1 + eval(mEx)
eval({ xx <- pi; xx^2}) ; xx
a <- 3 ; aa <- 4 ; evalq(evalq(a+b+aa, list(a=1)), list(b=5)) # == 10
a <- 3 ; aa <- 4 ; evalq(evalq(a+b+aa, -1), list(b=5)) # == 12
ev <- function() {
e1 <- parent.frame()
## Evaluate a in e1
aa <- eval(expression(a),e1)
## evaluate the expression bound to a in e1
a <- expression(x+y)
list(aa = aa, eval = eval(a, e1))
}
```
exists 127

tst.ev <- function(a = 7) { x <- pi; y <- 1; ev() }
tst.ev()#-> aa : 7,  ev : 4.14

a <- list(a=3, b=4)
with(a, a <- 5) # alters the copy of a from the list, discarded.

##
## Example of evalq()
##

N <- 3
ev <- new.env()
assign("N", 27, envir=env)
## this version changes the visible copy of N only, since the argument
## passed to eval is '4'.
eval(N <- 4, env)
N
get("N", envir=env)
## this version does the assignment in env, and changes N only there.
evalq(N <- 5, env)
N
get("N", envir=env)

##
## Uses of local()
##

# Mutually recursive.
# gg gets value of last assignment, an anonymous version of f.
gg <- local(
  k <- function(y)f(y)
  f <- function(x) if(x) x*k(x-1) else 1
)
gg(10)
sapply(1:5, gg)

# Nesting locals. a is private storage accessible to k
gg <- local(
  k <- local(
    a <- 1
    function(y){print(a <<- a+1);f(y})
  )
  f <- function(x) if(x) x*k(x-1) else 1
)
sapply(1:5, gg)

ls(envir=environment(gg))
ls(envir=environment(get("k", envir=environment(gg)))))

---

### Description

Look for an R object of the given name.
Usage

```r
exists(x, where = -1, envir = , frame, mode = "any",
    inherits = TRUE)
```

Arguments

- **x**: a variable name (given as a character string).
- **where**: where to look for the object (see the details section); if omitted, the function will search as if the name of the object appeared unquoted in an expression.
- **envir**: an alternative way to specify an environment to look in, but it is usually simpler to just use the `where` argument.
- **frame**: a frame in the calling list. Equivalent to giving `where` as `sys.frame(frame)`.
- **mode**: the mode or type of object sought: see the Details section.
- **inherits**: should the enclosing frames of the environment be searched?

Details

The `where` argument can specify the environment in which to look for the object in any of several ways: as an integer (the position in the search list); as the character string name of an element in the search list; or as an `environment` (including using `sys.frame` to access the currently active function calls). The `envir` argument is an alternative way to specify an environment, but is primarily there for back compatibility.

This function looks to see if the name `x` has a value bound to it in the specified environment. If `inherits` is `TRUE` and a value is not found for `x` in the specified environment, the enclosing frames of the environment are searched until the name `x` is encountered. See `environment` and the ‘R Language Definition’ manual for details about the structure of environments and their enclosures.

**Warning:** `inherits = TRUE` is the default behaviour for R but not for S.

If `mode` is specified then only objects of that type are sought. The `mode` may specify one of the collections "numeric" and "function" (see `mode`): any member of the collection will suffice. (This is true even if a member of a collection is specified, so for example `mode="special"` will seek any type of function.)

Value

Logical, true if and only if an object of the correct name and mode is found.

References

See Also

`get`.
## Define a substitute function if necessary:

```r
if(!exists("some.fun", mode="function"))
  some.fun <- function(x) { cat("some.fun(x)\n"); x }
search()
exists("ls", 2) # true even though ls is in pos=3
exists("ls", 2, inherits = FALSE) # false
```

### Examples

```r
## Define a substitute function if necessary:
if(!exists("some.fun", mode="function"))
  some.fun <- function(x) { cat("some.fun(x)\n"); x }
search()
exists("ls", 2) # true even though ls is in pos=3
exists("ls", 2, inherits = FALSE) # false
```

# expand.grid

**Create a Data Frame from All Combinations of Factors**

**Description**

Create a data frame from all combinations of the supplied vectors or factors. See the description of the return value for precise details of the way this is done.

**Usage**

```r
expand.grid(..., KEEP.OUT.ATTRS = TRUE)
```

**Arguments**

- `...` vectors, factors or a list containing these.
- `KEEP.OUT.ATTRS` a logical indicating the "out.attrs" attribute (see below) should be computed and returned.

**Value**

A data frame containing one row for each combination of the supplied factors. The first factors vary fastest. The columns are labelled by the factors if these are supplied as named arguments or named components of a list. The row names are 'automatic'.

Attribute "out.attrs" is a list which gives the dimension and dimnames for use by `predict` methods.

**References**

**See Also**

`combn` (package `utils`) for the generation of all combinations of n elements, taken m at a time.

**Examples**

```r
expand.grid(height = seq(60, 80, 5), weight = seq(100, 300, 50),
sex = c("Male","Female"))
```

```r
x <- seq(0,10, length=100)
y <- seq(-1,1, length=20)
d1 <- expand.grid(x=x, y=y)
d2 <- expand.grid(x=x, y=y, KEEP.OUT.ATTRS = FALSE)
```
expression

object.size(d1) - object.size(d2)
##-> 5992 or 8832 (on 32- / 64-bit platform)

---

expression

### Unevaluated Expressions

**Description**

Creates or tests for objects of mode "expression".

**Usage**

expression(...)

is.expression(x)

as.expression(x, ...)

**Arguments**

... expression: R objects, typically calls, symbols or constants.

as.expression: arguments to be passed to methods.

x an arbitrary R object.

**Details**

‘Expression’ here is not being used in its colloquial sense, that of mathematical expressions. Those are calls (see call) in R, and an R expression vector is a list of calls, symbols etc, typically as returned by parse.

As an object of mode "expression" is a list, it can be subsetted by both [ and by [[]], the latter extracting individual calls etc.

**Value**

expression returns a vector of type "expression" containing its arguments (unevaluated).

is.expression returns TRUE if expr is an expression object and FALSE otherwise.

as.expression attempts to coerce its argument into an expression object. It is generic, and only the default method is described here. NULL, calls, symbols (see as.symbol) and pairlists are returned as the element of a length-one expression vector. Vectors (including lists) are placed element-by-element into an expression vector. Other types are not currently supported.

**References**

**See Also**

call, eval, function. Further, text and legend for plotting mathematical expressions.
Examples

```
length(ex1 <- expression(1+ 0:9)) # 1
ex1
eval(ex1) # 1:10

length(ex3 <- expression(u,v, 1+ 0:9)) # 3
mode(ex3 [3]) # expression
mode(ex3[[3]]) # call
rm(ex3)
```

Extract or Replace Parts of an Object

Description

Operators acting on vectors, matrices, arrays and lists to extract or replace parts.

Usage

```
x[i]
x[i, j, ... , drop = TRUE]
x[[i]]
x[[i, j, ...]]
x$name
```

Arguments

- **x**: object from which to extract element(s) or in which to replace element(s).
- **i, j, ..., name**: indices specifying elements to extract or replace. i, j are numeric or character vectors or empty (missing) or NULL whereas name must be a character string or an (unquoted or backtick quoted) name. Numeric values are coerced to integer as by `as.integer`. For extraction with `[[` and `$` character strings are normally (see under Environments) partially matched to the names of the object if exact matching does not succeed.

For `[`-indexing only: i, j, ... can be logical vectors, indicating elements/slices to select. Such vectors are recycled if necessary to match the corresponding extent. i, j, ... can also be negative integers, indicating elements/slices to leave out of the selection.

When indexing arrays by `[` a single argument i can be a matrix with as many columns as there are dimensions of x; the result is then a vector with elements corresponding to the sets of indices in each row of i.

An index value of NULL is treated as if it were integer(0).

- **drop**: For matrices and arrays. If TRUE the result is coerced to the lowest possible dimension (see the examples). This only works for extracting elements, not for the replacement.
Details

These operators are generic. You can write methods to handle indexing of specific classes of objects, see `InternalMethods` as well as `[.data.frame` and `[.factor`. The descriptions here apply only to the default methods. Note that separate methods are required for the replacement functions `<-`, `[[<-` and `$<-` for use when indexing occurs on the assignment side of an expression.

The most important distinction between `[`, `[[` and `$` is that the `[` can select more than one element whereas the other two select a single element.

The default methods work somewhat differently for atomic vectors, matrices/arrays and for recursive (list-like, see `is.recursive`) objects. `$` returns NULL (with a warning) except for recursive objects, and is only discussed in the section below on recursive objects. Its use on non-recursive objects was deprecated in R 2.5.0.

Subsetting (except by an empty index) will drop all attributes except `names`, `dim` and `dimnames`. Indexing can occur on the right-hand-side of an expression for extraction, or on the left-hand-side for replacement. When an index expression appears on the left side of an assignment (known as subassignment) then that part of `x` is set to the value of the right hand side of the assignment. In this case no partial matching of indices is done, and the left-hand-side is coerced as needed to accept the values. Attributes are preserved (although `names`, `dim` and `dimnames` will be adjusted suitably).

Atomic vectors

The usual form of indexing is "[". "[[" can be used to select a single element, but "[" can also do so (but will not partially match a character index).

The index object `i` can be numeric, logical, character or empty. Indexing by factors is allowed and is equivalent to indexing by the numeric codes (see `factor`) and not by the character values which are printed (for which use `as.character(i)`).

An empty index selects all values: this is most often used to replace all the entries but keep the attributes.

Matrices and arrays

Matrices and arrays are vectors with a dimension attribute and so all the vector forms of indexing can be used with a single index. The result will be an unnamed vector unless `x` is one-dimensional when it will be a one-dimensional array.

The most common form of indexing a `k`-dimensional array is to specify `k` indices to `[`. As for vector indexing, the indices can be numeric, logical, character, empty or even factor. An empty index (a comma separated blank) indicates that all entries in that dimension are selected. The argument `drop` applies to this form of indexing.

A third form of indexing is via a numeric matrix with the one column for each dimension: each row of the index matrix then selects a single element of the array, and the result is a vector. Negative indices are not allowed in the index matrix. `NA` and zero values are allowed: rows of an index matrix containing a zero are ignored, whereas rows containing an `NA` produce an `NA` in the result.

A vector obtained by matrix indexing will be unnamed unless `x` is one-dimensional when the row names (if any) will be indexed to provide names for the result.

Recursive (list-like) objects

Indexing by `[` is similar to atomic vectors and selects a list of the specified element(s).

Both `[[` and `$` select a single element of the list. The main difference is that `$` does not allow computed indices, whereas `[[` does. `x$name` is equivalent to `x[["name"]].`
[ and [[ are sometimes applied to other recursive objects such as calls and expressions. Pairlists are coerced to lists for extraction by [, but all three operators can be used for replacement.

[[ can be applied recursively to lists, so that if the single index i is a vector of length p, alist[[i]] is equivalent to alist[[ii]]...[[ip]] providing all but the final indexing results in a list.

When $<-$ is applied to a NULL x, it first coerces x to list(). This is what also happens with [[<- if the replacement value value is of length greater than one: if value has length 1 or 0, x is first coerced to a zero-length vector of the type of value.

Environments

Both $ and [[ can be applied to environments. Only character arguments are allowed and no partial matching is done. The semantics of these operations are those of get(i, env=x, inherits=FALSE). If no match is found then NULL is returned. The assignment versions, $<-$ and [[<-, can also be used. Again, only character arguments are allowed. The semantics in this case are those of assign(i, value, env=x, inherits=FALSE). Such an assignment will either create a new binding or change the existing binding in x.

NAs in indexing

When extracting, a numerical, logical or character NA index picks an unknown element and so returns NA in the corresponding element of a logical, integer, numeric, complex or character result, and NULL for a list. (It returns 00 for a raw result.)

When replacing (that is using indexing on the lhs of an assignment) NA does not select any element to be replaced. As there is ambiguity as to whether an element of the rhs should be used or not, this is only allowed if the rhs value is of length one (so the two interpretations would have the same outcome).

Argument matching

Note that these operations do not match their index arguments in the standard way: argument names are ignored and positional matching only is used. So m[j=2,i=1] is equivalent to m[2,1] and not to m[1,2].

This may not be true for methods defined for them; for example it is not true for the data.frame methods described in [.data.frame.

To avoid confusion, do not name index arguments (but drop must be named).

Note

S uses partial matching when extracting by [ (Becker et al p. 358) whereas R does not.

The documented behaviour of S is that an NA replacement index ‘goes nowhere’ but uses up an element of value (Becker et al p. 359). However, that is not the current behaviour of S-PLUS.

References

Extract.data.frame

Extract or Replace Parts of a Data Frame

Description

Extract or replace subsets of data frames.

Usage

x[i]
x[i] <- value
x[i, j, drop]
x[i, j] <- value
\begin{verbatim}
x[[i]]
x[[i]] <- value
x[[i, j]]
x[[i, j]] <- value

x$name
x$name <- value
\end{verbatim}

**Arguments**

- **x**: data frame.
- **i, j**: elements to extract or replace. \( i, j \) are numeric or character or, for \([ \) only, empty. Numeric values are coerced to integer as if by `as.integer`. For replacement by \([ . \) a logical matrix is allowed.
- **drop**: logical. If \( \text{TRUE} \) the result is coerced to the lowest possible dimension. The default is to drop if only one column is left, but \( \text{not} \) to drop if only one row is left.
- **value**: A suitable replacement value: it will be repeated a whole number of times if necessary and it may be coerced: see the Coercion section. If \( \text{NULL} \), deletes the column if a single column is selected.
- **name**: name or literal character string.

**Details**

Data frames can be indexed in several modes. When \([ \) and \([ [ \) are used with a single index, they index the data frame as if it were a list. In this usage a drop argument is ignored, with a warning. Using \( \$ \) is equivalent to using \([ [ \) with a single index.

When \([ \) and \([ [ \) are used with two indices they act like indexing a matrix: \([ [ \) can only be used to select one element.

If \( \) returns a data frame it will have unique (and non-missing) row names, if necessary transforming the row names using `make.unique`. Similarly, column names will be transformed (if columns are selected more than once).

When \( \) \( \text{drop =TRUE} \), this is applied to the subsetting of any matrices contained in the data frame as well as to the data frame itself.

The replacement methods can be used to add whole column(s) by specifying non-existent column(s), in which case the column(s) are added at the right-hand edge of the data frame and numerical indices must be contiguous to existing indices. On the other hand, rows can be added at any row after the current last row, and the columns will be in-filled with missing values. Missing values in the indices are not allowed for replacement.

For \( \) the replacement value can be a list: each element of the list is used to replace (part of) one column, recycling the list as necessary. If columns specified by number are created, the names (if any) of the corresponding list elements are used to name the columns. If the replacement is not selecting rows, list values can contain \( \text{NULL} \) elements which will cause the corresponding columns to be deleted. (See the Examples.)

Matrix indexing using \( \) is not recommended, and barely supported. For extraction, \( x \) is first coerced to a matrix. For replacement a logical matrix (only) can be used to select the elements to be replaced in the same way as for a matrix.
Value

For \[\] a data frame, list or a single column (the latter two only when dimensions have been dropped). If matrix indexing is used for extraction a matrix results.

For \[[\] a column of the data frame (extraction with one index) or a length-one vector (extraction with two indices).

For \[<-\], \[[<-\] and \]$<-\$, a data frame.

Coercion

The story over when replacement values are coerced is a complicated one, and one that has changed during R’s development. This section is a guide only.

When \[\] and \[[\] are used to add or replace a whole column, no coercion takes place but \texttt{value} will be replicated (by calling the generic function \texttt{rep}) to the right length if an exact number of repeats can be used.

When \[\] is used with a logical matrix, each value is coerced to the type of the column in which it is to be placed.

When \[\] and \[[\] are used with two indices, the column will be coerced as necessary to accommodate the value.

Note that when the replacement value is an array (including a matrix) it is \texttt{not} treated as a series of columns (as \texttt{data.frame} and \texttt{as.data.frame} do) but inserted as a single column.

Warning

The default behaviour when only one \texttt{row} is left is equivalent to specifying \texttt{drop = FALSE}. To drop from a data frame to a list, \texttt{drop = TRUE} has to be specified explicitly.

See Also

\texttt{subset} which is often easier for extraction, \texttt{data.frame}, \texttt{Extract}.

Examples

\begin{verbatim}
sw <- swiss[1:5, 1:4]  # select a manageable subset

sw[1:3]  # select columns
sw[, 1:3]  # same
sw[4:5, 1:3]  # select rows and columns
sw[1]  # a one-column data frame
sw[, 1, drop = FALSE]  # the same
sw[, 1]  # a (unnamed) vector
sw[[1]]  # the same

sw[1,]  # a one-row data frame
sw[1,, drop=TRUE]  # a list

swiss[ c(1, 1:2), ]  # duplicate row, unique row names are created

sw[sw <= 6] <- 6  # logical matrix indexing

sw  #\# adding a column
sw["new1"] <- LETTERS[1:5]  # adds a character column
sw["new2"] <- letters[1:5]  # ditto
\end{verbatim}
sw[, "new3"] <- LETTERS[1:5] # ditto
sw$new4 <- 1:5
sapply(sw, class)
sw$new4 <- NULL # delete the column
sw
sw[6:8] <- list(letters[10:14], NULL, aa=1:5) # delete col7, update 6, append
sw

### matrices in a data frame
A <- data.frame(x=1:3, y=I(matrix(4:6)), z=I(matrix(letters[1:9],3,3)))
A[1:3, "y"] # a matrix
A[1:3, "z"] # a matrix
A[, "y"] # a matrix

---

**Extract.factor**

### Extract or Replace Parts of a Factor

**Description**

Extract or replace subsets of factors.

**Usage**

```r
## S3 method for class 'factor':
x[...], drop = FALSE
## S3 method for class 'factor':
x[[i]]
## S3 replacement method for class 'factor':
x[...] <- value
```

**Arguments**

- `x`: a factor
- `...`, `i`: a specification of indices – see `Extract`
- `drop`: logical. If true, unused levels are dropped.
- `value`: character: a set of levels. Factor values are coerced to character.

**Details**

When unused levels are dropped the ordering of the remaining levels is preserved.

If `value` is not in `levels(x)`, a missing value is assigned with a warning.

Any `contrasts` assigned to the factor are preserved unless `drop=TRUE`.

**Value**

A factor with the same set of levels as `x` unless `drop=TRUE`. (Prior to R 2.4.0, `[[]` returned the integer code.)

**See Also**

`factor`, `Extract`
## Extremes

### Description

Returns the (parallel) maxima and minima of the input values.

### Usage

```r
max(..., na.rm = FALSE)
min(..., na.rm = FALSE)
pmax(..., na.rm = FALSE)
pmin(..., na.rm = FALSE)
pmax.int(..., na.rm = FALSE)
pmin.int(..., na.rm = FALSE)
```

### Arguments

- `...`: numeric or character arguments (see Note).
- `na.rm`: a logical indicating whether missing values should be removed.

### Details

`max` and `min` return the maximum or minimum of all the values present in their arguments, as `integer` if all are logical or integer, as `double` if all are numeric, and character otherwise. If `na.rm` is `FALSE` an NA value in any of the arguments will cause a value of NA to be returned, otherwise NA values are ignored.

The minimum and maximum of a numeric empty set are `+Inf` and `-Inf` (in this order!) which ensures transitivity, e.g., `min(x1, min(x2)) == min(x1, x2)`. For numeric `x`, `max(x)` is `-Inf` and `min(x) == +Inf whenever length(x) == 0` (after removing missing values if requested). However, `pmax` and `pmin` return NA if all the parallel elements are NA even for `na.rm = TRUE`.

`pmax` and `pmin` take one or more vectors (or matrices) as arguments and return a single vector giving the “parallel” maxima (or minima) of the vectors. The first element of the result is the maximum (minimum) of the first elements of all the arguments, the second element of the result is the maximum (minimum) of the second elements of all the arguments and so on. Shorter inputs are recycled if necessary. `attributes` (such as `names` or `dim`) are transferred from the first argument (if applicable).

`pmax.int` and `pmin.int` are faster internal versions only used when all arguments are atomic vectors and there are no classes: they drop all attributes. (Note that all versions fail for raw and complex vectors since these have no ordered.)

### Examples

```r
## following example(factor)
(ff <- factor(substring("statistics", 1:10, 1:10), levels=letters))
ff[, drop=TRUE]
factor(letters[7:10])[2:3, drop = TRUE]
```
max and min are generic functions: methods can be defined for them individually or via the Summary group generic. For this to work properly, the arguments ... should be unnamed, and dispatch is on the first argument.

By definition the min/max of any vector containing an NaN is NaN, except that the min/max of any vector containing an NA is NA even if it also contains an NaN. Note that max(NA, Inf) == NA even though the maximum would be Inf whatever the missing value actually is.

The max/min of an empty character vector is a character NA. (One could argue that as "" is the smallest character element, the maximum should be ", but there is no obvious candidate for the minimum.)

Value

For min or max, a length-one vector. For pmin or pmax, a vector of length the longest of the input vectors.

The type of the result will be that of the highest of the inputs in the hierarchy integer < real < character.

For min and max if there are only numeric inputs and all are empty (after possible removal of NAs), the result is double (Inf or -Inf).

Note

'Numeric' arguments are vectors of type integer and numeric, and logical (coerced to integer). For historical reasons, NULL is accepted as equivalent to integer(0).

pmax and pmin will also work on classed objects with appropriate methods for comparison, is.na and rep (if recycling of arguments is needed).

References

See Also

range (both min and max) and which.min (which.max) for the arg min, i.e., the location where an extreme value occurs.

Examples

require(stats)
min(5:1, pi) #-> one number
pmin(5:1, pi) #-> 5 numbers
x <- sort(rnorm(100)); cH <- 1.35
pmin(cH, quantile(x)) # no names
pmin(quantile(x), cH) # has names
plot(x, pmin(cH, pmax(-cH, x)), type='b', main= "Huber's function")
Description

The function `factor` is used to encode a vector as a factor (the terms ‘category’ and ‘enumerated type’ are also used for factors). If `ordered` is `TRUE`, the factor levels are assumed to be ordered. For compatibility with S there is also a function `ordered`.

`is.factor`, `is.ordered`, `as.factor` and `as.ordered` are the membership and coercion functions for these classes.

Usage

```r
code
```

Arguments

- `x`: a vector of data, usually taking a small number of distinct values.
- `levels`: an optional vector of the values that `x` might have taken. The default is the set of values taken by `x`, sorted into increasing order.
- `labels`: either an optional vector of labels for the levels (in the same order as `levels` after removing those in `exclude`), or a character string of length 1.
- `exclude`: a vector of values to be excluded when forming the set of levels. This should be of the same type as `x`, and will be coerced if necessary.
- `ordered`: logical flag to determine if the levels should be regarded as ordered (in the order given).
- `...`: (in `ordered(.)`): any of the above, apart from `ordered` itself.

Details

The type of the vector `x` is not restricted.

Ordered factors differ from factors only in their class, but methods and the model-fitting functions treat the two classes quite differently.

The encoding of the vector happens as follows. First all the values in `exclude` are removed from `levels`. If `x[i]` equals `levels[j]`, then the `i`-th element of the result is `j`. If no match is found for `x[i]` in `levels`, then the `i`-th element of the result is set to `NA`.

Normally the ‘levels’ used as an attribute of the result are the reduced set of levels after removing those in `exclude`, but this can be altered by supplying `labels`. This should either be a set of new labels for the levels, or a character string, in which case the levels are that character string with a sequence number appended.
factor(x, exclude=NULL) applied to a factor is a no-operation unless there are unused levels: in that case, a factor with the reduced level set is returned. If exclude is used it should also be a factor with the same level set as x or a set of codes for the levels to be excluded.

The codes of a factor may contain NA. For a numeric x, set exclude=NULL to make NA an extra level ("NA"), by default the last level.

If "NA" is a level, the way to set a code to be missing is to use is.na on the left-hand-side of an assignment. Under those circumstances missing values are printed as <NA>.

is.factor is generic: you can write methods to handle specific classes of objects, see Internal-Methods.

Value

factor returns an object of class "factor" which has a set of integer codes the length of x with a "levels" attribute of mode character. If ordered is true (or ordered is used) the result has class c("ordered", "factor").

Applying factor to an ordered or unordered factor returns a factor (of the same type) with just the levels which occur: see also [.factor for a more transparent way to achieve this.

is.factor returns TRUE or FALSE depending on whether its argument is of type factor or not. Correspondingly, is.ordered returns TRUE when its argument is ordered and FALSE otherwise.

as.factor coerces its argument to a factor. It is an abbreviated form of factor.

as.ordered(x) returns x if this is ordered, and ordered(x) otherwise.

Warning

The interpretation of a factor depends on both the codes and the "levels" attribute. Be careful only to compare factors with the same set of levels (in the same order). In particular, as.numeric applied to a factor is meaningless, and may happen by implicit coercion. To “revert” a factor f to its original numeric values, as.numeric(levels(f))[f] is recommended and slightly more efficient than as.numeric(as.character(f)).

The levels of a factor are by default sorted, but the sort order may well depend on the locale at the time of creation, and should not be assumed to be ASCII.

Comparison operators and group generic methods

There are "factor" and "ordered" methods for the group generic Ops, which provide methods for the Comparison operators. (The rest of the group and the Math and Summary groups generate an error as they are not meaningful for factors.)

Only == and != can be used for factors: a factor can only be compared to another factor with an identical set of levels (not necessarily in the same ordering) or to a character vector. Ordered factors are compared in the same way, but the general dispatch mechanism precludes comparing ordered and unordered factors.

All the comparison operators are available for ordered factors. Sorting is done by the levels of the operands: if both operands are ordered factors they must have the same level set.

Note

Storing character data as a factor is more efficient storage if there is even a small proportion of repeats. On a 32-bit machine storing a string of n bytes takes 28 + 8[(n + 1)/8] bytes whereas storing a factor code takes 4 bytes. (On a 64-bit machine 28 is replaced by 56 or more.) Only if they were computed from the same values (or in some cases read from a file: see scan) will identical strings share storage.
References

See Also

 [.factor for subsetting of factors.

 gl for construction of “balanced” factors and C for factors with specified contrasts. levels and nlevels for accessing the levels, and unclass to get integer codes.

Examples

(ff <- factor(substring("statistics", 1:10, 1:10), levels=letters))
as.integer(ff)  # the internal codes
factor(ff)  # drops the levels that do not occur
ff[, drop=TRUE]  # the same, more transparently

factor(letters[1:20], label="letter")
class(ordered(4:1))  # "ordered", inheriting from "factor"

## suppose you want "NA" as a level, and to allowing missing values.
(x <- factor(c(1, 2, "NA"), exclude = ""))
is.na(x)[2] <- TRUE
x  # [1] 1   <NA> NA, <NA> used because NA is a level.
is.na(x)
# [1] FALSE TRUE FALSE
factor()

---

file.access Ascertain File Accessibility

Description

Utility function to access information about files on the user’s file systems.

Usage

file.access(names, mode = 0)

Arguments

names character vector containing file names.

mode integer specifying access mode required.

Details

The mode value can be the exclusive or of the following values

0 test for existence.

1 test for execute permission.

2 test for write permission.
test for read permission.

Permission will be computed for real user ID and real group ID (rather than the effective IDs).
Please note that it is not good to use this function to test before trying to open a file. On a multi-
tasking system, it is possible that the accessibility of a file will change between the time you call
\texttt{file.access()} and the time you try to open the file, and in recent Windows versions the under-
lying function in \texttt{msvcrt.dll} sometimes returns inaccurate values. It is better to wrap file open
attempts in \texttt{try} instead.

\textbf{Value}

An integer vector with values 0 for success and -1 for failure.

\textbf{Note}

This is intended as a replacement for the S-PLUS function \texttt{access}, a wrapper for the C function
of the same name, which explains the return value encoding. Note that the return value is \texttt{false} for
success.

\textbf{See Also}

\texttt{file.info,try}

\textbf{Examples}

\begin{verbatim}
fa <- file.access(dir("."))
table(fa) # count successes & failures
\end{verbatim}

\begin{verbatim}
file.choose
\end{verbatim}

\textit{Choose a File Interactively}

\textbf{Description}

Choose a file interactively.

\textbf{Usage}

\texttt{file.choose(new = FALSE)}

\textbf{Arguments}

\begin{description}
  \item[\texttt{new}] Logical: choose the style of dialog box presented to the user: at present only
  new = FALSE is used.
\end{description}

\textbf{Value}

A character vector of length one giving the file path.

\textbf{See Also}

\texttt{list.files} for non-interactive selection.
Description

Utility function to extract information about files on the user’s file systems.

Usage

file.info(...)

Arguments

... character vectors containing file names.

Details

What is meant by “file access” and hence the last access time is system-dependent.

On most systems symbolic links are followed, so information is given about the file to which the
link points rather than about the link.

Value

A data frame with row names the file names and columns

size double: File size in bytes.
isdire logical: Is the file a directory?
mode integer of class "octmode". The file permissions, printed in octal, for example 644.
mtime, ctime, atime integer of class "POSIXct": file modification, creation and last access times.
uid integer: the user ID of the file’s owner.
gid integer: the group ID of the file’s group.
uname character: uid interpreted as a user name.
grname character: gid interpreted as a group name.

Unknown user and group names will be NA.

Entries for non-existent or non-readable files will be NA. The uid, gid, uname and grname
columns may not be supplied on a non-POSIX Unix system.

Note

This function will only be operational on systems with the stat system call, but that seems very
widely available.

Some (broken) systems allow files of more than 2Gb to be created but not accessed by the stat
system call. Such files will show up as non-readable (and very likely not be readable by any of R’s
input functions).
See Also
   `files`, `file.access`, `list.files`, and `DateTimeClasses` for the date formats.

Examples
   ncol(finf <- file.info(dir()))# at least six
   ## Not run: finf # the whole list
   ## Those that are more than 100 days old:
   finf[difftime(Sys.time(), finf[, "mtime"], units = "days") > 100 , 1:4]
   file.info("no-such-file-exists")

---

**file.path**  
Construct Path to File

**Description**
Construct the path to a file from components in a platform-independent way.

**Usage**
   file.path(..., fsep = .Platform$file.sep)

**Arguments**

  ... character vectors.

  fsep the path separator to use.

**Value**
A character vector of the arguments concatenated term-by-term and separated by fsep if all arguments have positive length; otherwise, an empty character vector.

---

**file.show**  
Display One or More Files

**Description**
Display one or more files.

**Usage**
   file.show(..., header = rep("", nfiles), title = "R Information",
               delete.file = FALSE, pager = getOption("pager"), encoding = ")
Arguments

... one or more character vectors containing the names of the files to be displayed.
header character vector (of the same length as the number of files specified in ...) giving a header for each file being displayed. Defaults to empty strings.
title an overall title for the display. If a single separate window is used for the display, title will be used as the window title. If multiple windows are used, their titles should combine the title and the file-specific header.
delete.file should the files be deleted after display? Used for temporary files.
pager the pager to be used.
encoding charset to be assumed for the file(s).

Details

This function provides the core of the R help system, but it can be used for other purposes as well, such as `page`.
How the pager is implemented is highly system-dependent.
The basic Unix version concatenates the files (using the headers) to a temporary file, and displays it in the pager selected by the pager argument, which is a character vector specifying a system command (usually `less`) to run on the set of files.
Most GUI systems will use a separate pager window for each file, and let the user leave it up while R continues running. The selection of such pagers could either be done using "magic" pager names being intercepted by lower-level code (such as "internal" and "console" on Windows), or by letting pager be an R function which will be called with the same first four arguments as file.show and take care of interfacing to the GUI.

Not all implementations will honour delete.file.

Author(s)

Ross Ihaka, Brian Ripley.

See Also

`files`, `list.files`, `help`.

Examples

```r
file.show(file.path(R.home("doc"), "COPYRIGHTS"))
```

Description

These functions provide a low-level interface to the computer’s file system.
files

Usage

file.create(...)
file.exists(...)
file.remove(...)
file.rename(from, to)
file.append(file1, file2)
file.copy(from, to, overwrite = FALSE)
file.symlink(from, to)
dir.create(path, showWarnings = TRUE, recursive = FALSE)

Arguments

..., file1, file2, from, to
character vectors, containing file names.
path
a character vector containing a single path name.
overwrite
logical; should the destination files be overwritten?
showWarnings
logical; should the warnings on failure be shown?
recursive
logical: should elements of the path other than the last be created? If true, like Unix’s mkdir -p.

Details

The ... arguments are concatenated to form one character string: you can specify the files separately or as one vector. All of these functions expand path names: see path.expand.
file.create creates files with the given names if they do not already exist and truncates them if they do.
file.exists returns a logical vector indicating whether the files named by its argument exist.
file.remove attempts to remove the files named in its argument.
file.rename attempts to rename a single file.
file.append attempts to append the files named by its second argument to those named by its first. The R subscript recycling rule is used to align names given in vectors of different lengths.
file.copy works in a similar way to file.append but with the arguments in the natural order for copying. Copying to existing destination files is skipped unless overwrite = TRUE. The to argument can specify a single existing directory.
file.symlink makes symbolic links on those Unix-like platforms which support them. The to argument can specify a single existing directory.
dir.create creates the last element of the path, unless recursive = TRUE. As from R 2.2.1 trailing path separators are ignored.

Value

dir.create and file.rename return a logical, true for success.

The remaining functions return a logical vector indicating which operation succeeded for each of the files attempted.
dir.create will return failure if the directory already exists.

findInterval

Find Interval Numbers or Indices

Description

Find the indices of \( x \) in \( \text{vec} \), where \( \text{vec} \) must be sorted (non-decreasingly); i.e., if \( i \leftarrow \text{findInterval}(x, \text{vec}) \), we have \( v_j \leq x_j < v_{j+1} \) where \( v_0 := -\infty, v_{N+1} := +\infty \), and \( N \leftarrow \text{length}(\text{vec}) \). At the two boundaries, the returned index may differ by 1, depending on the optional arguments \( \text{rightmost.closed} \) and \( \text{all.inside} \).

Usage

\[
\text{findInterval}(x, \text{vec}, \text{rightmost.closed} = \text{FALSE}, \text{all.inside} = \text{FALSE})
\]

Arguments

- \( x \) numeric.
- \( \text{vec} \) numeric, sorted (weakly) increasingly, of length \( N \), say.
- \( \text{rightmost.closed} \) logical; if true, the rightmost interval, \( \text{vec}[N-1] \ldots \text{vec}[N] \) is treated as closed, see below.
- \( \text{all.inside} \) logical; if true, the returned indices are coerced into \( \{1, \ldots, N - 1\} \), i.e., 0 is mapped to 1 and \( N \) to \( N - 1 \).
Details

The function `findInterval` finds the index of one vector `x` in another, `vec`, where the latter must be non-decreasing. Where this is trivial, equivalent to `apply( outer(x, vec, ">="), 1, sum)`, as a matter of fact, the internal algorithm uses interval search ensuring `O(n \log N)` complexity where `n <- length(x)` (and `N <- length(vec)`). For (almost) sorted `x`, it will be even faster, basically `O(n)`.

This is the same computation as for the empirical distribution function, and indeed, `findInterval(t, sort(X))` is identical to `nF_n(t; X_1, ..., X_n)` where `F_n` is the empirical distribution function of `X_1, ..., X_n`.

When `rightmost.closed = TRUE`, the result for `x[j] = vec[N] (= max(vec))`, is `N - 1` as for all other values in the last interval.

Value

vector of length `length(x)` with values in `0:N` (and `NA`) where `N <- length(vec)`, or values coerced to `1:(N-1)` if and only if `all.inside = TRUE` (equivalently coercing all `x` values inside the intervals). Note that `NAs` are propagated from `x`, and `Inf` values are allowed in both `x` and `vec`.

Author(s)

Martin Maechler

See Also

`approx(*, method = "constant")` which is a generalization of `findInterval()`.

`ecdf` for computing the empirical distribution function which is (up to a factor of `n`) also basically the same as `findInterval()`.

Examples

```r
N <- 100
X <- sort(round(rt(N, df=2), 2))
tt <- c(-100, seq(-2,2, len=201), +100)
it <- findInterval(tt, X)
tt[it < 1 | it >= N] # only first and last are outside range(X)
```

---

**force**

**Force Evaluation of an Argument**

Description

Forces the evaluation of a function argument.

Usage

`force(x)`

Arguments

`x` a formal argument of the enclosing function.
Details

force forces the evaluation of a formal argument. This can be useful if the argument will be captured in a closure by the lexical scoping rules and will later be altered by an explicit assignment or an implicit assignment in a loop or an apply function.

Note

This is semantic sugar: just evaluating the symbol will do the same thing (see the examples).

force does not force the evaluation of other promises. (It works by forcing the promise that is created when the actual arguments of a call are matched to the formal arguments of a closure, the mechanism which implements lazy evaluation.)

Examples

f <- function(y) function() y
if <- vector("list", 5)
for (i in seq(along = if)) if[[i]] <- f(i)
if[[1]]() # returns 5

g <- function(y) { force(y); function() y }
lg <- vector("list", 5)
for (i in seq(along = lg)) lg[[i]] <- g(i)
lg[[1]]() # returns 1

## This is identical to
g <- function(y) { y; function() y }

Foreign Function Interface

Description

Functions to make calls to compiled code that has been loaded into R.

Usage

.C(name, ..., NAOK = FALSE, DUP = TRUE, PACKAGE, ENCODING)
.Fortran(name, ..., NAOK = FALSE, DUP = TRUE, PACKAGE, ENCODING)
.External(name, ..., PACKAGE)
.Call(name, ..., PACKAGE)
.External.graphics(name, ..., PACKAGE)
.Call.graphics(name, ..., PACKAGE)

Arguments

name a character string giving the name of a C function or Fortran subroutine, or an object of class "NativeSymbolInfo" or "NativeSymbol" referring to such a name.

... arguments to be passed to the foreign function.

NAOK if TRUE then any NA or NaN or Inf values in the arguments are passed on to the foreign function. If FALSE, the presence of NA or NaN or Inf values is regarded as an error.
DUP  if TRUE then arguments are “duplicated” before their address is passed to C or Fortran.

PACKAGE if supplied, confine the search for the name to the DLL given by this argument (plus the conventional extension, .so, .sl, .dll,...). This is intended to add safety for packages, which can ensure by using this argument that no other package can override their external symbols. Use PACKAGE="base" for symbols linked in to R.

ENCODING optional name for an encoding to be assumed for character vectors.

Details

The functions .C and .Fortran can be used to make calls to C and Fortran code.

.CExternal and .CExternal.graphics can be used to call compiled code that uses R objects in the same way as internal R functions.

.CCall and .Call.graphics can be used call compiled code which makes use of internal R objects. The arguments are passed to the C code as a sequence of R objects. It is included to provide compatibility with S version 4.

For details about how to write code to use with .Call and .External, see the chapter on “System and foreign language interfaces” in “Writing R Extensions” in the ‘doc/manual’ subdirectory of the R source tree.

Value

The functions .C and .Fortran return a list similar to the ... list of arguments passed in, but reflecting any changes made by the C or Fortran code.

.CExternal, .Call, .CExternal.graphics, and .Call.graphics return an R object.

These calls are typically made in conjunction with dyn.load which links DLLs to R.

The .graphics versions of .Call and .External are used when calling code which makes low-level graphics calls. They take additional steps to ensure that the device driver display lists are updated correctly.

Argument types

The mapping of the types of R arguments to C or Fortran arguments in .C or .Fortran is

<table>
<thead>
<tr>
<th>R Type</th>
<th>C Type</th>
<th>Fortran Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>integer</td>
<td>int *</td>
<td>integer</td>
</tr>
<tr>
<td>numeric</td>
<td>double *</td>
<td>double precision</td>
</tr>
<tr>
<td>– or – complex</td>
<td>float *</td>
<td>real</td>
</tr>
<tr>
<td>logical</td>
<td>int *</td>
<td>integer</td>
</tr>
<tr>
<td>character</td>
<td>char **</td>
<td>[see below]</td>
</tr>
<tr>
<td>raw</td>
<td>unsigned char *</td>
<td>not allowed</td>
</tr>
<tr>
<td>list</td>
<td>SEXP *</td>
<td>not allowed</td>
</tr>
<tr>
<td>other</td>
<td>SEXP</td>
<td>not allowed</td>
</tr>
</tbody>
</table>

Numeric vectors in R will be passed as type double * to C (and as double precision to Fortran) unless (i) .C or .Fortran is used, (ii) DUP is false and (iii) the argument has attribute Csingle set to TRUE (use as.single or single). This mechanism is only intended to be used to facilitate the interfacing of existing C and Fortran code.
The C type `Rcomplex` is defined in `Complex.h` as a typedef struct {double r; double i;}. Fortran type `double complex` is an extension to the Fortran standard, and the availability of a mapping of `complex` to Fortran may be compiler dependent.

**Note:** The C types corresponding to `integer` and `logical` are `int`, not `long` as in S. This difference matters on 64-bit platforms.

The first character string of a character vector is passed as a C character array to Fortran: that string may be usable as `character*255` if its true length is passed separately. Only up to 255 characters of the string are passed back. (How well this works, or even if it works at all, depends on the C and Fortran compilers and the platform.)

Missing (NA) string values are passed to `.C` as the string "NA". As the C `char` type can represent all possible bit patterns there appears to be no way to distinguish missing strings from the string "NA". If this distinction is important use `.Call`.

Functions, expressions, environments and other language elements are passed as the internal R pointer type `SEXP`. This type is defined in `Rinternals.h` or the arguments can be declared as generic pointers, `void *`. Lists are passed as C arrays of `SEXP` and can be declared as `void *` or `SEXP *`. Note that you cannot assign values to the elements of the list within the C routine. Assigning values to elements of the array corresponding to the list bypasses R’s memory management/garbage collection and will cause problems. Essentially, the array corresponding to the list is read-only. If you need to return S objects created within the C routine, use the `.Call` interface.

R functions can be invoked using `call_S` or `call_R` and can be passed lists or the simple types as arguments.

**Warning**

*DUP=FALSE* is dangerous.

There are two dangers with using *DUP=FALSE*.

The first is that if you pass a local variable to `.C/Fortran` with *DUP=FALSE*, your compiled code can alter the local variable and not just the copy in the return list. Worse, if you pass a local variable that is a formal parameter of the calling function, you may be able to change not only the local variable but the variable one level up. This will be very hard to trace.

The second is that lists are passed as a single R `SEXP` with *DUP=FALSE*, not as an array of `SEXP`. This means the accessor macros in `Rinternals.h` are needed to get at the list elements and the lists cannot be passed to `call_S`/`call_R`. New code using R objects should be written using `.Call` or `.External`, so this is now only a minor issue.

In addition, character vectors and lists cannot be used with *DUP=FALSE*.

It is safe and useful to set *DUP=FALSE* if you do not change any of the variables that might be affected, e.g.,

```
.C("Cfunction", input=x, output=numeric(10)).
```

In this case the output variable did not exist before the call so it cannot cause trouble. If the input variable is not changed in the C code of `Cfunction` you are safe.

Neither `.Call` nor `.External` copy their arguments. You should treat arguments you receive through these interfaces as read-only.

**Fortran symbol names**

All compilers that can be used with R map symbol names to lower case, and so does `.Fortran`. Symbol names containing underscores are not valid Fortran 77 (although they are valid in Fortran 9x). Many Fortran 77 compilers (including `g77`) will allow them but translate them in a different
way to names not containing underscores. As from R 2.4.0 such names will work with .Fortran, but portable code should not use Fortran names containing underscores.

Use .Fortran with care for compiled Fortran 9x code: it may not work if the Fortran 9x compiler used differs from the Fortran compiler used when configuring R, especially if the subroutine name is not lower-case or includes an underscore.

**Header files for external code**

Writing code for use with .External and .Call will need to use internal R structures. If possible use just those defined in ‘Rinternals.h’ and/or the macros in ‘Rdefines.h’, as other header files are not installed and are even more likely to be changed.

**formals**

Access to and Manipulation of the Formal Arguments

**Description**

Get or set the formal arguments of a function.

**Usage**

```r
formals(fun = sys.function(sys.parent()))
formals(fun, envir = environment(fun)) <- value
```

**Arguments**

- **fun**
  - a function object, or see Details.
- **envir**
  - environment in which the function should be defined.
- **value**
  - a list (or pairlist) of R expressions.

**Details**

For the first form, `fun` can also be a character string naming the function to be manipulated, which is searched for from the parent environment. If it is not specified, the function calling `formals` is used.

Only closures have formals, not primitive functions.
Value

formals returns the formal argument list of the function specified, as a pairlist, or NULL for a non-function or primitive.

The replacement form sets the formals of a function to the list/pairlist on the right hand side, and (potentially) resets the environment of the function.

See Also

args for a “human-readable” version, alist, body, function.

Examples

length(formals(lm))  # the number of formal arguments
names(formals(boxplot))  # formal arguments names

f <- function(x) a+b
formals(f) <- alist(a=,b=3)  # function(a,b=3)a+b
f(2)  # result = 5

Description

Format an R object for pretty printing.

Usage

format(x, ...)

## Default S3 method:
format(x, trim = FALSE, digits = NULL, nsmall = 0,
       justify = c("left", "right", "centre", "none"),
       width = NULL, na.encode = TRUE, scientific = NA,
       big.mark = ",", big.interval = 3,
       small.mark = ",", small.interval = 5,
       decimal.mark = ".", zero.print = NULL, ...)

## S3 method for class 'data.frame':
format(x, ..., justify = "none")

## S3 method for class 'factor':
format(x, ...)

## S3 method for class 'AsIs':
format(x, width = 12, ...)
Arguments

- **x**: any R object (conceptually); typically numeric.
- **trim**: logical; if FALSE, logical, numeric and complex values are right-justified to a common width; if TRUE the leading blanks for justification are suppressed.
- **digits**: how many significant digits are to be used for numeric and complex x. The default, NULL, uses `getOption(digits)`. This is a suggestion: enough decimal places will be used so that the smallest (in magnitude) number has this many significant digits, and also to satisfy `nsmall`. (For the interpretation for complex numbers see `signif`.)
- **nsmall**: the minimum number of digits to the right of the decimal point in formatting real/complex numbers in non-scientific formats. Allowed values are `0 <= nsmall <= 20`.
- **justify**: should a character vector be left-justified (the default), right-justified, centred or left alone.
- **width**: default method: the minimum field width or NULL or 0 for no restriction. AsIs method: the maximum field width for non-character objects. NULL corresponds to the default 12.
- **na.encode**: logical: should NA strings be encoded?
- **scientific**: Either a logical specifying whether elements of a real or complex vector should be encoded in scientific format, or an integer penalty (see `options("scipen")`). Missing values correspond to the current default penalty.
- **...**: further arguments passed to or from other methods.
- **big.mark**, **big.interval**, **small.mark**, **small.interval**, **decimal.mark**, **zero.print**: used for prettying longer decimal sequences, passed to `prettyNum`: that help page explains the details.

Details

`format` is a generic function. Apart from the methods described here there are methods for dates (see `format.Date`), date-times (see `format.POSIXct`) and for other classes such as `format.octmode` and `format.dist`.

`format.data.frame` formats the data frame column by column, applying the appropriate method of `format` for each column. Methods for columns are often similar to `as.character` but offer more control. Matrix and data-frame columns will be converted to separate columns in the result, and character columns (normally all) will be given class "AsIs".

`format.factor` converts the factor to a character vector and then calls the default method (and so `justify` applies).

`format.AsIs` deals with columns of complicated objects that have been extracted from a data frame. Character objects are passed to the default method (and so `width` does not apply). Otherwise it calls `toString` to convert the object to character (if a vector or list, element by element) and then right-justifies the result.

Justification for character vectors (and objects converted to character vectors by their methods) is done on display width (see `nchar`), taking double-width characters and the rendering of special characters (as escape sequences, including escaping backslash: see `print.default`) into account. Character strings are padded with blanks to the display width of the widest. (If `na.encode = FALSE` missing character strings are not included in the width computations and are not encoded.)
Numeric vectors are encoded with the minimum number of decimal places needed to display all the elements to at least the digit significant digits. However, if all the elements then have trailing zeroes, the number of decimal places is reduced until at least one element has a non-zero final digit. Raw vectors are converted to their 2-digit hexadecimal representation by `as.character`.

**Value**

An object of similar structure to `x` containing character representations of the elements of the first argument `x` in a common format.

For numeric or complex `x`, dims and dimnames are preserved on matrices/arrays and names on vectors: no other attributes are copied.

If `x` is a list, the result is a character vector obtained by applying `format.default(x, ...)` to each element of the list (after `unlist`ing elements which are themselves lists), and then collapsing the result for each element with `paste(collapse = "", ")`. The defaults in this case are `trim = TRUE`, `justify = "none"` since one does not usually want alignment in the collapsed strings.

**References**

**See Also**

`format.info` indicates how an atomic vector would be formatted.

`formatC, paste, as.character, sprintf, print, toString, encodeString`.

**Examples**

```r
format(1:10)
format(1:10, trim = TRUE)

zz <- data.frame("(row names)"= c("aaaaa", "b"), check.names=FALSE)
format(zz)
format(zz, justify = "left")

## use of nsmall
format(13.7)
format(13.7, nsmall = 3)
format(c(6.0, 13.1), digits = 2)
format(c(6.0, 13.1), digits = 2, nsmall = 1)

## use of scientific
format(2^31-1)
format(2^31-1, sci = TRUE)

## a list
z <- list(a=letters[1:3], b=(-pi+0i)^((-2:2)/2), c=c(1,10,100,1000),
          d=c("a", "longer", "character", "string"))
format(z, digits = 2)
format(z, digits = 2, justify = "left", trim = FALSE)
```
Format.Date

Date Conversion Functions to and from Character

Description

Functions to convert between character representations and objects of class "Date" representing calendar dates.

Usage

as.Date(x, ...)
## S3 method for class 'character':
as.Date(x, format = '', ...)

## S3 method for class 'Date':
format(x, ...)

## S3 method for class 'Date':
as.character(x, ...)

Arguments

x
An object to be converted.

format
A character string. The default is "%Y-%m-%d". For details see strftime.

...
Further arguments to be passed from or to other methods, including format for as.character and as.Date methods.

Details

The usual vector re-cycling rules are applied to x and format so the answer will be of length that of the longer of the vectors.

Locale-specific conversions to and from character strings are used where appropriate and available. This affects the names of the days and months.

The as.Date methods accept character strings, factors, logical NA and objects of classes "POSIXlt" and "POSIXct". (The last are converted to days by ignoring the time after midnight in the representation of the time in UTC.) Also objects of class "date" (from package date or survival) and "dates" (from package chron). Character strings are processed as far as necessary for the format specified: any trailing characters are ignored.

See the examples for how to convert a day given as the number of days since an epoch.

The format and as.character methods ignore any fractional part of the date.

Value

The format and as.character methods return a character vector representing the date.

The as.Date methods return an object of class "Date".
Note

The default formats follow the rules of the ISO 8601 international standard which expresses a day as "2001-02-03".

If the date string does not specify the date completely, the returned answer may be system-specific. The most common behaviour is to assume that a missing year, month or day is the current one. If it specifies a date incorrectly, reliable implementations will give an error and the date is reported as NA. Unfortunately some common implementations (such as 'glibc') are unreliable and guess at the intended meaning.

Years before 1CE (aka 1AD) will probably not be handled correctly.

References

See Also

Date for details of the date class; locales to query or set a locale.

Your system's help pages on strftime and strptime to see how to specify their formats.

Examples

## locale-specific version of the date
format(Sys.Date(), "%a %b %d")

## read in date info in format 'ddmmmyyyy'
## This will give NA(s) in some locales; setting the C locale
## as in the commented lines will overcome this on most systems.
## lct <- Sys.getlocale("LC_TIME"); Sys.setlocale("LC_TIME", "C")
x <- c("1jan1960", "2jan1960", "3mar1960", "30jul1960")
z <- as.Date(x, "%d%b%Y")

## read in date/time info in format 'm/d/y'
dates <- c("02/27/92", "02/27/92", "01/14/92", "02/28/92", "02/01/92")
as.Date(dates, "%m/%d/%y")

## date given as number of days since 1900-01-01 (a date in 1989)
as.Date("1900-01-01") + 32768

format.info

Description

Information is returned on how format (x, digits, nsmall) would be formatted.
format.info

Usage

format.info(x, digits = NULL, nsmall = 0)

Arguments

x an atomic vector; a potential argument of format(x, ...).
digits how many significant digits are to be used for numeric and complex x. The default, NULL, uses getOption(digits).
nsmall (see format(..., nsmall)).

Value

An integer vector of length 1, 3 or 6, say r.

For logical, integer and character vectors a single element, the width which would be used by
format if width = NULL.

For numeric vectors:

r[1] width (in characters) used by format(x)
r[2] number of digits after decimal point.
r[3] in 0:2; if ≥1, exponential representation would be used, with exponent length

For a complex vector the first three elements refer to the real parts, and there are three further
elements corresponding to the imaginary parts.

See Also

format, formatC.

Examples

dd <- options("digits") ; options(digits = 7) #-- for the following
format.info(123) # 3 0 0
format.info(pi) # 8 6 0
format.info(1e8) # 5 0 1 - exponential "1e+08"
format.info(1e222) # 6 0 2 - exponential "1e+222"

x <- pi*10^c(-10,-2,0:2,8,20)
names(x) <- formatC(x,w=1,dig=3,format="g")
cbind(sapply(x,format))
t(sapply(x, format.info))

## using at least 8 digits right of "."
t(sapply(x, format.info, nsmall = 8))

# Reset old options:
options(dd)
format.pval  

Format P Values

Description

format.pval is intended for formatting p-values.

Usage

format.pval(pv, digits = max(1,getOption("digits") - 2),
eps = .Machine$double.eps, na.form = "NA")

Arguments

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pv</td>
<td>a numeric vector.</td>
</tr>
<tr>
<td>digits</td>
<td>how many significant digits are to be used.</td>
</tr>
<tr>
<td>eps</td>
<td>a numerical tolerance: see Details.</td>
</tr>
<tr>
<td>na.form</td>
<td>character representation of NAs.</td>
</tr>
</tbody>
</table>

Details

format.pval is mainly an auxiliary function for print.summary.lm etc., and does separate formatting for fixed, floating point and very small values; those less than eps are formatted as "< [eps]" (where “[eps]” stands for format(eps, digits)).

Value

A character vector.

Examples

format.pval(c(runif(5), pi^-100, NA))
format.pval(c(0.1, 0.0001, 1e-27))

formatC  

Formatting Using C-style Formats

Description

Formatting numbers individually and flexibly, using C style format specifications.
formatC

Usage

formatC(x, digits = NULL, width = NULL,
    format = NULL, flag = "", mode = NULL,
    big.mark = "", big.interval = 3,
    small.mark = "", small.interval = 5,
    decimal.mark = ".", preserve.width = "individual")

prettyNum(x, big.mark = "", big.interval = 3,
    small.mark = "", small.interval = 5,
    decimal.mark = ".",
    preserve.width = c("common", "individual", "none"),
    zero.print = NULL, ...)

Arguments

x
an atomic numerical or character object, typically a vector of real numbers.
digits
the desired number of digits after the decimal point (format = "f") or sig-
nificant digits (format = "g", = "e" or = "fg"). Default: 2 for integer, 4 for real numbers. If less than 0, the C default of 6 digits is used.
width
the total field width; if both digits and width are unspecified, width defaults to 1, otherwise to digits + 1. width = 0 will use width = digits.width < 0 means left justify the number in this field (equivalent to flag ="-" ). If necessary, the result will have more characters than width.
format
equal to "d" (for integers), "f", "e", "E", "g", "G", "fg" (for reals), or "s" (for strings). Default is "d" for integers, "g" for reals.
"f" gives numbers in the usual xxx.xxx format; "e" and "E" give n.ddde+nn or n.dddE+nn (scientific format); "g" and "G" put x[i] into scientific format only if it saves space to do so.
"fg" uses fixed format as "f", but digits as the minimum number of significant digits. That this can lead to quite long result strings, see examples below. Note that unlike signif this prints large numbers with more significant digits than digits.
flag
For formatC, a character string giving a format modifier as in Kernighan and Ritchie (1988, page 243). "0" pads leading zeros; "-" does left adjustment, others are "+", " " and ".#". There can be more than one of these, in any order.
mode
"double" (or "real"), "integer" or "character". Default: Determined from the storage mode of x.
big.mark
character; if not empty used as mark between every big.interval decimals before (hence big) the decimal point.
big.interval see big.mark above; defaults to 3.
small.mark character; if not empty used as mark between every small.interval deci-
mals after (hence small) the decimal point.
small.interval see small.mark above; defaults to 5.
decimal.mark the character to be used to indicate the numeric decimal point.
formatC

preserve.width
  string specifying if the string widths should be preserved where possible in those cases where marks (big.mark or small.mark) are added. "common", the default, corresponds to format-like behavior whereas "individual" is the default in formatC().

zero.print
  logical, character string or NULL specifying if and how zeros should be formatted specially. Useful for pretty printing "sparse" objects.

... arguments passed to format.

Details

If you set format it overrides the setting of mode, so formatC(123.45, mode="double", format="d") gives 123.

The rendering of scientific format is platform-dependent: some systems use n.ddde+nnn or n.dddenn rather than n.ddde+nn.

formatC does not necessarily align the numbers on the decimal point, so formatC(c(6.11, 13.1), digits=2, format="fg") gives c("6.1", "13"). If you want common formatting for several numbers, use format.

prettyNum is the utility function for prettifying x. If x is not a character, format(x[i], ...) is applied to each element, and then it is left unchanged if all the other arguments are at their defaults. Note that prettyNum(x) may behave unexpectedly if x is a character vector not resulting from something like format(<number>): in particular it assumes that a period is a decimal mark.

Value

A character object of same size and attributes as x. Unlike format, each number is formatted individually. Looping over each element of x, the C function sprintf(...) is called (inside the C function str_signif).

formatC: for character x, do simple (left or right) padding with white space.

Author(s)

formatC was originally written by Bill Dunlap, later much improved by Martin Maechler. It was first adapted for R by Friedrich Leisch.

References

format.

sprintf for more general C like formatting.

Examples

xx <- pi * 10^(-5:4)
cbind(format(xx, digits=4), formatC(xx))
cbind(formatC(xx, wid = 9, flag = "-"))
cbind(formatC(xx, dig = 5, wid = 8, format = "f", flag = "0"))
cbind(format(xx, digits=4), formatC(xx, dig = 4, format = "fg"))

formatC( c("a", "Abc", "no way"), wid = -7)  # <-> flag = "-"
formatC(c((-1:1)/0, c(1,100)*pi), wid=8, dig=1)

xx <- c(1e-12,-3.98765e-10,1.45645e-69,1e-70,pi*1e37,3.44e4)
## 1 2 3 4 5 6
formatC(xx)
formatC(xx, format="fg")  # special "fixed" format.
formatC(xx, format="f", dig=80)  #> also long strings

x <- c("76491283764.97430", "29.12345678901", "-7.1234", "-100.1","1123")
## American:
prettyNum(r, big.mark = ",")
## Some Europeans:
prettyNum(r, big.mark = ",", decimal.mark = ",")

(dd <- sapply(1:10, function(i)paste((9:0)[1:i],collapse="")))
prettyNum(dd, big.mark=""')

## examples of 'small.mark'
pN <- stats::pnorm(1:7, lower=FALSE)
cbind(format (pN, small.mark = " ", digits = 15))

printC(pN, small.mark = " ", digits = 17, format = "f")

cbind(ff <- format(1.2345 + 10^(0:5), width = 11, big.mark = "'"))
## all with same width (one more than the specified minimum)

## individual formatting to common width:
fc <- formatC(1.234 + 10^(0:8), format="fg", width=11, big.mark = "'")

formatDL  

---

**Format Description Lists**

### Description

Format vectors of items and their descriptions as 2-column tables or LaTeX-style description lists.

### Usage

```r
formatDL(x, y, style = c("table", "list"),
          width = 0.9 * getOption("width"), indent = NULL)
```

### Arguments

- **x**
  - a vector giving the items to be described, or a list of length 2 or a matrix with 2 columns giving both items and descriptions.

- **y**
  - a vector of the same length as x with the corresponding descriptions. Only used if x does not already give the descriptions.

- **style**
  - a character string specifying the rendering style of the description information. If "table", a two-column table with items and descriptions as columns is produced (similar to Texinfo’s @table environment. If "list", a LaTeX-style tagged description list is obtained.
width
indent

width
indent

Details

After extracting the vectors of items and corresponding descriptions from the arguments, both are coerced to character vectors.

In table style, items with more than \(\text{indent} - 3\) characters are displayed on a line of their own.

Value

a character vector with the formatted entries.

Examples

```r
## Use R to create the 'INDEX' for package 'splines' from its 'CONTENTS'
x <- read.dcf(file = system.file("CONTENTS", package = "splines"),
  fields = c("Entry", "Description"))
x <- as.data.frame(x)
writeLines(formatDL(x$Entry, x$Description))
## or equivalently: writeLines(formatDL(x))
## Same information in tagged description list style:
writeLines(formatDL(x$Entry, x$Description, style = "list"))
## or equivalently: writeLines(formatDL(x, style = "list"))
```

Description

These functions provide the base mechanisms for defining new functions in the R language.

Usage

```r
function( arglist ) expr
return(value)
```

Arguments

- `arglist`: Empty or one or more name or name=expression terms.
- `value`: An expression.

Details

The names in an argument list can be back-quoted non-standard names (see `backquote`).

If `value` is missing, `NULL` is returned. If it is a single expression, the value of the evaluated expression is returned.

If the end of a function is reached without calling `return`, the value of the last evaluated expression is returned.
Warning

Prior to R 1.8.0, value could be a series of non-empty expressions separated by commas. In that case the value returned is a list of the evaluated expressions, with names set to the expressions where these are the names of R objects. That is, a=foo() names the list component `a` and gives it the value which results from evaluating `foo()`.

This has been deprecated (and a warning is given), as it was never documented in S, and whether or not the list is named differs by S versions.

References

See Also

`args` and `body` for accessing the arguments and body of a function.
`debug` for debugging; using `invisible` inside `return(.)` for returning invisibly.

Examples

```r
norm <- function(x) sqrt(x*x)
norm(1:4)

## An anonymous function:
(function(x,y){ z <- x^2 + y^2; x+y+z })(0:7, 1)
```

Description

A call of `gc` causes a garbage collection to take place. `gcinfo` sets a flag so that automatic collection is either silent (`verbose=FALSE`) or prints memory usage statistics (`verbose=TRUE`).

Usage

```r
gc(verbos=getOption("verbose"), reset=FALSE)
gcinfo(verbos)
```

Arguments

- `verbose` logical; if `TRUE`, the garbage collection prints statistics about cons cells and the space allocated for vectors.
- `reset` logical; if `TRUE` the values for maximum space used are reset to the current values.
Details

A call of `gc` causes a garbage collection to take place. This will also take place automatically without user intervention, and the primary purpose of calling `gc` is for the report on memory usage.

However, it can be useful to call `gc` after a large object has been removed, as this may prompt R to return memory to the operating system.

R allocates space for vectors in multiples of 8 bytes: hence the report of "Vcells", a relict of an earlier allocator (that used a vector heap).

When `gcinfo(TRUE)` is in force, messages are sent to the message connection at each garbage collection of the form

```
Garbage collection 12 = 10+0+2 (level 0) ...
6.4 Mbytes of cons cells used (58
2.0 Mbytes of vectors used (32
```

Here the last two lines give the current memory usage rounded up to the next 0.1Mb and as a percentage of the current trigger value. The first line gives a breakdown of the number of garbage collections at various levels (for an explanation see the ‘R Internals’ manual).

Value

`gc` returns a matrix with rows "Ncells" (cons cells), usually 28 bytes each on 32-bit systems and 56 bytes on 64-bit systems, and "Vcells" (vector cells, 8 bytes each), and columns "used" and "gc trigger", each also interpreted in megabytes (rounded up to the next 0.1Mb).

If maxima have been set for either "Ncells" or "Vcells", a fifth column is printed giving the current limits in Mb (with NA denoting no limit).

The final two columns show the maximum space used since the last call to `gc(reset=TRUE)` (or since R started).

`gcinfo` returns the previous value of the flag.

See Also

The ‘R Internals’ manual.

`Memory` on R's memory management, and `gctorture` if you are an R developer.

`reg.finalizer` for actions to happen at garbage collection.

Examples

```
# do it now
gc()

#-- in the future, show when R does it
gcinfo(TRUE)

#-- don't show it anymore
x <- integer(100000); for(i in 1:18) x <- c(x,i)
geninfo(verbose = FALSE)

gc(TRUE)

#-- reset

gc(reset=TRUE)
```
**gc.time**

Report Time Spent in Garbage Collection

**Description**

This function reports the time spent in garbage collection so far in the R session while GC timing was enabled.

**Usage**

```r
gc.time(on = TRUE)
```

**Arguments**

- `on` logical; if TRUE, GC timing is enabled.

**Value**

A numerical vector of length 5 giving the user CPU time, the system CPU time, the elapsed time and children’s user and system CPU times (normally both zero).

**Warnings**

This is experimental functionality, likely to be removed as soon as the next release.

The timings are rounded up by the sampling interval for timing processes, and so are likely to be over-estimates.

**See Also**

- `gc.proc.time` for the timings for the session.

**Examples**

```r
gc.time()
```

---

**gctorture**

Torture Garbage Collector

**Description**

Provokes garbage collection on (nearly) every memory allocation. Intended to ferret out memory protection bugs. Also makes R run very slowly, unfortunately.

**Usage**

```r
gctorture(on = TRUE)
```

**Arguments**

- `on` logical; turning it on/off.
get

Return the Value of a Named Object

Description

Search for an R object with a given name and return it.

Usage

```r
get(x, pos = -1, envir = as.environment(pos), mode = "any",
    inherits = TRUE)
mget(x, envir, mode = "any",
    ifnotfound = list(function(x) stop(paste("value for ",
        x, " not found", sep = ""), call. = FALSE)), inherits = FALSE)
```

Arguments

- `x` a variable name (given as a character string).
- `pos` where to look for the object (see the details section); if omitted, the function will search as if the name of the object appeared unquoted in an expression.
- `envir` an alternative way to specify an environment to look in; see the Details section.
- `mode` the mode or type of object sought: see the Details section.
- `inherits` should the enclosing frames of the environment be searched?
- `ifnotfound` A list of values to be used if the item is not found: it will be coerced to list if necessary.

Details

The `pos` argument can specify the environment in which to look for the object in any of several ways: as an integer (the position in the search list); as the character string name of an element in the search list; or as an `environment` (including using `sys.frame` to access the currently active function calls). The `envir` argument is an alternative way to specify an environment, but is primarily there for back compatibility.

This function looks to see if the name `x` has a value bound to it in the specified environment. If `inherits` is TRUE and a value is not found for `x` in the specified environment, the enclosing frames of the environment are searched until the name `x` is encountered. See `environment` and the ‘R Language Definition’ manual for details about the structure of environments and their enclosures.

**Warning**: `inherits = TRUE` is the default behaviour for R but not for S.

If `mode` is specified then only objects of that type are sought. The `mode` may specify one of the collections "numeric" and "function" (see `mode`): any member of the collection will suffice.
Using a NULL environment is equivalent to using the current environment.

For `mget` multiple values are returned in a named list. This is true even if only one value is requested. The value in `mode` and `ifnotfound` can be either the same length as the number of requested items or of length 1. The argument `ifnotfound` must be a list containing either the value to use if the requested item is not found or a function of one argument which will be called if the item is not found, with argument the name of the item being requested. The default value for `inherits` is `FALSE`, in contrast to the default behavior for `get`.

`mode` here is a mixture of the meanings of `typeof` and `mode`: "function" covers primitive functions and operators, "numeric", "integer", "real" and "double" all refer to any numeric type, "symbol" and "name" are equivalent but "language" must be used.

Value

The object found. (If no object is found an error results.)

Note

The reverse of `a <- get(nam)` is `assign(nam, a)`.

References

See Also

`exists`, `assign`.

Examples

```r
get("%o%")
```

```r
## test mget
e1 <- new.env()
mget(letters, e1, ifnotfound = as.list(LETTERS))
```

---

**getDescription**

**Compute DLL for native interface call**

**Description**

This is an internal function that is called from R’s C code to determine the enclosing name space of a `.C`, `.Call`, `.Fortran`, `.External` call which has no `PACKAGE` argument. If the call has been made from a function within a name space, then we can find the DLL associated with that name space. The purpose of this is to avoid having to use the `PACKAGE` argument in these native calls and so better support versions of packages.

This is an internal function that may be migrated to internal C code in the future and so should not be used by R programmers.
getDLLRegisteredRoutines

Usage

getCallingDLL(f = sys.function(-1), doStop = FALSE)
getCallingDLL(e)

Arguments

f
the function whose name space and DLL are to be found. By default, this is the current function being called which is the one in which the native routine is being invoked.
doStop
a logical value indicating whether failure to find a name space and/or DLL is an error (TRUE) or not (FALSE). The default is FALSE so that when this is called because there is no PACKAGE argument in a .C, .Call, .Fortran, .External call, no error occurs and the regular lookup is performed by searching all DLLs in order.
e
an environment.

See Also

Examples

if(exists("ansari.test"))
  getCallingDLL(ansari.test)

getDLLRegisteredRoutines

Reflectance Information for C/Fortran routines in a DLL

Description

This function allows us to query the set of routines in a DLL that are registered with R to enhance dynamic lookup, error handling when calling native routines, and potentially security in the future. This function provides a description of each of the registered routines in the DLL for the different interfaces, i.e. .C, .Call, .Fortran and .External.

Usage

getDLLRegisteredRoutines(dll, addNames = TRUE)

Arguments

dll
a character string or DLLInfo object (as returned by getLoadedDLLs).
addNames
a logical value. If this is TRUE, the elements of the returned lists are named using the names of the routines (as seen by R via registration or raw name). If FALSE, these names are not computed and assigned to the lists. As a result, the call should be quicker. The name information is also available in the NativeSymbolInfo objects in the lists.
Details

This takes the registration information after it has been registered and processed by the R internals. In other words, it uses the extended information.

Value

A list with four elements corresponding to the routines registered for the .C, .Call, .Fortran and .External interfaces. Each element is a list with as many elements as there were routines registered for that interface. Each element identifies a routine and is an object of class NativeSymbolInfo. An object of this class has the following fields:

- name: the registered name of the routine (not necessarily the name in the C code).
- address: the memory address of the routine as resolved in the loaded DLL. This may be NULL if the symbol has not yet been resolved.
- dll: an object of class DLLInfo describing the DLL. This is same for all elements returned.
- numParameters: the number of arguments the native routine is to be called with. In the future, we will provide information about the types of the parameters also.

g LoadedDLLs

Examples

dlls <- getLoadedDLLs()
gDLLRegisteredRoutines(dlls["base"])
gDLLRegisteredRoutines("stats")

getLoadedDLLs  Get DLLs Loaded in Current Session

Description

This function provides a way to get a list of all the Dynamically Loadable Libraries (DLLs) that are currently loaded in the current R session.

Usage

g LoadedDLLs ()
Details
This queries the internal table that manages the DLLs.

Value
An object of class "DLLInfoList" which is a list with an element corresponding to each DLL that is currently loaded in the session. Each element is an object of class "DLLInfo" which has the following entries.

name the abbreviated name.
path the fully qualified name of the file which was dynamically loaded.
dynamicLookup a logical value indicating whether R uses only the registration information to resolve symbols or whether it searches the entire symbol table of the DLL.
handle a reference to the C-level data structure that provides access to the contents of the DLL. This is an object of class "DLLHandle".

Note that the class DLLInfo has an overloaded method for $ which can be used to resolve native symbols within that DLL. Therefore, one must access the R-level elements described above using [[, e.g. x[["name"]]] or x[["handle"]].

Note
We are starting to use the handle elements in the DLL object to resolve symbols more directly in R.

Author(s)
Duncan Temple Lang (duncan@wald.ucdavis.edu).

See Also
getDLLRegisteredRoutines, getNativeSymbolInfo

Examples
getLoadedDLLs()
getNativeSymbolInfo

this provides a way to explicitly share symbols between different dynamically loaded package libraries. Also, it provides a way to query where symbols were resolved, and aids diagnosing strange behavior associated with dynamic resolution.

This is now vectorized in the name argument so can process multiple symbols in a single call. The result is a list that can be indexed by the given symbol names.

Usage

getNativeSymbolInfo(name, PACKAGE, unlist = TRUE, withRegistrationInfo = FALSE)

Arguments

name the name(s) of the native symbol(s) as used in a call to is.loaded, etc. Note that Fortran symbols should be supplied as-is, not wrapped in symbol.For.

PACKAGE an optional argument that specifies to which dynamically loaded library we restrict the search for this symbol. If this is "base", we search in the R executable itself.

unlist a logical value which controls how the result is returned if the function is called with the name of a single symbol. If unlist is TRUE and the number of symbol names in name is one, then the NativeSymbolInfo object is returned. If it is FALSE, then a list of NativeSymbolInfo objects is returned. This is ignored if the number of symbols passed in name is more than one. To be compatible with earlier versions of this function, this defaults to TRUE.

withRegistrationInfo a logical value indicating whether, if TRUE, to return information that was registered with R about the symbol and its parameter types if such information is available, or if FALSE to return the address of the symbol.

Details

This uses the same mechanism for resolving symbols as is used in all the native interfaces (.Call, etc.). If the symbol has been explicitly registered by the shared library in which it is contained, information about the number of arguments and the interface by which it should be called will be returned. Otherwise, a generic native symbol object is returned.

Value

Generally, a list of NativeSymbolInfo elements whose elements can be indexed by the elements of name in the call. Each NativeSymbolInfo object is a list containing the following elements:

name the name of the symbol, as given by the name argument.

address if withRegistrationInfo is FALSE, this is the native memory address of the symbol which can be used to invoke the routine, and also to compare with other symbol addresses. This is an external pointer object and of class NativeSymbol. If withRegistrationInfo is TRUE and registration information is available for the symbol, then this is an object of class RegisteredNativeSymbol and is a reference to an internal data type that has access to the routine pointer and registration information. This too can be used in calls to .Call, .C, .Fortran and .External.

package a list containing 3 elements:
name the short form of the library name which can be used as the value of the PACKAGE argument in the different native interface functions.

path the fully qualified name of the shared library file.

dynamicLookup a logical value indicating whether dynamic resolution is used when looking for symbols in this library, or only registered routines can be located.

numParameters the number of arguments that should be passed in a call to this routine.

Additionally, the list will have an additional class, being CRoutine, CallRoutine, FortranRoutine or ExternalRoutine corresponding to the R interface by which it should be invoked.

If any of the symbols is not found, an error is immediately raised.

If name contains only one symbol name and unlist is TRUE, then the single NativeSymbolInfo is returned rather than the list containing that one element.

Note

One motivation for accessing this reflectance information is to be able to pass native routines to C routines as “function pointers” in C. This allows us to treat native routines and R functions in a similar manner, such as when passing an R function to C code that makes callbacks to that function at different points in its computation (e.g., nls). Additionally, we can resolve the symbol just once and avoid resolving it repeatedly or using the internal cache. In the future, one may be able to treat NativeSymbol objects directly as callback objects.

Author(s)

Duncan Temple Lang

References

See Also

Examples

library(stats) # normally loaded
getNativeSymbolInfo("dansari")

getNativeSymbolInfo("hcass2") # a Fortran symbol
Description

These functions provide facilities to manage the extensible list of converters used to translate R objects to C pointers for use in `.C` calls. The number and a description of each element in the list can be retrieved. One can also query and set the activity status of individual elements, temporarily ignoring them. And one can remove individual elements.

Usage

- `getNumCConverters()`
- `getCConverterDescriptions()`
- `getCConverterStatus()`
- `setCConverterStatus(id, status)`
- `removeCConverter(id)`

Arguments

- **id**: either a number or a string identifying the element of interest in the converter list. A string is matched against the description strings for each element to identify the element. Integers are specified starting at 1 (rather than 0).
- **status**: a logical value specifying whether the element is to be considered active (TRUE) or not (FALSE).

Details

The internal list of converters is potentially used when converting individual arguments in a `.C` call. If an argument has a non-trivial class attribute, we iterate over the list of converters looking for the first that “matches”. If we find a matching converter, we have it create the C-level pointer corresponding to the R object. When the call to the C routine is complete, we use the same converter for that argument to reverse the conversion and create an R object from the current value in the C pointer. This is done separately for all the arguments.

The functions documented here provide R user-level capabilities for investigating and managing the list of converters. There is currently no mechanism for adding an element to the converter list within the R language. This must be done in C code using the routine `R_addToCConverter()`.

Value

- `getNumCConverters` returns an integer giving the number of elements in the list, both active and inactive.
- `getCConverterDescriptions` returns a character vector containing the description string of each element of the converter list.
- `getCConverterStatus` returns a logical vector with a value for each element in the converter list. Each value indicates whether that converter is active (TRUE) or inactive (FALSE). The names of the elements are the description strings returned by `getCConverterDescriptions`.
- `setCConverterStatus` returns the logical value indicating the activity status of the specified element before the call to change it took effect. This is TRUE for active and FALSE for inactive.
- `removeCConverter` returns TRUE if an element in the converter list was identified and removed. In the case that no such element was found, an error occurs.
getpid

Get the Process ID of the R Session

Description
Get the process ID of the R Session. It is guaranteed by the operating system that two R sessions running simultaneously will have different IDs, but it is possible that R sessions running at different times will have the same ID.

Usage
Sys.getpid()

Value
An integer, usually a small integer between 0 and 32767 under Unix-alikes and a much small integer under Windows.

Examples
Sys.getpid()
**gettext**

*Translate Text Messages*

**Description**

If Native Language Support was enabled in this build of R, attempt to translate character vectors or set where the translations are to be found.

**Usage**

```r
gettext(..., domain = NULL)
ngettext(n, msg1, msg2, domain = NULL)
bindtextdomain(domain, dirname = NULL)
```

**Arguments**

- `...`: One or more character vectors.
- `domain`: The ‘domain’ for the translation.
- `n`: A non-negative integer.
- `msg1`: The message to be used in English for \( n = 1 \).
- `msg2`: The message to be used in English for \( n = 0, 2, 3, \ldots \).
- `dirname`: The directory in which to find translated message catalogs for the domain.

**Details**

If `domain` is `NULL` or `""`, a domain is searched for based on the name space which contains the function calling `gettext` or `ngettext`. If a suitable domain can be found, each character string is offered for translation, and replaced by its translation into the current language if one is found.

Conventionally the domain for R warning/error messages in package `pkg` is "R-pkg", and that for C-level messages is "pkg".

For `gettext`, leading and trailing whitespace is ignored when looking for the translation.

`ngettext` is used where the message needs to vary by a single integer. Translating such messages is subject to very specific rules for different languages: see the GNU Gettext Manual. The string will often contain a single instance of `%d` to be used in `sprintf`. If English is used, `msg1` is returned if \( n == 1 \) and `msg2` in all other cases.

**Value**

For `gettext`, a character vector, one element per string in `...`. If translation is not enabled or no domain is found or no translation is found in that domain, the original strings are returned.

For `ngettext`, a character string.

For `bindtextdomain`, a character string giving the current base directory, or `NULL` if setting it failed.
getwd

Description

getwd returns an absolute filename representing the current working directory of the R process; setwd(dir) is used to set the working directory to dir.

Usage

getwd()
setwd(dir)

Arguments

dir A character string.

Value

getwd returns a character vector, or NULL if the working directory is not available.
setwd returns the current directory before the change, invisibly. It will give an error if it does not succeed.
**Note**

These functions are not implemented on all platforms.

**See Also**

`list.files` for the contents of a directory.

**Examples**

```r
(WD <- getwd())
if (!is.null(WD)) setwd(WD)
```

---

### gl

**Generate Factor Levels**

**Description**

Generate factors by specifying the pattern of their levels.

**Usage**

```r
gl(n, k, length = n*k, labels = 1:n, ordered = FALSE)
```

**Arguments**

- **n**: an integer giving the number of levels.
- **k**: an integer giving the number of replications.
- **length**: an integer giving the length of the result.
- **labels**: an optional vector of labels for the resulting factor levels.
- **ordered**: a logical indicating whether the result should be ordered or not.

**Value**

The result has levels from 1 to n with each value replicated in groups of length k out to a total length of length.

`gl` is modelled on the `GLIM` function of the same name.

**See Also**

The underlying `factor()`.

**Examples**

```r
## First control, then treatment:
gl(2, 8, label = c("Control", "Treat"))
## 20 alternating 1s and 2s
gl(2, 1, 20)
## alternating pairs of 1s and 2s
gl(2, 2, 20)
```
grep

Pattern Matching and Replacement

Description

grep searches for matches to pattern (its first argument) within the character vector x (second argument). regexpr and gregexpr do too, but return more detail in a different format.

sub and gsub perform replacement of matches determined by regular expression matching.

Usage

grep(pattern, x, ignore.case = FALSE, extended = TRUE,
     perl = FALSE, value = FALSE, fixed = FALSE, useBytes = FALSE)

sub(pattern, replacement, x,
     ignore.case = FALSE, extended = TRUE, perl = FALSE,
     fixed = FALSE, useBytes = FALSE)

gsub(pattern, replacement, x,
     ignore.case = FALSE, extended = TRUE, perl = FALSE,
     fixed = FALSE, useBytes = FALSE)

regexpr(pattern, text, extended = TRUE, perl = FALSE,
     fixed = FALSE, useBytes = FALSE)

gregexpr(pattern, text, extended = TRUE, perl = FALSE,
     fixed = FALSE, useBytes = FALSE)

Arguments

pattern character string containing a regular expression (or character string for fixed = TRUE) to be matched in the given character vector. Coerced by as.character to a character string if possible.
x, text a character vector where matches are sought, or an object which can be coerced by as.character to a character vector.
ignore.case if FALSE, the pattern matching is case sensitive and if TRUE, case is ignored during matching.
extended if TRUE, extended regular expression matching is used, and if FALSE basic regular expressions are used.
perl logical. Should perl-compatible regexps be used? Has priority over extended.
value if FALSE, a vector containing the (integer) indices of the matches determined by grep is returned, and if TRUE, a vector containing the matching elements themselves is returned.
fixed logical. If TRUE, pattern is a string to be matched as is. Overrides all conflicting arguments.
useBytes logical. If TRUE the matching is done byte-by-byte rather than character-by-character. See Details.
replacement  a replacement for matched pattern in sub and gsub. Coerced to character if possible. For fixed = FALSE this can include backreferences \1 to \9 to parenthesized subexpressions of pattern. For perl = TRUE only, it can also contain \U or \L to convert the rest of the replacement to upper or lower case.

Details

Arguments which should be character strings or character vectors are coerced to character if possible.

The two *sub functions differ only in that sub replaces only the first occurrence of a pattern whereas gsub replaces all occurrences.

For regexpr it is an error for pattern to be NA, otherwise NA is permitted and matches only itself.

The regular expressions used are those specified by POSIX 1003.2, either extended or basic, depending on the value of the extended argument, unless perl = TRUE when they are those of PCRE, http://www.pcre.org/. (The exact set of patterns supported may depend on the version of PCRE installed on the system in use, if R was configured to use the system PCRE. R’s internal copy used PCRE 6.7.)

useBytes is only used if fixed = TRUE or perl = TRUE. For grep its main effect is to avoid errors/warnings about invalid inputs, but for regexpr it changes the interpretation of the output.

Value

For grep a vector giving either the indices of the elements of x that yielded a match or, if value is TRUE, the matched elements of x (after coercion, preserving names but no other attributes).

For sub and gsub a character vector of the same length and with the same attributes as x (after possible coercion).

For regexpr an integer vector of the same length as text giving the starting position of the first match, or −1 if there is none, with attribute "match.length" giving the length of the matched text (or −1 for no match). In a multi-byte locale these quantities are in characters rather than bytes unless useBytes = TRUE is used with fixed = TRUE or perl = TRUE.

For gregexpr a list of the same length as text each element of which is an integer vector as in regexpr, except that the starting positions of every match are given.

If in a multi-byte locale the pattern or replacement is not a valid sequence of bytes, an error is thrown. An invalid string in x or text is a non-match with a warning for grep or regexpr, but an error for sub or gsub.

Warning

The standard regular-expression code has been reported to be very slow when applied to extremely long character strings (tens of thousands of characters or more): the code used when perl = TRUE seems much faster and more reliable for such usages.

The standard version of gsub does not substitute correctly repeated word-boundaries (e.g. pattern = \b). Use perl = TRUE for such matches.

The perl = TRUE option is only implemented for single-byte and UTF-8 encodings, and will warn if used in a non-UTF-8 multi-byte locale (unless useBytes = TRUE).

*tolower*, *toupper* and *chartr* for character translations. *charmatch*, *pmatch*, *match*. *apropos* uses regexps and has nice examples.

Examples

```r
grep("[a-z]", letters)
```

```r
txt <- c("arm","foot","lefroo", "bafoobar")
if(any(i <- grep("foo",txt)))
  cat("'foo' appears at least once in
      "txt,"\n"
i # 2 and 4
txt[i]
```

```r
## Double all 'a' or 'b's; "\" must be escaped, i.e., 'doubled'
gsub("([^ab])", "\1\1\1", "abc and ABC")
```

```r
txt <- c("The", "licenses", "for", "most", "software", "are", "designed", "to", "take", "away", "your", "freedom", "to", "share", "and", "change", "it.", "By", "contrast," "the", "GNU", "General", "Public", "License", "is", "intended", "to", "guarantee", "your", "freedom", "to", "share", "and", "change", "free", "software", "--", "to", "make", "sure", "the", "software", "is", "free", "for", "all", "its", "users")
(i <- grep("[gu]", txt)) # indices
stopifnot( txt[i] == grep("[gu]", txt, value = TRUE) )
```

```r
## Note that in locales such as en_US this includes B as the
## collation order is aAbBcCdEe ...
(ot <- sub("[b-e]", ".", txt))
txt[ot != gsub("[b-e]", ".", txt)] # gsub does "global" substitution
txt[gsub("g","g", txt) !=
gsub("g","g", txt, ignore.case = TRUE)] # the "G" words
```

```r
regexpr("en", txt)
gregexpr("e", txt)
```

```r
## trim trailing white space
str = 'Now is the time'
sub(' \+\$',' ', str) ## spaces only
sub('([^:space:]+)\+$',' ', str) ## white space, POSIX-style
sub('([^a-z]+)\+$',' ', str, perl = TRUE) ## Perl-style white space
```

```r
## capitalizing
```
groupGeneric

S3 Group Generic Functions

Description

Group generic methods can be defined for four pre-specified groups of functions, Math, Ops, Summary and Complex. (There are no objects of these names in base R, but there are in the methods package.)

A method defined for an individual member of the group takes precedence over a method defined for the group as a whole.

Usage

## S3 methods for group generics have prototypes:
Math(x, ...)
Ops(e1, e2)
Complex(z)
Summary(..., na.rm = FALSE)

Arguments

x, z, e1, e2 objects.

... further arguments passed to methods.

na.rm logical: should missing values be removed?

Details

There are four groups for which S3 methods can be written, namely the "Math", "Ops", "Summary" and "Complex" groups. These are not R objects, but methods can be supplied for them and base R contains factor, data.frame and difftime methods for the first three groups. (There is also an ordered method for Ops, POSIXt and Date methods for Math and Ops, package_version methods for Ops and Summary, as well as a ts method for Ops in package stats.)

1. Group "Math":

- abs, sign, sqrt, floor, ceiling, trunc, round, signif
- exp, log, cos, sin, tan, acos, asin, atan
cosh, sinh, tanh, acosh, asinh, atanh
- lgamma, gamma, gammaCody, digamma, trigamma
cumsum, cumprod, cummax, cummin
Members of this group dispatch on \( x \). Not all members will accept more than one argument: most members have default methods expecting one argument. (Specifically, \( \text{atan} \) and the gamma functions accept only one argument and \( \log \), \( \text{round} \) and \( \text{signif} \) accept one or two.)

2. Group "Ops":
   - \( + \), \( - \), \( * \), \( / \), \( ^{\text{\%\%}} \), \( \%/\% \)
   - \( \& \), \( | \), \( ! \)
   - \( == \), \( != \), \( < \), \( <= \), \( > \), \( >= \)

This group contains both binary and unary operators (\(+\), \(-\) and \(!\)): when a unary operator is encountered the \text{Ops} method is called with one argument and \( e2 \) is missing.

The classes of both arguments are considered in dispatching any member of this group. For each argument its vector of classes is examined to see if there is a matching specific (preferred) or \text{Ops} method. If a method is found for just one argument or the same method is found for both, it is used. If different methods are found, there is a warning about ‘incompatible methods’: in that case or if no method is found for either argument the internal method is used.

3. Group "Summary":
   - all, any
   - sum, prod
   - min, max
   - range

Members of this group dispatch on the first argument supplied.

4. Group "Complex":
   - \( \text{Arg} \), \( \text{Conj} \), \( \text{Im} \), \( \text{Mod} \), \( \text{Re} \)

Members of this group dispatch on \( z \).

Note that a method will used for either one of these groups or one of its members only if it corresponds to a "class" attribute, as the internal code dispatches on \text{oldClass} and not on \text{class}. This is for efficiency: having to dispatch on, say, \text{Ops.integer} would be too slow.

The number of arguments supplied for primitive members of the "Math" group generic methods is not checked prior to dispatch.

There is no lazy evaluation of arguments for group-generic functions.

Technical Details

The details of method dispatch and variables such as \text{.Generic} are discussed in the help for \text{UseMethod}. There are a few small differences:

- For the operators of group \text{Ops}, the object \text{.Method} is a length-two character vector with elements the methods selected for the left and right arguments respectively. (If no method was selected, the corresponding element is " ".)
- Object \text{.Group} records the group used for dispatch (if a specific method is used this is ".").

References

gzcon

(De)compress I/O Through Connections

Description

gzcon provides a modified connection that wraps an existing connection, and decompresses reads or compresses writes through that connection. Standard gzip headers are assumed.

Usage

gzcon(con, level = 6, allowNonCompressed = TRUE)

Arguments

con a connection.
level integer between 0 and 9, the compression level when writing.
allowNonCompressed logical. When reading, should non-compressed input be allowed?

Details

If con is open then the modified connection is opened. Closing the wrapper connection will also close the underlying connection.

Reading from a connection which does not supply a gzip magic header is equivalent to reading from the original connection if allowNonCompressed is true, otherwise an error.

The original connection becomes unusable: any object pointing to it will now refer to the modified connection.

When the connection is opened for reading, the input is expected to start with the gzip magic header. If it does not and if allowNonCompressed = TRUE (the default) the input is read as-is.

Value

An object inheriting from class "connection". This is the same connection number as supplied, but with a modified internal structure.

See Also

methods for methods of non-Internal generic functions.
S4groupGeneric for group generics for S4 methods.

Examples

d.fr <- data.frame(x=1:9, y=rnorm(9))
class(1 + d.fr) == "data.frame" #-- add to d.f. ...

methods("Math")
methods("Ops")
methods("Summary")
methods("Complex") # none in base R
hexmode

Display Numbers in Hexadecimal

Description

Convert or print integers in hexadecimal format, with as many digits as are needed to display the largest, using leading zeroes as necessary.

Usage

## S3 method for class 'hexmode':
as.character(x, ...)

## S3 method for class 'hexmode':
format(x, ...)

## S3 method for class 'hexmode':
print(x, ...)

Arguments

x An object inheriting from class "hexmode".
...
further arguments passed to or from other methods.

See Also
gzfile

Examples

## Not run:
## This example is no longer available
## print the value to see what objects were created.
con <- url("http://hesweb1.med.virginia.edu/biostat/s/data/sav/kprats.sav")
print(load(con))
close(con)
## End(Not run)

## gzipfile and gzipcon can inter-work.
## Of course here one would used gzipfile, but file() can be replaced by
## any other connection generator.
zz <- gzipfile("ex.gz", "w")
cat("TITLE extra line", "2 3 5 7", "", "11 13 17", file = zz, sep = "\n")
close(zz)
readLines(zz <- gzipcon(file("ex.gz", "rb")))
close(zz)
unlink("ex.gz")

zz <- gzipcon(file("ex.gz", "wb"))
cat("TITLE extra line", "2 3 5 7", "", "11 13 17", file = zz, sep = "\n")
close(zz)
readLines(zz <- gzipfile("ex.gz"))
close(zz)
unlink("ex.gz")
Details

Class "hexmode" consists of integer vectors with that class attribute, used merely to ensure that they are printed in hex.

See Also

octmode

Hyperbolic Functions

Description

These functions give the obvious hyperbolic functions. They respectively compute the hyperbolic cosine, sine, tangent, and their inverses, arc-cosine, arc-sine, arc-tangent (or "area cosine", etc).

Usage

\[ \text{cosh}(x) \]
\[ \text{sinh}(x) \]
\[ \text{tanh}(x) \]
\[ \text{acosh}(x) \]
\[ \text{asinh}(x) \]
\[ \text{atanh}(x) \]

Arguments

\( x \)
a numeric or complex vector

Details

These are generic functions: methods can be defined for them individually or via the `Math` group generic.

Branch cuts are consistent with the inverse trigonometric functions `asin()` et seq. and agree with those defined in Abramowitz and Stegun, figure 4.7, page 86.

References

See Also

The trigonometric functions, `cos`, `sin`, `tan`, and their inverses `acos`, `asin`, `atan`.

The logistic distribution function `plogis` is a shifted version of `tanh()` for numeric \( x \).
iconv

Convert Character Vector between Encodings

Description

This uses system facilities to convert a character vector between encodings: the ‘i’ stands for ‘internationalization’.

Usage

iconv(x, from = "", to = "", sub=NA)

iconvlist()

Arguments

x
A character vector, or an object to be converted to a character vector by \texttt{as.character}.

from
A character string describing the current encoding.

to
A character string describing the target encoding.

sub
character string. If not \texttt{NA} it is used to replace any non-convertible bytes in the input. (This would normally be a single character, but can be more.) If "byte", the indication is "<xx>" with the hex code of the byte.

Details

The names of encodings and which ones are available (and indeed, if any are) is platform-dependent. On all systems that support \texttt{iconv} you can use "" for the encoding of the current locale, as well as "latin1" and "UTF-8".

On many platforms \texttt{iconvlist} provides an alphabetical list of the supported encodings. On others, the information is on the man page for \texttt{iconv(5)} or elsewhere in the man pages (and beware that the system command \texttt{iconv} may not support the same set of encodings as the C functions \texttt{R} calls). Unfortunately, the names are rarely common across platforms.

Elements of \texttt{x} which cannot be converted (perhaps because they are invalid or because they cannot be represented in the target encoding) will be returned as \texttt{NA} unless \texttt{sub} is specified.

Some versions of \texttt{iconv} will allow transliteration by appending //TRANSLIT to the \texttt{to} encoding: see the examples.

Value

A character vector of the same length and the same attributes as \texttt{x} (after conversion).

The elements of the result have a declared encoding if \texttt{from} is "latin1" or "UTF-8", or if \texttt{from} = "" and the current locale’s charset is detected as Latin-1 or UTF-8.

Note

Not all platforms support these functions. See also \texttt{capabilities("iconv")}. 
identical

Test Objects for Exact Equality

Description

The safe and reliable way to test two objects for being exactly equal. It returns TRUE in this case, FALSE in every other case.

Usage

identical(x, y)

Arguments

x, y  any R objects.
Details
A call to `identical` is the way to test exact equality in `if` and `while` statements, as well as in logical expressions that use `&&` or `||`. In all these applications you need to be assured of getting a single logical value.

Users often use the comparison operators, such as `==` or `!=`, in these situations. It looks natural, but it is not what these operators are designed to do in R. They return an object like the arguments. If you expected \( x \) and \( y \) to be of length 1, but it happened that one of them wasn’t, you will not get a single \texttt{FALSE}. Similarly, if one of the arguments is \texttt{NA}, the result is also \texttt{NA}. In either case, the expression `if(x == y)....` won’t work as expected.

The function `all.equal` is also sometimes used to test equality this way, but was intended for something different: It allows for “reasonable” differences in numeric results.

The computations in `identical` are also reliable and usually fast. There should never be an error. The only known way to kill `identical` is by having an invalid pointer at the C level, generating a memory fault. It will usually find inequality quickly. Checking equality for two large, complicated objects can take longer if the objects are identical or nearly so, but represent completely independent copies. For most applications, however, the computational cost should be negligible.

`identical` sees \texttt{NaN} as different from `as.double(NA)`, but all \texttt{NaN}s are equal (and all \texttt{NA} of the same type are equal).

Comparison of character strings allows for embedded \texttt{nul} characters. Comparison of attributes view them as a set (and not a vector, so order is not tested).

Value
A single logical value, \texttt{TRUE} or \texttt{FALSE}, never \texttt{NA} and never anything other than a single value.

Author(s)
John Chambers

References

See Also
`all.equal` for descriptions of how two objects differ; `Comparison` for operators that generate elementwise comparisons. \texttt{isTRUE} is a simple wrapper based on `identical`.

Examples
```r
identical(1, NULL) ## FALSE -- don't try this with ==
identical(1, 1.) ## TRUE in R (both are stored as doubles)
identical(1, as.integer(1)) ## FALSE, stored as different types

x <- 1.0; y <- 0.99999999999
## how to test for object equality allowing for numeric fuzz :
(E <- all.equal(x,y))
isTRUE(E) # which is simply defined to just use identical(TRUE, E)
## If all.equal thinks the objects are different, it returns a
## character string, and the above expression evaluates to FALSE
```
Conditional Element Selection

Description

`ifelse` returns a value with the same shape as `test` which is filled with elements selected from either `yes` or `no` depending on whether the element of `test` is `TRUE` or `FALSE`.

Usage

`ifelse(test, yes, no)`

Arguments

- `test`: an object which can be coerced to logical mode.
- `yes`: return values for true elements of `test`.
- `no`: return values for false elements of `test`.

Details

- If `yes` or `no` are too short, their elements are recycled. `yes` will be evaluated if and only if any element of `test` is true, and analogously for `no`.
- Missing values in `test` give missing values in the result.

Value

A vector of the same length and attributes (including class) as `test` and data values from the values of `yes` or `no`. The mode of the answer will be coerced from logical to accommodate first any values taken from `yes` and then any values taken from `no`.

Warning

- The mode of the result may depend on the value of `test`, and the class attribute of the result is taken from `test` and may be inappropriate for the values selected from `yes` and `no`.
- Sometimes it is better to use a construction such as `(tmp <- yes; tmp[!test] <- no[!test]; tmp)`, possibly extended to handle missing values in `test`.

References

See Also

`if`.
Examples

x <- c(6:-4)
sqrt(x)#- gives warning
sqrt(ifelse(x >= 0, x, NA))# no warning

## Note: the following also gives the warning !
ifelse(x >= 0, sqrt(x), NA)

## example of different return modes:
yes <- 1:3
no <- pi^(0:3)
typeof(ifelse(NA, yes, no)) # logical
typeof(ifelse(TRUE, yes, no)) # integer
typeof(ifelse(FALSE, yes, no))# double

---

integer  

Integer Vectors

Description

Creates or tests for objects of type "integer".

Usage

integer(length = 0)
as.integer(x, ...)
is.integer(x)

Arguments

length desired length.
x object to be coerced or tested.
... further arguments passed to or from other methods.

Details

Integer vectors exist so that data can be passed to C or Fortran code which expects them, and so that small integer data can be represented exactly and compactly.

Note that on almost all implementations of R the range of representable integers is restricted to about \( \pm 2 \times 10^9 \): doubles can hold much larger integers exactly.

Value

integer creates a integer vector of the specified length. Each element of the vector is equal to 0.
as.integer attempts to coerce its argument to be of integer type. The answer will be NA unless the coercion succeeds. Real values larger in modulus than the largest integer are coerced to NA (unlike S which gives the most extreme integer of the same sign). Non-integral numeric values are truncated towards zero (i.e., as.integer(x) equals trunc(x) there), and imaginary parts of complex numbers are discarded (with a warning). Character strings containing either a decimal representation or a hexadecimal representation (starting with 0x or 0X) can be converted, as well as any
allowed by the platform for real numbers. Like `as.vector` it strips attributes including names. (To ensure that an object is of integer type without stripping attributes, use `storage.mode`.) `is.integer` returns TRUE or FALSE depending on whether its argument is of integer type or not, unless it is a factor when it returns FALSE.

References

See Also

`numeric, storage.mode, round` (and `ceiling` and `floor` on that help page) to convert to integral values.

Examples

```r
## as.integer() truncates:
x <- pi * c(-1:1,10)
as.integer(x)
```

---

**interaction**

**Compute Factor Interactions**

**Description**

interaction computes a factor which represents the interaction of the given factors. The result of interaction is always unordered.

**Usage**

`interaction(..., drop = FALSE, sep = ".", lex.order = FALSE)`

**Arguments**

- `...` the factors for which interaction is to be computed, or a single list giving those factors.
- `drop` if drop is TRUE, unused factor levels are dropped from the result. The default is to retain all factor levels.
- `sep` string to construct the new level labels by joining the constituent ones.
- `lex.order` logical indicating if the order of factor concatenation should be lexically ordered.

**Value**

A factor which represents the interaction of the given factors. The levels are labelled as the levels of the individual factors joined by `sep` which is . by default.

By default, when `lex.order = FALSE`, the levels are ordered so the level of the first factor varies fastest, then the second and so on. This is the reverse of lexicographic ordering (which you can get by `lex.order = TRUE`), and differs from :. (It is done this way for compatibility with S.)
References

See Also

`factor; :` where `f:g` is similar to `interaction(f, g, sep=";")` when `f` and `g` are factors.

Examples

```r
a <- gl(2, 4, 8)
b <- gl(2, 2, 8, label = c("ctrl", "treat"))
s <- gl(2, 1, 8, label = c("M", "F"))
interaction(a, b)
interaction(a, b, s, sep = ";")
stopifnot(identical(a:s, interaction(a, s, sep = ":", lex.order = TRUE)),
           identical(a:s:b, interaction(a, s, b, sep = ":", lex.order = TRUE)))
```

---

**interactive**  
*Is R Running Interactively?*

Description

Return `TRUE` when R is being used interactively and `FALSE` otherwise.

Usage

```r
interactive()
```

See Also

`source, .First`

Examples

```r
.First <- function() if(interactive()) x11()
```

---

**Internal**  
*Call an Internal Function*

Description

`Internal` performs a call to an internal code which is built in to the R interpreter.
Only true R wizards should even consider using this function, and only R developers can add to the list of internal functions.

Usage

```r
.Internal(call)
```
Arguments

call       a call expression

See Also

.Primitive, .External (the nearest equivalent available to users).

Description

Many R-internal functions are generic and allow methods to be written for.

Details

The following primitive and internal functions are generic, i.e., you can write methods for them:

\[ \ldots \ldots \] ,
length, length<- , dimnames, dimnames<- , dim, dim<- , names, names<- ,
levels<-

c, unlist, cbind, rbind,
as.character, as.vector, is.array, is.matrix, is.na, is.nan, is.numeric,
rep and seq.int (which dispatches methods for "seq").

In addition, is.name is a synonym for is.symbol and dispatches methods for the latter.

Note that most of the group generic functions are also internal/primitive and allow methods to be written for them.

.S3PrimitiveGenerics is a character vector listing the primitives which are internal generic and not group generic.

For efficiency, internal dispatch only occurs on objects, that is those for which is.object returns true.

See Also

methods for the methods which are available.

invisible       Change the Print Mode to Invisible

Description

Return a (temporarily) invisible copy of an object.

Usage

invisible(x)
Arguments

\(x\) an arbitrary \(R\) object.

Details

This function can be useful when it is desired to have functions return values which can be assigned, but which do not print when they are not assigned.

References

See Also

\texttt{withVisible}, \texttt{return}, \texttt{function}.

Examples

\begin{verbatim}
# These functions both return their argument
f1 <- function(x) x
f2 <- function(x) invisible(x)
f1(1)# prints
f2(1)# does not
\end{verbatim}

\texttt{is.finite} \hspace{1cm} \textit{Finite, Infinite and NaN Numbers}

Description

\texttt{is.finite} and \texttt{is.infinite} return a vector of the same length as \(x\), indicating which elements are finite (not infinite and not missing).

\(\text{Inf}\) and \(-\text{Inf}\) are positive and negative “infinity” whereas \(\text{NaN}\) means “Not a Number”. (These apply to numeric values and real and imaginary parts of complex values but not to values of integer vectors.)

Usage

\begin{verbatim}
is.finite(x)
is.infinite(x)
Inf
NaN
is.nan(x)
\end{verbatim}

Arguments

\(x\) (numerical) object to be tested.
is.finite

Details

is.finite returns a vector of the same length as x the jth element of which is TRUE if x[j] is finite (i.e., it is not one of the values NA, NaN, Inf or -Inf). All elements of types other than logical, integer, numeric and complex vectors are false. Complex numbers are finite if both the real and imaginary parts are.

is.infinite returns a vector of the same length as x the jth element of which is TRUE if x[j] is infinite (i.e., equal to one of Inf or -Inf). This will be false unless x is numeric or complex. Complex numbers are infinite if either the real and imaginary part is.

is.nan tests if a numeric value is NaN. Do not test equality to NaN, or even use identical, since systems typically have many different NaN values. One of these is used for the numeric missing value NA, and is.nan is false for that value. It is generic: you can write methods to handle specific classes of objects, see InternalMethods. The default method handles real and complex vectors: a complex number is regarded as NaN if either the real or imaginary part is NaN but not NA.

Note

In R, basically all mathematical functions (including basic Arithmetic), are supposed to work properly with +/- Inf and NaN as input or output.

The basic rule should be that calls and relations with Infs really are statements with a proper mathematical limit.

References

The IEC 60559 standard, also know as the ANSI/IEEE 754 Floating-Point Standard.

The C99 function isfinite is used for is.finite if available.

See Also

NA, ‘Not Available’ which is not a number as well, however usually used for missing values and applies to many modes, not just numeric.

Examples

pi / 0  ## = Inf a non-zero number divided by zero creates infinity
0 / 0   ## = NaN

1/0 + 1/0# Inf
1/0 - 1/0# NaN

stopifnot(
  1/0 == Inf,
  1/Inf == 0
)
sin(Inf)
cos(Inf)
tan(Inf)
is.function  Is an Object of Type (Primitive) Function?

Description
Checks whether its argument is a (primitive) function.

Usage

is.function(x)

Arguments

x an R object.

Details

is.primitive(x) tests if x is a primitive function (either a "builtin" or "special" as from typeof)?

Value

TRUE if x is a (primitive) function, and FALSE otherwise.

Examples

is.function(1) # FALSE
is.function(is.primitive) # TRUE: it is a function, but ..
is.primitive(is.primitive) # FALSE:it's not a primitive one, whereas
is.primitive(is.function) # TRUE: that one *is*

is.language  Is an Object a Language Object?

Description

is.language returns TRUE if x is a variable name, a call, or an expression.

Usage

is.language(x)

Arguments

x object to be tested.

References

is.object

Examples

```r
dl <- list(a = expression(x^2 - 2*x + 1), b = as.name("Jim"),
c = as.expression(exp(1)), d = call("sin", pi))
sapply(dl, typeof)
sapply(dl, mode)
stopifnot(sapply(dl, is.language))
```

is.object  Is an Object “internally classed”?  

Description

A function rather for internal use. It returns TRUE if the object x has the R internal OBJECT bit set, and FALSE otherwise. The OBJECT bit is set when a "class" attribute is added and removed when that attribute is removed, so this is a very efficient way to check if an object has a class attribute. (S4 objects always should.)

Usage

```r
is.object(x)
```

Arguments

x  object to be tested.

See Also

class, and methods.

isS4.

Examples

```r
is.object(1)  # FALSE
is.object(as.factor(1:3))  # TRUE
```

is.R  Are we using R, rather than S?  

Description

Test if running under R.

Usage

```r
is.R()
```
is.atomic returns TRUE if x is an atomic vector (or NULL) and FALSE otherwise.
isrecursive returns TRUE if x has a recursive (list-like) structure and FALSE otherwise.

Usage
is.atomic(x)
isrecursive(x)

Arguments
x object to be tested.

Details
is.atomic is true for the atomic vector types ("logical", "integer", "numeric", "complex", "character" and "raw") and NULL.
Most types of language objects are regarded as recursive: those which are not are the atomic vector types, NULL and symbols (as given by as.name).

References
is.single

See Also

is.list, is.language, etc, and the demo("is.things").

Examples

is.a.r <- function(x) c(is.atomic(x), is.recursive(x))

is.a.r(c(a=1,b=3))  # TRUE FALSE
is.a.r(list())      # FALSE TRUE ??
is.a.r(list(2))     # FALSE TRUE
is.a.r(lm)          # FALSE TRUE
is.a.r(y ~ x)       # FALSE TRUE
is.a.r(expression(x+1)) # FALSE TRUE (not in 0.62.3!)

is.single

Description

is.single reports an error. There are no single precision values in R.

Usage

is.single(x)

Arguments

x           object to be tested.

References

isS4

Test for an S4 object

Description

Tests whether the object was created from a formally defined class.

Usage

isS4(object)

asS4(object, value = TRUE)

Arguments

object     Any R object.
value      A single logical value; not NA.
Details

Note that `isS4` does not rely on the `methods` package, so in particular it can be used to detect the need to `require()` that package. (But `asS4` does depend on `methods`.)

You should not set the flag directly unless you really know why. In the future, S4 methods may be restricted to S4 objects for primitive functions; then `asS4` would allow method dispatch of S4 methods for S3 classes. For all other purposes, an object will satisfy `isS4(x)` if and only if it should.

Value

`isS4` always returns `TRUE` or `FALSE` according to whether the internal flag marking an S4 object has been turned on for this object.

`asS4` will turn this flag on or off. But see the details.

Examples

```r
isS4(pi) # FALSE
isS4(getClass("MethodDefinition")) # TRUE
```

---

**isSymmetric**

*Test if a Matrix or other Object is Symmetric*

Description

Generic function to test if `object` is symmetric or not. Currently only a matrix method is implemented.

Usage

```r
isSymmetric(object, ...)  # # S3 method for class 'matrix':
isSymmetric(object, tol = 100 * .Machine$double.eps, ...)  #
```

Arguments

- `object` any R object; a `matrix` for the matrix method.
- `tol` numeric scalar `>= 0`. Smaller differences are not considered, see `all.equal.numeric`.
- `...` further arguments passed to methods; the matrix method passes these to `all.equal`.

Details

The `matrix` method is used inside `eigen` by default to test symmetry of matrices “up to rounding error”, using `all.equal`. It might not be appropriate in all situations.

Value

logical indicating if `object` is symmetric or not.
See Also

`eigen` which calls `isSymmetric` when its `symmetric` argument is missing, as per default.

Examples

```r
isSymmetric(D3 <- diag(3)) # -> TRUE

D3[2,1] <- 1e-100
D3
isSymmetric(D3) # TRUE
isSymmetric(D3, tol = 0) # FALSE for zero-tolerance
```

Description

Add a small amount of noise to a numeric vector.

Usage

```r
jitter(x, factor=1, amount = NULL)
```

Arguments

- `x` numeric vector to which `jitter` should be added.
- `factor` numeric
- `amount` numeric; if positive, used as `amount` (see below), otherwise, if = 0 the default is `factor * z/50`. Default (NULL): `factor * d/5` where `d` is about the smallest difference between `x` values.

Details

The result, say `r`, is `r <- x + runif(n, -a, a)` where `n <- length(x)` and `a` is the amount argument (if specified).

Let `z <- max(x) - min(x)` (assuming the usual case). The amount `a` to be added is either provided as `positive` argument `amount` or otherwise computed from `z`, as follows:

If `amount == 0`, we set `a <- factor * z/50` (same as S).

If `amount` is NULL (default), we set `a <- factor * d/5` where `d` is the smallest difference between adjacent unique (apart from fuzz) `x` values.

Value

`jitter(x,...)` returns a numeric of the same length as `x`, but with an amount of noise added in order to break ties.

Author(s)

Werner Stahel and Martin Maechler, ETH Zurich
**kappa**

Estimate the Condition Number

An estimate of the condition number of a matrix or of the $R$ matrix of a QR decomposition, perhaps of a linear fit. The condition number is defined as the ratio of the largest to the smallest non-zero singular value of the matrix.

### Usage

```r
kappa(z, ...)
```

**Examples**

```r
round(jitter(c(rep(1,3), rep(1.2, 4), rep(3,3))), 3)
## These two 'fail' with S-plus 3.x:
jitter(rep(0, 7))
jitter(rep(10000,5))
```

### Arguments

- **z**: A matrix or a the result of `qr` or a fit from a class inheriting from "lm".
- **exact**: logical. Should the result be exact?
- **...**: further arguments passed to or from other methods.

### Details

If `exact = FALSE` (the default) the condition number is estimated by a cheap approximation. Following S, this uses the LINPACK routine `dtrco.f`. However, in R (or S) the exact calculation is also likely to be quick enough.

`kappa.tri` is an internal function called by `kappa.qr`.

### References

### See Also

- `rug` which you may want to combine with `jitter`.

---

**rug**

Which you may want to combine with `jitter`.

### Examples

```r
round(jitter(c(rep(1,3), rep(1.2, 4), rep(3,3))), 3)
## These two 'fail' with S-plus 3.x:
jitter(rep(0, 7))
jitter(rep(10000,5))
```
Value

The condition number, \( \kappa \), or an approximation if \( \text{exact} = \text{FALSE} \).

Author(s)

The design was inspired by (but differs considerably from) the S function of the same name described in Chambers (1992).

References

See Also

\texttt{svd} for the singular value decomposition and \texttt{qr} for the QR one.

Examples

\begin{verbatim}
  kappa(x1 <- cbind(1,1:10))# 15.71
  kappa(x1, exact = TRUE) # 13.68
  kappa(x2 <- cbind(x1,2:11))# high! [x2 is singular!]

  hilbert <- function(n) { i <- 1:n; 1 / outer(i - 1, i, "+") }
  sv9 <- svd(h9 <- hilbert(9))$d
  kappa(h9)# pretty high!
  kappa(h9, exact = TRUE) == max(sv9) / min(sv9)
  kappa(h9, exact = TRUE) / kappa(h9) # .677 (i.e., rel.error = 32%)
\end{verbatim}

---

\textbf{kronecker} \hspace{1cm} \textit{Kronecker products on arrays}

Description

Computes the generalised kronecker product of two arrays, \( X \) and \( Y \). \texttt{kronecker(X, Y)} returns an array \( A \) with dimensions \( \text{dim}(X) \times \text{dim}(Y) \).

Usage

\begin{verbatim}
  kronecker(X, Y, FUN = "\*", make.dimnames = FALSE, ...)
  X %x% Y
\end{verbatim}

Arguments

\begin{itemize}
  \item \textbf{X} \hspace{1cm} A vector or array.
  \item \textbf{Y} \hspace{1cm} A vector or array.
  \item \textbf{FUN} \hspace{1cm} a function; it may be a quoted string.
  \item \textbf{make.dimnames} \hspace{1cm} provide dimnames that are the product of the dimnames of \( X \) and \( Y \).
  \item \ldots \hspace{1cm} optional arguments to be passed to \texttt{FUN}.
\end{itemize}
Details

If \( X \) and \( Y \) do not have the same number of dimensions, the smaller array is padded with dimensions of size one. The returned array comprises submatrices constructed by taking \( X \) one term at a time and expanding that term as \( \text{FUN}(x, Y, \ldots) \).

\%x\% is an alias for \( \text{kronecker} \) (where \( \text{FUN} \) is hardwired to "\*").

Author(s)

Jonathan Rougier, (J.C.Rougier@durham.ac.uk)

References

\( \text{outer} \), on which \( \text{kronecker} \) is built and \%*\% for usual matrix multiplication.

Examples

```r
# simple scalar multiplication
( M <- matrix(1:6, ncol=2) )
kronecker(4, M)
# Block diagonal matrix:
kronrcker(diag(1, 3), M)

# ask for dimnames

fred <- matrix(1:12, 3, 4, dimnames=list(LETTERS[1:3], LETTERS[4:7]))
bill <- c("happy" = 100, "sad" = 1000)
kronrcker(fred, bill, make.dimnames = TRUE)
bill <- outer(bill, c("cat"=3, "dog"=4))
kronrcker(fred, bill, make.dimnames = TRUE)
```

l10n_info  Localization Information

Description

Report on localization information.

Usage

l10n_info()

Value

A list with three logical components:

- **MBCS**  If a multi-byte character set in use?
- **UTF-8**  Is this a UTF-8 locale?
- **Latin-1**  Is this a Latin-1 locale?
labels

See Also

Sys.getlocale, localeconv

Examples

l10n_info()

---

labels  

Find Labels from Object

Description

Find a suitable set of labels from an object for use in printing or plotting, for example. A generic function.

Usage

labels(object, ...)

Arguments

object  

Any R object: the function is generic.

...

further arguments passed to or from other methods.

Value

A character vector or list of such vectors. For a vector the results is the names or seq(along=x) and for a data frame or array it is the dimnames (with NULL expanded to seq(len=d[i]).

References

---

lapply  

Apply a Function over a List or Vector

Description

lapply returns a list of the same length as X, each element of which is the result of applying FUN to the corresponding element of X.

sapply is a “user-friendly” version of lapply by default returning a vector or matrix if appropriate.

replicate is a wrapper for the common use of sapply for repeated evaluation of an expression (which will usually involve random number generation).
Usage

lapply(X, FUN, ...)  
sapply(X, FUN, ..., simplify = TRUE, USE.NAMES = TRUE)  
replicate(n, expr, simplify = TRUE)

Arguments

X  
a vector (atomic or list) or an expressions vector. Other objects (including classed objects) will be coerced by as.list.
FUN  
the function to be applied to each element of X: see Details. In the case of functions like +, %*%, etc., the function name must be backquoted or quoted.
...  
optional arguments to FUN.
simplify  
logical; should the result be simplified to a vector or matrix if possible?
USE.NAMES  
logical; if TRUE and if X is character, use X as names for the result unless it had names already.
n  
number of replications.
expr  
expression (language object, usually a call) to evaluate repeatedly.

Details

FUN is found by a call to match.fun and typically is specified as a function or a symbol (e.g. a backquoted name) or a character string specifying a function to be searched for from the environment of the call to lapply.

Function FUN must be able to accept as input any of the elements of X. If the latter is an atomic vector, FUN will always be passed a length-one vector of the same type as X.

Simplification in sapply is only attempted if X has length greater than zero and if the return values from all elements of X are all of the same (positive) length. If the common length is one the result is a vector, and if greater than one is a matrix with a column corresponding to each element of X.

The mode of the simplified answer is chosen to accommodate the modes of all the values returned by the calls to FUN: see unlist.

if X has length 0, the return value of sapply is always a 0-length list.

Note

sapply(*, simplify = FALSE, USE.NAMES = FALSE) is equivalent to lapply(*).

References

See Also

apply, tapply, mapply for applying a function to multiple arguments, and rapply for a recursive version of lapply(), eapply for applying a function to each entry in an environment.
Examples

```r
x <- list(a = 1:10, beta = exp(-3:3), logic = c(TRUE, FALSE, FALSE, TRUE))
# compute the list mean for each list element
lapply(x, mean)
# median and quartiles for each list element
lapply(x, quantile, probs = 1:3/4)
sapply(x, quantile)
i39 <- sapply(3:9, seq) # list of vectors
sapply(i39, fivenum)

hist(replicate(100, mean(rexp(10))))
```

Description

The value of the internal evaluation of a top-level R expression is always assigned to `.Last.value` (in package:base) before further processing (e.g., printing).

Usage

`.Last.value`

Details

The value of a top-level assignment is put in `.Last.value`, unlike S.

Do not assign to `.Last.value` in the workspace, because this will always mask the object of the same name in package:base.

See Also

eval

Examples

```r
## These will not work correctly from example(),
## but they will in make check or if pasted in,
## as example() does not run them at the top level
gamma(1:15) # think of some intensive calculation...
fac14 <- .Last.value # keep them

library("splines") # returns invisibly
.Last.value    # shows what library(.) above returned
```
\textbf{length} \hspace{0.5cm} \textit{Length of an Object}

\textbf{Description}

Get or set the length of vectors (including lists) and factors, and of any other \texttt{R} object for which a method has been defined.

\textbf{Usage}

\begin{verbatim}
length(x) length(x) <- value
\end{verbatim}

\textbf{Arguments}

\begin{itemize}
  \item \texttt{x} \hspace{0.5cm} an \texttt{R} object. For replacement, a vector or factor.
  \item \texttt{value} \hspace{0.5cm} an integer.
\end{itemize}

\textbf{Details}

Both functions are generic: you can write methods to handle specific classes of objects, see \texttt{InternalMethods}. \texttt{length<-} has a \texttt{"factor"} method.

The replacement form can be used to reset the length of a vector. If a vector is shortened, extra values are discarded and when a vector is lengthened, it is padded out to its new length with \texttt{NAs} (\texttt{null} for raw vectors).

\textbf{Value}

The default method currently returns an \texttt{integer} of length 1. Since this may change in the future and may differ for other methods, programmers should not rely on it. (Should the length exceed the maximum representable integer, it is returned as \texttt{NA}.)

For vectors (including lists) and factors the length is the number of elements. For an environment it is the number of objects in the environment, and \texttt{NULL} has length 0. For expressions and pairlists (including language objects and dotlists) it is the length of the pairlist chain. All other objects (including functions) have length one: note that for functions this differs from S.

The replacement form removes all the attributes of \texttt{x} except its names.

\textbf{References}

\textbf{See Also}

\texttt{nchar} for counting the number of characters in character vectors.
Examples

```
length(diag(4)) # = 16 (4 x 4)
length(options()) # 12 or more
length(y ~ x1 + x2 + x3) # 3
length(expression(x, {y <- x^2; y+2}, x^y)) # 3
```

```r
## from example(warpbreaks)
fm1 <- lm(breaks ~ wool * tension, data = warpbreaks)
length(fm1$call) # 3, lm() and two arguments.
length(formula(fm1)) # 3, ~ lhs rhs
```

levels

## Levels Attributes

### Description

levels provides access to the levels attribute of a variable. The first form returns the value of the levels of its argument and the second sets the attribute.

The replacement form ("levels<-") of levels is a generic function and new methods can be written for it. The most important method is that for factors:

### Usage

```r
levels(x)
levels(x) <- value
```

### Arguments

- **x**
  - an object, for example a factor.
- **value**
  - A valid value for levels(x). For the default method, NULL or a character vector. For the factor method, a vector of character strings with length at least the number of levels of x, or a named list specifying how to rename the levels.

### Details

For the factor replacement method, a NA in value causes that level to be removed from the levels and the elements formerly with that level to be replaced by NA.

### References

### See Also

nlevels, relevel, reorder.
Examples

```r
## assign individual levels
x <- gl(2, 4, 8)
levels(x)[1] <- "low"
levels(x)[2] <- "high"
x

## or as a group
y <- gl(2, 4, 8)
levels(y) <- c("low", "high")
y

## combine some levels
z <- gl(3, 2, 12)
levels(z) <- c("A", "B", "A")
z

## same, using a named list
z <- gl(3, 2, 12)
levels(z) <- list(A=c(1,3), B=2)
z

## we can add levels this way:
f <- factor(c("a","b"))
levels(f) <- c("c", "a", "b")
f

f <- factor(c("a","b"))
levels(f) <- list(C="C", A="a", B="b")
f
```

libPaths

Search Paths for Packages

Description

.libPaths gets/sets the library trees within which packages are looked for.

Usage

.libPaths(new)

.Library

.Library.site

Arguments

new a character vector with the locations of R library trees. Tilde expansion (path.expand) is done, and if any element contains one of *?[, globbing is done where supported by the platform: see Sys.glob.
Details

.Library is a character string giving the location of the default library, the ‘library’ subdirectory of R_HOME.

.Library.site is a (possibly empty) character vector giving the locations of the site libraries, by default the ‘site-library’ subdirectory of R_HOME (which may not exist).

.libPaths is used for getting or setting the library trees that R knows about (and hence uses when looking for packages). If called with argument new, the library search path is set to the existing directories in unique(c(new, .Library.site, .Library)) and this is returned. If given no argument, a character vector with the currently active library trees is returned.

The library search path is initialized at startup from the environment variable R_LIBS (which should be a colon-separated list of directories at which R library trees are rooted) followed by those in environment variable R_LIBS_USER. Only directories which exist at the time will be included.

By default R_LIBS is unset, and R_LIBS_USER is set to directory ‘R/R.version$platform-library/x.y’ of the home directory, for R x.y.z.

.Library.site can be set via the environment variable R_LIBS_SITE (as a colon-separated list of library trees).

Function .libPaths always uses the values of .Library and .Library.site in the base name space. .Library.site can be set by the site in ‘Rprofile.site’, which should be followed by a call to .libPaths(.libPaths()) to make use of the updated value.

Value

A character vector of file paths.

.libPaths() # all library trees R knows about

---

library Loading and Listing of Packages

Description

library and require load add-on packages.

.First.lib is called when a package is loaded; .Last.lib is called when a package is detached.
library

Usage

library(package, help, pos = 2, lib.loc = NULL,
character.only = FALSE, logical.return = FALSE,
warn.conflicts = TRUE,
keep.source = getOption("keep.source.pkgs"),
verbose =getOption("verbose"),
version)

require(package, lib.loc = NULL, quietly = FALSE, warn.conflicts = TRUE,
keep.source =getOption("keep.source.pkgs"),
character.only = FALSE, version, save = TRUE)

.First.lib(libname, pkgname)
.Last.lib(libpath)

Arguments

package, help
the name of a package, given as a name or literal character string, or a character string, depending on whether character.only is FALSE (default) or TRUE.

pos
the position on the search list at which to attach the loaded package. Note that .First.lib may attach other packages, and pos is computed after .First.lib has been run. Can also be the name of a position on the current search list as given by search().

lib.loc
a character vector describing the location of R library trees to search through, or NULL. The default value of NULL corresponds to all libraries currently known. Non-existent library trees are silently ignored.

character.only
a logical indicating whether package or help can be assumed to be character strings.

version
A character string denoting a version number of the package to be loaded, for use with versioned installs: see the section later in this document.

logical.return
logical. If it is TRUE, FALSE or TRUE is returned to indicate success.

warn.conflicts
logical. If TRUE, warnings are printed about conflicts from attaching the new package, unless that package contains an object .conflicts.OK. A conflict is a function masking a function, or a non-function masking a non-function.

keep.source
logical. If TRUE, functions “keep their source” including comments, see argument keep.source to options. This applies only to the named package, and not to any packages or name spaces which might be loaded to satisfy dependencies or imports.

This argument does not apply to packages using lazy-loading or saved images. Whether they have kept source is determined when they are installed (and is most likely false).

verbose
a logical. If TRUE, additional diagnostics are printed.

quietly
a logical. If TRUE, no message confirming package loading is printed.

save
logical or environment. If TRUE, a call to require from the source for a package will save the name of the required package in the variable ".required",...
allowing function detach to warn if a required package is detached. See section ‘Packages that require other packages’ below.

libname a character string giving the library directory where the package was found.

pkgname a character string giving the name of the package, including the version number if the package was installed with --with-package-versions.

libpath a character string giving the complete path to the package.

### Details

library(package) and require(package) both load the package with name package. require is designed for use inside other functions; it returns FALSE and gives a warning (rather than an error as library() does by default) if the package does not exist. Both functions check and update the list of currently loaded packages and do not reload a package which is already loaded. (Furthermore, if the package has a name space and a name space of that name is already loaded, they work from the existing names space rather than reloading from the file system.)

If library is called with no package or help argument, it lists all available packages in the libraries specified by lib.loc, and returns the corresponding information in an object of class "libraryIQR". The structure of this class may change in future versions. In earlier versions of R, only the names of all available packages were returned; use .packages(all = TRUE) for obtaining these. Note that installed.packages() returns even more information.

library(help = somename) computes basic information about the package somename, and returns this in an object of class "packageInfo". The structure of this class may change in future versions. When used with the default value (NULL) for lib.loc, the loaded packages are searched before the libraries.

.First.lib is called when a package without a name space is loaded by library. (For packages with name spaces see .onLoad.) It is called with two arguments, the name of the library directory where the package was found (i.e., the corresponding element of lib.loc), and the name of the package (in that order, and with the package name including the version for a versioned install, e.g. tree_1.0-16). It is a good place to put calls to library.dynam which are needed when loading a package into this function (don’t call library.dynam directly, as this will not work if the package is not installed in a “standard” location). .First.lib is invoked after the search path interrogated by search() has been updated, so as.environment(match("package:name", search())) will return the environment in which the package is stored. If calling .First.lib gives an error the loading of the package is abandoned, and the package will be unavailable. Similarly, if the option ".First.lib" has a list element with the package’s name, this element is called in the same manner as .First.lib when the package is loaded. This mechanism allows the user to set package “load hooks” in addition to startup code as provided by the package maintainers, but setHook is preferred.

.Last.lib is called when a package is detached. Beware that it might be called if .First.lib has failed, so it should be written defensively. (It is called within try, so errors will not stop the package being detached.)

### Value

library returns the list of loaded (or available) packages (or TRUE if logical.return is TRUE). require returns a logical indicating whether the required package is available.

### Packages that require other packages

**NB:** This mechanism has been almost entirely superseded by using the Depends: field in the ‘DESCRIPTION’ file of a package.
The source code for a package that requires one or more other packages should have a call to `require`, preferably near the beginning of the source, and of course before any code that uses functions, classes or methods from the other package. The default for argument `save` will save the names of all required packages in the environment of the new package. The saved package names are used by `detach` when a package is detached to warn if other packages still require the to-be-detached package. Also, if a package is installed with saved image (see `INSTALL`), the saved package names are used to require these packages when the new package is attached.

**Formal methods**

`library` takes some further actions when package `methods` is attached (as it is by default). Packages may define formal generic functions as well as re-defining functions in other packages (notably `base`) to be generic, and this information is cached whenever such a package is loaded after `methods` and re-defined functions are excluded from the list of conflicts. The check requires looking for a pattern of objects; the pattern search may be avoided by defining an object `.noGenerics` (with any value) in the package. Naturally, if the package *does* have any such methods, this will prevent them from being used.

**Versioned installs**

Packages can be installed with version information by `R CMD INSTALL --with-package-versions` or `install.packages(installWithVers = TRUE)`. This allows more than one version of a package to be installed in a library directory, using package directory names like `foo_1.5-1`. When such packages are loaded, it is this *versioned* name that `search()` returns. Some utility functions require the versioned name and some the unversioned name (here `foo`).

If `version` is not specified, `library` looks first for a packages of that name, and then for versioned installs of the package, selecting the one with the latest version number. If `version` is specified, a versioned install with an exactly matching version is looked for.

If `version` is not specified, `require` will accept any version that is already loaded, whereas `library` will look for an unversioned install even if a versioned install is already loaded.

Loading more than one version of a package into an R session is not currently supported. Support for versioned installs is patchy.

**Note**

`library` and `require` can only load an *installed* package, and this is detected by having a ‘DESCRIPTION’ file containing a `Built:` field.

Under Unix-alikes, the code checks that the package was installed under a similar operating system as given by `R.version$platform` (the canonical name of the platform under which R was compiled), provided it contains compiled code. Packages which do not contain compiled code can be shared between Unix-alikes, but not to other OSes because of potential problems with line endings and OS-specific help files.

The package name given to `library` and `require` must match the name given in the package’s ‘DESCRIPTION’ file exactly, even on case-insensitive file systems such as MS Windows.

Examples

library() # list all available packages
library(lib = .Library) # list all packages in the default library
library(help = splines) # documentation on package 'splines'
library(splines) # load package 'splines'
require(splines) # the same
search() # "splines", too
detach("package:splines")

# if the package name is in a character vector, use
pkg <- "splines"
library(pkg, character.only = TRUE)
detach(pos = match(paste("package", pkg, sep=":"), search()))

require(pkg, character.only = TRUE)
detach(pos = match(paste("package", pkg, sep=":"), search()))

require(nonexistent) # FALSE
## Not run:
## Suppose a package needs to call a shared library named 'fooEXT',
## where 'EXT' is the system-specific extension. Then you should use
.First.lib <- function(lib, pkg) {
  library.dynam("foo", pkg, lib)
}

## if you want to mask as little as possible, use
library(mypkg, pos = "package:base")
## End(Not run)

library.dynam Loading Shared Libraries

Description

Load the specified file of compiled code if it has not been loaded already, or unloads it.

Usage

library.dynam(chname, package = NULL, lib.loc = NULL,
  verbose = getOption("verbose"),
  file.ext = .Platform$dynlib.ext, ...)

library.dynam.unload(chname, libpath,
  verbose = getOption("verbose"),
  file.ext = .Platform$dynlib.ext)

.dynLibs(new)
library.dynam

Arguments

- **chname**: a character string naming a shared library to load.
- **package**: a character vector with the names of packages to search through, or NULL. By default, all packages in the search path are used.
- **lib.loc**: a character vector describing the location of R library trees to search through, or NULL. The default value of NULL corresponds to all libraries currently known.
- **libpath**: the path to the loaded package whose shared library is to be unloaded.
- **verbose**: a logical value indicating whether an announcement is printed on the console before loading the shared library. The default value is taken from the verbose entry in the system options.
- **file.ext**: the extension to append to the file name to specify the library to be loaded. This defaults to the appropriate value for the operating system.
- **...**: additional arguments needed by some libraries that are passed to the call to dyn.load to control how the library is loaded.
- **new**: a list of "DLLInfo" objects corresponding to the shared libraries loaded by packages. Can be missing.

Details

library.dynam is designed to be used inside a package rather than at the command line, and should really only be used inside .First.lib or .onLoad. The system-specific extension for shared libraries (e.g., `.so` or `.sl` on Unix systems) should not be added. Note that to allow for versioned installs, the chname argument should not be set to the pkgname argument of .First.lib or .onLoad.

library.dynam.unload is designed for use in .Last.lib or .onUnload: it unloads the shared object and updates the value of .dynLibs().

.dynLibs is used for getting (with no argument) or setting the shared libraries which are currently loaded by packages (using library.dynam).

Value

If chname is not specified, library.dynam returns an object of class "DLLInfoList" corresponding to the shared libraries loaded by packages.

If chname is specified, an object of class "DLLInfo" that identifies the DLL and can be used in future calls is returned invisibly. For packages that have name spaces, a list of these objects is stored in the name space’s environment for use at run-time.

Note that the class DLLInfo has an overloaded method for $ which can be used to resolve native symbols within that DLL.

library.dynam.unload invisibly returns an object of class "DLLInfo" identifying the DLL successfully unloaded.

.dynLibs returns an object of class "DLLInfoList" corresponding corresponding to its current value.

Warning

Do not use dyn.unload on a shared object loaded by library.dynam: use library.dynam.unload to ensure that .dynLibs gets updated. Otherwise a subsequent call to library.dynam will be told the object is already loaded.

list

Lists – Generic and Dotted Pairs

Description

Functions to construct, coerce and check for both kinds of R lists.
Usage

list(...)  
pairlist(...)  

as.list(x, ...)  
## S3 method for class 'environment':  
as.list(x, all.names = FALSE, ...)  
as.pairlist(x)

is.list(x)  
is.pairlist(x)

alist(...)

Arguments

... objects, possibly named.

x object to be coerced or tested.

call.names a logical indicating whether to copy all values or (default) only those whose names do not begin with a dot.

Details

Most lists in R internally are Generic Vectors, whereas traditional dotted pair lists (as in LISP) are available but rarely seen by users (except as forms of functions).

The arguments to list or pairlist are of the form value or tag=value. The functions return a list or dotted pair list composed of its arguments with each value either tagged or untagged, depending on how the argument was specified.

alist handles its arguments as if they described function arguments. So the values are not evaluated, and tagged arguments with no value are allowed whereas list simply ignores them. alist is most often used in conjunction with forms.

as.list attempts to coerce its argument to a list. For functions, this returns the concatenation of the list of formal arguments and the function body. For expressions, the list of constituent elements is returned. as.list is generic, and as the default method calls as.vector (mode="list") methods for as.vector may be invoked. As from R 2.4.0, as.list turns a factor into a list of one-element factors. All attributes will be dropped unless the argument already is a list. (This is inconsistent with functions such as as.character, and is for efficiency since lists can be expensive to copy.)

is.list returns TRUE if and only if its argument is a list or a pairlist of length > 0. is.pairlist returns TRUE if and only if the argument is a pairlist or NULL (see below).

The "environment" method for as.list copies the name-value pairs (for names not beginning with a dot) from an environment to a named list. The user can request that all named objects are copied. The list is in no particular order (the order depends on the order of creation of objects and whether the environment is hashed). No parent environments are searched. (Objects copied are duplicated so this can be an expensive operation.)

An empty pairlist, pairlist() is the same as NULL. This is different from list().

list.files

See Also

vector("list", length) for creation of a list with empty components; c, for concatenation;
formals.unlist is an approximate inverse to as.list().

Examples

# create a plotting structure
pts <- list(x=cars[,1], y=cars[,2])
plot(pts)

is.pairlist(.Options)  # a user-level pairlist

## "pre-allocate" an empty list of length 5
vector("list", 5)

# Argument lists
f <- function() x
# Note the specification of a "..." argument:
formals(f) <- al <- alist(x=, y=2+3, ...=)
f
al

## environment->list coercion
e1 <- new.env()
e1$a <- 10
e1$b <- 20
as.list(e1)

list.files

List the Files in a Directory/Folder

Description

These functions produce a character vector of the names of files in the named directory.

Usage

list.files(path = ".", pattern = NULL, all.files = FALSE,
full.names = FALSE, recursive = FALSE)
dir(path = ".", pattern = NULL, all.files = FALSE,
full.names = FALSE, recursive = FALSE)

Arguments

path a character vector of full path names; the default corresponds to the working
directory getwd().

pattern an optional regular expression. Only file names which match the regular expres-
sion will be returned.

all.files a logical value. If FALSE, only the names of visible files are returned. If TRUE,
all file names will be returned.
load

Description

Reload datasets written with the function save.

Usage

load(file, envir = parent.frame())

Arguments

file a (readable binary) connection or a character string giving the name of the file to load.

envir the environment where the data should be loaded.

full.names a logical value. If TRUE, the directory path is prepended to the file names. If FALSE, only the file names are returned.

recursive logical. Should the listing recurse into directories?

Value

A character vector containing the names of the files in the specified directories, or "" if there were no files. If a path does not exist or is not a directory or is unreadable it is skipped, with a warning.

The files are sorted in alphabetical order, on the full path if full.names = TRUE.

Note

File naming conventions are very platform dependent.

recursive = TRUE is not supported on all platforms, and may be ignored, with a warning.

Author(s)

Ross Ihaka, Brian Ripley

See Also

file.info, file.access and files for many more file handling functions and file.choose for interactive selection.

glob2rx to convert wildcards (as used by system file commands and shells) to regular expressions.

Sys.glob for wildcard expansion on file paths.

Examples

list.files(R.home())
## Only files starting with a-l or r
dir("../..", pattern = "^[a-lr]",full.names=TRUE)
Details

load can load \textit{R} objects saved in the current or any earlier format. It can read a compressed file (see \texttt{save}) directly from a file or from a suitable connection (including a call to \texttt{url}). Only \textit{R} objects saved in the current format (used since \texttt{R} 1.4.0) can be read from a connection. If no input is available on a connection a warning will be given, but any input not in the current format will result in an error.

Loading from an earlier version will give a warning about the ‘magic number’: magic numbers 1971:1977 are from \texttt{R} < 0.99.0, and \texttt{R[ADX]1} from \texttt{R} 0.99.0 to \texttt{R} 1.3.1.

Value

A character vector of the names of objects created, invisibly.

Warning

Saved \textit{R} objects are binary files, even those saved with \texttt{ascii = TRUE}, so ensure that they are transferred without conversion of end of line markers. \texttt{load} tries to detect this case and give an informative error message.

Note

Prior to \texttt{R} 2.4.0 an object saved as a \texttt{pairlist} was coerced to a \texttt{list}, silently (and undocumented).

See Also

\texttt{save}, \texttt{download.file}.

Examples

```r
## save all data
xx <- pi  # to ensure there is some data
save(list = ls(all=TRUE), file = "all.Rdata")
rm(xx)

## restore the saved values to the current environment
local({
  load("all.Rdata")
  ls()
})

## restore the saved values to the user's workspace
load("all.Rdata", .GlobalEnv)
unlink("all.Rdata")

## Not run:
con <- url("http://some.where.net/R/data/example.rda")
## print the value to see what objects were created.
print(load(con))
close(con)  # url() always opens the connection
## End(Not run)
```
localeconv

Find Details of the Numerical and Monetary Representations in the Current Locale

Description

Get details of the numerical and monetary representations in the current locale.

Usage

Sys.localeconv()

Details

These settings are usually controlled by the environment variables LC_NUMERIC and LC_MONETARY and if not set the values of LC_ALL or LANG.

Normally R is run without looking at the value of LC_NUMERIC, so the decimal point remains `.('. So the first three of these values will not be useful unless you have set LC_NUMERIC in the current R session.

Value

A character vector with 18 named components. See your ISO C documentation for details of the meaning.

It is possible to compile R without support for locales, in which case the value will be NULL.

See Also

Sys.setlocale for ways to set locales.

Examples

Sys.localeconv()

## The results in the C locale are
## decimal_point thousands_sep grouping int_curr_symbol
## "." " " " "
## currency_symbol mon_decimal_point mon_thousands_sep mon_grouping
## "" " " " "
## positive_sign negative_sign int_frac_digits frac_digits
## "" " " " "
## p_cs_precedes p_sep_by_space n_cs_precedes n_sep_by_space
## "127" "127" "127" "127"
## p_sign_posn n_sign_posn
## "127" "127"

## Now try your default locale (which might be "C")
## Not run:
old <- Sys.getlocale()
Sys.setlocale(locale = "")
Sys.localeconv()
Sys.setlocale(locale = old)
## End(Not run)

## Not run: read.table("foo", dec=Sys.localeconv()["decimal_point"],...)
Description

Get details of or set aspects of the locale for the R process.

Usage

```r
Sys.getlocale(category = "LC_ALL")
Sys.setlocale(category = "LC_ALL", locale = "")
```

Arguments

- **category**: character string. The following categories should always be supported: "LC_ALL", "LC_COLLATE", "LC_CTYPE", "LC_MONETARY", "LC_NUMERIC" and "LC_TIME". Some systems will also support "LC_MESSAGES", "LC_PAPER" and "LC_MEASUREMENT".

- **locale**: character string. A valid locale name on the system in use. Normally "" (the default) will pick up the default locale for the system.

Details

The locale describes aspects of the internationalization of a program. Initially most aspects of the locale of R are set to "C" (which is the default for the C language and reflects North-American usage). R sets "LC_CTYPE" and "LC_COLLATE", which allow the use of a different character set and alphabetic comparisons in that character set (including the use of `sort`), "LC_MONETARY" (for use by `Sys.localeconv`) and "LC_TIME" may affect the behaviour of `as.POSIXlt` and `strptime` and functions which use them (but not `date`).

R can be built with no support for locales, but it is normally available on Unix and is available on Windows.

The first seven categories described here are those specified by POSIX. "LC_MESSAGES" will be "C" on systems that do not support message translation, and is not supported on Windows. Trying to use an unsupported category is an error for `Sys.setlocale`.

Note that setting "LC_ALL" sets only "LC_COLLATE", "LC_CTYPE", "LC_MONETARY" and "LC_TIME".

Attempts to set an invalid locale are (silently) ignored. (Most OSes give no indication if the request succeeded, and the name of the locale set need bear little resemblance to that asked for.)

Value

A character string of length one describing the locale in use (after setting for `Sys.setlocale`), or an empty character string if the current locale settings are invalid or NULL if locale information is unavailable.

For `category = "LC_ALL"` the details of the string are system-specific: it might be a single locale or a set of locales separated by "/" (Solaris) or ";" (Windows, Linux). For portability, it is best to query categories individually. It is guaranteed that the result of `foo <- Sys.getlocale()` can be used in `Sys.setlocale("LC_ALL", locale = foo)` on the same machine.
Warning

Setting "LC_NUMERIC" may cause R to function anomalously, so gives a warning. (The known problems are with input conversion in locales with , as the decimal point.) Setting it temporarily to produce graphical or text output may work well enough, but options(OutDec) is often preferable.

See Also

strptime for uses of category = "LC_TIME". Sys.localeconv for details of numerical and monetary representations.

Examples

Sys.getlocale()  
Sys.getlocale("LC_TIME")  
## Not run:  
Sys.setlocale("LC_TIME", "de") # Solaris 7: details are OS-dependent  
Sys.setlocale("LC_TIME", "de_DE.utf8") # Modern Linux etc.  
Sys.setlocale("LC_TIME", "German") # Windows  
## End(Not run)  
Sys.getlocale("LC_PAPER") # may or may not be set  
Sys.setlocale("LC_COLLATE", "C") # turn off locale-specific sorting

log

Logarithms and Exponentials

Description

log computes natural logarithms, log10 computes common (i.e., base 10) logarithms, and log2 computes binary (i.e., base 2) logarithms. The general form logb(x, base) computes logarithms with base base.

log1p(x) computes log(1 + x) accurately also for |x| ≪ 1 (and less accurately when x ≈ −1).

exp computes the exponential function.

expm1(x) computes exp(x) − 1 accurately also for |x| ≪ 1.

Usage

log(x, base = exp(1))  
logb(x, base = exp(1))  
log10(x)  
log2(x)  
exp(x)  
expm1(x)  
log1p(x)
Logic

Arguments

x        a numeric or complex vector.
base     positive number. The base with respect to which logarithms are computed. Defaults to \( e^{\exp(1)} \).

Details

\( \exp \) and \( \log \) are generic functions: methods can be defined for them individually or via the \texttt{Math} group generic.

\( \log10 \) and \( \log2 \) are only special cases, but will be computed more efficiently and accurately where supported by the OS.

Value

A vector of the same length as \( x \) containing the transformed values. \( \log(0) \) gives \(-\infty\) (when available).

Note

\( \log \) and \( \logb \) are the same thing in \texttt{R}, but \( \logb \) is preferred if \( \text{base} \) is specified, for S-PLUS compatibility.

References

See Also

\texttt{Trig, sqrt, Arithmetic}.

Examples

\[
\begin{align*}
\log(\exp(3))
\log10(1e7) \# &= 7 \\
x & \leftarrow 10^{-(1+2 \times 1:9)}
\text{cbind}(x, \log(1+x), \log1p(x), \exp(x)-1, \expm1(x))
\end{align*}
\]

Logic

Logical Operators

Description

These operators act on logical vectors.
Usage

! x
x & y
x && y
x | y
x || y
xor(x, y)
isTRUE(x)

Arguments

x, y

logical vectors, or objects which can be coerced to such or for which methods have been written.

Details

! indicates logical negation (NOT).
& and && indicate logical AND and | and || indicate logical OR. The shorter form performs elementwise comparisons in much the same way as arithmetic operators. The longer form evaluates left to right examining only the first element of each vector. Evaluation proceeds only until the result is determined. The longer form is appropriate for programming control-flow and typically preferred in if clauses.
xor indicates elementwise exclusive OR.
isTRUE(x) is an abbreviation of identical(TRUE, x), and so is true if and only if x is a length-one logical vector with no attributes (not even names).

Numeric and complex vectors will be coerced to logical values, with zero being false and all non-zero values being true. Raw vectors are handled without any coercion for !, & and |, with these operators being applied bitwise (so ! is the 1-complement).

The operators !, & and | are generic functions: methods can be written for them individually or via the Ops group generic function. (See Ops for how dispatch is computed.)

NA is a valid logical object. Where a component of x or y is NA, the result will be NA if the outcome is ambiguous. In other words NA & TRUE evaluates to NA, but NA & FALSE evaluates to FALSE. See the examples below.

See Syntax for the precedence of these operators: unlike many other languages (including S) the AND and OR operators do not have the same precedence (the AND operators are higher than the OR operators).

Value

For !, a logical or raw vector of the same length as x.

For |, & and xor a logical or raw vector. The elements of shorter vectors are recycled as necessary (with a warning when they are recycled only fractionally). The rules for determining the attributes of the result are rather complicated. Most attributes are taken from the longer argument, the first if they are of the same length. Names will be copied from the first if it is the same length as the answer, otherwise from the second if that is. For time series, these operations are allowed only if the series are compatible, when the class and tsp attribute of whichever is a time series (the same, if both are) are used. For arrays (and an array result) the dimensions and dimnames are taken from first argument if it is an array, otherwise the second.

For ||, && and isTRUE, a length-one logical vector.
logical

References

See Also

TRUE or logical.

any and all for OR and AND on many scalar arguments.

Syntax for operator precedence.

Examples

```r
y <- 1 + (x <- rpois(50, lambda=1.5) / 4 - 1)
x[(x > 0) & (x < 1)]  # all x values between 0 and 1
if (any(x == 0) || any(y == 0)) "zero encountered"

## construct truth tables :
x <- c(NA, FALSE, TRUE)
names(x) <- as.character(x)
outer(x, x, "&")  ## AND table
outer(x, x, "|")  ## OR table
```

---

logical Logical Vectors

Description

Create or test for objects of type "logical", and the basic logical “constants”.

Usage

```r
TRUE
FALSE
T; F
```

```r
logical(length = 0)
as.logical(x, ...)
is.logical(x)
```

Arguments

- `length`: desired length.
- `x`: object to be coerced or tested.
- `...`: further arguments passed to or from other methods.

Details

TRUE and FALSE are part of the R language, where T and F are global variables set to these. All four are logical(1) vectors.
Value

logical creates a logical vector of the specified length. Each element of the vector is equal to FALSE.

as.logical attempts to coerce its argument to be of logical type. For factors, this uses the levels (labels). Like as.vector it strips attributes including names.

is.logical returns TRUE or FALSE depending on whether its argument is of logical type or not.

References

lower.tri

Lower and Upper Triangular Part of a Matrix

Description

Returns a matrix of logicals the same size of a given matrix with entries TRUE in the lower or upper triangle.

Usage

lower.tri(x, diag = FALSE)
upper.tri(x, diag = FALSE)

Arguments

x a matrix.

diag logical. Should the diagonal be included?

See Also

diag, matrix.

Examples

(m2 <- matrix(1:20, 4, 5))
lower.tri(m2)
m2[lower.tri(m2)] <- NA
m2
**Description**

*ls* and *objects* return a vector of character strings giving the names of the objects in the specified environment. When invoked with no argument at the top level prompt, *ls* shows what data sets and functions a user has defined. When invoked with no argument inside a function, *ls* returns the names of the functions local variables. This is useful in conjunction with *browser*.

**Usage**

```r
ls(name, pos = -1, envir = as.environment(pos),
   all.names = FALSE, pattern)
objects(name, pos = -1, envir = as.environment(pos),
   all.names = FALSE, pattern)
```

**Arguments**

- **name**: which environment to use in listing the available objects. Defaults to the *current* environment. Although called *name* for back compatibility, in fact this argument can specify the environment in any form; see the details section.
- **pos**: An alternative argument to *name* for specifying the environment as a position in the search list. Mostly there for back compatibility.
- **envir**: an alternative argument to *name* for specifying the environment evaluation environment. Mostly there for back compatibility.
- **all.names**: a logical value. If *TRUE*, all object names are returned. If *FALSE*, names which begin with a ‘.’ are omitted.
- **pattern**: an optional regular expression. Only names matching *pattern* are returned. *glob2rx* can be used to convert wildcard patterns to regular expressions.

**Details**

The *name* argument can specify the environment from which object names are taken in one of several forms: as an integer (the position in the search list); as the character string name of an element in the search list; or as an explicit environment (including using *sys.frame* to access the currently active function calls). By default, the environment of the call to *ls* or *objects* is used. The *pos* and *envir* arguments are an alternative way to specify an environment, but are primarily there for back compatibility.

**References**

**See Also**

*glob2rx* for converting wildcard patterns to regular expressions.

*ls.str* for a long listing based on *str. apropos* (or *find*) for finding objects in the whole search path; *grep* for more details on “regular expressions”; *class, methods*, etc., for object-oriented programming.
Examples

```r
.Ob <- 1
ls(pat="O")
ls(pat="O", all = TRUE)  # also shows ".[foo]"

# shows an empty list because inside myfunc no variables are defined
myfunc <- function() {ls()}
myfunc()

# define a local variable inside myfunc
myfunc <- function() {y <- 1; ls()}
myfunc()  # shows "y"
```

make.names  

Make Syntactically Valid Names

Description

Make syntactically valid names out of character vectors.

Usage

```r
make.names(names, unique = FALSE, allow_ = TRUE)
```

Arguments

- `names`: character vector to be coerced to syntactically valid names. This is coerced to character if necessary.
- `unique`: logical; if TRUE, the resulting elements are unique. This may be desired for, e.g., column names.
- `allow_`: logical. For compatibility with R prior to 1.9.0.

Details

A syntactically valid name consists of letters, numbers and the dot or underline characters and starts with a letter or the dot not followed by a number. Names such as ".2way" are not valid, and neither are the reserved words.

The character "X" is prepended if necessary. All invalid characters are translated to ".". A missing value is translated to "NA". Names which match R keywords have a dot appended to them. Duplicated values are altered by `make.unique`.

Value

A character vector of same length as `names` with each changed to a syntactically valid name.

Note

Prior to R version 1.9.0, underscores were not valid in variable names, and code that relies on them being converted to dots will no longer work. Use `allow_ = FALSE` for back-compatibility. `allow_ = FALSE` is also useful when creating names for export to applications which do not allow underline in names (for example, S-PLUS and some DBMSs).
See Also

`make.unique`, `names`, `character`, `data.frame`.

Examples

```r
make.names(c("a and b", "a-and-b"), unique=TRUE)
# "a.and.b"  "a.and.b.1"

make.names(c("a and b", "a_and_b"), unique=TRUE)
# "a.and.b"  "a_and_b"

make.names(c("a and b", "a_and_b"), unique=TRUE, allow_=FALSE)
# "a.and.b"  "a_and_b.1"

state.name[make.names(state.name) != state.name]  # those 10 with a space
```

---

**make.unique**  
**Make Character Strings Unique**

**Description**

Makes the elements of a character vector unique by appending sequence numbers to duplicates.

**Usage**

```r
make.unique(names, sep = ".")
```

**Arguments**

- `names`  
a character vector

- `sep`  
a character string used to separate a duplicate name from its sequence number.

**Details**

The algorithm used by `make.unique` has the property that `make.unique(c(A, B)) == make.unique(c(make.unique(A), B))`.

In other words, you can append one string at a time to a vector, making it unique each time, and get the same result as applying `make.unique` to all of the strings at once.

If character vector `A` is already unique, then `make.unique(c(A, B))` preserves `A`.

**Value**

A character vector of same length as `names` with duplicates changed.

**Author(s)**

Thomas P Minka

**See Also**

`make.names`
Examples

make.unique(c("a", "a", "a"))
make.unique(c(make.unique(c("a", "a")), "a"))

make.unique(c("a", "a", "a.2", "a"))
make.unique(c(make.unique(c("a", "a")), "a.2", "a"))

rbind(data.frame(x=1), data.frame(x=2), data.frame(x=3))
rbind(rbind(data.frame(x=1), data.frame(x=2)), data.frame(x=3))

manglePackageName  Mangle the Package Name

Description

This function takes the package name and the package version number and pastes them together with a separating underscore.

Usage

manglePackageName(pkgName, pkgVersion)

Arguments

pkgName  The package name, as a character string.
pkgVersion  The package version, as a character string.

Value

A character string with the two inputs pasted together.

Examples

manglePackageName("foo", "1.2.3")

mapply  Apply a function to multiple list or vector arguments

Description

mapply is a multivariate version of sapply. mapply applies FUN to the first elements of each ... argument, the second elements, the third elements, and so on. Arguments are recycled if necessary.

Vectorize returns a new function that acts as if mapply was called.
Usage

\[ \text{mapply}(\text{FUN}, \ldots, \text{MoreArgs} = \text{NULL}, \text{SIMPLIFY} = \text{TRUE}, \text{USE.NAMES} = \text{TRUE}) \]

\[ \text{Vectorize}(\text{FUN}, \text{vectorize.args} = \text{arg.names}, \text{SIMPLIFY} = \text{TRUE}, \text{USE.NAMES} = \text{TRUE}) \]

Arguments

- **FUN**: function to apply, found via `match.fun`.
- **\ldots**: arguments to vectorize over (list or vector).
- **MoreArgs**: a list of other arguments to `FUN`.
- **SIMPLIFY**: logical; attempt to reduce the result to a vector or matrix?
- **USE.NAMES**: logical; use names if the first \ldots argument has names, or if it is a character vector, use that character vector as the names.
- **vectorize.args**: a character vector of arguments which should be vectorized. Defaults to all arguments to `FUN`.

Details

The arguments named in the `vectorize.args` argument to `Vectorize` correspond to the arguments passed in the \ldots list to `mapply`. However, only those that are actually passed will be vectorized; default values will not. See the example below.

Vectorize cannot be used with primitive functions as they have no formal list.

Value

- `mapply` returns a list, vector, or matrix.
- `Vectorize` returns a function with the same arguments as `FUN`, but wrapping a call to `mapply`.

See Also

- `sapply`, `outer`

Examples

```r
mapply(rep, 1:4, 4:1)
mapply(rep, times=1:4, x=4:1)
mapply(rep, times=1:4, MoreArgs=list(x=42))
# Repeat the same using Vectorize: use rep.int as rep is primitive
vrep <- Vectorize(rep.int)
vrep(1:4, 4:1)
vrep(times=1:4, x=4:1)

vrep <- Vectorize(rep.int, "times")
vrep(times=1:4, x=42)
mapply(function(x,y) seq_len(x) + y,
```
margin.table

Compute table margin

Description
For a contingency table in array form, compute the sum of table entries for a given index.

Usage
margin.table(x, margin=NULL)

Arguments
x an array
margin index number (1 for rows, etc.)

Details
This is really just apply(x, margin, sum) packaged up for newbies, except that if margin has length zero you get sum(x).

Value
The relevant marginal table. The class of x is copied to the output table, except in the summation case.
mat.or.vec

Create a Matrix or a Vector

Description

mat.or.vec creates an \( nr \) by \( nc \) zero matrix if \( nc \) is greater than 1, and a zero vector of length \( nr \) if \( nc \) equals 1.

Usage

mat.or.vec(nr, nc)

Arguments

nr, nc numbers of rows and columns.

Examples

mat.or.vec(3, 1)
m.at.or.vec(3, 2)

match

Value Matching

Description

match returns a vector of the positions of (first) matches of its first argument in its second.

\%in\% is a more intuitive interface as a binary operator, which returns a logical vector indicating if there is a match or not for its left operand.

Usage

match(x, table, nomatch = NA, incomparables = FALSE)

x \%in\% table
Arguments

x  vector or NULL: the values to be matched.
table  vector or NULL: the values to be matched against.
nomatch  the value to be returned in the case when no match is found. Note that it is coerced to integer.
incomparables  a vector of values that cannot be matched. Any value in x matching a value in this vector is assigned the nomatch value. Currently, FALSE is the only possible value, meaning that all values can be matched.

details

%in% is currently defined as
"%in%" <- function(x, table) match(x, table, nomatch = 0) > 0
Factors, raw vectors and lists are converted to character vectors, and then x and table are coerced to a common type (the later of the two types in R’s ordering, logical < integer < numeric < complex < character) before matching.
Matching for lists is potentially very slow and best avoided except in simple cases.
Exactly what matches what is to some extent a matter of definition. For all types, NA matches NA and no other value. For real and complex values, NaN values are regarded as matching any other NaN value, but not matching NA.

value

A vector of the same length as x.
malla integer vector giving the position in table of the first match if there is a match, otherwise nomatch.
If x[i] is found to equal table[j] then the value returned in the i-th position of the return value is j, for the smallest possible j. If no match is found, the value is nomatch.
%in%: A logical vector, indicating if a match was located for each element of x.

references

see also

pmatch and charmatch for (partial) string matching, match.arg, etc for function argument matching. findInterval similarly returns a vector of positions, but finds numbers within intervals, rather than exact matches.
is.element for an S-compatible equivalent of %in%.

examples

### The intersection of two sets:
intersect <- function(x, y) y[match(x, y, nomatch = 0)]
intersect(1:10, 7:20)
1:10 %in% c(1, 3, 5, 9)
sstr <- c("c","ab","B","bba","c","@","bla","a","Ba","%")
sstr[sstr %in% c(letters,LETTERS)]

"%w/o%" <- function(x,y) x[!x %in% y] #-- x without y
(1:10) %w/o% c(3,7,12)

**match.arg**

**Argument Verification Using Partial Matching**

Description

match.arg matches arg against a table of candidate values as specified by choices, where NULL means to take the first one.

Usage

match.arg(arg, choices, several.ok = FALSE)

Arguments

arg a character vector (of length one unless several.ok is TRUE) or NULL.
choices a character vector of candidate values
several.ok logical specifying if arg should be allowed to have more than one element.

Details

In the one-argument form match.arg(arg), the choices are obtained from a default setting for the formal argument arg of the function from which match.arg was called.

Matching is done using pmatch, so arg may be abbreviated.

Value

The unabbreviated version of the unique partial match if there is one; otherwise, an error is signalled if several.ok is false, as per default. When several.ok is true and there is more than one match, all unabbreviated versions of matches are returned.

See Also

pmatch,match.fun,match.call.

Examples

require(stats)
## Extends the example for 'switch'
center <- function(x, type = c("mean", "median", "trimmed")) {
  type <- match.arg(type)
  switch(type,
    mean = mean(x),
    median = median(x),
    trimmed = mean(x, trim = .1))
}
x <- rcauchy(10)
match.call

Description

match.call returns a call in which all of the specified arguments are specified by their full names.

Usage

match.call(definition = NULL, call = sys.call(sys.parent()), expand.dots = TRUE)

Arguments

definition a function, by default the function from which match.call is called.
call an unevaluated call to the function specified by definition, as generated by call.
expand.dots logical. Should arguments matching ... in the call be included or left as a ... argument?

Details

match.call is most commonly used in two circumstances:

- To record the call for later re-use: for example most model-fitting functions record the call as element call of the list they return. Here the default expand.dots = TRUE is appropriate.
- To pass most of the call to another function, often model.frame. Here the common idiom is that expand.dots = FALSE is used, and the ... element of the matched call is removed. An alternative is to explicitly select the arguments to be passed on, as is done in lm.

Value

An object of class call.

References

See Also
call, pmatch, match.arg, match.fun.

Examples

match.call(get, call("get", "abc", i = FALSE, p = 3))
## -> get(x = "abc", pos = 3, inherits = FALSE)
fun <- function(x, lower = 0, upper = 1) {
  structure((x - lower) / (upper - lower), CALL = match.call())
}
fun(4 * atan(1), u = pi)

Description

When called inside functions that take a function as argument, extract the desired function object while avoiding undesired matching to objects of other types.

Usage

match.fun(FUN, descend = TRUE)

Arguments

FUN item to match as function: a function, symbol or character string. See Details.
descend logical; control whether to search past non-function objects.

Details

match.fun is not intended to be used at the top level since it will perform matching in the parent of the caller.
If FUN is a function, it is returned. If it is a symbol (for example, enclosed in backquotes) or a character vector of length one, it will be looked up using get in the environment of the parent of the caller. If it is of any other mode, it is attempted first to get the argument to the caller as a symbol (using substitute twice), and if that fails, an error is declared.
If descend = TRUE, match.fun will look past non-function objects with the given name; otherwise if FUN points to a non-function object then an error is generated.
This is used in base functions such as apply, lapply, outer, and sweep.

Value

A function matching FUN or an error is generated.

Bugs

The descend argument is a bit of misnomer and probably not actually needed by anything. It may go away in the future.
It is impossible to fully foolproof this. If one attaches a list or data frame containing a length-one character vector with the same name as a function, it may be used (although name spaces will help).
Author(s)

Peter Dalgaard and Robert Gentleman, based on an earlier version by Jonathan Rougier.

See Also

match.arg, get

Examples

# Same as get("*"):
match.fun("*")

# Overwrite outer with a vector
outer <- 1:5
## Not run:
match.fun(outer, descend = FALSE) #-> Error: not a function
## End(Not run)
match.fun(outer) # finds it anyway
is.function(match.fun("outer")) # as well

Math

Miscellaneous Mathematical Functions

Description

These functions compute miscellaneous mathematical functions. The naming follows the standard
for computer languages such as C or Fortran.

Usage

abs(x)
sqrt(x)

Arguments

x         a numeric or complex vector or array.

Details

These are generic functions: methods can be defined for them individually or via the Math
group generic. For complex arguments (and the default method), z, \( \text{abs}(z) = \text{Mod}(z) \) and
\( \text{sqrt}(z) = z^{0.5} \).

\( \text{abs}(x) \) returns an integer vector when \( x \) is integer or logical.

References

Brooks/Cole.

See Also

Arithmetic for simple, log for logarithmic, sin for trigonometric, and Special for special
mathematical functions.
Examples

```r
require(stats) # for spline
xx <- -9:9
plot(xx, sqrt(abs(xx)), col = "red")
lines(spline(xx, sqrt(abs(xx)), n=101), col = "pink")
```

---

**Matrix Multiplication**

**Description**

Multiplies two matrices, if they are conformable. If one argument is a vector, it will be promoted to either a row or column matrix to make the two arguments conformable. If both are vectors it will return the inner product.

**Usage**

```r
a % * % b
```

**Arguments**

- `a`, `b`: numeric or complex matrices or vectors.

**Details**

When a vector is promoted to a matrix, its names are not promoted to row or column names, unlike `as.matrix`.

**Value**

The matrix product. Use `drop` to get rid of dimensions which have only one level.

**References**

**See Also**

`matrix`, `Arithmetic`, `diag`.

**Examples**

```r
x <- 1:4
(z <- x % * % x) # scalar ("inner") product (1 x 1 matrix)
drop(z) # as scalar

y <- diag(x)
z <- matrix(1:12, ncol = 3, nrow = 4)
y % * % z
y % * % x
x % * % z
```
matrix

Matrices

Description

matrix creates a matrix from the given set of values.

as.matrix attempts to turn its argument into a matrix.

is.matrix tests if its argument is a (strict) matrix.

Usage

matrix(data = NA, nrow = 1, ncol = 1, byrow = FALSE,
       dimnames = NULL)

as.matrix(x, ...)
## S3 method for class 'data.frame':
as.matrix(x, rownames.force = NA, ...)

is.matrix(x)

Arguments

data an optional data vector.
nrow the desired number of rows.
ncol the desired number of columns.
byrow logical. If FALSE (the default) the matrix is filled by columns, otherwise the matrix is filled by rows.
dimnames A dimnames attribute for the matrix: a list of length 2 giving the row and column names respectively.
x an R object.
... additional arguments to be passed to or from methods.
rownames.force logical indicating if the resulting matrix should have character (rather than NULL) rownames. The default, NA, uses NULL rownames if the data frame has ‘automatic’ row.names or for a zero-row data frame.

Details

If either of nrow or ncol is not given, an attempt is made to infer it from the length of data and the other parameter.

If there are too few elements in data to fill the array, then the elements in data are recycled. If data has length zero, NA of an appropriate type is used for atomic vectors (0 for raw vectors) and NULL for lists.

is.matrix returns TRUE if x is a matrix and has a dim attribute of length 2) and FALSE otherwise. Note that a data.frame is not a matrix by this test. It is generic: you can write methods to handle specific classes of objects, see InternalMethods.

as.matrix is a generic function. The method for data frames will return a character matrix if there is any non-(numeric/logical/complex) column, applying format to non-character columns.
maxCol

Otherwise, the usual coercion hierarchy (logical < integer < double < complex) will be used, e.g.,
all-logical data frames will be coerced to a logical matrix, mixed logical-integer will give a integer
matrix, etc.

When coercing a vector, it produces a one-column matrix, and promotes the names (if any) of the
vector to the rownames of the matrix.

data.matrix, which attempts to convert to a numeric matrix.

Examples

is.matrix(as.matrix(1:10))
!is.matrix(warpbreaks)# data.frame, NOT matrix!
warpbreaks[1:10,]
as.matrix(warpbreaks[1:10,])# using as.matrix.data.frame(.) method

# Example of setting row and column names
mdat <- matrix(c(1,2,3, 11,12,13), nrow = 2, ncol=3, byrow=TRUE,
dimnames = list(c("row1", "row2"), c("C.1", "C.2", "C.3")))
mdat

maxCol

Find Maximum Position in Matrix

Description

Find the maximum position for each row of a matrix, breaking ties at random.

Usage

max.col(m, ties.method=c("random", "first", "last"))

Arguments

m    numerical matrix

ties.method a character string specifying how "ties" are handled, "random" by default; can
        be abbreviated; see Details.

Details

When ties.method = "random", as per default, ties are broken at random. In this case, the
determination of "tie" assumes that the entries are probabilities: there is a relative tolerance of 10^-5,
relative to the largest (in magnitude, omitting infinity) entry in the row.

If ties.method = "first", max.col returns the column number of the first of several max-
ima in every row, the same as unname(unname(m, 1, unname)).
Correspondingly, ties.method = "last" returns the last of possibly several indices.
Value

index of a maximal value for each row, an integer vector of length \texttt{nrow(m)}.

References

See Also

\texttt{which.max} for vectors.

Examples

```r
table(mc <- max.col(swiss)) # mostly "1" and "5", 5 x "2" and once "4"
swiss[unique(print(mr <- max.col(t(swiss)))) , ] # 3 33 45 45 33 6

set.seed(1)# reproducible example:
(mm <- rbind(x = round(2*runif(12)),
            y = round(5*runif(12)),
            z = round(8*runif(12))))
## Not run:
x 1 1 1 2 0 2 2 1 1 0 0 0 
y 3 2 4 2 4 5 2 4 5 1 3 1 
z 2 3 0 3 7 3 4 5 4 1 7 5 
## End(Not run)
## column indices of all row maxima :
str(lapply(1:3, function(i) which(mm[i,] == max(mm[i,]))))
max.col(mm) ; max.col(mm) # "random"
max.col(mm, "first") # -> 4 6 5
max.col(mm, "last") # -> 7 9 11
```

---

**mean**

Arithmetic Mean

Description

Generic function for the (trimmed) arithmetic mean.

Usage

```r
mean(x, ...)
```

## Default S3 method:

```r
mean(x, trim = 0, na.rm = FALSE, ...)
```
Arguments

x
An R object. Currently there are methods for numeric data frames, numeric vectors and dates. A complex vector is allowed for trim = 0, only.

trim
the fraction (0 to 0.5) of observations to be trimmed from each end of x before the mean is computed. Values outside that range are taken as the nearest endpoint.

na.rm
a logical value indicating whether NA values should be stripped before the computation proceeds.

... further arguments passed to or from other methods.

Value

For a data frame, a named vector with the appropriate method being applied column by column.

If trim is zero (the default), the arithmetic mean of the values in x is computed, as a numeric or complex vector of length one. If x is not logical (coerced to numeric), integer, numeric or complex, NA is returned, with a warning.

If trim is non-zero, a symmetrically trimmed mean is computed with a fraction of trim observations deleted from each end before the mean is computed.

References

weighted.mean, mean.POSIXct

Examples

x <- c(0:10, 50)
xm <- mean(x)
c(xm, mean(x, trim = 0.10))
mean(USArrests, trim = 0.2)

Memory

Memory Available for Data Storage

Description

Use command line options to control the memory available for R.

Usage

R --min-vsize=vl --max-vsize=vu --min-nsize=nl --max-nsize=nu --max-ppsize=N
mem.limits(nsize = NA, vsize = NA)
Arguments

\textit{vl, vu, vsize}

Heap memory in bytes.

\textit{nl, nu, nsize}

Number of cons cells.

\textit{N}

Number of nested \texttt{PROTECT} calls.

Details

\texttt{R} has a variable-sized workspace. There is much less need to set memory options than prior to \texttt{R 1.2.0}, and most users will never need to set these. They are provided both as a way to control the overall memory usage (which can also be done by operating-system facilities such as \texttt{limit} on Unix), and since setting larger values of the minima will make \texttt{R} slightly more efficient on large tasks.

To understand the options, one needs to know that \texttt{R} maintains separate areas for fixed and variable sized objects. The first of these is allocated as an array of "cons cells" (Lisp programmers will know what they are, others may think of them as the building blocks of the language itself, parse trees, etc.), and the second are thrown on a "heap" of "Vcells" of 8 bytes each. Effectively, the inputs \textit{vl} and \textit{vu} are rounded up to the next multiple of 8.

Each cons cell occupies 28 bytes on a 32-bit machine, (usually) 56 bytes on a 64-bit machine.

The \texttt{--*-nsize} options can be used to specify the number of cons cells and the \texttt{--*-vsize} options specify the size of the vector heap in bytes. Both options must be integers or integers followed by \texttt{G}, \texttt{M}, \texttt{K}, or \texttt{k} meaning \texttt{Giga} \((2^{30} = 1073741824)\), \texttt{Mega} \((2^{20} = 1048576)\), \texttt{Kilo} \((2^{10} = 1024)\), or regular \texttt{kilo} (1000).

The \texttt{--min-\*} options set the minimal sizes for the number of cons cells and for the vector heap. These values are also the initial values, but thereafter \texttt{R} will grow or shrink the areas depending on usage, but never exceeding the limits set by the \texttt{--max-\*} options nor decreasing below the initial values.

The default values are currently minima of 350k cons cells, 6Mb of vector heap and no maxima (other than machine resources). The maxima can be changed during an \texttt{R} session by calling \texttt{mem.limits}. (If this is called with the default values, it reports the current settings.)

You can find out the current memory consumption (the heap and cons cells used as numbers and megabytes) by typing \texttt{gc()} at the \texttt{R} prompt. Note that following \texttt{gcinfo(TRUE)}, automatic garbage collection always prints memory use statistics. Maxima will never be reduced below the current values for triggering garbage collection, and attempts to do so will be silently ignored.

The command-line option \texttt{--max-ppsize} controls the maximum size of the pointer protection stack. This defaults to 50000, but can be increased to allow deep recursion or large and complicated calculations to be done. \texttt{Note} that parts of the garbage collection process goes through the full reserved pointer protection stack and hence becomes slower when the size is increased. Currently the maximum value accepted is 500000.

Value

\texttt{mem.limits()} returns an integer vector giving the current settings of the maxima, possibly \texttt{NA}.

Memory-limits for the design limitations.

ge for information on the garbage collector and total memory usage. object.size(a) for the (approximate) size of R object a. memory.profile for profiling the usage of cons cells.

Examples

# Start R with 10MB of heap memory and 500k cons cells, limit to
# 100Mb and 1M cells
## Not run:
## Unix
R --min-vsize=10M --max-vsize=100M --min-nsize=500k --max-nsize=1M
## End(Not run)

Memory-limits

Memory Limits in R

Description

R holds objects it is using in memory. This help file documents the current design limitations on large objects: these differ between 32-bit and 64-bit builds of R.

Details

R holds all objects in memory, and there are limits based on the amount of memory that can be used by all objects:

- There may be limits on the size of the heap and the number of cons cells allowed – see Memory – but these are usually not imposed.
- There is a limit on the address space of a single process such as the R executable. This is system-specific, but 32-bit OSes imposes a limit of no more than 4Gb: it is often 3Gb or less.
- The environment may impose limitations on the resources available to a single process – see the OS/shell’s help on commands such as limit or ulimit.

Error messages beginning cannot allocate vector of size indicate a failure to obtain memory, either because the size exceeded the address-space limit for a process or, more likely, because the system was unable to provide the memory. Note that on a 32-bit OS there may well be enough free memory available, but not a large enough contiguous block of address space into which to map it.

There are also limits on individual objects. On all versions of R, the maximum length (number of elements) of a vector is \(2^{31} - 1 \approx 2 \times 10^9\), as lengths are stored as signed integers. In addition, the storage space cannot exceed the address limit, and if you try to exceed that limit, the error message begins cannot allocate vector of length. The number of characters in a character string is in theory only limited by the address space.

See Also

object.size(a) for the (approximate) size of R object a.
memory.profile  Profile the Usage of Cons Cells

Description
 Lists the usage of the cons cells by SEXPREC type.

Usage
 memory.profile()

Details
 The current types and their uses are listed in the include file ‘Rinternals.h’.

Value
 A vector of counts, named by the types. See typeof for an explanation of types.

See Also
 gc for the overall usage of cons cells.

Examples
 memory.profile()

merge  Merge Two Data Frames

Description
 Merge two data frames by common columns or row names, or do other versions of database “join” operations.

Usage
 merge(x, y, ...) ## Default S3 method:
 merge(x, y, ...) 

## S3 method for class 'data.frame':
 merge(x, y, by = intersect(names(x), names(y)),
 by.x = by, by.y = by, all = FALSE, all.x = all, all.y = all,
 sort = TRUE, suffixes = c(".x",".y"), ...)
merge

Arguments

- **x, y**
  - data frames, or objects to be coerced to one.
- **by, by.x, by.y**
  - specifications of the common columns. See Details.
- **all**
  - logical; all = L is shorthand for all.x = L and all.y = L.
- **all.x**
  - logical; if TRUE, then extra rows will be added to the output, one for each row in x that has no matching row in y. These rows will have NAs in those columns that are usually filled with values from y. The default is FALSE, so that only rows with data from both x and y are included in the output.
- **all.y**
  - logical; analogous to all.x above.
- **sort**
  - logical. Should the results be sorted on the by columns?
- **suffixes**
  - character(2) specifying the suffixes to be used for making non-by names() unique.
- **...**
  - arguments to be passed to or from methods.

Details

By default the data frames are merged on the columns with names they both have, but separate specifications of the columns can be given by by.x and by.y. Columns can be specified by name, number or by a logical vector: the name "row.names" or the number 0 specifies the row names. The rows in the two data frames that match on the specified columns are extracted, and joined together. If there is more than one match, all possible matches contribute one row each.

If by or both by.x and by.y are of length 0 (a length zero vector or NULL), the result, r, is the “Cartesian product” of x and y, i.e., dim(r) = c(nrow(x) * nrow(y), ncol(x) + ncol(y)).

If all.x is true, all the non matching cases of x are appended to the result as well, with NA filled in the corresponding columns of y; analogously for all.y.

If the remaining columns in the data frames have any common names, these have suffixes (*.x" and ".y" by default) appended to make the names of the result unique.

Prior to R 2.4.0 the complexity was proportional to the product of the numbers of rows of x and y. As from R 2.4.0 it is proportional to the length of the answer, which can be much less if there are few matches (for example, only 1–1 matches).

Value

A data frame. The rows are by default lexicographically sorted on the common columns, but for sort = FALSE are in an unspecified order. The columns are the common columns followed by the remaining columns in x and then those in y. If the matching involved row names, an extra character column called Row.names is added at the left, and in all cases the result has ‘automatic’ row names.

See Also

data.frame, by, cbind
Examples

```r
## use character columns of names to get sensible sort order
authors <- data.frame(
  surname = I(c("Tukey", "Venables", "Tierney", "Ripley", "McNeil")),
  nationality = c("US", "Australia", "US", "UK", "Australia"),
  deceased = c("yes", rep("no", 4)))
books <- data.frame(
  name = I(c("Tukey", "Venables", "Tierney",
    "Ripley", "Ripley", "McNeil", "R Core")),
  title = c("Exploratory Data Analysis",
    "Modern Applied Statistics ...",
    "LISP-STAT",
    "Spatial Statistics", "Stochastic Simulation",
    "Interactive Data Analysis",
    "An Introduction to R"),
  other.author = c(NA, "Ripley", NA, NA, NA, NA,
    "Venables & Smith"))

(m1 <- merge(authors, books, by.x = "surname", by.y = "name"))
(m2 <- merge(books, authors, by.x = "name", by.y = "surname"))
stopifnot(as.character(m1[,1]) == as.character(m2[,1]),
  all.equal(m1[, -1], m2[, -1][ names(m1)[-1 ]]),
  dim(merge(m1, m2, by = integer(0))) == c(36, 10))
```

```
## "R core" is missing from authors and appears only here :
merge(authors, books, by.x = "surname", by.y = "name", all = TRUE)
```

---

**message**

**Diagnostic Messages**

**Description**

Generate a diagnostic message from its arguments.

**Usage**

```r
message(..., domain = NULL, appendLF = TRUE)
suppressMessages(expr)

packageStartupMessage(..., domain = NULL, appendLF = TRUE)
suppressPackageStartupMessages(expr)

.makeMessage(..., domain = NULL, appendLF = FALSE)
```

**Arguments**

- `...`: zero or more objects which can be coerced to character (and which are pasted together with no separator) or (for `message` only) a single condition object.
- `domain`: see `gettext`. If NA, messages will not be translated.
- `appendLF`: logical: should messages given as a character string have a newline appended?
- `expr`: expression to evaluate.
Details

message is used for generating “simple” diagnostic messages which are neither warnings nor errors, but nevertheless represented as conditions. Unlike warnings and errors, a final newline is regarded as part of the message, and is optional. The default handler sends the message to the stderr() connection.

If a condition object is supplied to message it should be the only argument, and further arguments will be ignored, with a warning.

While the message is being processed, a muffleMessage restart is available.

suppressMessages evaluates its expression in a context that ignores all “simple” diagnostic messages.

packageStartupMessage is a variant whose messages can be suppressed separately by suppressPackageStartupMessages. (They are still messages, so can be suppressed by suppressMessages.)

.makeMessage is a utility used by message, warning and stop to generate a text message from the ... arguments by possible translation (see gettext) and concatenation (with no separator).

See Also

warning and stop for generating warnings and errors; conditions for condition handling and recovery.

gettext for the mechanisms for the automated translation of text.

Examples

message("ABC", "DEF")
suppressMessages(message("ABC"))

testit <- function() {
  message("testing package startup messages")
  packageStartupMessage("initializing ...", appendLF = FALSE)
  Sys.sleep(1)
  packageStartupMessage(" done")
}

testit()
suppressPackageStartupMessages(testit())
suppressMessages(testit())

missing

Does a Formal Argument have a Value?

Description

missing can be used to test whether a value was specified as an argument to a function.

Usage

missing(x)
mode

The (Storage) Mode of an Object

Description
Get or set the type or storage mode of an object.

Usage
\[
\text{mode}(x) \\
\text{mode}(x) \leftarrow \text{value} \\
\text{storage.mode}(x) \\
\text{storage.mode}(x) \leftarrow \text{value}
\]

Arguments
\[
x \quad \text{any R object.} \\
\text{value} \quad \text{a character string giving the desired (storage) mode of the object.}
\]

Details
\text{missing}(x) \text{ is only reliable if } x \text{ has not been altered since entering the function: in particular it will always be false after } x \leftarrow \text{match.arg}(x).

The example shows how a plotting function can be written to work with either a pair of vectors giving \(x\) and \(y\) coordinates of points to be plotted or a single vector giving \(y\) values to be plotted against their indexes.

Currently \text{missing} can only be used in the immediate body of the function that defines the argument, not in the body of a nested function or a \texttt{local} call. This may change in the future.

References

See Also
\texttt{substitute} for argument expression; \texttt{NA} for “missing values” in data.

Examples
\begin{verbatim}
myplot <- function(x,y) {
  if(missing(y)) {
    y <- x
    x <- 1:length(y)
  }
  plot(x,y)
}
\end{verbatim}
Details

Both `mode` and `storage.mode` return a character string giving the (storage) mode of the object — often the same — both relying on the output of `typeof(x)`, see the example below.

The two replacement versions are currently identical. Both `mode(x) <- "newmode"` and `storage.mode(x) <- "newmode"` change the mode or storage.mode of object `x` to `newmode`. This is only supported if there is an appropriate `as.newmode` function, for example `"logical", "integer", "double", "complex", "raw", "character", "list", "expression", "name", "symbol" and "function".

As storage mode "single" is only a pseudo-mode in R, it will not be reported by `mode` or `storage.mode`: use `attr(object, "Csingle")` to examine this. However, the replacement versions can be used to set the mode to "single", which sets the real mode to "double" and the "Csingle" attribute to TRUE. Setting any other mode will remove this attribute. (Use of `storage.mode<-` for setting or unsetting this attribute is deprecated as from R 2.5.0.)

Note (in the examples below) that some `calls` have mode "(" which is S compatible.

Mode names

Modes have the same set of names as types (see `typeof`) except that

- types "integer" and "double" are returned as "numeric".
- types "special" and "builtin" are returned as "function".
- type "symbol" is called mode "name".
- type "language" is returned as "(" or "call".

References

See Also

`typeof` for the R-internal “mode”, `attributes`.

Examples

```r
sapply(options(), mode)

cex3 <- c("NULL","1","1:1","1i","list(1)", "data.frame(x=1)", "pairlist(pi)",
  "c", "lm", "formals(lm)[[1]]"", "formals(lm)[[2]]"",
  "y~x","expression(lm)([[1]]", "(y-x)[[1]]", "expression(x <- pi)[[1]][[1]][[1]]")

lex3 <- sapply(cex3, function(x) eval(parse(text=x)))
mex3 <- t(sapply(lex3, function(x) c(typeof(x), storage.mode(x), mode(x))))
dimnames(mex3) <- list(cex3, c("typeof(.)","storage.mode(.)","mode(.)"))
mex3

# This also makes a local copy of 'pi':
storage.mode(pi) <- "complex"
storage.mode(pi)
rm(pi)
```
**Description**

NA is a logical constant of length 1 which contains a missing value indicator. NA can be freely coerced to any other vector type except raw. As from R 2.5.0 there are constants NA_integer_, NA_real_, NA_complex_ and NA_character_ of the other atomic vector types which support missing values.

The generic function is.na indicates which elements are missing.

The generic function is.na<- sets elements to NA.

**Usage**

```r
NA
is.na(x)
## S3 method for class 'data.frame':
is.na(x)
  is.na(x) <- value
```

**Arguments**

- `x`  
  an R object to be tested.

- `value`  
  a suitable index vector for use with `x`.

**Details**

The NA of character type is distinct from the string "NA". Programmers who need to specify an explicit string NA should use as.character(NA) rather than "NA", or set elements to NA using is.na<-. is.na(x) works elementwise when x is a list. It is generic: you can write methods to handle specific classes of objects, see InternalMethods. A complex value is regarded as NA if either its real or imaginary part is NA or NaN.

Function is.na<- may provide a safer way to set missingness. It behaves differently for factors, for example.

**Value**

The default method for is.na returns a logical vector of the same “form” as its argument x, containing TRUE for those elements marked NA or NaN (!) and FALSE otherwise. dim, dimnames and names attributes are preserved.

The method is.na.data.frame returns a logical matrix with the same dimensions as the data frame, and with dimnames taken from the row and column names of the data frame.

**References**

See Also

NaN, is.nan, etc., and the utility function complete.cases. na.action, na.omit, na.fail on how methods can be tuned to deal with missing values.

Examples

```r
is.na(c(1, NA))  #> FALSE TRUE
is.na(paste(c(1, NA))) #> FALSE FALSE

(xx <- c(0:4))
is.na(xx) <- c(2, 4)
xx #> 0 NA 2 NA 4
```

---

**Names and Symbols**

Description

as.symbol coerces its argument to be a symbol, or equivalently, a name. The argument must be of mode "character". as.name is an alias for as.symbol.

is.symbol (and is.name equivalently) returns TRUE or FALSE depending on whether its argument is a symbol (i.e., name) or not.

Usage

```r
as.symbol(x)
is.symbol(x)

as.name(x)
is.name(x)
```

Arguments

- `x` object to be coerced or tested.

Note

The term “symbol” is from the LISP background of R, whereas “name” has been the standard S term for this.

References

See Also

call, is.language. For the internal object mode, typeof.
Examples
  an <- as.name("arrg")
  is.name(an) # TRUE
  mode(an) # name
  typeof(an) # symbol

names The Names of an Object

Description
  Functions to get or set the names of an object.

Usage
  names(x)
  names(x) <- value

Arguments
  x    an R object.
  value a character vector of up to the same length as x, or NULL.

Details
  names is a generic accessor function, and names<- is a generic replacement function. The default
  methods get and set the "names" attribute of a vector (including a list) or pairlist.
  If value is shorter than x, it is extended by character NAs to the length of x.
  It is possible to update just part of the names attribute via the general rules: see the exam-
  ples. This works because the expression there is evaluated as z <- "names<-"(z, "[<-"
  "(names(z)), 3, "c2")
  The name "" is special: it is used to indicate that there is no name associated with an element of a
  (atomic or generic) vector. Subscripting by "" will match nothing (not even elements which have
  no name).
  A name can be character NA, but such a name will never be matched and is likely to lead to confu-
  sion.

Value
  For names, NULL or a character vector of the same length as x. (NULL is given if the object has
  no names, including for objects of types which cannot have names.)
  For names<-, the updated object. (Note that the value of names(x) <- value is that of the
  assignment, value, not the return value from the left-hand side.)

Note
  For vectors, the names are one of the attributes with restrictions on the possible values. For pairlists,
  the names are the tags and converted to and from a character vector.
  For a one-dimensional array the names attribute really is dimnames[[1]].
nargs

References

Examples

# print the names attribute of the islands data set
names(islands)

# remove the names attribute
names(islands) <- NULL
islands
rm(islands) # remove the copy made

z <- list(a=1, b="c", c=1:3)
names(z)

# change just the name of the third element.
names(z)[3] <- "c2"

z

z <- 1:3
names(z)

## assign just one name
names(z)[2] <- "b"

z

nargs

The Number of Arguments to a Function

Description

When used inside a function body, nargs returns the number of arguments supplied to that function, including positional arguments left blank.

Usage

nargs()

References

See Also

args, formals and sys.call.
Examples

```r
tst <- function(a, b = 3, ...) { nargs() }
tst() # 0
tst(clicketyclack) # 1 (even non-existing)
tst(c1, a2, rr3) # 3

foo <- function(x, y, z, w) {
  cat("call was", deparse(match.call()), ", \n")
  nargs()
}
foo() # 0
foo(,,3) # 3
foo(z=3) # 1, even though this is the same call
nargs()# not really meaningful
```

---

**nchar**

*Count the Number of Characters (Bytes)*

**Description**

The `nchar` function takes a character vector as an argument and returns a vector whose elements contain the sizes of the corresponding elements of `x`.

**Usage**

```r
nchar(x, type = "bytes")
```

**Arguments**

- `x`: character vector, or a vector to be coerced to a character vector.
- `type`: character string: partial matching to one of `c("bytes", "chars", "width")`. See Details.

**Details**

The ‘size’ of a character string can be measured in one of three ways

- **bytes**: The number of bytes needed to store the string (plus in C a final terminator which is not counted).
- **chars**: The number of human-readable characters.
- **width**: The number of columns `cat` will use to print the string in a monospaced font. The same as `chars` if this cannot be calculated.

These will often be the same, and almost always will be in single-byte locales. There will be differences between the first two with multibyte character sequences, e.g. in UTF-8 locales. If the byte stream contains embedded null bytes, `type = "bytes"` looks at all the bytes whereas the other two types look only at the string as printed by `cat`, up to the first null byte.

The internal equivalent of the default method of `as.character` is performed on `x` (so there is no method dispatch). If you want to operate on non-vector objects passing them through `deparse` first will be required.
nlevels

The Number of Levels of a Factor

Description

Return the number of levels which its argument has.

Usage

nlevels(x)

Arguments

x

an object, usually a factor.

Details

If the argument is not a factor, NA is returned.

The actual factor levels (if they exist) can be obtained with the levels function.

Value

An integer vector giving the sizes of each element, currently always 2 for missing values (for NA).

If an element is invalid in a multi-byte character set such as UTF-8, its number of characters and the width will be NA. Otherwise the number of characters will be non-negative, so !is.na(nchar(x, "chars")) is a test of validity.

Names, dims and dimnames are copied from the input.

Note

This does not by default give the number of characters that will be used to print() the string. Use encodeString to find the characters used to print the string.

Embedded null bytes are included in the byte count (but not the final null).

strwidth giving width of strings for plotting; paste, substr, strsplit

Examples

x <- c("asfek","qwert","yuiop","b","stuff.blah.yech")
nchar(x)
# 5 6 6 1 15

nchar(deparse(mean))
# 18 17
noquote

Class for “no quote” Printing of Character Strings

Description

Print character strings without quotes.

Usage

noquote(obj)

## S3 method for class 'noquote':
print(x, ...)

## S3 method for class 'noquote':
c(..., recursive = FALSE)

Arguments

obj an R object, typically a vector of character strings.
x an object of class "noquote".
... further options passed to next methods, such as print.
recursive for compatibility with the generic c function.

Details

noquote returns its argument as an object of class "noquote". There is a method for c() and subscript method ("[.noquote") which ensures that the class is not lost by subsetting. The print method (print.noquote) prints character strings without quotes ("...").

These functions exist both as utilities and as an example of using (S3) class and object orientation.

Examples

letters
nql <- noquote(letters)
nql
nql[1:4] <- "oh"
nql[1:12]
cmp.logical <- function(log.v)
NotYet

{
    ## Purpose: compact printing of logicals
    log.v <- as.logical(log.v)
    noquote(if(length(log.v)==0)"()" else c(".",",")[1+log.v])
}
cmp.logical(runif(20) > 0.8)

NotYet

Not Yet Implemented Functions and Unused Arguments

Description

In order to pinpoint missing functionality, the R core team uses these functions for missing R functions and not yet used arguments of existing R functions (which are typically there for compatibility purposes).

You are very welcome to contribute your code …

Usage

 .NotYetImplemented()
 .NotYetUsed(arg, error = TRUE)

Arguments

arg an argument of a function that is not yet used.
error a logical. If TRUE, an error is signalled; if FALSE; only a warning is given.

See Also

the contrary, Deprecated and Defunct for outdated code.

Examples

require(graphics)
require(stats)
plot.mlm    # to see how the "NotYetImplemented"
            # reference is made automagically
try(plot.mlm())
barplot(1:5, inside = TRUE) # 'inside' is not yet used
The Number of Rows/Columns of an Array

Description

nrow and ncol return the number of rows or columns present in \( x \). NCOL and NROW do the same treating a vector as 1-column matrix.

Usage

nrow(x)
ncol(x)
NCOL(x)
NROW(x)

Arguments

x  
a vector, array or data frame

Value

an integer of length 1 or NULL.

References

See Also

dim which returns all dimensions; array, matrix.

Examples

ma <- matrix(1:12, 3, 4)
nrow(ma)  # 3
ncol(ma)  # 4

ncol(array(1:24, dim = 2:4))  # 3, the second dimension
NCOL(1:12)  # 1
NROW(1:12)  # 12
Double Colon and Triple Colon Operators

Description

Accessing exported and internal variables in a name space.

Usage

pkg::name
pkg:::name

Arguments

pkg   package name symbol or literal character string.
name  variable name symbol or literal character string.

Details

The expression pkg::name returns the value of the exported variable name in package pkg if the package has a name space. The expression pkg:::name returns the value of the internal variable name in package pkg if the package has a name space. The package will be loaded if it was not loaded already before the call. Assignment into name spaces is not supported.

If the package pkg does not have a name space but is on the search path then pkg::name returns the value of name in the package environment.

See Also

get to access an object masked by another of the same name.

Examples

base::log
base::*

Hooks for Name Space events

Description

Packages with name spaces can supply functions to be called when loaded, attached or unloaded.

Usage

.onLoad(libname, pkgnane)
.onAttach(libname, pkgnane)
.onUnload(libpath)
Arguments

libname  
a character string giving the library directory where the package defining the namespace was found.

pkgname  
a character string giving the name of the package, including the version number if the package was installed with --with-package-versions.

libpath  
a character string giving the complete path to the package.

Details

These functions apply only to packages with name spaces.

After loading, loadNamespace looks for a hook function named .onLoad and runs it before sealing the namespace and processing exports.

If a name space is unloaded (via unloadNamespace), a hook function .onUnload is run before final unloading.

Note that the code in .onLoad and .onUnload is run without the package being on the search path, but (unless circumvented) lexical scope will make objects in the namespace and its imports visible. (Do not use the double colon operator in .onLoad as exports have not been processed at the point it is run.)

When the package is attached (via library), the hook function .onAttach is looked for and if found is called after the exported functions are attached and before the package environment is sealed. This is less likely to be useful than .onLoad, which should be seen as the analogue of .First.lib (which is only used for packages without a name space).

.onLoad, .onUnload and .onAttach are looked for as internal variables in the name space and should not be exported.

If a function .Last.lib is visible in the package, it will be called when the package is detached: this does need to be exported.

Anything needed for the functioning of the name space should be handled at load/unload times by the .onLoad and .onUnload hooks. For example, shared libraries can be loaded (unless done by a useDynLib directive in the ‘NAMESPACE’ file) and initialized in .onLoad and unloaded in .onUnload. Use .onAttach only for actions that are needed only when the package becomes visible to the user, for example a start-up message.

If a package was installed with --with-package-versions, the pkgname supplied will be something like tree_1.0-16.

See Also

setHook shows how users can set hooks on the same events.
**Usage**

```r
attachNamespace(ns, pos = 2, dataPath = NULL)
loadNamespace(package, lib.loc = NULL,
       keep.source = getOption("keep.source.pkgs"),
       partial = FALSE, declarativeOnly = FALSE)
loadedNamespaces()
unloadNamespace(ns)
```

**Arguments**

- **ns**: string or namespace object.
- **pos**: integer specifying position to attach.
- **dataPath**: path to directory containing a database of datasets to be lazy-loaded into the attached environment.
- **package**: string naming the package/name space to load.
- **lib.loc**: character vector specifying library search path.
- **keep.source**: logical specifying whether to retain source. This applies only to the specified name space, and not to other name spaces which might be loaded to satisfy imports.
  
  For more details see this argument to `library`
- **partial**: logical; if true, stop just after loading code.
- **declarativeOnly**: logical; disables `.Import`, etc, if true.

**Details**

The functions `loadNamespace` and `attachNamespace` are usually called implicitly when `library` is used to load a name space and any imports needed. However it may be useful to call these functions directly at times.

`loadNamespace` loads the specified name space and registers it in an internal data base. A request to load a name space that is already loaded has no effect. The arguments have the same meaning as the corresponding arguments to `library`, whose help page explains the details of how a particular installed package comes to be chosen. After loading, `loadNamespace` looks for a hook function named `.onLoad` as an internal variable in the name space (it should not be exported). This function is called with the same arguments as `.First.lib`. Partial loading is used to support installation with the `--save` and `--lazy` options.

`loadNamespace` does not attach the name space it loads to the search path. `attachNamespace` can be used to attach a frame containing the exported values of a name space to the search path. The hook function `.onAttach` is run after the name space exports are attached.

`loadedNamespaces` returns a character vector of the names of the loaded name spaces.

`unloadNamespace` can be used to force a name space to be unloaded. An error is signaled if the name space is imported by other loaded name spaces. If defined, a hook function `.onUnload` is run before removing the name space from the internal registry. `unloadNamespace` will first `detach` a package of the same name if one is on the path, thereby running a `.Last.lib` function in the package if one is exported.

**Author(s)**

Luke Tierney
Description

Finding the top level environment.

Usage

topenv(envir = parent.frame(),
       matchThisEnv = getOption("topLevelEnvironment"))

Arguments

envir  environment.
matchThisEnv  return this environment, if it matches before any other criterion is satisfied.

The default, the option “topLevelEnvironment”, is set by sys.source, which treats a specific environment as the top level environment. Supplying the argument as NULL means it will never match.

Details

topenv returns the first top level environment found when searching envir and its parent environments. An environment is considered top level if it is the internal environment of a name space, a package environment in the search path, or .GlobalEnv.

Examples

topenv(.GlobalEnv)
topenv(new.env())

NULL  The Null Object

Description

NULL represents the null object in R. NULL is used mainly to represent the lists with zero length, and is often returned by expressions and functions whose value is undefined.

as.null ignores its argument and returns the value NULL.

is.null returns TRUE if its argument is NULL and FALSE otherwise.

Usage

NULL
as.null(x, ...)
is.null(x)
Arguments

- **x**: an object to be tested or coerced.
- **...**: ignored.

References

Examples

```r
is.null(list())  # FALSE (on purpose!)
is.null(integer(0)) # F
is.null(logical(0)) # F
as.null(list(a=1,b='c'))
```

### Numeric Vectors

#### Description

Creates or tests for objects of type "numeric".

#### Usage

```r
numeric(length = 0)
as.numeric(x, ...)
is.numeric(x)
```

#### Arguments

- **length**: desired length.
- **x**: object to be coerced or tested.
- **...**: further arguments passed to or from other methods.

#### Details

- `as.numeric` is a generic function, but methods must be written for `as.double`, which it calls.
- `is.numeric` is generic: you can write methods to handle specific classes of objects, see [Internal-Methods](https://www.r-project.org/doc/manuals/R-intro.html).

#### Value

- `numeric` creates a real vector of the specified length. The elements of the vector are all equal to 0.
- `as.numeric` attempts to coerce its argument to "double" (even if it is already "integer"). `as.numeric` for factors yields the codes underlying the factor levels, not the numeric representation of the labels, see also [factor](https://www.r-project.org/doc/manuals/R-intro.html).

The default method for `is.numeric` returns TRUE if its argument is of mode "numeric" (type "double" or type "integer") and not a factor, and FALSE otherwise. That is, `is.integer(x) || is.double(x), or (mode(x) == "numeric") && !is.factor(x)`.
Note

R has no single precision data type. All real numbers are stored in double precision format.
numeric and as.numeric are the identical to double and as.double (unless someone defines S4 methods on one of them).

References

See Also

double, integer, storage.mode.

Examples

as.numeric(c("-.1"," 2.7 ","B")) # (-0.1, 2.7, NA) + warning
as.numeric(factor(5:10))

Description

How R parses numeric constants.

Details

R parses numeric constants in its input in a very similar way to C floating-point constants. Inf and NaN are numeric constants (with typeof(.) "double"). All other numeric constants start with a digit or period. Hexadecimal constants start with 0x or 0X followed by a non-empty sequence from 0-9 a-f A-F which is interpreted as a hexadecimal number ("double", not "integer"). Decimal constants consists of a nonempty sequence of digits possibly containing a period (the decimal point), optionally followed by a decimal exponent. A decimal exponent consists of an E or e followed by an optional plus or minus sign followed by a non-empty sequence of digits, and indicates multiplication by a power of ten. A numeric constant immediately followed by i is regarded as an imaginary complex number. An numeric constant immediately followed by L is regarded as an integer number when possible (and with a warning if it contains a "."). Only the ASCII digits 0–9 are recognized as digits, even in languages which have other representations of digits. The ‘decimal separator’ is always a period and never a comma. Note that a leading plus or minus is not part of numeric constant but a unary operator applied to the constant.

See Also

Syntax.
Quotes for the parsing of character constants,
octmode

Examples

2.1
typeof(2)
sqrt(1i) # remember elementary math?
str(0xA0)
identical(1L, as.integer(1))

## You can combine the "0x" prefix with the "L" suffix :
identical(0xFL, as.integer(15)) # (with a regard to Fritz :-)

octmode

Display Numbers in Octal

Description

Convert or print integers in octal format, with as many digits as are needed to display the largest, using leading zeroes as necessary.

Usage

## S3 method for class 'octmode':
as.character(x, ...)

## S3 method for class 'octmode':
format(x, ...)

## S3 method for class 'octmode':
print(x, ...)

Arguments

x
An object inheriting from class "octmode".

... further arguments passed to or from other methods.

Details

Class "octmode" consists of integer vectors with that class attribute, used merely to ensure that they are printed in octal notation, specifically for Unix-like file permissions such as 755. Subsetting ([]) works too.

See Also

These are auxiliary functions for file.info.

hexmode

Examples

(on <- structure(c(16, 32, 127:129), class = "octmode")) #-> print. *()
##-> "020" "040" "177" "200" "201"
unclass(on[3:4]) # subsetting
on.exit  

Function Exit Code

Description

on.exit records the expression given as its argument as needing to be executed when the current function exits (either naturally or as the result of an error). This is useful for resetting graphical parameters or performing other cleanup actions.

If no expression is provided, i.e., the call is on.exit(), then the current on.exit code is removed.

on.exit is a primitive function so positional matching is used and names of supplied arguments are ignored.

Usage

on.exit(expr, add = FALSE)

Arguments

expr  
an expression to be executed.

add  
if TRUE, add expr to be executed after any previously set expressions; otherwise (the default) expr will overwrite any previously set expressions.

Value

Invisible NULL.

References

See Also

sys.on.exit which returns the expression stored for use by on.exit() in the function in which sys.on.exit() is evaluated.

Examples

opar <- par(mai = c(1,1,1,1))
on.exit(par(opar))
Operators on the Date Class

Description

Operators for the "Date" class.

There is an Ops method and specific methods for + and − for the Date class.

Usage

date + x
date - x
date1 lop date2

Arguments

date      date objects
date1, date2 date objects or character vectors. (Character vectors are converted by as.Date.)
x        a numeric vector (in days) or an object of class "difftime".
lop        One of ==, ! =, <, <=, > or >=.

Examples

(z <- Sys.Date())
z + 10
z < c("2006-06-01", "2007-01-01", "2010-01-01")

Options Settings

Description

Allow the user to set and examine a variety of global “options” which affect the way in which R computes and displays its results.

Usage

options(...)
getOption(x)
.Options

Arguments

... any options can be defined, using name = value or by passing a list of such tagged values. However, only the ones below are used in “base R”. Further, options(’name’) == options()[’name’], see the example.

x        a character string holding an option name.
Details

Invoking `options()` with no arguments returns a list with the current values of the options. Note that not all options listed below are set initially. To access the value of a single option, one should use `getOption("width")`, e.g., rather than `options("width")` which is a `list` of length one.

Options also always contains the `options()` list (as a pairlist, unsorted), for S compatibility. Assigning to it will make a local copy and not change the original.

Value

For `getOption`, the current value set for option `x`, or `NULL` if the option is unset.

For `options()`, a list of all set options sorted by name. For `options(name)`, a list of length one containing the set value, or `NULL` if it is unset. For uses setting one or more options, a list with the previous values of the options changed (returned invisibly).

Options used in base R

- **add.smooth**: typically logical, defaulting to `TRUE`. Could also be set to an integer for specifying how many (simulated) smooths should be added. This is currently only used by `plot.lm`.
- **check.bounds**: logical, defaulting to `FALSE`. If true, a `warning` is produced whenever a “generalized vector” (atomic or `list`) is extended, by something like `x <- 1:3; x[5] <- 6`.
- **continue**: a non-empty string setting the prompt used for lines which continue over one line.
- **defaultPackages**: the packages that are attached by default when R starts up. Initially set from value of the environment variable `R_DEFAULT_PACKAGES`, or if that is unset to `c("datasets", "utils", "grDevices", "graphics", "stats", "methods")`. (Set `R_DEFAULT_PACKAGES` to `NULL` or a comma-separated list of package names.) A call to `options` should be in your `.Rprofile` file to ensure that the change takes effect before the base package is initialized (see `Startup`).
- **deparse.max.lines**: controls the number of lines used when deparsing in `traceback` and `browser`. Initially unset, and only used if set to a positive integer.
- **digits**: controls the number of digits to print when printing numeric values. It is a suggestion only. Valid values are 1…22 with default 7. See the warning in `print.default` about values greater than 15.
- **digits.secs**: controls the maximum number of digits to print when formatting time values in seconds. Valid values are 0…6 with default 0. See `strftime`.
- **download.file.method**: Method to be used for `download.file`. Currently download methods "internal", "wget" and " lynx" are available. There is no default for this option, when method = "auto" is chosen: see `download.file`.
- **echo**: logical. Only used in non-interactive mode, when it controls whether input is echoed. Command-line option `-slave` sets this to `FALSE`, but otherwise it starts the session as `TRUE`.
- **encoding**: The name of an encoding, default "native.enc"). See `connections`.
- **error**: either a function or an expression governing the handling of non-catastrophic errors such as those generated by `stop` as well as by signals and internally detected errors. If the option is a function, a call to that function, with no arguments, is generated as the expression. The default value is `NULL`; see `stop` for the behaviour in that case. The functions `dump.frames` and `recover` provide alternatives that allow post-mortem debugging.
expressions: sets a limit on the number of nested expressions that will be evaluated. Valid values are 25...500000 with default 5000. If you increase it, you may also want to start R with a larger protection stack; see \texttt{--max-ppsize} in Memory. Note too that you may cause a segfault from overflow of the C stack, and on OSes where it is possible you may want to increase that.

keep.source: When TRUE, the source code for functions (newly defined or loaded) is stored in their "source" attribute (see \texttt{attr}) allowing comments to be kept in the right places. The default is \texttt{interactive()}, i.e., TRUE for interactive use.

keep.source.pkgs: As for keep.source, for functions in packages loaded by \texttt{library} or \texttt{require}. Defaults to FALSE unless the environment variable \texttt{R\_KEEP\_PKG\_SOURCE} is set to yes.

Note this does not apply to packages using lazy-loading or saved images. Whether they have kept source is determined when they are installed (and is almost certainly false).

mailer: default mailer used by \texttt{bug.report()}. Can be "none".

max.contour.segments: positive integer, defaulting to 250000 and usually not set. A limit on the number of segments in a single contour line in \texttt{contour} or \texttt{contourLines}.

max.print: integer, defaulting to 99999. \texttt{print} or \texttt{show} methods can make use of this option, to limit the amount of information that is printed, to something in the order of (and typically slightly less than) \texttt{max.print entries}.

OutDec: one-character string. The character to be used as the decimal point in output conversions, that is in printing, plotting and \texttt{as.character} but not deparsing.

pager: the command used for displaying text files by \texttt{file.show}. Defaults to \texttt{'$R\_HOME/bin/pager'}, which selects a pager via the \texttt{PAGER} environment variable (and that usually defaults to \texttt{less}). Can be a character string or an R function, in which case it needs to accept the same first four arguments as \texttt{file.show}.

papersize: the default paper format used by \texttt{postscript}; set by environment variable \texttt{R\_PAPERSIZE} when R is started: if that is unset or invalid it defaults to a value derived from the locale category \texttt{LC\_PAPER}, or if that is unavailable to a default set when R was built.

printcmd: the command used by \texttt{postscript} for printing; set by environment variable \texttt{R\_PRINTCMD} when R is started. This should be a command that expects either input to be piped to \texttt{’stdin’} or to be given a single filename argument.

prompt: a non-empty string to be used for R’s prompt; should usually end in a blank (" ").

save.defaults, save.image.defaults: see \texttt{save}.

scipen: integer. A penalty to be applied when deciding to print numeric values in fixed or exponential notation. Positive values bias towards fixed and negative towards scientific notation: fixed notation will be preferred unless it is more than \texttt{scipen} digits wider.

show.error.messages: a logical. Should error messages be printed? Intended for use with \texttt{try} or a user-installed error handler.

stringsAsFactors: The default setting for arguments of \texttt{data.frame} and \texttt{read.table}.

texi2dvi: used by the unexported function \texttt{texi2dvi} in name space \texttt{tools}.

timeout: integer. The timeout for some Internet operations, in seconds. Default 60 seconds. See \texttt{download.file} and \texttt{connections}.

topLevelEnvironment: see \texttt{topenv} and \texttt{sys.source}.

verbose: logical. Should R report extra information on progress? Set to \texttt{TRUE} by the command-line option \texttt{’-verbose’}.  

**warn**: sets the handling of warning messages. If **warn** is negative all warnings are ignored. If **warn** is zero (the default) warnings are stored until the top–level function returns. If fewer than 10 warnings were signalled they will be printed otherwise a message saying how many (max 50) were signalled. An object called **last.warning** is created and can be printed through the function **warnings**. If **warn** is one, warnings are printed as they occur. If **warn** is two or larger all warnings are turned into errors.

**warning.expression**: an R code expression to be called if a warning is generated, replacing the standard message. If non-null it is called irrespective of the value of option **warn**.

**warnings.length**: sets the truncation limit for error and warning messages. A non-negative integer, with allowed values 100...8170, default 1000.

**width**: controls the maximum number of columns on a line used in printing vectors, matrices and arrays, and when filling by **cat**. Columns are normally the same as characters except in CJK languages.

You may want to change this if you re-size the window that R is running in. Valid values are 10...10000 with default normally 80. (The limits on valid values are in file ‘Print.h’ and can be changed by re-compiling R.) Some R consoles automatically change the value when they are resized.

The ‘factory-fresh’ default settings of some of these options are

```plaintext
add.smooth       TRUE
check.bounds     FALSE
continue         "+ "
digits           7
echo             TRUE
encoding         "native.enc"
error            NULL
expressions      5000
keep.source      interactive()
keep.source.pkgs FALSE
max.print         99999
OutDec           "."  
prompt           "> "
scipen           0
show.error.messages TRUE
timeout          60
verbose          FALSE
warn             0
warnings.length  1000
width            80
```

Others are set from environment variables or are platform-dependent.

### Options set in package grDevices

These will be set when package **grDevices** (or its name space) is loaded if not already set.

**device**: a character string giving the name of a function, or the function object itself, which when called creates a new graphics device of the default type for that session. The value of this option defaults to the normal screen device (e.g., x11, windows or quartz) for an interactive session, and **postscript** in batch use or if a screen is not available.
**locatorBell**: logical. Should selection in `locator` and `identify` be confirmed by a bell? Default TRUE. Honoured at least on X11 and Windows devices.

**par.ask.default**: logical. The default for `par("ask")` when a device is opened.

**X11colortype**: The default colour type for X11 devices. Default "true".

**X11fonts**: character vector of length 2. See X11.

**gamma**: double. The default value of `gamma` for X11 devices, defaulting to 1 if unset (the default).

### Options set in package stats

These will be set when package `stats` (or its name space) is loaded if not already set.

**contrasts**: the default `contrasts` used in model fitting such as with `aov` or `lm`. A character vector of length two, the first giving the function to be used with unordered factors and the second the function to be used with ordered factors. By default the elements are named `c("unordered", "ordered")`, but the names are unused.

**na.action**: the name of a function for treating missing values (NA's) for certain situations.

**show.coef.Pvalues**: logical, affecting whether P values are printed in summary tables of coefficients. See `printCoefmat`.

**show.signif.stars**: logical, should stars be printed on summary tables of coefficients? See `printCoefmat`.

**ts.eps**: the relative tolerance for certain time series (ts) computations. Default 1e-05.

**ts.S.compat**: logical. Used to select S compatibility for plotting time-series spectra. See the description of argument `log` in `plot.spec`.

### Options set in package utils

These will be set when package `utils` (or its name space) is loaded if not already set.

**browser**: default HTML browser used by `help.start()` on UNIX, or a non-default browser on Windows.

**de.cellwidth**: integer: the cell widths (number of characters) to be used in the data editor `dataentry`. If this is unset (the default), 0, negative or NA, variable cell widths are used.

**editor**: a non-empty string. Sets the default text editor, e.g., for `edit`. Set from the environment variable `VISUAL` on UNIX.

**example.ask**: default for the `ask` argument of `example`.

**help.try.all.packages**: default for an argument of `help`.

**HTTPUserAgent**: string used as the user agent in HTTP requests. If NULL, HTTP requests will be made without a user agent header. The default is R `<version> <platform> <arch> <os>`)  

**internet.info**: The minimum level of information to be printed on URL downloads etc. Default is 2, for failure causes. Set to 1 or 0 to get more information.

**menu.graphics**: Logical: should graphical menus be used if available?. Defaults to TRUE. Currently applies to `chooseCRANmirror`, `setRepositories` and to select from multiple help files in `help`.

**pkgType**: The default type of packages to be downloaded and installed – see `install.packages`. Possible values are "source" (the default except under the CRAN Mac OS X build) and "mac.binary".
repos: URLs of the repositories for use by `update.packages`. Defaults to `c(CRAN="@CRAN@")`, a value that causes some utilities to prompt for a CRAN mirror. To avoid this do set the CRAN mirror, by something like `local({r <-getOption("repos"); r["CRAN"] <- "http://my.local.cran"; options(repos=r)}).

Note that you can add more repositories (Bioconductor and Omegahat, notably) using `setRepositories()`.

SweaveHooks, SweaveSyntax: see Sweave.

unzip: a character string, the path of the command used for unzipping help files, or "internal". Defaults to the value of `R_UNZIPCMD`, which is set in ‘etc/Renviron’ if an unzip command was found during configuration.

Options used on Unix only

latexcmd, dvipscmd: character strings giving commands to be used in off-line printing of help pages.

pdfviewer: default PDF viewer. Set from the environment variable `R_PDFVIEWER`.

References

Examples

```r
options() # printing all current options
op <- options(); str(op) # nicer printing

getOption("width") == options()$Width # the latter needs more memory
options(digits = 15)
pi

# set the editor, and save previous value
old.o <- options(editor = "nedit")
old.o

options(check.bounds = TRUE, warn = 1)
x <- NULL; x[4] <- "yes" # gives a warning

options(digits=5)
print(1e5)

options(scipen=3); print(1e5)

options(op) # reset (all) initial options
options("digits")

## Not run:
## set contrast handling to be like S
options(contrasts = c("contr.helmert", "contr.poly"))
## End(Not run)

## Not run:
## on error, terminate the R session with error status 66
options(error = quote(q("no", status=66, runLast=FALSE)))
stop("test it")
```
## Not run:
## Set error actions for debugging:
## enter browser on error, see ?recover:
## allows to call debugger() afterwards, see ?debugger:
## A possible setting for non-interactive sessions
## End(Not run)

### Description

`order` returns a permutation which rearranges its first argument into ascending or descending order, breaking ties by further arguments. `sort.list` is the same, using only one argument. See the examples for how to use these functions to sort data frames, etc.

### Usage

```r
order(..., na.last = TRUE, decreasing = FALSE)
sort.list(x, partial = NULL, na.last = TRUE, decreasing = FALSE, 
          method = c("shell", "quick", "radix"))
```

### Arguments

- `...`: a sequence of numeric, complex, character or logical vectors, all of the same length.
- `x`: a vector.
- `partial`: vector of indices for partial sorting. (Non-NULL values are not implemented.)
- `decreasing`: logical. Should the sort order be increasing or decreasing?
- `na.last`: for controlling the treatment of NAs. If `TRUE`, missing values in the data are put last; if `FALSE`, they are put first; if `NA`, they are removed.
- `method`: the method to be used: partial matches are allowed.

### Details

In the case of ties in the first vector, values in the second are used to break the ties. If the values are still tied, values in the later arguments are used to break the tie (see the first example). The sort used is stable (except for `method = "quick"`), so any unresolved ties will be left in their original ordering.

Complex values are sorted first by the real part, then the imaginary part.

The sort order for character vectors will depend on the collating sequence of the locale in use: see `Comparison`.

The default method for `sort.list` is a good compromise. Method "quick" is only supported for numeric `x` with `na.last=NA`, and is not stable, but will be faster for long vectors. Method
"radix" is only implemented for integer \( x \) with a range of less than 100,000. For such \( x \) it is very fast (and stable), and hence is ideal for sorting factors.

**partial** is supplied for compatibility with other implementations of S, but no other values are accepted and ordering is always complete.

Note that these functions are only defined for vectors, so any class of the object supplied is ignored: this means factors are sorted on their internal codes and not their printed representation.

**Note**

**sort.list** can get called by mistake as a method for **sort** with a list argument, and gives a suitable error message for list \( x \).

**References**

**See Also**

**sort** and **rank**.

**Examples**

```r
(ii <- order(x <- c(1,1,3:1,1:4,3), y <- c(9,9:1), z <-c(2,1:9)))
## 6 5 2 1 7 4 10 8 3 9
rbind(x,y,z)[,ii] # shows the reordering (ties via 2nd & 3rd arg)

## Suppose we wanted descending order on y. A simple solution is
rbind(x,y,z)[, order(x, -y, z)]
## For character vectors we can make use of rank:
cy <- as.character(y)
rbind(x,y,z)[, order(x, -rank(cy), z)]

## Sorting data frames:
dd <- transform(data.frame(x,y,z),
    z = factor(z, labels=LETTERS[9:1]))
## Either as above (for factor 'z' : using internal coding):
dd[ order(x, -y, z) ,]
## or along 1st column, ties along 2nd, ... *arbitrary* no.{columns}:
dd[ do.call(order, dd) ,]
```

set.seed(1)# reproducible example:
```r
d4 <- data.frame(x = round( rnorm(100)), y = round(10*runif(100)),
    z = round( 8*rnorm(100)), u = round(50*runif(100)))
d4s <- d4[ do.call(order, d4) ,]  
(i <- which(diff(d4s[,3]) == 0))# in 2 places, needed 3 cols to break ties:
d4s[ rbind(i,i+1), ]
```

```
## rearrange matched vectors so that the first is in ascending order
x <- c(5:1, 6:8, 12:9)
y <- (x - 5)^2
o <- order(x)
rbind(x[o], y[o])
```

## tests of na.last
a <- c(4, 3, 2, NA, 1)
b <- c(4, NA, 2, 7, 1)
z <- cbind(a, b)
(o <- order(a, b)); z[o, ]
(o <- order(a, b, na.last = FALSE)); z[o, ]
(o <- order(a, b, na.last = NA)); z[o, ]

## Not run:
## speed examples for long vectors:
x <- factor(sample(letters, 1e6, replace=TRUE))
system.time(o <- sort.list(x)) ## 1.2 secs
stopifnot(!is.unsorted(x[o]))
system.time(o <- sort.list(x, method="quick", na.last=NA)) # 0.15 sec
stopifnot(!is.unsorted(x[o]))
system.time(o <- sort.list(x, method="radix")) # 0.02 sec
stopifnot(!is.unsorted(x[o]))
xx <- sample(1:26, 1e7, replace=TRUE)
system.time(o <- sort.list(xx, method="radix")) # 0.2 sec
xx <- sample(1:100000, 1e7, replace=TRUE)
system.time(o <- sort.list(xx, method="radix")) # 0.8 sec
system.time(o <- sort.list(xx, method="quick", na.last=NA)) # 1.4 sec
## End(Not run)

---

outer

Outer Product of Arrays

Description

The outer product of the arrays X and Y is the array A with dimension c(dim(X), dim(Y)) where element \( A[c(arrayindex.x, arrayindex.y)] = FUN(X[arrayindex.x], Y[arrayindex.y], \ldots) \).

Usage

outer(X, Y, FUN="*", \ldots)
X %o% Y

Arguments

- **X, Y**
  - First and second arguments for function \( FUN \). Typically a vector or array.
- **FUN**
  - a function to use on the outer products, found via `match.fun` (except for the special case "*").
- **\ldots**
  - optional arguments to be passed to \( FUN \).

Details

\( FUN \) must be a function (or the name of it) which expects at least two arguments and which operates elementwise.

X and Y must be suitable arguments for \( FUN \). Each will be extended by `rep` to length the products of the lengths of X and Y before \( FUN \) is called.

Where they exist, the \[dim\]names of X and Y will be copied to the answer, and a dimension assigned which is the concatenation of the dimensions of X and Y (or lengths if dimensions do not exist).
FUN = "*" is handled internally as a special case, via `as.vector(X) %*% t(as.vector(Y))`, and is intended only for numeric vectors and arrays. %o% is binary operator providing a wrapper for `outer(x, y, "*")`.

Author(s)
Jonathan Rougier

References

See Also
%*% for usual (inner) matrix vector multiplication; `kronecker` which is based on `outer`.

Examples
```r
x <- 1:9; names(x) <- x
# Multiplication & Power Tables
x %o% x
y <- 2:8; names(y) <- paste(y, "\n", sep = "")
outer(y, x, "\n")
outer(month.abb, 1999:2003, FUN = "\n")
## three way multiplication table:
x %o% x %o% y[1:3]
```

---

**package-version**

**Package versions**

Description
A simple S3 class for representing package versions, and associated methods.

Usage
```r
package_version(x, strict = TRUE)
```

getRversion()

Arguments

- **x**
  a character vector with package version strings, or an R version object as obtained by `R.version`.

- **strict**
  a logical indicating whether invalid package versions should result in an error (default) or not.
Details

R (package) versions are sequences of at least two non-negative integers, usually (e.g., in package 'DESCRIPTION' files) represented as character strings with the elements of the sequence concatenated and separated by single '.' or '-' characters.

package_version creates a representation from such strings which allows for coercion and testing, combination, comparison, summaries (min/max), inclusion in data frames, subscripting, and printing.

getRversion returns the version of the running R as an object of class "package_version".

See Also

compareVersion

Examples

```r
x <- package_version(c("1.2-4", "1.2-3", "2.1"))
x < "1.4-2.3"
c(min(x), max(x))
x[2, 2]
x$major
x$minor
```

Description

Open parenthesis, (, and open brace, {, are .Primitive functions in R.

Effectively, ( is semantically equivalent to the identity function(x) x, whereas { is slightly more interesting, see examples.

Usage

```r
( ... )
```

Value

For (, the result of evaluating the argument. This has visibility set, so will auto-print if used at top-level.

For {, the result of the last expression evaluated. This has the visibility of the last evaluation.

References

parse

See Also

if, return, etc for other objects used in the R language itself.

Syntax for operator precedence.

Examples

f <- get("(")
e <- expression(3 + 2 * 4)
identical(f(e), e)

do <- get("{")
do(x <- 3, y <- 2*x-3, 6-x-y); x; y

## note the differences
(2+3)
(2+3; 4+5)
(invisible(2+3))
(invisible(2+3))

Description

parse returns the parsed but unevaluated expressions in a list.

Usage

parse(file = "", n = NULL, text = NULL, prompt = "?", srcfile, encoding = "unknown")

Arguments

file a connection, or a character string giving the name of a file or a URL to read the expressions from. If file is "" and text is missing or NULL then input is taken from the console.

n integer (or coerced to integer). The maximum number of expressions to parse. If n is NULL or negative or NA the input is parsed in its entirety.

text character vector. The text to parse. Elements are treated as if they were lines of a file. Other R objects will be coerced to character (without method dispatch) if possible.

prompt the prompt to print when parsing from the keyboard. NULL means to use R’s prompt, getOption("prompt").

srcfile NULL, or a srcfile object. See the Details section.

encoding encoding to be assumed for input strings. It is used to mark character strings as known to be in Latin-1 or UTF-8: it is not used to re-encode the input.
Details

If `text` has length greater than zero (after coercion) it is used in preference to `file`.

All versions of R accept input from a connection with end of line marked by LF (as used on Unix), CRLF (as used on DOS/Windows) or CR (as used on classic MacOS). The final line can be incomplete, that is missing the final EOL marker.

See `source` for the limits on the size of functions that can be parsed (by default). There is also a limit of 8192 bytes on the size of strings which can be parsed.

When input is taken from the console, `n = NULL` is equivalent to `n = 1`, and `n < 0` will read until an EOF character is read.

The default for `srcfile` is set as follows. If `options("keep.source")` is `FALSE`, `srcfile` defaults to `NULL`. Otherwise, if `text` is used, `srcfile` will be set to a `srcfilecopy` containing the text. If a character string is used for `file`, a `srcfile` object referring to that file will be used.

Value

An object of type "expression", with up to `n` elements if specified as a non-negative integer.

When `srcfile` is non-NULL, a "srcref" attribute will be attached to the result containing a list of `srcref` records corresponding to each element.

A syntax error (including an incomplete expression) will throw an error.

Character strings in the result will have a declared encoding if `encoding` is "latin1" or "UTF-8".

References

See Also

`scan, source, eval, deparse`.

Examples

cat("x <- c(1,4)\n x ^ 3 -10 ; outer(1:7,5:9)\n", file="xyz.Rdmped")
# parse 3 statements from the file "xyz.Rdmped"
parse(file = "xyz.Rdmped", n = 3)
unlink("xyz.Rdmped")

Description

Concatenate vectors after converting to character.

Usage

`paste(..., sep = "\", collapse = NULL)`
Arguments

... one or more R objects, to be converted to character vectors.
sep a character string to separate the terms.
collapse an optional character string to separate the results.

Details

paste converts its arguments (via as.character) to character strings, and concatenates them (separating them by the string given by sep). If the arguments are vectors, they are concatenated term-by-term to give a character vector result. Vector arguments are recycled as needed, with zero-length arguments being recycled to "".

If a value is specified for collapse, the values in the result are then concatenated into a single string, with the elements being separated by the value of collapse.

Value

A character vector of the concatenated values. This will be of length zero if all the objects are, unless collapse is non-NULL, in which case it is a single empty string.

References

See Also

String manipulation with as.character, substr, nchar, strsplit; further, cat which concatenates and writes to a file, and sprintf for C like string construction.

Examples

paste(1:12) # same as as.character(1:12)
paste("A", 1:6, sep = ")
paste("Today is", date())

path.expand (Expand File Paths)

Description

Expand a path name, for example by replacing a leading tilde by the user’s home directory (if defined on that platform).

Usage

path.expand(path)

Arguments

path character vector containing one or more path names.
**pmatch**

**Partial String Matching**

**Details**

On some Unix versions, a leading `~user` will expand to the home directory of `user`, but not on Unix versions without readline installed.

**See Also**

basename

**Examples**

```r
class(path.expand("~foo"))
```

---

**Description**

`pmatch` seeks matches for the elements of its first argument among those of its second.

**Usage**

```r
pmatch(x, table, nomatch = NA, duplicates.ok = FALSE)
```

**Arguments**

- `x`: the values to be matched: converted to a character vector by `as.character`.
- `table`: the values to be matched against: converted to a character vector.
- `nomatch`: the value to be returned at non-matching or multiply partially matching positions.
- `duplicates.ok`: should elements be in `table` be used more than once?

**Details**

The behaviour differs by the value of `duplicates.ok`. Consider first the case if this is true. First exact matches are considered, and the positions of the first exact matches are recorded. Then unique partial matches are considered, and if found recorded. (A partial match occurs if the whole of the element of `x` matches the beginning of the element of `table`.) Finally, all remaining elements of `x` are regarded as unmatched. In addition, an empty string can match nothing, not even an exact match to an empty string. This is the appropriate behaviour for partial matching of character indices, for example.

If `duplicates.ok` is FALSE, values of `table` once matched are excluded from the search for subsequent matches. This behaviour is equivalent to the R algorithm for argument matching, except for the consideration of empty strings (which in argument matching are matched after exact and partial matching to any remaining arguments).

`charmatch` is similar to `pmatch` with `duplicates.ok` true, the differences being that it differentiates between no match and an ambiguous partial match, it does match empty strings, and it does not allow multiple exact matches.

NA values are treated as if they were the string constant "NA".
Value

A numeric vector of integers (including NA if nomatch = NA) of the same length as x, giving the indices of the elements in table which matched, or nomatch.

References

See Also

match, charmatch and match.arg, match.fun, match.call, for function argument matching etc., grep etc for more general (regexp) matching of strings.

Examples

pmatch("", ") # returns NA
pmatch("m", c("mean", "median", "mode")) # returns NA
pmatch("med", c("mean", "median", "mode")) # returns 2

pmatch(c("", "ab", "ab"), c("abc", "ab"), dup=FALSE)

pmatch(c("", "ab", "ab"), c("abc", "ab"), dup=TRUE)

## compare
charmatch(c("", "ab", "ab"), c("abc", "ab"))

polyroot

Find Zeros of a Real or Complex Polynomial

Description

Find zeros of a real or complex polynomial.

Usage

polyroot(z)

Arguments

z

the vector of polynomial coefficients in increasing order.

Details

A polynomial of degree \( n - 1 \),

\[ p(x) = z_1 + z_2 x + \cdots + z_n x^{n-1} \]

is given by its coefficient vector \( z[1:n] \). polyroot returns the \( n - 1 \) complex zeros of \( p(x) \) using the Jenkins-Traub algorithm.

If the coefficient vector \( z \) has zeroes for the highest powers, these are discarded.
Value

A complex vector of length \( n - 1 \), where \( n \) is the position of the largest non-zero element of \( z \).

References

See Also

`uniroot` for numerical root finding of arbitrary functions; `complex` and the `zero` example in the demos directory.

Examples

```r
polyroot(c(1, 2, 1))
round(polyroot(choose(8, 0:8)), 11) # guess what!
for (n1 in 1:4) print(polyroot(1:n1), digits = 4)
polyroot(c(1, 2, 1, 0, 0)) # same as the first
```

---

**pos.to.env**

Convert Positions in the Search Path to Environments

Description

Returns the environment at a specified position in the search path.

Usage

```r
pos.to.env(x)
```

Arguments

- `x` an integer between 1 and `length(search())`, the length of the search path.

Details

Several \( \text{R} \) functions for manipulating objects in environments (such as `get` and `ls`) allow specifying environments via corresponding positions in the search path. `pos.to.env` is a convenience function for programmers which converts these positions to corresponding environments; users will typically have no need for it.

Examples

```r
pos.to.env(1) # R_GlobalEnv
# the next returns the base environment
pos.to.env(length(search()))
```
pretty  

Pretty Breakpoints

Description

Compute a sequence of about \( n+1 \) equally spaced nice values which cover the range of the values in \( x \). The values are chosen so that they are 1, 2 or 5 times a power of 10.

Usage

\[
\text{pretty}(x, n = 5, \text{min.n} = n \%\% 3, \ \text{shrink.sml} = 0.75, \\
\text{high.u.bias} = 1.5, \ \text{u5.bias} = 0.5 + 1.5 \times \text{high.u.bias}, \\
\text{eps.correct} = 0)
\]

Arguments

- \( x \): numeric vector
- \( n \): integer giving the desired number of intervals. Non-integer values are rounded down.
- \( \text{min.n} \): nonnegative integer giving the minimal number of intervals. If \( \text{min.n} == 0 \), pretty(.) may return a single value.
- \( \text{shrink.sml} \): positive numeric by a which a default scale is shrunk in the case when \( \text{range}(x) \) is “very small” (usually 0).
- \( \text{high.u.bias} \): non-negative numeric, typically > 1. The interval unit is determined as \{1,2,5,10\} times \( b \), a power of 10. Larger \( \text{high.u.bias} \) values favor larger units.
- \( \text{u5.bias} \): non-negative numeric multiplier favoring factor 5 over 2. Default and “optimal”: \( \text{u5.bias} = 0.5 + 1.5 \times \text{high.u.bias} \).
- \( \text{eps.correct} \): integer code, one of \{0,1,2\}. If non-0, an “epsilon correction” is made at the boundaries such that the result boundaries will be outside \( \text{range}(x) \); in the small case, the correction is only done if \( \text{eps.correct} >= 2 \).

Details

pretty ignores non-finite values in \( x \).

Let \( d \leftarrow \max(x) - \min(x) \geq 0 \). If \( d \) is not (very close) to 0, we let \( c \leftarrow d/n \), otherwise more or less \( c \leftarrow \max(\text{abs}(\text{range}(x))) \times \text{shrink.sml} / \text{min.n} \). Then, the 10 base \( b \) is \( 10^{\lfloor \log_{10}(c) \rfloor} \) such that \( b \leq c < 10b \).

Now determine the basic unit \( u \) as one of \{1,2,5,10\} \( b \), depending on \( c/b \in [1,10) \) and the two “bias” coefficients, \( h = \text{high.u.bias} \) and \( f = \text{u5.bias} \).

References

See Also

`axTicks` for the computation of pretty axis tick locations in plots, particularly on the log scale.

Examples

```r
pretty(1:15)  # 0 2 4 6 8 10 12 14 16
pretty(1:15, h=2)# 0 5 10 15
pretty(1:15, n=4)# 0 5 10 15
pretty(1:15 * 2) # 0 5 10 15 20 25 30
pretty(1:20)   # 0 5 10 15 20
pretty(1:20, n=2) # 0 10 20
pretty(1:20, n=10)# 0 2 4 ... 20

for(k in 5:11) {
  cat("k=",k,"": "); print(diff(range(pretty(100 + c(0, pi*10^-k)))))}

##-- more bizarre, when min(x) == max(x):
pretty(pi)

add.names <- function(v) { names(v) <- paste(v); v}
str(lapply(add.names(-10:20), pretty))
str(lapply(add.names(0:20), pretty, min = 0))
sapply( add.names(0:20), pretty, min = 4)
```

```r
pretty(1.234e100)
pretty(1001.1001)
pretty(1001.1001, shrink = .2)
for(k in -7:3) {
  cat("shrink=",formatC(2^k,wid=9),":",
       formatC(pretty(1001.1001, shrink = 2^k), wid=6),"\n")
```

---

**Primitive**

Call a “Primitive” Internal Function

Description

`.Primitive` returns an entry point to a “primitive” (internally implemented) function.

Usage

`.Primitive(name)`

Arguments

name name of the R function.

Details

The advantage of `.Primitive` over `.Internal` functions is the potential efficiency of argument passing. However, this is done by ignoring argument names and using positional matching of arguments (unless arranged differently for specific primitives such as `rep`), so this is discouraged for functions of more than one argument.

All primitive functions are in the base name space.
See Also

.Internal.

Examples

mysqrt <- .Primitive("sqrt")
c.Internal # this one *must* be primitive!
get("if") # just 'if' or 'print(if)' are not syntactically ok.

print

Print Values

Description

print prints its argument and returns it invisibly (via invisible(x)). It is a generic function which means that new printing methods can be easily added for new classes.

Usage

print(x, ...)

## S3 method for class 'factor':
print(x, quote = FALSE, max.levels = NULL,
       width =getOption("width"), ...)

## S3 method for class 'table':
print(x, digits =getOption("digits"), quote = FALSE,
       na.print = "", zero.print = "0", justify = "none", ...)

Arguments

x an object used to select a method.

... further arguments passed to or from other methods.

quote logical, indicating whether or not strings should be printed with surrounding quotes.

max.levels integer, indicating how many levels should be printed for a factor; if 0, no extra "Levels" line will be printed. The default, NULL, entails choosing max.levels such that the levels print on one line of width width.

width only used when max.levels is NULL, see above.

digits minimal number of significant digits, see print.default.

na.print character string (or NULL) indicating NA values in printed output, see print.default.

zero.print character specifying how zeros (0) should be printed; for sparse tables, using "." can produce stronger results.

justify character indicating if strings should left- or right-justified or left alone, passed to format.
Details
The default method, `print.default` has its own help page. Use `methods("print")` to get all the methods for the `print` generic.

`print.factor` allows some customization and is used for printing `ordered` factors as well.
`print.table` for printing `tables` allows other customization.
See `noquote` as an example of a class whose main purpose is a specific `print` method.

References

See Also
The default method `print.default`, and help for the methods above; further options, `noquote`.
For more customizable (but cumbersome) printing, see `cat`, `format` or also `write`.

Examples
```
rs <- ts(1:20)#-- print is the "Default function" --> print.ts(.) is called
rr <- for(i in 1:3) print(1:i)
rr
```

```r
## Printing of factors
attenu$station ## 117 levels -> 'max.levels' depending on width

## ordered factors: levels "l1 < l2 < .."
esoph$agegp[1:12]
esoph$alcgp[1:12]

## Printing of sparse (contingency) tables
set.seed(521)
t1 <- round(abs(rt(200, df=1.8)))
t2 <- round(abs(rt(200, df=1.4)))
table(t1,t2) # simple
print(table(t1,t2), zero.print = ".")# nicer to read
```

---

**print.data.frame**  
**Printing Data Frames**

Description
Print a data frame.

Usage
```
## S3 method for class 'data.frame':
print(x, ..., digits = NULL, quote = FALSE, right = TRUE)
```
Arguments

x  object of class data.frame.

... optional arguments to print or plot methods.
digits the minimum number of significant digits to be used: see print.default.
quote logical, indicating whether or not entries should be printed with surrounding quotes.
right logical, indicating whether or not strings should be right-aligned. The default is right-alignment.

Details
This calls format which formats the data frame column-by-column, then converts to a character matrix and dispatches to the print method for matrices.

When quote = TRUE only the entries are quoted not the row names nor the column names.

See Also
data.frame.

print.default      Default Printing

Description
print.default is the default method of the generic print function which prints its argument.

Usage
## Default S3 method:
print(x, digits = NULL, quote = TRUE, na.print = NULL,
     print.gap = NULL, right = FALSE, max = NULL, useSource = TRUE, ...)

Arguments

x  the object to be printed.
digits a non-null value for digits specifies the minimum number of significant digits to be printed in values. The default, NULL, usesgetOption(digits). (For the interpretation for complex numbers see signif.) Non-integer values will be rounded down, and only values greater than or equal to one are accepted.
quote logical, indicating whether or not strings (characters) should be printed with surrounding quotes.
na.print a character string which is used to indicate NA values in printed output, or NULL (see Details)
print.gap a non-negative integer ≤ 1024, or NULL (meaning 1), giving the spacing between adjacent “columns” in printed vectors, matrices and arrays.
right logical, indicating whether or not strings should be right aligned. The default is left alignment.
**print.default**

- **max**
  - A non-null value for `max` specifies the approximate maximum number of entries to be printed. The default, `NULL`, uses `getOption(max.print)`; see that help page for more details.

- **useSource**
  - Logical, indicating whether to use source references or copies rather than deparsing language objects. The default is to use the original source if it is available.

- **...**
  - Further arguments to be passed to or from other methods. They are ignored in this function.

**Details**

The default for printing `NA`s is to print `NA` (without quotes) unless this is a character `NA` and `quote = FALSE`, when `<NA>` is printed.

The same number of decimal places is used throughout a vector. This means that `digits` specifies the minimum number of significant digits to be used, and that at least one entry will be encoded with that minimum number. However, if all the encoded elements then have trailing zeroes, the number of decimal places is reduced until at least one element has a non-zero final digit. Decimal points are only included if at least one decimal place is selected.

Attributes are printed respecting their class(es), using the values of `digits` to `print.default`, but using the default values (for the methods called) of the other arguments.

When the **methods** package is attached, `print` will call `show` for R objects with formal classes if called with no optional arguments.

**Warning**

Using too large a value of `digits` may lead to representation errors in the calculation of the number of significant digits and the decimal representation: these are likely for `digits >= 16`, and as from R 2.5.0 these possible errors are taken into account in assessing the number of significant digits to be printed in that case.

Whereas earlier versions of R might have printed further digits for `digits >= 16` on some platforms, they were not necessarily reliable.

**Single-byte locales**

If a non-printable character is encountered during output, it is represented as one of the ANSI escape sequences (`a`, `b`, `f`, `n`, `r`, `t`, `v`, `\` and `0`; see **Quotes**), or failing that as a 3-digit octal code: for example the UK currency pound sign in the C locale (if implemented correctly) is printed as `243`. Which characters are non-printable depends on the locale.

**Unicode and other multi-byte locales**

In all locales, the characters in the ASCII range (`0x00` to `0x7f`) are printed in the same way, as-is if printable, otherwise via ANSI escape sequences or 3-digit octal escapes as described for single-byte locales.
Multi-byte non-printing characters are printed as an escape sequence of the form \uxxxx or \Uxxxxxxxx (in hexadecimal). This is the internal code for the wide-character representation of the character. If this is not known to be the Unicode point, a warning is issued. The only known exceptions are certain Japanese ISO2022 locales on commercial Unixes, which use a concatenation of the bytes: it is unlikely that R compiles on such a system.

It is possible to have a character string in a character vector that is not valid in the current locale. If a byte is encountered that is not part of a valid character it is printed in hex in the form \xab and this is repeated until the start of a valid character. (This will rapidly recover from minor errors in UTF-8.)

See Also

The generic \texttt{print}, \texttt{options}. The "\texttt{noquote}" class and print method. \texttt{encodeString}, which encodes a character vector the way it would be printed.

Examples

\begin{verbatim}
pi
print(pi, digits = 16)
LETTERS[1:16]
print(LETTERS, quote = FALSE)

M <- cbind(I=1, matrix(1:10000, nc=10, dimnames=list(NULL, LETTERS[1:10])))
head(M) # makes more sense than
print(M, max= 1000)# prints 90 rows and a message about omitting 910
\end{verbatim}

---

\texttt{prmatrix} \hspace{1cm} Print Matrices, Old-style

Description

An earlier method for printing matrices, provided for S compatibility.

Usage

\begin{verbatim}
prmatrix(x, rowlab =, collab =,
quote = TRUE, right = FALSE, na.print = NULL, ...)
\end{verbatim}

Arguments

\begin{itemize}
  \item \texttt{x} \hspace{1cm} numeric or character matrix.
  \item \texttt{rowlab}, \texttt{collab} \hspace{1cm} (optional) character vectors giving row or column names respectively. By default, these are taken from \texttt{dimnames(x)}.
  \item \texttt{quote} \hspace{1cm} logical; if \texttt{TRUE} and \texttt{x} is of mode "character", \texttt{quotes (\texttt{"})} are used.
  \item \texttt{right} \hspace{1cm} if \texttt{TRUE} and \texttt{x} is of mode "character", the output columns are \texttt{right}-justified.
  \item \texttt{na.print} \hspace{1cm} how NAs are printed. If this is non-null, its value is used to represent NA.
  \item \texttt{...} \hspace{1cm} arguments for \texttt{print} methods.
\end{itemize}
Details

prmatrix is an earlier form of print.matrix, and is very similar to the S function of the same name.

Value

Invisibly returns its argument, x.

References

See Also

print.default, and other print methods.

Examples

prmatrix(m6 <- diag(6), row = rep("",6), coll=rep("",6))

chm <- matrix(scan(system.file("help", "AnIndex", package = "splines"), what = ""), , 2, byrow = TRUE)
chm # uses print.matrix()
prmatrix(chm, collab = paste("Column",1:3), right=TRUE, quote=FALSE)

proc.time  Running Time of R

Description

proc.time determines how much real and CPU time (in seconds) the currently running R process has already taken.

Usage

proc.time()

Details

proc.time returns five elements for backwards compatibility, but as from R 2.5.0 its print method prints a named vector of length 3. The first two entries are the total user and system CPU times of the current R process and any child processes on which it has waited, and the third entry is the ‘real’ elapsed time since the process was started.
Value
An object of class "proc_time" which is a numeric vector of length 5, containing the user, system, and total elapsed times for the currently running R process, and the cumulative sum of user and system times of any child processes spawned by it on which it has waited. (The print method combines the child times with those of the main process.)

The resolution of the times will be system-specific and times are rounded to the nearest 1ms. On modern systems they will be that accurate, but on older systems they might be accurate to 1/100 or 1/60 sec.

It is most useful for “timing” the evaluation of R expressions, which can be done conveniently with system.time.

Note
It is possible to compile R without support for proc.time, when the function will throw an error.

References

See Also
system.time for timing a valid R expression, gc.time for how much of the time was spent in garbage collection.

Examples
## Not run:
## a way to time an R expression: system.time is preferred
ptm <- proc.time()
for (i in 1:50) mad(runif(500))
proc.time() - ptm
## End(Not run)

prod

Product of Vector Elements

Description
prod returns the product of all the values present in its arguments.

Usage
prod(..., na.rm = FALSE)

Arguments
... numeric or complex or logical vectors.
na.rm logical. Should missing values be removed?
prop.table

Details

If `na.rm` is FALSE an NA value in any of the arguments will cause a value of NA to be returned, otherwise NA values are ignored.

This is a generic function: methods can be defined for it directly or via the `Summary` group generic. For this to work properly, the arguments ... should be unnamed, and dispatch is on the first argument.

Logical true values are regarded as one, false values as zero. For historical reasons, `NULL` is accepted and treated as if it were `numeric(0)`.

Value

The product, a numeric (of type "double") or complex vector of length one. **NB:** the product of an empty set is one, by definition.

References

See Also

`sum`, `cumprod`, `cumsum`.

Examples

```
print(prod(1:7)) == print(gamma(8))
```

prop.table

*Express Table Entries as Fraction of Marginal Table*

Description

This is really `sweep(x, margin, margin.table(x, margin), "/")` for newbies, except that if `margin` has length zero, then one gets `x/sum(x)`.

Usage

```
prop.table(x, margin=NULL)
```

Arguments

- `x` table
- `margin` index, or vector of indices to generate margin for

Value

Table like `x` expressed relative to `margin`

Author(s)

Peter Dalgaard
pushBack

**pushBack**

*Push Text Back on to a Connection*

**Description**

Functions to push back text lines onto a connection, and to enquire how many lines are currently pushed back.

**Usage**

```r
pushBack(data, connection, newLine = TRUE)
pushBackLength(connection)
```

**Arguments**

- `data`: a character vector.
- `connection`: A connection.
- `newLine`: logical. If true, a newline is appended to each string pushed back.

**Details**

Several character strings can be pushed back on one or more occasions. The occasions form a stack, so the first line to be retrieved will be the first string from the last call to `pushBack`. Lines which are pushed back are read prior to the normal input from the connection, by the normal text-reading functions such as `readLines` and `scan`.

Pushback is only allowed for readable connections.

Not all uses of connections respect pushbacks, in particular the input connection is still wired directly, so for example parsing commands from the console and `scan("\n")` ignore pushbacks on `stdin`.

**Value**

- `pushBack` returns nothing.
- `pushBackLength` returns number of lines currently pushed back.

**See Also**

`connections`, `readLines`. 

**Examples**

```r
m <- matrix(1:4, 2)
m
prop.table(m, 1)
```
Examples

```r
zz <- textConnection(LETTERS)
readLines(zz, 2)
pushBack(c("aa", "bb"), zz)
pushBackLength(zz)
readLines(zz, 1) # Example: read 1 line from the connection
pushBackLength(zz)
readLines(zz, 1) # Example: read 1 line from the connection
readLines(zz, 1)
close(zz)
```

---

**qr**

*The QR Decomposition of a Matrix*

**Description**

* `qr` computes the QR decomposition of a matrix. It provides an interface to the techniques used in the LINPACK routine DQRDC or the LAPACK routines DGEQP3 and (for complex matrices) ZGEQP3.

**Usage**

```r
qr(x, tol = 1e-07 , LAPACK = FALSE)
qr.coef(qr, y)
qr.qy(qr, y)
qr.qty(qr, y)
qr.resid(qr, y)
qr.fitted(qr, y, k = qr$rank)
qr.solve(a, b, tol = 1e-7)
# S3 method for class 'qr':
solve(a, b, ...)
```

**Arguments**

- **x**        a matrix whose QR decomposition is to be computed.
- **tol**      the tolerance for detecting linear dependencies in the columns of x. Only used if LAPACK is false and x is real.
- **qr**       a QR decomposition of the type computed by qr.
- **y, b**     a vector or matrix of right-hand sides of equations.
- **a**        A QR decomposition or (qr.solve only) a rectangular matrix.
- **k**        effective rank.
- **LAPACK**   logical. For real x, if true use LAPACK otherwise use LINPACK.
- **...**      further arguments passed to or from other methods
Details

The QR decomposition plays an important role in many statistical techniques. In particular it can
be used to solve the equation \( Ax = b \) for given matrix \( A \), and vector \( b \). It is useful for computing
regression coefficients and in applying the Newton-Raphson algorithm.

The functions \( \text{qr.coef} \), \( \text{qr.resid} \), and \( \text{qr.fitted} \) return the coefficients, residuals and fitted
values obtained when fitting \( y \) to the matrix with QR decomposition \( qr \). \( \text{qr.qy} \) and \( \text{qr.qty} \)
return \( Q \%*% y \) and \( t(Q) \%*% y \), where \( Q \) is the (complete) \( Q \) matrix.

All the above functions keep \text{dimnames} (and \text{names}) of \( x \) and \( y \) if there are.

\( \text{solve.qr} \) is the method for \( \text{solve} \) for \( qr \) objects. \( \text{qr.solve} \) solves systems of equations
via the QR decomposition: if \( a \) is a QR decomposition it is the same as \( \text{solve.qr} \), but if \( a \) is
a rectangular matrix the QR decomposition is computed first. Either will handle over- and under-
determined systems, providing a minimal-length solution or a least-squares fit if appropriate.

\( \text{is.qr} \) returns \( \text{TRUE} \) if \( x \) is a \text{list} with components named \( qr \), \text{rank} and \text{qraux} and \text{FALSE}
otherwise.

It is not possible to coerce objects to mode "\( qr \)". Objects either are QR decompositions or they
are not.

Value

The QR decomposition of the matrix as computed by LINPACK or LAPACK. The components in
the returned value correspond directly to the values returned by DQRDC/DGEQP3/ZGEQP3.

\( qr \) a matrix with the same dimensions as \( x \). The upper triangle contains the \( R \) of
the decomposition and the lower triangle contains information on the \( Q \) of
the decomposition (stored in compact form). Note that the storage used by DQRDC
and DGEQP3 differs.

\( \text{qraux} \) a vector of length \( \text{ncol}(x) \) which contains additional information on \( Q \).

\( \text{rank} \) the rank of \( x \) as computed by the decomposition: always full rank in the LA-
PACK case.

\( \text{pivot} \) information on the pivoting strategy used during the decomposition.

Non-complex QR objects computed by LAPACK have the attribute "\text{useLAPACK}" with value
\( \text{TRUE} \).

Note

To compute the determinant of a matrix (do you really need it?), the QR decomposition is much
more efficient than using Eigen values (\text{eigen}). See \text{det}.

Using LAPACK (including in the complex case) uses column pivoting and does not attempt to
detect rank-deficient matrices.

QR.Auxiliaries

See Also

`det` (using `qr`) to compute the determinant of a matrix.

Examples

```r
hilbert <- function(n) { i <- 1:n; 1 / outer(i - 1, i, "+") }
h9 <- hilbert(9); h9
qr(h9)$rank  #--> only 7
qrh9 <- qr(h9, tol = 1e-10)
qrh9$rank    #--> 9
##-- Solve linear equation system H %*% x = y :
y <- 1:9/10
x <- qr.solve(h9, y, tol = 1e-10)  # or equivalently :
x <- qr.coef(qrh9, y)  #-- is == but much better than
                      #-- solve(h9) %*% y
h9 %*% x             # = y
```

QR.Auxiliaries Reconstruct the Q, R, or X Matrices from a QR Object

Description

Returns the original matrix from which the object was constructed or the components of the decomposition.

Usage

```r
qr.X(qr, complete = FALSE, ncol =)
qr.Q(qr, complete = FALSE, Dvec =)
qr.R(qr, complete = FALSE)
```

Arguments

- **qr** object representing a QR decomposition. This will typically have come from a previous call to `qr` or `lsfit`.
- **complete** logical expression of length 1. Indicates whether an arbitrary orthogonal completion of the Q or X matrices is to be made, or whether the R matrix is to be completed by binding zero-value rows beneath the square upper triangle.
- **ncol** integer in the range 1:nrow(qr$qr). The number of columns to be in the reconstructed X. The default when `complete` is `FALSE` is the first `min(ncol(X), nrow(X))` columns of the original X from which the qr object was constructed. The default when `complete` is `TRUE` is a square matrix with the original X in the first `ncol(X)` columns and an arbitrary orthogonal completion (unitary completion in the complex case) in the remaining columns.
- **Dvec** vector (not matrix) of diagonal values. Each column of the returned Q will be multiplied by the corresponding diagonal value. Defaults to all 1s.
Value

qr.X returns X, the original matrix from which the qr object was constructed, provided ncol(X) <= nrow(X). If complete is TRUE or the argument ncol is greater than ncol(X), additional columns from an arbitrary orthogonal (unitary) completion of X are returned.

qr.Q returns part or all of Q, the order-nrow(X) orthogonal (unitary) transformation represented by qr. If complete is TRUE, Q has nrow(X) columns. If complete is FALSE, Q has ncol(X) columns. When Dvec is specified, each column of Q is multiplied by the corresponding value in Dvec.

qr.R returns R. The number of rows of R is nrow(X) or ncol(X), depending on whether complete is TRUE or FALSE.

See Also

qr, qr.qy.

Examples

p <- ncol(x <- LifeCycleSavings[, -1]) # not the 'sr'
qrstr <- qr(x) # dim(x) == c(n,p)
qrstr $ rank # = 4 = p
Q <- qr.Q(qrstr) # dim(Q) == dim(x)
R <- qr.R(qrstr) # dim(R) == ncol(x)
X <- qr.X(qrstr) # X == x
range(X - as.matrix(x)) # ~ < 6e-12
## X == Q %*% R if there has been no pivoting, as here.
Q %*% R

Description

The function quit or its alias q terminate the current R session.

Usage

quit(save = "default", status = 0, runLast = TRUE)
q(save = "default", status = 0, runLast = TRUE)
.Last <- function(x) { ...... }

Arguments

save a character string indicating whether the environment (workspace) should be saved, one of "no", "yes", "ask" or "default".

status the (numerical) error status to be returned to the operating system, where relevant. Conventionally 0 indicates successful completion.

runLast should .Last() be executed?
Details
save must be one of "no", "yes", "ask" or "default". In the first case the workspace is not saved, in the second it is saved and in the third the user is prompted and can also decide not to quit. The default is to ask in interactive use but may be overridden by command-line arguments (which must be supplied in non-interactive use).

Immediately before terminating, the function .Last() is executed if it exists and runLast is true. If in interactive use there are errors in the .Last function, control will be returned to the command prompt, so do test the function thoroughly. There is a system analogue, .Last.sys(), which is run after .Last() if runLast is true.

Some error statuses are used by \texttt{R} itself. The default error handler for non-interactive use effectively calls \texttt{q("no", 1, FALSE)} and returns error code 1. Error status 2 is used for R 'suicide', that is a catastrophic failure, and other small numbers are used by specific ports for initialization failures. It is recommended that users choose statuses of 10 or more.

Valid values of status are system-dependent, but 0:255 are normally valid.

References

See Also
.proc for setting things on startup.

Examples
## Not run:
## Unix-flavour example
.Last <- function()
  cat("Now sending PostScript graphics to the printer:\n")
  system("lpr Rplots.ps")
  cat("bye bye...\n")
} quit("yes")
## End(Not run)
Character constants

Single and double quotes delimit character constants. They can be used interchangeably but double quotes are preferred (and character constants are printed using double quotes), so single quotes are normally only used to delimit character constants containing double quotes.

Backslash is used to start an escape sequence inside character constants. Unless specified in the following table, an escaped character is interpreted as the character itself. (Note that the parser will warn about most such uses as from \R 2.5.0, as they are most often erroneous, e.g. using \., where \\\. was intended.)

Single quotes need to be escaped by backslash in single-quoted strings, and double quotes in double-quoted strings.

\n newline
\r carriage return
\t tab
\b backspace
\a alert (bell)
\f form feed
\v vertical tab
\ backslash \ 
\nnn character with given octal code (1, 2 or 3 digits)
\xnn character with given hex code (1 or 2 hex digits)
\unnnn Unicode character with given code (1–4 hex digits)
\Unnnnnnnn Unicode character with given code (1–8 hex digits)

The last two are only supported on versions of \R built with MBCS support, and the last is not supported on Windows. (They are an error if used where not supported.) All except the Unicode escape sequences are also supported when reading character strings by \scan and \read.table if allowEscapes = TRUE.

These forms will also be used by \print.default when outputting non-printable characters (including backslash).

Names and Identifiers

Identifiers consist of a sequence of letters, digits, the period (.) and the underscore. They must not start with a digit nor underscore, nor with a period followed by a digit.

The definition of a letter depends on the current locale, but only ASCII digits are considered to be digits.

Such identifiers are also known as syntactic names and may be used directly in \R code. Almost always, other names can be used provided they are quoted. The preferred quote is the backtick (‘), and deparse will normally use it, but under many circumstances single or double quotes can be used (as a character constant will often be converted to a name). One place where backticks may be essential is to delimit variable names in formulae: see \formula.

See Also

\Syntax for other aspects of the syntax.
\sQuote for quoting English text.
\shQuote for quoting OS commands.

The \R Language Definition manual.
Description

Return the R home directory.

Usage

R.home(component="home")

Arguments

component  As well as "home" which gives the R home directory, other known values are "bin", "doc", "etc" and "share" giving the paths to the corresponding parts of an R installation.

Details

The R home directory is the top-level directory of the R installation being run.

The R home directory is often referred to as R_HOME, and is the value of an environment variable of that name in an R session. It can be found outside an R session by R RHOME.

Value

A character string giving the R home directory or path to a particular component. Normally the components are all subdirectories of the R home directory, but this may not be the case in a Unix-like installation.

Description

R.Version() provides detailed information about the version of R running.

R.version is a variable (a list) holding this information (and version is a copy of it for S compatibility).

Usage

R.Version()
R.version
R.version.string
version
Value

`R.Version` returns a list with character-string components

- **platform** the platform for which \( R \) was built. A triplet of the form `CPU-VENDOR-OS`, as determined by the configure script. E.g., "i586-unknown-linux" or "i386-pc-mingw32".
- **arch** the architecture (CPU) \( R \) was built on/for.
- **os** the underlying operating system
- **system** CPU and OS, separated by a comma.
- **status** the status of the version (e.g., "Alpha")
- **major** the major version number
- **minor** the minor version number, including the patchlevel
- **year** the year the version was released
- **month** the month the version was released
- **day** the day the version was released
- **svn rev** the Subversion revision number, which should be either "unknown" or a single number. (A range of numbers or a number with ‘M’ or ‘S’ appended indicates inconsistencies in the sources used to build this version of \( R \).)
- **language** always "R".
- **version.string** a character string concatenating some of the info above, useful for plotting, etc.

`R.version` and `version` are lists of class "simple.list" which has a print method.

Note

Do not use `R.version$os` to test the platform the code is running on: use `.Platform$OS.type` instead. Slightly different versions of the OS may report different values of `R.version$os`, as may different versions of \( R \).

`R.version.string` is a copy of `R.version$version.string` for simplicity and backwards compatibility.

See Also

`sessionInfo` which provides additional information; `getRversion`, `.Platform`

Examples

```r
R.version$os # to check how lucky you are ...
plot(0) # any plot
mtext(R.version.string, side=1, line=4, adj=1)# a useful bottom-right note
```
Random Number Generation

Description

.Random.seed is an integer vector, containing the random number generator (RNG) state for random number generation in R. It can be saved and restored, but should not be altered by the user.

RNGkind is a more friendly interface to query or set the kind of RNG in use.

RNGversion can be used to set the random generators as they were in an earlier R version (for reproducibility).

set.seed is the recommended way to specify seeds.

Usage

.Random.seed <- c(rng.kind, n1, n2, ...)
save.seed <- .Random.seed

RNGkind(kind = NULL, normal.kind = NULL)
RNGversion(vstr)
set.seed(seed, kind = NULL)

Arguments

kind character or NULL. If kind is a character string, set R’s RNG to the kind desired. If it is NULL, return the currently used RNG. Use "default" to return to the R default.

normal.kind character string or NULL. If it is a character string, set the method of Normal generation. Use "default" to return to the R default.

seed a single value, interpreted as an integer.

vstr a character string containing a version number, e.g., "1.6.2"

rng.kind integer code in 0:k for the above kind.

n1, n2, ... integers. See the details for how many are required (which depends on rng.kind).

Details

The currently available RNG kinds are given below. kind is partially matched to this list. The default is "Mersenne-Twister".

"Wichmann-Hill" The seed, .Random.seed[-1] == r[1:3] is an integer vector of length 3, where each r[i] is in 1:(p[i] - 1), where p is the length 3 vector of primes, p = (30269, 30307, 30323). The Wichmann-Hill generator has a cycle length of \(6.9536 \times 10^{12} = \prod_{p-1}/4\), see Applied Statistics (1984) 33, 123 which corrects the original article.

"Marsaglia-Multicarry": A multiply-with-carry RNG is used, as recommended by George Marsaglia in his post to the mailing list ‘sci.stat.math’. It has a period of more than \(2^{60}\) and has passed all tests (according to Marsaglia). The seed is two integers (all values allowed).
"Super-Duper": Marsaglia’s famous Super-Duper from the 70’s. This is the original version which does not pass the MTUPLE test of the Diehard battery. It has a period of \( \approx 4.6 \times 10^{18} \) for most initial seeds. The seed is two integers (all values allowed for the first seed: the second must be odd).

We use the implementation by Reeds et al. (1982–84).

The two seeds are the Tausworthe and congruence long integers, respectively. A one-to-one mapping to S’s `Random.seed[1:12]` is possible but we will not publish one, not least as this generator is not exactly the same as that in recent versions of S-PLUS.

"Mersenne-Twister": From Matsumoto and Nishimura (1998). A twisted GFSR with period \( 2^{19937} - 1 \) and equidistribution in 623 consecutive dimensions (over the whole period). The "seed" is a 624-dimensional set of 32-bit integers plus a current position in that set.

"Knuth-TAOCP": From Knuth (1997). A GFSR using lagged Fibonacci sequences with subtraction. That is, the recurrence used is

\[
X_j = (X_{j-100} - X_{j-37}) \mod 2^{30}
\]

and the "seed" is the set of the 100 last numbers (actually recorded as 101 numbers, the last being a cyclic shift of the buffer). The period is around \( 2^{129} \).

"Knuth-TAOCP-2002": The 2002 version which not backwards compatible with the earlier version: the initialization of the GFSR from the seed was altered. R did not allow you to choose consecutive seeds, the reported ‘weakness’, and already scrambled the seeds.

"user-supplied": Use a user-supplied generator. See `Random.user` for details.

The `normal.kind` can be "Kinderman-Ramage", "Buggy Kinderman-Ramage", "Ahrens-Dieter", "Box-Muller", "Inversion" (the default), or "user-supplied". (For inversion, see the reference in `qnorm`.) The Kinderman-Ramage generator used in versions prior to 1.7.1 had several approximation errors and should only be used for reproduction of older results.

`set.seed` uses its single integer argument to set as many seeds as are required. It is intended as a simple way to get quite different seeds by specifying small integer arguments, and also as a way to get valid seed sets for the more complicated methods (especially "Mersenne-Twister" and "Knuth-TAOCP").

Value

`.Random.seed` is an `integer` vector whose first element codes the kind of RNG and normal generator. The lowest two decimal digits are in 0:(k-1) where k is the number of available RNGs. The hundreds represent the type of normal generator (starting at 0).

In the underlying C, `.Random.seed[-1]` is `unsigned`; therefore in R `.Random.seed[-1]` can be negative, due to the representation of an unsigned integer by a signed integer.

`RNGkind` returns a two-element character vector of the RNG and normal kinds in use before the call, invisibly if either argument is not `NULL`. `RNGversion` returns the same information.

`set.seed` returns `NULL`, invisibly.

Note

Initially, there is no seed; a new one is created from the current time when one is required. Hence, different sessions will give different simulation results, by default.

`.Random.seed` saves the seed set for the uniform random-number generator, at least for the system generators. It does not necessarily save the state of other generators, and in particular does
not save the state of the Box–Muller normal generator. If you want to reproduce work later, call `set.seed` rather than `set.Random.seed`.

The object `.Random.seed` is only looked for in the user’s workspace.

All the supplied uniform generators return 32-bit integer values that are converted to doubles, so they take at most $2^{32}$ distinct values and long runs will return duplicated values.

Examples

```r
## the default random seed is 626 integers, so only print a few
runif(1); .Random.seed[1:6]; runif(1); .Random.seed[1:6]

## If there is no seed, a "random" new one is created:
rm(.Random.seed); runif(1); .Random.seed[1:6]
```
RNGkind("Wich")# (partial string matching on 'kind')

## This shows how 'runif(.)' works for Wichmann-Hill,
## using only R functions:

p.WH <- c(30269, 30307, 30323)
a.WH <- c(171, 172, 170)
next.WHseed <- function(i.seed = .Random.seed[-1])
  { (a.WH * i.seed) %% p.WH }
my.runif1 <- function(i.seed = .Random.seed)
  { ns <- next.WHseed(i.seed[-1]); sum(ns / p.WH) %% 1 }
rs <- .Random.seed
(WHs <- next.WHseed(rs[-1]))
u <- runif(1)
stopifnot(
  next.WHseed(rs[-1]) == .Random.seed[-1],
  all.equal(u, my.runif1(rs))
)

## ----
 Random.seed
ok <- RNGkind()
RNGkind("Super")#matches "Super-Duper"
RNGkind()
.Random.seed # new, corresponding to Super-Duper

## Reset:
RNGkind(ok[1])

## ----
sum(duplicated(runif(1e6))) # around 110
## and we would expect about almost sure duplicates beyond about
qbirthday(1-1e-6, classes=2e9) # 235,000

Random.user

### User-supplied Random Number Generation

**Description**

Function **RNGkind** allows user-coded uniform and normal random number generators to be supplied. The details are given here.

**Details**

A user-specified uniform RNG is called from entry points in dynamically-loaded compiled code. The user must supply the entry point **user_unif_rand**, which takes no arguments and returns a pointer to a double. The example below will show the general pattern.

Optionally, the user can supply the entry point **user_unif_init**, which is called with an unsigned int argument when **RNGkind** (or **set.seed**) is called, and is intended to be used to initialize the user’s RNG code. The argument is intended to be used to set the “seeds”; it is the seed argument to **set.seed** or an essentially random seed if **RNGkind** is called.

If only these functions are supplied, no information about the generator’s state is recorded in **.Random.seed**. Optionally, functions **user_unif_nseed** and **user_unif_seedloc** can
be supplied which are called with no arguments and should return pointers to the number of “seeds” and to an integer array of “seeds”. Calls to `GetRNGstate` and `PutRNGstate` will then copy this array to and from `.Random.seed`.

A user-specified normal RNG is specified by a single entry point `user_norm_rand`, which takes no arguments and returns a pointer to a double.

**Warning**

As with all compiled code, mis-specifying these functions can crash R. Do include the ‘`R_ext/Random.h`’ header file for type checking.

**Examples**

```c
## Not run:
## Marsaglia's congruential PRNG
#include <R_ext/Random.h>

static Int32 seed;
static double res;
static int nseed = 1;

double * user_unif_rand()
{
    seed = 69069 * seed + 1;
    res = seed * 2.32830643653869e-10;
    return &res;
}

void user_unif_init(Int32 seed_in) { seed = seed_in; }
int * user_unif_nseed() { return &nseed; }
int * user_unif_seedloc() { return (int *) &seed; }

/* ratio-of-uniforms for normal */
#include <math.h>
static double x;

double * user_norm_rand()
{
    double u, v, z;
    do {
        u = unif_rand();
        v = 0.857764 * (2. * unif_rand() - 1);
        x = v/u; z = 0.25 * x * x;
        if (z < 1. - u) break;
        if (z > 0.259/u + 0.35) continue;
    } while (z > -log(u));
    return &x;
}

## Use under Unix:
R CMD SHLIB urand.c
R> dyn.load("urand.so")
> RNGkind("user")
> runif(10)
> .Random.seed
```
> RNGkind(, "user")
> rnorm(10)
> RNGkind()
[1] "user-supplied" "user-supplied"
## End(Not run)

**range**

**Range of Values**

**Description**

`range` returns a vector containing the minimum and maximum of all the given arguments.

**Usage**

`range(..., na.rm = FALSE)`

## Default S3 method:
`range(..., na.rm = FALSE, finite = FALSE)`

**Arguments**

- `...` any numeric or character objects.
- `na.rm` logical, indicating if NA’s should be omitted.
- `finite` logical, indicating if all non-finite elements should be omitted.

**Details**

`range` is a generic function: methods can be defined for it directly or via the `Summary` group generic. For this to work properly, the arguments ... should be unnamed, and dispatch is on the first argument.

If `na.rm` is FALSE, NA and NaN values in any of the arguments will cause NA values to be returned, otherwise NA values are ignored.

If `finite` is TRUE, the minimum and maximum of all finite values is computed, i.e., `finite=TRUE includes na.rm=TRUE`.

A special situation occurs when there is no (after omission of NAs) nonempty argument left, see `min`.

**References**

**See Also**

The `extendrange()` utility; `min`, `max`, `Methods`. 
Examples

```r
(r.x <- range(rnorm(100)))
diff(r.x) # the SAMPLE range

x <- c(NA, 1:3, -1:1/0); x
range(x)
range(x, na.rm = TRUE)
range(x, finite = TRUE)
```

---

### rank

#### Sample Ranks

**Description**

Returns the sample ranks of the values in a vector. Ties (i.e., equal values) and missing values can be handled in several ways.

**Usage**

```r
rank(x, na.last = TRUE,
     ties.method = c("average", "first", "random", "max", "min"))
```

**Arguments**

- `x` a numeric, complex, character or logical vector.
- `na.last` for controlling the treatment of `NA`s. If `TRUE`, missing values in the data are put last; if `FALSE`, they are put first; if `NA`, they are removed; if "keep" they are kept with rank NA.
- `ties.method` a character string specifying how ties are treated, see below; can be abbreviated.

**Details**

If all components are different (and no NA's), the ranks are well defined, with values in `seq_len(x)`. With some values equal (called 'ties'), the argument `ties.method` determines the result at the corresponding indices. The "first" method results in a permutation with increasing values at each index set of ties. The "random" method puts these in random order whereas the default, "average", replaces them by their mean, and "max" and "min" replaces them by their maximum and minimum respectively, the latter being the typical "sports" ranking.

NA values are never considered to be equal: for `na.last = TRUE` and `na.last = FALSE` they are given distinct ranks in the order in which they occur in `x`.

**References**

**See Also**

`order` and `sort`. 
Examples

(r1 <- rank(x1 <- c(3, 1, 4, 15, 92)))
x2 <- c(3, 1, 4, 1, 5, 9, 2, 6, 5, 3, 5)
names(x2) <- letters[1:11]
(r2 <- rank(x2)) # ties are averaged

## rank() is "idempotent": rank(rank(x)) == rank(x)
stopifnot(rank(r1) == r1, rank(r2) == r2)

## ranks without averaging
rank(x2, ties.method= "first") # first occurrence wins
rank(x2, ties.method= "random") # ties broken at random
rank(x2, ties.method= "random") # and again

## keep ties ties, no average
(rma <- rank(x2, ties.method= "max")) # as used classically
(rmi <- rank(x2, ties.method= "min")) # as in Sports
stopifnot(rma + rmi == round(r2 + r2))

rapply

Recursively Apply a Function to a List

Description

rapply is a recursive version of `lapply`.

Usage

rapply(object, f, classes = "ANY", deflt = NULL,
how = c("unlist", "replace", "list"), ...)

Arguments

object A list.
f A function of a single argument.
classes A character vector of `class` names, or "ANY" to match any class.
deflt The default result (not used if `how = "replace"`).
how A character string matching the three possibilities given: see Details.
... additional arguments passed to the call to `f`.

Details

This function has two basic modes. If `how = "replace"`, each element of the list which is not itself a list and has a class included in `classes` is replaced by the result of applying `f` to the element.

If the mode is `how = "list"` or `how = "unlist"`, the list is copied, all non-list elements which have a class included in `classes` are replaced by the result of applying `f` to the element and all others are replaced by `deflt`. Finally, if `how = "unlist"`, `unlist(recursive = TRUE)` is called on the result.

The semantics differ in detail from `lapply`: in particular the arguments are evaluated before calling the C code.
Value

If how = "unlist", a vector, otherwise a list of similar structure to object.

References

(rapply is only described briefly there.)

See Also

lapply, dendrapply.

Examples

X <- list(list(a=pi, b=list(c=1:1)), d="a test")
rapply(X, function(x) x, how="replace")
rapply(X, sqrt, classes="numeric", how="replace")
rapply(X, nchar, classes="character", deflt = as.integer(NA), how="list")
rapply(X, nchar, classes="character", deflt = as.integer(NA), how="unlist")
rapply(X, log, classes="numeric", how="replace", base=2)

raw

Raw Vectors

Description

Creates or tests for objects of type "raw".

Usage

raw(length = 0)
as.raw(x)
is.raw(x)

Arguments

length      desired length.
x           object to be coerced.

Details

The raw type is intended to hold raw bytes. It is possible to extract subsequences of bytes, and to replace elements (but only by elements of a raw vector). The relational operators (see Comparison) work, as do the logical operators (see Logic) with a bitwise interpretation.

A raw vector is printed with each byte separately represented as a pair of hex digits. If you want to see a character representation (with escape sequences for non-printing characters) use rawToChar. Coercion to raw treats the input values as representing a small (decimal) integers, so the input is first coerced to integer, and then values which are outside the range [0 ... 255] or are NA are set to 0 (the nul byte).
Value

\texttt{raw} creates a raw vector of the specified length. Each element of the vector is equal to 0. Raw vectors are used to store fixed-length sequences of bytes.

\texttt{as.raw} attempts to coerce its argument to be of raw type. The (elementwise) answer will be 0 unless the coercion succeeds.

\texttt{is.raw} returns true if and only if \texttt{typeof(x) == "raw"}.

See Also

\texttt{charToRaw, rawShift, etc.}

Examples

\begin{verbatim}
xx <- raw(2)
xx[1] <- as.raw(40)  # NB, not just 40.
xx[2] <- charToRaw("A")
xx

x <- "A test string"
(y <- charToRaw(x))
is.vector(y)  # TRUE
rawToChar(y)
is.raw(x)
is.raw(y)

isASCII <- function(txt) all(charToRaw(txt) <= as.raw(127))
isASCII(x)  # true
isASCII("\x9c25.63")  # false  (in Latin-1, this is an amount in UK pounds)
\end{verbatim}
Arguments

x object to be converted or shifted.
multiple logical: should the conversion be to a single character string or multiple individual characters?
n the number of bits to shift. Positive numbers shift right and negative numbers shift left: allowed values are \(-8 \ldots 8\).
type the result type.

Details

packBits accepts raw, integer or logical inputs, the last two without any NAs.

Note that ‘bytes’ are not necessarily the same as characters, e.g. in UTF-8 domains.

Value

charToRaw converts a length-one character string to raw bytes. It does so without taking into account any declared encoding (see Encoding).

rawToChar converts raw bytes either to a single character string or a character vector of single bytes. (Note that a single character string could contain embedded nuls.)

rawToBits returns a raw vector of 8 times the length of a raw vector with entries 0 or 1. intToBits returns a raw vector of 32 times the length of an integer vector with entries 0 or 1. In both cases the unpacking is least-significant bit first.

packBits packs its input (using only the lowest bit for raw or integer vectors) least-significant bit first to a raw or integer vector.

Examples

```r
x <- "A test string"
(y <- charToRaw(x))
is.vector(y) # TRUE

rawToChar(y)
rawToChar(y, multiple = TRUE)
(xx <- c(y, as.raw(0), charToRaw("more")))
rawToChar(xx)
xxx <- xx
xxx[length(y)+1] <- charToRaw("&")
xxx
rawToChar(xxx)

rawShift(y, 1)
rawShift(y, -2)

rawToBits(y)
```
RdUtils  

Utilities for Processing Rd Files

Description

Utilities for converting files in R documentation (Rd) format to other formats or create indices from them, and for converting documentation in other formats to Rd format.

Usage

R CMD Rdconv [options] file
R CMD Rd2dvi [options] files
R CMD Rd2txt [options] file
R CMD Sd2Rd [options] file

Arguments

file  
the path to a file to be processed.

files  
a list of file names specifying the R documentation sources to use, by either giving the paths to the files, or the path to a directory with the sources of a package.

options  
further options to control the processing, or for obtaining information about usage and version of the utility.

Details

Rdconv converts Rd format to other formats. Currently, plain text, HTML, LaTeX, S version 3 (Sd), and S version 4 (.sgml) formats are supported. It can also extract the examples for run-time testing.

Rd2dvi and Rd2txt are user-level programs for producing DVI/PDF output or pretty text output from Rd sources.

Sd2Rd converts S (version 3 or 4) documentation formats to Rd format.

Use R CMD foo --help to obtain usage information on utility foo.

Note

Conversion to S version 3/4 formats is rough: there are some .Rd constructs for which there is no natural analogue. They are intended as a starting point for hand-tuning.

See Also

The chapter “Processing Rd format” in “Writing R Extensions” (see the ‘doc/manual’ subdirectory of the R source tree).
readBin  Transfer Binary Data To and From Connections

Description

Read binary data from a connection, or write binary data to a connection.

Usage

readBin(con, what, n = 1, size = NA, signed = TRUE, endian = .Platform$endian)
writeBin(object, con, size = NA, endian = .Platform$endian)

Arguments

con  A connection object or a character string naming a file or a raw vector.
what Either an object whose mode will give the mode of the vector to be read, or a character vector of length one describing the mode: one of "numeric", "double", "integer", "int", "logical", "complex", "character", "raw".
n  integer. The (maximal) number of records to be read. You can use an overestimate here, but not too large as storage is reserved for n items.
size integer. The number of bytes per element in the byte stream. The default, NA, uses the natural size. Size changing is not supported for raw and complex vectors.
signed logical. Only used for integers of sizes 1 and 2, when it determines if the quantity on file should be regarded as a signed or unsigned integer.
endian The endian-ness ("big" or "little" of the target system for the file. Using "swap" will force swapping endian-ness.
object An R object to be written to the connection.

Details

If con is a character string, the functions call file to obtain an file connection which is opened for the duration of the function call.

If the connection is open it is read/written from its current position. If it is not open, it is opened for the duration of the call and then closed again. The connection must be open or open-able in binary mode.

If readBin is called with con a raw vector, the data in the vector is used as input. If writeBin is called with con a raw vector, it is just an indication that a raw vector should be returned.

If size is specified and not the natural size of the object, each element of the vector is coerced to an appropriate type before being written or as it is read. Possible sizes are 1, 2, 4 and possibly 8 for integer or logical vectors, and 4, 8 and possibly 12/16 for numeric vectors. (Note that coercion occurs as signed types except if signed = FALSE when reading integers of sizes 1 and 2.) Changing sizes is unlikely to preserve NAs, and the extended precision sizes are unlikely to be portable across platforms.
readBin and writeBin read and write C-style zero-terminated character strings. Input strings are limited to 10000 characters. readChar and writeChar can be used to read and write fixed-length strings.

Handling R's missing and special (Inf, -Inf and NaN) values is discussed in the R Data Import/Export manual.

Value

For readBin, a vector of appropriate mode and length the number of items read (which might be less than n).

For writeBin, a raw vector (if con is a raw vector) or invisibly NULL.

Note

Integer read/writes of size 8 will be available if either C type long is of size 8 bytes or C type long long exists and is of size 8 bytes.

Real read/writes of size sizeof(long double) (usually 12 or 16 bytes) will be available only if that type is available and different from double.

If readBin(what = character()) is used incorrectly on a file which does not contain C-style character strings, warnings (usually many) are given. From a file or connection, the input will be broken into pieces of length 10000 with any final part being discarded.

readChar to read/write fixed-length strings.

connections, readLines, writeLines.

.Machine for the sizes of long, long long and long double.

Examples

```r
zz <- file("testbin", "wb")
writeBin(1:10, zz)
writeBin(pi, zz, endian="swap")
writeBin(pi, zz, size=4)
writeBin(pi^2, zz, size=4, endian="swap")
writeBin(pi+3i, zz)
writeBin("A test of a connection", zz)
z <- paste("A very long string", 1:100, collapse=" + ")
writeBin(z, zz)
if(.Machine$sizeof.long == 8 || .Machine$sizeof.longlong == 8)
  writeBin(as.integer(5^(1:10)), zz, size = 8)
if((s <-.Machine$sizeof.longdouble) > 8)
  writeBin((pi/3)^(1:10), zz, size = s)
close(zz)

zz <- file("testbin", "rb")
readBin(zz, integer(), 4)
readBin(zz, integer(), 6)
readBin(zz, numeric(), 1, endian="swap")
readBin(zz, numeric(), size=4)
readBin(zz, numeric(), size=4, endian="swap")
readBin(zz, complex(), 1)
```
readBin(zz, character(), 1)
z2 <- readBin(zz, character(), 1)
if(.Machine$sizeof.long == 8 || .Machine$sizeof.longlong == 8)
  readBin(zz, integer(), 10, size = 8)
if((s <- .Machine$sizeof.longdouble) > 8)
  readBin(zz, numeric(), 10, size = s)
close(zz)
unlink("testbin")
stopifnot(z2 == z)

## signed vs unsigned ints
zz <- file("testbin", "wb")
x <- as.integer(seq(0, 255, 32))
writeBin(x, zz, size=1)
writeBin(x, zz, size=1)
x <- as.integer(seq(0, 60000, 10000))
writeBin(x, zz, size=2)
writeBin(x, zz, size=2)
close(zz)
zz <- file("testbin", "rb")
readBin(zz, integer(), 8, size=1)
readBin(zz, integer(), 8, size=1, signed=FALSE)
readBin(zz, integer(), 7, size=2)
readBin(zz, integer(), 7, size=2, signed=FALSE)
close(zz)
unlink("testbin")

## use of raw
z <- writeBin(pi^1:5, raw(), size = 4)
readBin(z, numeric(), 5, size = 4)
z <- writeBin(c("a", "test", "of", "character"), raw())
rawToChar(z)
readBin(z, character(), 4)

---

**readChar**  
Transfer Character Strings To and From Connections

**Description**
Transfer character strings to and from connections, without assuming they are null-terminated on the connection.

**Usage**
```
readChar(con, nchars)
writeChar(object, con,
  nchars = nchar(object, type="chars"), eos = "")
```

**Arguments**
- **con** A connection object, or a character string naming a file, or a raw vector.
- **nchars** integer, giving the lengths in characters of (unterminated) character strings to be read or written. Must be >= 0 and not missing.
**readChar**

object  A character vector to be written to the connection, at least as long as nchars.

eos  'end of string': character string. The terminator to be written after each string, followed by an ASCII null; use NULL for no terminator at all.

**Details**

These functions complement `readBin` and `writeBin` which read and write C-style zero-terminated character strings. They are for strings of known length, and can optionally write an end-of-string mark. They are intended only for character strings valid in the current locale.

If `con` is a character string, the functions call `file` to obtain an file connection which is opened for the duration of the function call.

If the connection is open it is read/written from its current position. If it is not open, it is opened for the duration of the call and then closed again. Connections can be open in either text or binary mode.

If `readChar` is called with `con` a raw vector, the data in the vector is used as input. If `writeChar` is called with `con` a raw vector, it is just an indication that a raw vector should be returned.

In a single-byte locale, character strings containing ASCII null(s) will be read correctly by `readChar` and appear with embedded nulls in the character vector returned. This may not work for multi-byte locales, and does not work for `writeChar`.

If the character length requested for `readChar` is longer than the data available on the connection, what is available is returned. For `writeChar` if too many characters are requested the output is zero-padded, with a warning.

Missing strings are written as NA.

**Value**

For `readChar`, a character vector of length the number of items read (which might be less than length(nchars)).

For `writeChar`, a raw vector (if `con` is a raw vector) or invisibly NULL.

**See Also**

The *R Data Import/Export* manual.

`connections`, `readLines`, `writeLines`, `readBin`

**Examples**

```r
## test fixed-length strings
zz <- file("testchar", "wb")
x <- c("a", "this will be truncated", "abc")
nc <- c(3, 10, 3)
writeChar(x, zz, nc, eos=NULL)
writeChar(x, zz, eos="\r\n")
close(zz)

zz <- file("testchar", "rb")
readChar(zz, nc)
readChar(zz, nchar(x)+3) # need to read the terminator explicitly
close(zz)
unlink("testchar")
```
**readline**

*Read a Line from the Terminal*

**Description**

`readline` reads a line from the terminal

**Usage**

```r
readline(prompt = "")
```

**Arguments**

- `prompt`: the string printed when prompting the user for input. Should usually end with a space " ".

**Details**

The prompt string will be truncated to a maximum allowed length, normally 256 chars (but can be changed in the source code).

**Value**

A character vector of length one.

**See Also**

`readLines` for reading text lines of connections, including files.

**Examples**

```r
fun <- function() {
  ANSWER <- readline("Are you a satisfied R user? ")
  if (substr(ANSWER, 1, 1) == "n")
    cat("This is impossible. YOU LIED!\n")
  else
    cat("I knew it.\n")
}
fun()
```

**readLines**

*Read Text Lines from a Connection*

**Description**

Read some or all text lines from a connection.

**Usage**

```r
readLines(con = stdin(), n = -1, ok = TRUE, warn = TRUE, encoding = "unknown")
```
readLines

Arguments

- **con** (a connection object or a character string).
- **n** (integer. The (maximal) number of lines to read. Negative values indicate that one should read up to the end of the connection).
- **ok** (logical. Is it OK to reach the end of the connection before \( n > 0 \) lines are read? If not, an error will be generated).
- **warn** (logical. Warn if a text file is missing a final EOL).
- **encoding** (encoding to be assumed for input strings. It is used to mark character strings as known to be in Latin-1 or UTF-8: it is not used to re-encode the input).

Details

If the **con** is a character string, the function calls `file` to obtain a file connection which is opened for the duration of the function call.

If the connection is open it is read from its current position. If it is not open, it is opened for the duration of the call and then closed again.

If the final line is incomplete (no final EOL marker) the behaviour depends on whether the connection is blocking or not. For a blocking text-mode connection (or a non-text-mode connection) the line will be accepted, with a warning. For a non-blocking text-mode connection the incomplete line is pushed back, silently.

Whatever mode the connection is opened in, any of LF, CRLF or CR will be accepted as the EOL marker for a line.

Value

A character vector of length the number of lines read.

The elements of the result have a declared encoding if **encoding** is "latin1" or "UTF-8".

Note

The default connection, **stdin**, may be different from **con = "stdin"**: see `file`.

See Also

`connections, writeLines, readBin, scan`

Examples

```r
cat("TITLE extra line", "2 3 5 7", ",", "11 13 17", file="ex.data", sep="\n")
readLines("ex.data", n=-1)
unlink("ex.data") # tidy up

## difference in blocking
cat("123\nabc", file = "test1")
readLines("test1") # line with a warning

con <- file("test1", "r", blocking = FALSE)
readLines(con) # empty
cat(" def\n", file = "test1", append = TRUE)
readLines(con) # gets both
close(con)
```
unlink("test1") # tidy up

real  

Real Vectors

Description

real creates a double precision vector of the specified length. Each element of the vector is equal to 0.

as.real attempts to coerce its argument to be of double type.

is.real returns TRUE or FALSE depending on whether its argument is of double type or not.

Usage

real(length = 0)

as.real(x, ...)

is.real(x)

Arguments

length  desired length.

x  object to be coerced or tested.

...  further arguments passed to or from other methods.

Note

R has no single precision data type. All real numbers are stored in double precision format. These functions are the same as their double equivalents.

Recall  

Recursive Calling

Description

Recall is used as a placeholder for the name of the function in which it is called. It allows the definition of recursive functions which still work after being renamed, see example below.

Usage

Recall(...)

Arguments

...  all the arguments to be passed.

Note

Recall will not work correctly when passed as a function argument, e.g. to the apply family of functions.
See Also

`do.call` and `call`.

`local` for another way to write anonymous recursive functions.

Examples

```r
## A trivial (but inefficient!) example:
fib <- function(n) if(n<=2) {if(n>=0) 1 else 0} else Recall(n-1) + Recall(n-2)
fibonacci <- fib; rm(fib)
## renaming wouldn't work without Recall
fibonacci(10) # 55
```

---

**reg.finalizer**  
**Finalization of Objects**

Description

Registers an R function to be called upon garbage collection of object or (optionally) at the end of an R session.

Usage

```r
reg.finalizer(e, f, onexit = FALSE)
```

Arguments

- `e`: Object to finalize. Must be environment or external pointer.
- `f`: Function to call on finalization. Must accept a single argument, which will be the object to finalize.
- `onexit`: logical: should the finalizer be run if the object is still uncollected at the end of the R session?

Value

NULL.

Note

The purpose of this function is mainly to allow objects that refer to external items (a temporary file, say) to perform cleanup actions when they are no longer referenced from within R. This only makes sense for objects that are never copied on assignment, hence the restriction to environments and external pointers.

See Also

`gc` and `Memory` for garbage collection and memory management.

Examples

```r
f <- function(e) print("cleaning....")
g <- function(x){ e <- environment(); reg.finalizer(e,f) }
g()
invisible(gc()) # trigger cleanup
```
Regular Expressions as used in R

Description

This help page documents the regular expression patterns supported by grep and related functions regexpr, gregexpr, sub and gsub, as well as by strsplit.

Details

A 'regular expression' is a pattern that describes a set of strings. Three types of regular expressions are used in R, extended regular expressions, used by grep(extended = TRUE) (its default), basic regular expressions, as used by grep(extended = FALSE), and Perl-like regular expressions used by grep(perl = TRUE).

Other functions which use regular expressions (often via the use of grep) include apropos, browseEnv, help.search, list.files, ls and strsplit. These will all use extended regular expressions, unless strsplit is called with argument extended = FALSE or perl = TRUE.

Patterns are described here as they would be printed by cat: do remember that backslashes need to be doubled when entering R character strings from the keyboard.

Extended Regular Expressions

This section covers the regular expressions allowed if extended = TRUE in grep, regexpr, gregexpr, sub, gsub and strsplit. They use the glibc 2.3.6 implementation of the POSIX 1003.2 standard.

Regular expressions are constructed analogously to arithmetic expressions, by using various operators to combine smaller expressions.

The fundamental building blocks are the regular expressions that match a single character. Most characters, including all letters and digits, are regular expressions that match themselves. Any metacharacter with special meaning may be quoted by preceding it with a backslash. (Escaping other characters with a backslash is undefined.) The metacharacters are in EREs are . \ | ( ) [ { ^ $ * + ? , but note that whether these have a special meaning depends on the context.

A character class is a list of characters enclosed by [ and ] which matches any single character in that list; if the first character of the list is the caret ^, then it matches any character not in the list. For example, the regular expression [0123456789] matches any single digit, and [^abc] matches anything except the characters a, b or c. A range of characters may be specified by giving the first and last characters, separated by a hyphen. (Because their interpretation is so system-dependent, they are best avoided.)

The precise way character ranges are interpreted depends on the values of perl and ignore.case. For basic and extended regular expressions the collation order is taken from the OS’s implementation of the setting of the locale category LC_COLLATE, so [W-Z] may include x and if it does may or may not include w. (In most English locales the collation order is wWXyYzZ.) For caseless matching the characters in a range are interpreted as if in lower case, so in an English locale [W-z] matches WXYZWXYZ.

For Perl regexps, the ranges are interpreted in the numerical order of the characters, either as bytes in an 8-bit locale or as Unicode points in a UTF-8 locale.

Certain named classes of characters are predefined. Their interpretation depends on the locale (see locales); the interpretation below is that of the POSIX locale.
Alphanumeric characters: [:alpha:] and [:digit:].

Alphabetic characters: [:lower:] and [:upper:].

Blank characters: space and tab.

Control characters. In ASCII, these characters have octal codes 000 through 037, and 177 (DEL). In another character set, these are the equivalent characters, if any.

Digits: 0 1 2 3 4 5 6 7 8 9.

Graphical characters: [:alnum:] and [:punct:].

Lower-case letters in the current locale.

Printable characters: [:alnum:], [:punct:] and space.

Punctuation characters: ! " # $ % & ' ( ) * + , - . / : ; < = > ? @ [ \ ] ^ ` { | } ~.

Space characters: tab, newline, vertical tab, form feed, carriage return, and space.

Upper-case letters in the current locale.

Hexadecimal digits: 0 1 2 3 4 5 6 7 8 9 A B C D E F a b c d e f.

For example, [:alnum:] means [0-9A-Za-z], except the latter depends upon the locale and the character encoding, whereas the former is independent of locale and character set. (Note that the brackets in these class names are part of the symbolic names, and must be included in addition to the brackets delimiting the bracket list.) Most metacharacters lose their special meaning inside lists. To include a literal ], place it first in the list. Similarly, to include a literal ^, place it anywhere but first. Finally, to include a literal -, place it first or last (or, for perl = TRUE only, precede it by a backslash.). (Only these and \ remain special inside character classes.)

The period . matches any single character. The symbol \w is documented to be synonym for [:alnum:] and \W is its negation. However, \w also matches underscore in the GNU grep code used in R.

The caret ^ and the dollar sign $ are metacharacters that respectively match the empty string at the beginning and end of a line. The symbols \< and \> respectively match the empty string at the beginning and end of a word. The symbol \b matches the empty string at the edge of a word, and \B matches the empty string provided it is not at the edge of a word.

A regular expression may be followed by one of several repetition quantifiers:

? The preceding item is optional and will be matched at most once.

* The preceding item will be matched zero or more times.

+ The preceding item will be matched one or more times.

{n} The preceding item is matched exactly n times.

{n,} The preceding item is matched n or more times.

{n, m} The preceding item is matched at least n times, but not more than m times.

Repetition is greedy, so the maximal possible number of repeats is used.

Two regular expressions may be concatenated; the resulting regular expression matches any string formed by concatenating two substrings that respectively match the concatenated subexpressions.

Two regular expressions may be joined by the infix operator |; the resulting regular expression matches any string matching either subexpression. For example, abba|cde matches either the string abba or the string cde. Note that alternation does not work inside character classes, where | has its literal meaning.
Repetition takes precedence over concatenation, which in turn takes precedence over alternation. A whole subexpression may be enclosed in parentheses to override these precedence rules.

The backreference \N, where N is a single digit, matches the substring previously matched by the Nth parenthesized subexpression of the regular expression.

Basic Regular Expressions

This section covers the regular expressions allowed if extended = FALSE in grep, regexpr, gregexpr, sub, gsub and strsplit.

In basic regular expressions the metacharacters ?, +, {, |, ( and ) lose their special meaning; instead use the backslashed versions \?, \+, \{, \|, \(, and \). Thus the metacharacters are . \ [ ^ $ * .

Perl Regular Expressions

The perl = TRUE argument to grep, regexpr, gregexpr, sub, gsub and strsplit switches to the PCRE library that ‘implements regular expression pattern matching using the same syntax and semantics as Perl 5.6 or later, with just a few differences’.

For complete details please consult the man pages for PCRE, especially man pcrepattern and man pcreapi) on your system or from the sources at http://www.pcre.org. If PCRE support was compiled from the sources within R, the PCRE version is 7.0 as described here (version ≥ 4.0 is required if R is configured to use the system’s PCRE library).

All the regular expressions described for extended regular expressions are accepted except \< and \>: in Perl all backslashed metacharacters are alphanumeric and backslashed symbols always are interpreted as a literal character. { is not special if it would be the start of an invalid interval specification. There can be more than 9 backreferences.

The construct (?...) is used for Perl extensions in a variety of ways depending on what immediately follows the ?.

Perl-like matching can work in several modes, set by the options (?i) (caseless, equivalent to Perl’s /i), (?m) (multiline, equivalent to Perl’s /m), (?s) (single line, so a dot matches all characters, even new lines: equivalent to Perl’s /s) and (?x) (extended, whitespace data characters are ignored unless escaped and comments are allowed: equivalent to Perl’s /x). These can be concatenated, so for example, (?im) sets caseless multiline matching. It is also possible to unset these options by preceding the letter with a hyphen, and to combine setting and unsetting such as (?im-sx). These settings can be applied within patterns, and then apply to the remainder of the pattern. Additional options not in Perl include (?U) to set ‘ungreedy’ mode (so matching is minimal unless ? is used, when it is greedy). Initially none of these options are set.

If you want to remove the special meaning from a sequence of characters, you can do so by putting them between \Q and \E. This is different from Perl in that $ and @ are handled as literals in \Q...\E sequences in PCRE, whereas in Perl, $ and @ cause variable interpolation.

The escape sequences \d, \s and \w represent any decimal digit, space character and ‘word’ character (letter, digit or underscore in the current locale) respectively, and their upper-case versions represent their negation. Unlike POSIX and earlier versions of Perl and PCRE, vertical tab is not regarded as a whitespace character.

Escape sequence \a is BEL, \e is ESC, \f is FF, \n is LF, \r is CR and \t is TAB. In addition \cx is cntrl-x for any x, \ddd is the octal character ddd (for up to three digits unless interpretable as a backreference), and \xhh specifies a character in hex.

Outside a character class, \b matches a word boundary, \B is its negation, \A matches at start of a subject (even in multiline mode, unlike ^), \Z matches at end of a subject or before newline at end, \z matches at end of a subject. and \G matches at first matching position in a subject. \C matches
a single byte, including a newline. \R matches any Unicode newline character (not just CR). \X matches any number of Unicode characters that form an extended Unicode sequence.

The same repetition quantifiers as extended POSIX are supported. However, if a quantifier is followed by ? the match is ‘ungreedy’, that is as short as possible rather than as long as possible (unless the meanings are reversed by the (?U) option.)

The sequence (?# marks the start of a comment which continues up to the next closing parenthesis. Nested parentheses are not permitted. The characters that make up a comment play no part at all in the pattern matching.

If the extended option is set, an unescaped # character outside a character class introduces a comment that continues up to the next newline character in the pattern.

The pattern (?:...) groups characters just as parentheses do but does not make a backreference.

Patterns (?=...) and (!=...) are zero-width positive and negative lookahead assertions: they match if an attempt to match the ... forward from the current position would succeed (or not), but use up no characters in the string being processed. Patterns (?<=...) and (?<!...) are the lookbehind equivalents: they do not allow repetition quantifiers nor \C in ... .

Named subpatterns, atomic grouping, possessive qualifiers and conditional and recursive patterns are not covered here.

Author(s)

---

remove Remove Objects from a Specified Environment

Description

remove and rm can be used to remove objects. These can be specified successively as character strings, or in the character vector list, or through a combination of both. All objects thus specified will be removed.

If envir is NULL then the currently active environment is searched first.

If inherits is TRUE then parents of the supplied directory are searched until a variable with the given name is encountered. A warning is printed for each variable that is not found.
Usage

remove(..., list = character(0), pos = -1,
       envir = as.environment(pos), inherits = FALSE)
rm (..., list = character(0), pos = -1,
      envir = as.environment(pos), inherits = FALSE)

Arguments

... the objects to be removed, as names (unquoted) or character strings (quoted).
list a character vector naming objects to be removed.
pos where to do the removal. By default, uses the current environment. See the
details for other possibilities.
envir the environment to use. See the details section.
inherits should the enclosing frames of the environment be inspected?

Details

The pos argument can specify the environment from which to remove the objects in any of several
ways: as an integer (the position in the search list); as the character string name of an element
in the search list; or as an environment (including using sys.frame to access the currently
active function calls). The envir argument is an alternative way to specify an environment, but is
primarily there for back compatibility.

It is not allowed to remove variables from the base environment and base name space, nor from any
environment which is locked (see lockEnvironment).

Earlier versions of R incorrectly claimed that supplying a character vector in ... removed the
objects named in the character vector, but it removed the character vector. Use the list argument
to specify objects via a character vector.

ls, objects

Examples

tmp <- 1:4
## work with tmp and cleanup
rm(tmp)

## Not run:
## remove (almost) everything in the working environment.
## You will get no warning, so don't do this unless you are really sure.
rm(list = ls())
## End(Not run)
Replicate Elements of Vectors and Lists

Description

rep replicates the values in x. It is a generic function, and the (internal) default method is described here.

rep.int is a faster simplified version for the most common case.

Usage

rep(x, ...)

rep.int(x, times)

Arguments

x

a vector (of any mode including a list) or a pairlist or a factor or (except for rep.int) a POSIXct or POSIXlt or date object.

... further arguments to be passed to or from other methods. For the internal default method these can include:

\textbf{times} A vector giving the number of times to repeat each element if of length \texttt{length(x)}, or to repeat the whole vector if of length 1.

\textbf{length.out} non-negative integer. The desired length of the output vector. Ignored if \texttt{NA} or invalid.

\textbf{each} non-negative integer. Each element of x is repeated each times. Treated as 1 if \texttt{NA} or invalid.

times see ....

Details

The default behaviour is as if the call was rep(x, times=1, length.out=NA, each=1). Normally just one of the additional arguments is specified, but if codeeach is specified with either of the other two, its replication is performed first, and then that implied by \texttt{times} or \texttt{length.out}.

If \texttt{times} consists of a single integer, the result consists of the whole input repeated this many times. If \texttt{times} is a vector of the same length as \texttt{x} (after replication by \texttt{each}), the result consists of \texttt{x[1]} repeated \texttt{times[1]} times, \texttt{x[2]} repeated \texttt{times[2]} times and so on.

\texttt{length.out} may be given in place of \texttt{times}, in which case \texttt{x} is repeated as many times as is necessary to create a vector of this length. If both are given, \texttt{length.out} takes priority and \texttt{times} is ignored.

Non-integer values of \texttt{times} will be truncated towards zero. If \texttt{times} is a computed quantity it is prudent to add a small fuzz.

If \texttt{x} has length zero and \texttt{length.out} is supplied and is positive, the values are filled in using the extraction rules, that is by an \texttt{NA} of the appropriate class for an atomic vector (0 for raw vectors) and \texttt{NULL} for a list.
Value

An object of the same type as \( x \) (except that \( \text{rep} \) will coerce pairlists to vector lists).

\( \text{rep.int} \) returns no attributes.

The default method of \( \text{rep} \) gives the result names (which will almost always contain duplicates) if \( x \) had names, but retains no other attributes except for factors.

Note

Function \( \text{rep.int} \) is a simple case handled by internal code, and provided as a separate function purely for S compatibility.

As from R 2.4.0, function \( \text{rep} \) is a primitive, but (partial) matching of argument names is performed as for normal functions. You can no longer pass a missing argument to, e.g. \( \text{length.out} \).

References

See Also

\( \text{seq, sequence} \).

Examples

\[
\begin{align*}
\text{rep}(1:4, 2) \\
\text{rep}(1:4, \text{each} = 2) & \text{ # not the same.} \\
\text{rep}(1:4, c(2,2,2,2)) & \text{ # same as second.} \\
\text{rep}(1:4, c(2,1,2,1)) \\
\text{rep}(1:4, \text{each} = 2, \text{len} = 4) & \text{ # first 4 only.} \\
\text{rep}(1:4, \text{each} = 2, \text{len} = 10) & \text{ # 8 integers plus two recycled 1's.} \\
\text{rep}(1:4, \text{each} = 2, \text{times} = 3) & \text{ # length 24, 3 complete replications} \\
\text{rep}(1, 40*(1-.8)) & \text{ # length 7 on most platforms} \\
\text{rep}(1, 40*(1-.8)+1e-7) & \text{ # better} \\
\end{align*}
\]

## replicate a list
\[
\text{fred <- list(happy = 1:10, name = "squash")} \\
\text{rep(fred, 5)}
\]

## date-time objects
\[
x <- \text{.leap.seconds}[1:3] \\
\text{rep}(x, 2) \\
\text{rep(as.POSIXlt(x), rep(2, 3))}
\]

## named factor
\[
x <- \text{factor(LETTERS[1:4]); names(x) <- letters[1:4]} \\
x \\
\text{rep}(x, 2) \\
\text{rep}(x, \text{each}=2) \\
\text{rep.int}(x, 2) & \text{ # no names}
\]
**replace**  
*Replace Values in a Vector*

**Description**

`replace` replaces the values in `x` with indexes given in `list` by those given in `values`. If necessary, the values in `values` are recycled.

**Usage**

`replace(x, list, values)`

**Arguments**

- `x`: vector
- `list`: an index vector
- `values`: replacement values

**Value**

A vector with the values replaced.

**Note**

`x` is unchanged: remember to assign the result.

**References**

---

**rev**  
*Reverse Elements*

**Description**

`rev` provides a reversed version of its argument. It is generic function with a default method for vectors and one for `dendrograms`.  

Note that this is no longer needed (nor efficient) for obtaining vectors sorted into descending order, since that is now rather more directly achievable by `sort(x, decreasing = TRUE)`.

**Usage**

`rev(x)`

**Arguments**

- `x`: a vector or another object for which reversal is defined.
rle

References

See Also

seq, sort.

Examples

```r
x <- c(1:5,5:3)
## sort into descending order; first more efficiently:
stopifnot(sort(x, decreasing = TRUE) == rev(sort(x)))
stopifnot(rev(1:7) == 7:1)#- don't need 'rev' here
```

**rle**

*Run Length Encoding*

Description

Compute the lengths and values of runs of equal values in a vector – or the reverse operation.

Usage

```r
rle(x)
inverse.rle(x, ...)
```

Arguments

x

a simple vector for `rle()` or an object of class "rle" for `inverse.rle()`.

... further arguments which are ignored in R.

Value

`rle()` returns an object of class "rle" which is a list with components

- `lengths` an integer vector containing the length of each run.
- `values` a vector of the same length as `lengths` with the corresponding values.

`inverse.rle()` is the inverse function of `rle()`.

Examples

```r
x <- c(1:5,5:3)
## sort into descending order; first more efficiently:
stopifnot(sort(x, decreasing = TRUE) == rev(sort(x)))
stopifnot(rev(1:7) == 7:1)#- don't need 'rev' here

rle(x)
## lengths [1:5] 5 4 3 2 1
## values [1:5] 10 9 8 7 6

z <- c(TRUE,TRUE,FALSE,FALSE,TRUE,FALSE,TRUE,TRUE,TRUE)
```

```r
rle(z)
rle(as.character(z))
```

```r
stopifnot(x == inverse.rle(rle(x)),
          z == inverse.rle(rle(z)))
```
Description

ceiling takes a single numeric argument \( x \) and returns a numeric vector containing the smallest integers not less than the corresponding elements of \( x \).

floor takes a single numeric argument \( x \) and returns a numeric vector containing the largest integers not greater than the corresponding elements of \( x \).

trunc takes a single numeric argument \( x \) and returns a numeric vector containing the integers formed by truncating the values in \( x \) toward 0.

round rounds the values in its first argument to the specified number of decimal places (default 0).

signif rounds the values in its first argument to the specified number of significant digits.

zapsmall determines a digits argument \( dr \) for calling \( \text{round}(x, \text{digits} = dr) \) such that values “close to zero” (compared with the maximal absolute value) are “zapped”, i.e., treated as 0.

Usage

ceiling(x)
floor(x)
trunc(x)

round(x, digits = 0)
signif(x, digits = 6)
zapsmall(x, digits =getOption("digits"))

Arguments

\( x \) a numeric vector. A complex vector is allowed for \( \text{round}, \text{signif} \) and \( \text{zapsmall} \).

digits integer indicating the precision to be used.

Details

All but \( \text{zapsmall} \) are generic functions: methods can be defined for them individually or via the \texttt{Math} group generic.

Note that for rounding off a 5, the IEC 60559 standard is expected to be used, “go to the even digit”. Therefore \( \text{round}(0.5) \) is 0 and \( \text{round}(-1.5) = -2 \). However, this is dependent on OS services and on representation error (since e.g. 0.15 is not represented exactly, the rounding rule applies to the represented number and not to the printed number, and so \( \text{round}(0.15, 1) \) could be either 0.1 or 0.2).

For \( \text{signif} \) the recognized values of \( \text{digits} \) are 1...22. Complex numbers are rounded to retain the specified number of digits in the larger of the components. Each element of the vector is rounded individually, unlike printing.
round.POSIXt

Round / Truncate Data-Time Objects

Description

Round or truncate date-time objects.

Usage

## S3 method for class 'POSIXt':
round(x, units = c("secs", "mins", "hours", "days"))
## S3 method for class 'POSIXt':
trunc(x, units = c("secs", "mins", "hours", "days"))

## S3 method for class 'Date':
round(x, ...)
## S3 method for class 'Date':
trunc(x)

Arguments

x an object inheriting from "POSIXt" or "Date".
units one of the units listed. Can be abbreviated.
... arguments to be passed to or from other methods, notably digits.
Details

The time is rounded or truncated to the second, minute, hour or day. Timezones are only relevant to
days, when midnight in the current timezone is used.
The methods for class "Date" are of little use except to remove fractional days.

Value

An object of class "POSIXlt".

See Also

round for the generic function and default methods.
DateTimeClasses, Date

Examples

round(.leap.seconds + 1000, "hour")
trunc(Sys.time(), "day")

Description

Returns a matrix of integers indicating their row number in the matrix.

Usage

row(x, as.factor = FALSE)

Arguments

x a matrix.
as.factor a logical value indicating whether the value should be returned as a factor rather
than as numeric.

Value

An integer matrix with the same dimensions as x and whose i,j-th element is equal to i.

References

Brooks/Cole.

See Also

col to get columns.
**Examples**

```r
x <- matrix(1:12, 3, 4)
# extract the diagonal of a matrix
dx <- x[row(x) == col(x)]
dx

# create an identity 5-by-5 matrix
x <- matrix(0, nr = 5, nc = 5)
x[row(x) == col(x)] <- 1
x
```

---

**Get and Set Row Names for Data Frames**

**Description**

All data frames have a row names attribute, a character vector of length the number of rows with no duplicates nor missing values.

For convenience, these are generic functions for which users can write other methods, and there are default methods for arrays. The description here is for the `data.frame` method.

**Usage**

```r
row.names(x)
row.names(x) <- value
```

**Arguments**

- `x`  
  object of class "data.frame", or any other class for which a method has been defined.

- `value`  
  an object to be coerced to character unless an integer vector. It should have (after coercion) the same length as the number of rows of `x` with no duplicated nor missing values. `NULL` is also allowed: see Details.

**Details**

A data frame has (by definition) a vector of `row names` which has length the number of rows in the data frame, and contains neither missing nor duplicated values. Where a row names sequence has been added by the software to meet this requirement, they are regarded as 'automatic'.

Prior to R 2.4.0, row names were character. As from R 2.4.0, they are allowed to be integer or character, but for backwards compatibility `row.names` will always return a character vector. (Use `attr(x, "row.names")` if you need an integer value.)

Using `NULL` for the value resets the row names to `seq_len(nrow(x))`, regarded as 'automatic'.

**Value**

- `row.names` returns a character vector.

- `row.names<-` returns a data frame with the row names changed.
Note

Row names of the form 1:n for n > 2 are stored internally in a compact form, which might be seen from C code or by deparsing but never via row.names or attr(x, "row.names"). Additionally, some names of this sort are marked as ‘automatic’ and handled differently by as.matrix and data.matrix (and potentially other functions). (All zero-row data frames are regarded as having automatic row.names.)

References

See Also
data.frame, rownames, names.
.row_names_info for the internal representations.

Description

Retrieve or set the row or column names of a matrix-like object.

Usage

rownames(x, do.NULL = TRUE, prefix = "row")
rownames(x) <- value

colnames(x, do.NULL = TRUE, prefix = "col")
colnames(x) <- value

Arguments

x a matrix-like R object, with at least two dimensions for colnames.
do.NULL logical. Should this create names if they are NULL?
prefix for created names.
value a valid value for that component of dimnames(x). For a matrix or array this is either NULL or a character vector of non-zero length equal to the appropriate dimension.
Details

The extractor functions try to do something sensible for any matrix-like object \( x \). If the object has \texttt{dimnames} the first component is used as the row names, and the second component (if any) is used for the column names. For a data frame, \texttt{rownames} and \texttt{colnames} are calls to \texttt{row.names} and \texttt{names} respectively, but the latter are preferred.

If \texttt{do.NULL} is \texttt{FALSE}, a character vector (of length \texttt{NROW(x)} or \texttt{NCOL(x)}) is returned in any case, prepending \texttt{prefix} to simple numbers, if there are no dimnames or the corresponding component of the dimnames is \texttt{NULL}.

The replacement methods for arrays/matrices coerce vector and factor values of \texttt{value} to character, but do not dispatch methods for \texttt{as.character}.

For a data frame, \texttt{value} for \texttt{rownames} should be a character vector of non-duplicated and non-missing names (this is enforced), and for \texttt{colnames} a character vector of (preferably) unique syntactically-valid names. In both cases, \texttt{value} will be coerced by \texttt{as.character}, and setting \texttt{colnames} will convert the row names to character.

See Also

\texttt{dimnames, case.names, variable.names}.

Examples

\begin{verbatim}
m0 <- matrix(NA, 4, 0)
rownames(m0)
m2 <- cbind(1,1:4)
colnames(m2, do.NULL = FALSE)
colnames(m2) <- c("x","y")
rownames(m2) <- rownames(m2, do.NULL = FALSE, prefix = "Obs.")
m2
\end{verbatim}

\textbf{rowsum} \hspace{1cm} Give column sums of a matrix or data frame, based on a grouping variable

Description

Compute column sums across rows of a matrix-like object for each level of a grouping variable. \texttt{rowsum} is generic, with a method for data frames and a default method for vectors and matrices.

Usage

\begin{verbatim}
rowsum(x, group, reorder = TRUE, ...)
## S3 method for class 'data.frame':
rowsum(x, group, reorder = TRUE, na.rm = FALSE, ...)
## Default S3 method:
rowsum(x, group, reorder = TRUE, na.rm = FALSE, ...)
\end{verbatim}
Arguments

- **x**: a matrix, data frame or vector of numeric data. Missing values are allowed. A numeric vector will be treated as a column vector.
- **group**: a vector or factor giving the grouping, with one element per row of x. Missing values will be treated as another group and a warning will be given.
- **reorder**: if TRUE, then the result will be in order of sort(unique(group)), if FALSE, it will be in the order that groups were encountered.
- **na.rm**: logical (TRUE or FALSE). Should NA values be discarded?
- **...**: other arguments to be passed to or from methods

Details

The default is to reorder the rows to agree with tapply as in the example below. Reordering should not add noticeably to the time except when there are very many distinct values of group and x has few columns.

The original function was written by Terry Therneau, but this is a new implementation using hashing that is much faster for large matrices.

To sum over all the rows of a matrix (ie, a single group) use colSums, which should be even faster.

Value

A matrix or data frame containing the sums. There will be one row per unique value of group.

See Also

tapply, aggregate, rowSums

Examples

```r
x <- matrix(runif(100), ncol=5)
group <- sample(1:8, 20, TRUE)
(xsum <- rowsum(x, group))
## Slower versions
tapply(x, list(group[row(x)], col(x)), sum)
t(sapply(split(as.data.frame(x), group), colSums))
aggregate(x, list(group), sum)[-1]
```

Description

sample takes a sample of the specified size from the elements of x using either with or without replacement.

Usage

```r
sample(x, size, replace = FALSE, prob = NULL)
```
sample

Arguments

  x       Either a (numeric, complex, character or logical) vector of more than one element from which to choose, or a positive integer.
  size    non-negative integer giving the number of items to choose.
  replace Should sampling be with replacement?
  prob    A vector of probability weights for obtaining the elements of the vector being sampled.

Details

If x has length 1 and x >= 1, sampling takes place from 1:x. Note that this convenience feature may lead to undesired behaviour when x is of varying length sample(x). See the resample() example below.

By default size is equal to length(x) so that sample(x) generates a random permutation of the elements of x (or 1:x).

The optional prob argument can be used to give a vector of weights for obtaining the elements of the vector being sampled. They need not sum to one, but they should be nonnegative and not all zero. If replace is true, Walker’s alias method (Ripley, 1987) is used when there are more than 250 reasonably probable values: this gives results incompatible with those from R < 2.2.0, and there will be a warning the first time this happens in a session.

If replace is false, these probabilities are applied sequentially, that is the probability of choosing the next item is proportional to the probabilities amongst the remaining items. The number of nonzero weights must be at least size in this case.

References

Examples

```r
x <- 1:12
# a random permutation
sample(x)
# bootstrap sampling -- only if length(x) > 1 !
sample(x, replace=TRUE)

# 100 Bernoulli trials
sample(c(0,1), 100, replace = TRUE)

## More careful bootstrapping -- Consider this when using sample()
## programmatically (i.e., in your function or simulation)!

## sample()'s surprise -- example
x <- 1:10
  sample(x[x > 8]) # length 2
  sample(x[x > 9]) # oops -- length 10!
try(sample(x[x > 10])) # error!

## This is safer, but only for sampling without replacement
resample <- function(x, size, ...)
```

if(length(x) <= 1) { if(!missing(size) && size == 0) x[FALSE] else x } else sample(x, size, ...)

resample(x[x > 8])# length 2
resample(x[x > 9])# length 1
resample(x[x > 10])# length 0

---

**save**

**Save R Objects**

**Description**

`save` writes an external representation of R objects to the specified file. The objects can be read back from the file at a later date by using the function `load` (or `data` in some cases).

`save.image()` is just a short-cut for “save my current workspace”, i.e., `save(list = ls(all=TRUE), file = ".RData"). It is also what happens with `q("yes")`.

**Usage**

```r
save(..., list = character(0),
     file = stop("'file' must be specified"),
     ascii = FALSE, version = NULL, envir = parent.frame(),
     compress = !ascii, eval.promises = TRUE)

save.image(file = ".RData", version = NULL, ascii = FALSE,
           compress = !ascii, safe = TRUE)
```

**Arguments**

- `...` the names of the objects to be saved.
- `list` A character vector containing the names of objects to be saved.
- `file` a connection or the name of the file where the data will be saved. Must be a file name for workspace format version 1.
- `ascii` if TRUE, an ASCII representation of the data is written. The default value of `ascii` is FALSE which leads to a more compact binary file being written.
- `version` the workspace format version to use. NULL specifies the current default format. The version used from R 0.99.0 to R 1.3.1 was version 1. The default format as from R 1.4.0 is version 2.
- `envir` environment to search for objects to be saved.
- `compress` logical specifying whether saving to a named file is to use compression. Ignored when `file` is a connection and for workspace format version 1.
- `eval.promises` logical: should objects which are promises be forced before saving?
- `safe` logical. If TRUE, a temporary file is used for creating the saved workspace. The temporary file is renamed to `file` if the save succeeds. This preserves an existing workspace `file` if the save fails, but at the cost of using extra disk space during the save.
Details

The names of the objects specified either as symbols in ... or as a character vector in list are used to look up the objects from environment envir. By default promises are evaluated, but if eval.promises = FALSE promises are saved (together with their evaluation environments). (Promises embedded in objects are always saved unevaluated.)

All R platforms use the XDR representation of binary objects in binary save-d files, and these are portable across all R platforms. (ASCII saves used to be useful for moving data between platforms but are now only of historical interest.)

Default values for the ascii, compress, safe and version arguments can be modified with the save.defaults option (used both by save and save.image), see also the example section below. If a save.image.defaults option is set it overrides save.defaults for function save.image (which allows this to have different defaults).

It is possible to compress later (with gzip) a file saved with compress = FALSE: the effect is the same as saving with compress = TRUE.

Warnings

The ... arguments only give the names of the objects to be saved: they are searched for in the environment given by the envir argument, and the actual objects given as arguments need not be those found.

Saved R objects are binary files, even those saved with ascii = TRUE, so ensure that they are transferred without conversion of end of line markers and of 8-bit characters. The lines are delimited by LF on all platforms.

Although the default version has not changed since R 1.4.0, this does not mean that saved files are necessarily backwards compatible. You will be able to load a saved image into an earlier version of R unless use is made of later additions (for example, raw vectors or external pointers).

Note

The defaults were changed to use compressed saves for save in 2.3.0 and for save.image in 2.4.0. Any recent version of R can read compressed save files, and a compressed file can be uncompressed (by gzip -d) for use with very old versions of R.

Examples

x <- runif(20)
y <- list(a = 1, b = TRUE, c = "oops")
save(x, y, file = "xy.Rdata")
save.image()
unlink("xy.Rdata")
unlink(".RData")

# set save defaults using option:
options(save.defaults=list(ascii=TRUE, safe=FALSE))
save.image()
unlink(".RData")
Description

scale is generic function whose default method centers and/or scales the columns of a numeric matrix.

Usage

scale(x, center = TRUE, scale = TRUE)

Arguments

x a numeric matrix(like object).

center either a logical value or a numeric vector of length equal to the number of columns of x.

scale either a logical value or a numeric vector of length equal to the number of columns of x.

Details

The value of center determines how column centering is performed. If center is a numeric vector with length equal to the number of columns of x, then each column of x has the corresponding value from center subtracted from it. If center is TRUE then centering is done by subtracting the column means (omitting NAs) of x from their corresponding columns, and if center is FALSE, no centering is done.

The value of scale determines how column scaling is performed (after centering). If scale is a numeric vector with length equal to the number of columns of x, then each column of x is divided by the corresponding value from scale. If scale is TRUE then scaling is done by dividing the (centered) columns of x by their root-mean-square, and if scale is FALSE, no scaling is done.

The root-mean-square for a column is obtained by computing the square-root of the sum-of-squares of the non-missing values in the column divided by the number of non-missing values minus one.

Value

For scale.default, the centered, scaled matrix. The numeric centering and scalings used (if any) are returned as attributes "scaled:center" and "scaled:scale"

References

See Also

sweep which allows centering (and scaling) with arbitrary statistics.

For working with the scale of a plot, see par.
Examples

```r
require(stats)
x <- matrix(1:10, nc=2)
(centered.x <- scale(x, scale=FALSE))
cov(centered.scaled.x <- scale(x)) # all 1
```

Description

Read data into a vector or list from the console or file.

Usage

```r
scan(file = "", what = double(0), nmax = -1, n = -1, sep = "",
quote = if(identical(sep, "\n")) "" else "'\n", dec = ".",
skip = 0, nlines = 0, na.strings = "NA",
flush = FALSE, fill = FALSE, strip.white = FALSE,
quiet = FALSE, blank.lines.skip = TRUE, multi.line = TRUE,
comment.char = "", allowEscapes = FALSE, encoding = "unknown")
```

Arguments

- `file` the name of a file to read data values from. If the specified file is "", then input is taken from the keyboard (or whatever `stdin()` reads if input is redirected or `R` is embedded). (In this case input can be terminated by a blank line or an EOF signal, Ctrl-D on Unix and Ctrl-Z on Windows.) Otherwise, the file name is interpreted relative to the current working directory (given by `getwd()`), unless it specifies an absolute path. Tilde-expansion is performed where supported. When running R from a script, `file="stdin"` can be used to refer to the process’s `stdin` file stream. Alternatively, `file` can be a `connection`, which will be opened if necessary, and if so closed at the end of the function call. Whatever mode the connection is opened in, any of LF, CRLF or CR will be accepted as the EOL marker for a line and so will match `sep = "n"`. `file` can also be a complete URL.

- `what` the type of what gives the type of data to be read. The supported types are `logical`, `integer`, `numeric`, `complex`, `character`, `raw` and `list`. If `what` is a list, it is assumed that the lines of the data file are records each containing `length(what)` items ("fields") and the list components should have elements which are one of the first six types listed or `NULL`, see section ‘Details’ below.

- `nmax` integer: the maximum number of data values to be read, or if `what` is a list, the maximum number of records to be read. If omitted or not positive or an invalid value for an integer (and `nlines` is not set to a positive value), `scan` will read to the end of `file`. 

n  integer: the maximum number of data values to be read, defaulting to no limit. Invalid values will be ignored.

sep  by default, scan expects to read white-space delimited input fields. Alternatively, sep can be used to specify a character which delimits fields. A field is always delimited by an end-of-line marker unless it is quoted. If specified this should be the empty character string (the default) or NULL or a character string containing just one single-byte character.

quote  the set of quoting characters as a single character string or NULL. In a multibyte locale the quoting characters must be ASCII (single-byte).

dec  decimal point character. This should be a character string containing just one single-byte character. (NULL and a zero-length character vector are also accepted, and taken as the default.)

skip  the number of lines of the input file to skip before beginning to read data values.

nlines  if positive, the maximum number of lines of data to be read.

na.strings  character vector. Elements of this vector are to be interpreted as missing (NA) values. Blank fields are also considered to be missing values in logical, integer, numeric and complex fields.

flush  logical: if TRUE, scan will flush to the end of the line after reading the last of the fields requested. This allows putting comments after the last field, but precludes putting more that one record on a line.

fill  logical: if TRUE, scan will implicitly add empty fields to any lines with fewer fields than implied by what.

strip.white  vector of logical value(s) corresponding to items in the what argument. It is used only when sep has been specified, and allows the stripping of leading and trailing white space from character fields (numeric fields are always stripped).

If strip.white is of length 1, it applies to all fields; otherwise, if strip.white[i] is TRUE and the i-th field is of mode character (because what[i] is) then the leading and trailing white space from field i is stripped.

quiet  logical: if FALSE (default), scan() will print a line, saying how many items have been read.

blank.lines.skip  logical: if TRUE blank lines in the input are ignored, except when counting skip and nlines.

multi.line  logical. Only used if what is a list. If FALSE, all of a record must appear on one line (but more than one record can appear on a single line). Note that using fill = TRUE implies that a record will terminated at the end of a line.

comment.char  character: a character vector of length one containing a single character or an empty string. Use "" to turn off the interpretation of comments altogether (the default).

allowEscapes  logical. Should C-style escapes such as \n be processed (the default) or read verbatim? Note that if not within quotes these could be interpreted as a delimiter (but not as a comment character). The escapes which are interpreted are the control characters \a, \b, \f, \n,
scan

\r, 
\t, 
v and octal and hexadecimal representations like 040 and 0x2A. Any other escaped character is treated as itself, including backslash.

**encoding** encoding to be assumed for input strings. It is used to mark character strings as known to be in Latin-1 or UTF-8: it is not used to re-encode the input.

**Details**

The value of `what` can be a list of types, in which case `scan` returns a list of vectors with the types given by the types of the elements in `what`. This provides a way of reading columnar data. If any of the types is `NULL`, the corresponding field is skipped (but a `NULL` component appears in the result).

The type of `what` or its components can be one of the six atomic vector types or `NULL` (see `is.atomic`).

‘White space’ is defined for the purposes of this function as one or more contiguous characters from the set space, horizontal tab, carriage return and line feed. It does not include form feed, vertical tab or other non-ASCII space characters.

Empty numeric fields are always regarded as missing values. Empty character fields are scanned as empty character vectors, unless `na.strings` contains "" when they are regarded as missing values.

If `sep` is the default (""), the character \ in a quoted string escapes the following character, so quotes may be included in the string by escaping them.

If `sep` is non-default, the fields may be quoted in the style of `.csv` files where separators inside quotes ("" or "") are ignored and quotes may be put inside strings by doubling them. However, if `sep = "\n"` it is assumed by default that one wants to read entire lines verbatim.

Quoting is only interpreted in character fields and in `NULL` fields (which might be skipping character fields).

Note that since `sep` is a separator and not a terminator, reading a file by `scan("foo", sep="\n", blank.lines.skip=FALSE)` will give an empty final line if the file ends in a linefeed and not if it does not. This might not be what you expected; see also `readLines`.

If `comment.char` occurs (except inside a quoted character field), it signals that the rest of the line should be regarded as a comment and be discarded. Lines beginning with a comment character (possibly after white space with the default separator) are treated as blank lines.

`scan` attempts to share storage with character strings that have already been read in the call. If an upper bound on the number of character strings cannot be deduced from `nmax` or `n`, sharing is used for the first 10000 unique strings which are read in.

There is a check for a user interrupt every 1000 lines if `what` is a list, otherwise every 10000 items.

**Value**

if `what` is a list, a list of the same length and same names (as any) as `what`.

Otherwise, a vector of the type of `what`.

Character strings in the result will have a declared encoding if `encoding` is "latin1" or "UTF-8".
search

Note

The default for multi.line differs from S. To read one record per line, use flush = TRUE and multi.line = FALSE. (Note that quoted character strings can still include embedded new lines.)

If number of items is not specified, the internal mechanism re-allocates memory in powers of two and so could use up to three times as much memory as needed. (It needs both old and new copies.)

If you can, specify either n or nmax whenever inputting a large vector, and nmax or nlines when inputting a large list.

Using scan on an open connection to read partial lines can lose chars: use an explicit separator to avoid this.

References

See Also

`read.table` for more user-friendly reading of data matrices; `readLines` to read a file a line at a time. `write`.

Quotes for the details of C-style escape sequences.

`readChar` and `readBin` to read fixed or variable length character strings or binary representations of numbers a few at a time from a connection.

Examples

```r
pp <- scan("ex.data", skip = 1, quiet= TRUE)
  scan("ex.data", skip = 1)
  scan("ex.data", skip = 1, nlines=1)# only 1 line after the skipped one
  scan("ex.data", what = list("","","")) # flush is F -> read "7"
  scan("ex.data", what = list("","",""), flush = TRUE)

unlink("ex.data") # tidy up
```

description

Give Search Path for R Objects

Description

Gives a list of attached packages (see library), and R objects, usually data.frames.

Usage

```r
search()
searchpaths()
```

Value

A character vector, starting with ".GlobalEnv", and ending with "package:base" which is R's *base* package required always.

`searchpaths` gives a similar character vector, with the entries for packages being the path to the package used to load the code.
seek

Functions to Reposition Connections

Description

Functions to re-position connections.

Usage

seek(con, ...)  
## S3 method for class 'connection':  
seek(con, where = NA, origin = "start", rw = ",", ...)  

isSeekable(con)  

truncate(con, ...)  

Arguments

con  
a connection.  

where  
numeric. A file position (relative to the origin specified by origin), or NA.  

rw  
character. Empty or "read" or "write", partial matches allowed.  

origin  
character. One of "start", "current", "end": see Details.  

...  
further arguments passed to or from other methods.
**Details**

`seek` with `where = NA` returns the current byte offset of a connection (from the beginning), and with a non-missing `where` argument the connection is re-positioned (if possible) to the specified position. `isSeekable` returns whether the connection in principle supports `seek`: currently only (possibly gz-compressed) file connections do. `gzfile` connections do not support `origin = "end"`; the file position they use is that of the uncompressed file.

`where` is stored as a real but should represent an integer: non-integer values are likely to be truncated. Note that the possible values can exceed the largest representable number in an R `integer` on 64-bit OSes, and on some 32-bit OSes.

File connections can be open for both writing/appending, in which case R keeps separate positions for reading and writing. Which `seek` refers to can be set by its `rw` argument: the default is the last mode (reading or writing) which was used. Most files are only opened for reading or writing and so default to that state. If a file is open for reading and writing but has not been used, the default is to give the reading position (0).

The initial file position for reading is always at the beginning. The initial position for writing is at the beginning of the file for modes "r+" and "r+b", otherwise at the end of the file. Some platforms only allow writing at the end of the file in the append modes. (The reported write position for a file opened in an append mode will typically be unreliable until the file has been written to.)

`truncate` truncates a file opened for writing at its current position. It works only for file connections, and is not implemented on all platforms: on others (including Windows) it will not work for large (> 2Gb) files.

**Value**

`seek` returns the current position (before any move), as a (numeric) byte offset from the origin, if relevant, or 0 if not. Note that the position can exceed the largest representable number in an R `integer` on 64-bit OSes, and on some 32-bit OSes.

`truncate` returns NULL: it stops with an error if it fails (or is not implemented).

`isSeekable` returns a logical value, whether the connection supports `seek`.

`connections`

---

**Sequence Generation**

Generate regular sequences. `seq` is a standard generic with a default method. `seq.int` is an internal generic which can be much faster but has a few restrictions. `seq_along` and `seq_len` are very fast primitives for two common cases.
Usage

seq(...)

## Default S3 method:
seq(from = 1, to = 1, by = ((to - from)/(length.out - 1)),
length.out = NULL, along.with = NULL, ...)

seq.int(from, to, by, length.out, along.with, ...)

seq_along(along.with)
seq.len(length.out)

Arguments

... arguments passed to or from methods.
from, to the starting and (maximal) end value of the sequence.
by number: increment of the sequence.
length.out desired length of the sequence. A non-negative number, which for seq and
seq.int will be rounded up if fractional.
along.with take the length from the length of this argument.

Details

The interpretation of the unnamed arguments of seq and seq.int is not standard, and it is rec-
commended always to name the arguments when programming.

Both seq are seq.int are generic, and only the default method is described here. Typical usages
are

seq(from, to)
seq(from, to, by=)
seq(from, to, length.out=)
seq(along.with=)
seq(from)
seq(length.out=)

The first form generates the sequence from, from+/-1, ..., to (identical to from:to).
The second form generates from, from+by,...., up to the sequence value less than or equal to
to. Specifying to - from and by of opposite signs is an error.
The third generates a sequence of length.out equally spaced values from from to to.
(length.out is usually abbreviated to length or len, and seq.len is much faster.)
The fourth form generates the sequence 1, 2, ..., length(along.with).
(along.with is usually abbreviated to along, and seq_along is much faster.)
The fifth form generates the sequence 1, 2, ..., length(from) (as if argument
along.with had been specified), unless the argument is numeric of length 1 when it is inter-
preted as 1:from (even for seq(0) for compatibility with S).
The final form generates 1, 2, ..., length.out unless length.out = 0, when it gen-
erates integer(0).

Very small sequences (with from - to of the order of 10^{-14} times the larger of the ends) will
return from.
For `seq(only)`, up to two of `from`, `to` and `by` can be supplied as complex values provided `length.out` or `along.with` is specified.

**Value**

Currently, the default method returns a result of type "integer" if `from` is (numerically equal to an) integer and, e.g., only `to` is specified, or also if only `length` or only `along.with` is specified. **Note:** this may change in the future and programmers should not rely on it.

**References**

**See Also**

The methods `seq.Date` and `seq.POSIXt`.

`:rep, sequence, row, col`.

**Examples**

```r
seq(0, 1, length=11)
seq(rnorm(20))
seq(1, 9, by = 2) # match
seq(1, 9, by = pi)# stay below
seq(1, 6, by = 3)
seq(1.575, 5.125, by=0.05)
seq(17) # same as 1:17
```

---

**seq.Date**

*Generate Regular Sequences of Dates*

**Description**

The method for `seq` for date-time classes.

**Usage**

```r
## S3 method for class 'Date':
seq(from, to, by, length.out = NULL, along.with = NULL, ...)
```

**Arguments**

- `from` starting date. Required
- `to` end date. Optional.
- `by` increment of the sequence. Optional. See Details.
- `length.out` integer, optional. desired length of the sequence.
- `along.with` take the length from the length of this argument.
- `...` arguments passed to or from other methods.
Details

by can be specified in several ways.

- A number, taken to be in days.
- A object of class `difftime`
- A character string, containing one of "day", "week", "month" or "year". This can optionally be preceded by a (positive or negative) integer and a space, or followed by "s".
  
  See `seq.POSIXt` for the details of "month".

Value

A vector of class "Date".

See Also

Date

Examples

```r
## first days of years
seq(as.Date("1910/1/1"), as.Date("1999/1/1"), "years")
## by month
seq(as.Date("2000/1/1"), by="month", length=12)
## quarters
seq(as.Date("2000/1/1"), as.Date("2003/1/1"), by="3 months")

## find all 7th of the month between two dates, the last being a 7th.
st <- as.Date("1998-12-17")
en <- as.Date("2000-1-7")
ll <- seq.Date(en, st, by="-1 month")
rev(ll[ll > st & ll < en])

```

Description

The method for `seq` for date-time classes.

Usage

```r
## S3 method for class 'POSIXt':
seq(from, to, by, length.out = NULL, along.with = NULL, ...)
```

Arguments

- `from` starting date. Required.
- `to` end date. Optional.
- `by` increment of the sequence. Optional. See Details.
- `length.out` integer, optional. desired length of the sequence.
- `along.with` take the length from the length of this argument.
- `...` arguments passed to or from other methods.
Details

by can be specified in several ways.

- A number, taken to be in seconds.
- A object of class `difftime`
- A character string, containing one of "sec", "min", "hour", "day", "DSTday", "week", "month" or "year". This can optionally be preceded by a (positive or negative) integer and a space, or followed by "s".

The difference between "day" and "DSTday" is that the former ignores changes to/from daylight savings time and the latter takes the same clock time each day. ("week" ignores DST (it is a period of 144 hours), but "7 DSTdays") can be used as an alternative. "month" and "year" allow for DST.

The timezone of the result is taken from `from`: remember than GMT does not have daylight savings time.

Using "month" first advances the month without changing the day: if this results in an invalid day of the month, it is counted forward into the next month: see the examples.

Value

A vector of class "POSIXct".

See Also

`DateTimeClasses`

Examples

```r
## first days of years
seq(ISOdate(1910,1,1), ISOdate(1999,1,1), "years")
## by month
seq(ISOdate(2000,1,1), by = "month", length = 12)
seq(ISOdate(2000,1,31), by = "month", length = 4)
## quarters
seq(ISOdate(1990,1,1), ISOdate(2000,1,1), by = "3 months")
## days vs DSTdays: use c() to lose the timezone.
seq(c(ISOdate(2000,3,20)), by = "day", length = 10)
seq(c(ISOdate(2000,3,20)), by = "DSTday", length = 10)
seq(c(ISOdate(2000,3,20)), by = "7 DSTdays", length = 4)
```

---

**sequence**

Create A Vector of Sequences

Description

For each element of `nvec` the sequence `seq(nvec[i])` is created. These are appended and the result returned.

Usage

`sequence(nvec)`
**set**

**Arguments**

`nvec`  
an integer vector each element of which specifies the upper bound of a sequence.

**See Also**

`gl, seq, rep`

**Examples**

```r
sequence(c(3, 2))  # the concatenated sequences 1:3 and 1:2.
#> [1] 1 2 3 1 2
```

---

**sets**

*Set Operations*

**Description**

Performs set union, intersection, (asymmetric!) difference, equality and membership on two vectors.

**Usage**

```r
union(x, y)
intersect(x, y)
setdiff(x, y)
setequal(x, y)
is.element(el, set)
```

**Arguments**

`x, y, el, set`  
vectors (of the same mode) containing a sequence of items (conceptually) with no duplicated values.

**Details**

Each of `union, intersect, setdiff` and `setequal` will discard any duplicated values in the arguments, and they apply `as.vector` to their arguments (and so in particular coerce factors to character vectors).

`is.element(x, y)` is identical to `x %in% y`.

**Value**

A vector of the same mode as `x` or `y` for `setdiff` and `intersect`, respectively, and of a common mode for `union`.

A logical scalar for `setequal` and a logical of the same length as `x` for `is.element`.

**See Also**

`%in%`
Examples

(x <- c(sort(sample(1:20, 9)),NA))
(y <- c(sort(sample(3:23, 7)),NA))
union(x, y)
intersect(x, y)
setdiff(x, y)
setdiff(y, x)
setequal(x, y)

## True for all possible x & y :
setequal( union(x,y),
   c(setdiff(x,y), intersect(x,y), setdiff(y,x)))

is.element(x, y)# length 10
is.element(y, x)# length 8

showConnections  Display Connections

Description
Display aspects of connections.

Usage

showConnections(all = FALSE)
getConnection(what)
closeAllConnections()

stdin()
stdout()
stderr()

Arguments

all  logical: if true all connections, including closed ones and the standard ones are displayed. If false only open user-created connections are included.
what  integer: a row number of the table given by showConnections.

Details

stdin(), stdout() and stderr() are standard connections corresponding to input, output and error on the console respectively (and not necessarily to file streams). They are text-mode connections of class "terminal" which cannot be opened or closed, and are read-only, write-only and write-only respectively. The stdout() and stderr() connections can be re-directed by sink.

The encoding for stdin() when redirected can be set by the command-line flag --encoding.

showConnections returns a matrix of information. If a connection object has been lost or forgotten, getConnection will take a row number from the table and return a connection object for that connection, which can be used to close the connection, for example.

closeAllConnections closes (and destroys) all open user connections, restoring all sink diversions as it does so.
Value

stdin(), stdout() and stderr() return connection objects.

showConnections returns a character matrix of information with a row for each connection, by
default only for open non-standard connections.

getConnection returns a connection object, or NULL.

Note

stdin() refers to the ‘console’ and not to the C-level ‘stdin’ of the process. The distinction mat-
ters in GUI consoles (which may not have an active ‘stdin’, and if they do it may not be connected
to console input), and also in embedded applications. If you want access to the C-level file stream
‘stdin’, use file("stdin").

When R is reading a script from a file, the file is the ‘console’: this is traditional usage to allow
in-line data (see ‘An Introduction to R’ for an example).

# class description mode text isopen can read can write
#3 "letters" "textConnection" "c" "text" "opened" "yes" "no"
## Not run: close(getConnection(3))

showConnections()

---

shQuote

Quote Strings for Use in OS Shells

Description

Quote a string to be passed to an operating system shell.

Usage

shQuote(string, type = c("sh", "csh", "cmd"))

Arguments

string a character vector, usually of length one.

| type | character: the type of shell. Partial matching is supported. "cmd" refers to the
|      | Windows NT shell, and is the default under Windows. |
Details

The default type of quoting supported under Unix-alikes is that for the Bourne shell `sh`. If the string does not contain single quotes, we can just surround it with single quotes. Otherwise, the string is surrounded in double quotes, which suppresses all special meanings of metacharacters except dollar, backquote and backslash, so these (and of course double quote) are preceded by backslash. This type of quoting is also appropriate for `ksh`, `zsh` and `bash`.

The other type of quoting is for the C-shell (`csh` and `tcsh`). Once again, if the string does not contain single quotes, we can just surround it with single quotes. If it does contain single quotes, we can use double quotes provided it does not contain dollar or backquote (and we need to escape backslash, exclamation mark and double quote). As a last resort, we need to split the string into pieces not containing single quotes and surround each with single quotes, and the single quotes with double quotes.

See Also

Quotes for quoting R code.

`sQuote` for quoting English text.

Examples

test <- "abc$def`gh`i\j"
cat(shQuote(test), "\n")
## Not run: system(paste("echo", shQuote(test)))
test <- "don't do it!"
cat(shQuote(test), "\n")

tryit <- "use the '-c' switch\nlike this"
cat(shQuote(tryit), "\n")
## Not run: system(paste("echo", shQuote(tryit)))
cat(shQuote(tryit, type="csh"), "\n")

## Windows-only example.
perlcmd <- 'print "Hello World\n";
## Not run: shell(paste("perl -e", shQuote(perlcmd, type="cmd")))

---

sign Sign Function

Description

`sign` returns a vector with the signs of the corresponding elements of `x` (the sign of a real number is 1, 0, or −1 if the number is positive, zero, or negative, respectively).

Note that `sign` does not operate on complex vectors.

Usage

`sign(x)`
Signals

Arguments

\[ x \]
a numeric vector

Details

This is a generic function: methods can be defined for it directly or via the Math group generic.

See Also

abs

Examples

\[
\text{sign}(\pi) \# == 1 \\
\text{sign}(-2:3) \# -1 -1 0 1 1 1
\]

Signals

Interrupting Execution of R

Description

On receiving SIGUSR1 R will save the workspace and quit. SIGUSR2 has the same result except that the .Last function and on.exit expressions will not be called.

Usage

\[
\text{kill} \ -\text{USR1} \ \text{pid} \\
\text{kill} \ -\text{USR2} \ \text{pid}
\]

Arguments

\[ \text{pid} \]
The process ID of the R process

Warning

It is possible that one or more R objects will be undergoing modification at the time the signal is sent. These objects could be saved in a corrupted form.
sink  

Send R Output to a File

Description

sink diverts R output to a connection.
sink.number() reports how many diversions are in use.
sink.number(type = "message") reports the number of the connection currently being used for error messages.

Usage

sink(file = NULL, append = FALSE, type = c("output", "message"), split = FALSE)
sink.number(type = c("output", "message"))

Arguments

file a connection or a character string naming the file to write to, or NULL to stop sink-ing.
append logical. If TRUE, output will be appended to file; otherwise, it will overwrite the contents of file.
type character. Either the output stream or the messages stream.
split logical: if TRUE, output will be sent to the new sink and to the current output stream, like the Unix program tee.

Details

sink diverts R output to a connection. If file is a character string, a file connection with that name will be established for the duration of the diversion.

Normal R output (to connection stdout()) is diverted by the default type = "output". Only prompts and (most) messages continue to appear on the console. Messages sent to stdout() (including those from message, warning and stop) can be diverted by sink(type = "message") (see below).
sink() or sink(file=NULL) ends the last diversion (of the specified type). There is a stack of diversions for normal output, so output reverts to the previous diversion (if there was one). The stack is of up to 21 connections (20 diversions).
If file is a connection it will be opened if necessary.
Sink-ing the messages stream should be done only with great care. For that stream file must be an already open connection, and there is no stack of connections.

Value

sink returns NULL.
For sink.number() the number (0, 1, 2,...) of diversions of output in place.
For sink.number("message") the connection number used for messages, 2 if no diversion has been used.
Warning

Don't use a connection that is open for `sink` for any other purpose. The software will stop you closing one such inadvertently.

Do not `sink` the messages stream unless you understand the source code implementing it and hence the pitfalls.

Note

`sink(split = TRUE)` is only available on systems which support the C99 function `va_copy` (or under the name `__va_copy`), but we know of no current systems which do not.

References

capture.output

Examples

```r
sink("sink-examp.txt")
i <- 1:10
exterior(i, i, "*")
sink()
unlink("sink-examp.txt")
## Not run:
## capture all the output to a file.
zz <- file("all.Rout", open="wt")
sink(zz)
sink(zz, type="message")
try(log("a"))
## back to the console
sink(type="message")
sink()
try(log("a"))
## End(Not run)
```

---

**slice.index**

Slice Indexes in an Array

Description

Returns a matrix of integers indicating the number of their slice in a given array.

Usage

```
slice.index(x, MARGIN)
```
Arguments

x  an array. If x has no dimension attribute, it is considered a one-dimensional array.
MARGIN  an integer giving the dimension number to slice by.

Value

An integer array y with dimensions corresponding to those of x such that all elements of slice number i with respect to dimension MARGIN have value i.

See Also

row and col for determining row and column indexes; in fact, these are special cases of slice.index corresponding to MARGIN equal to 1 and 2, respectively when x is a matrix.

Examples

x <- array(1:24, c(2, 3, 4))
slice.index(x, 2)

---

slotOp  Extract Slots

Description

Extract the contents of a slot in an object with a formal class structure.

Usage

object@name

Arguments

object  An object from a formally defined class.
name  The character-string name of the slot.

Details

This operator supports the formal classes of package methods, and is disabled unless the methods package is loaded. See slot for further details.

Currently there is no checking that the object is an instance of a formal class, nor that name is a slot name.

See Also

Extract, slot
socketSelect

Wait on Socket Connections

Description

Waits for the first of several socket connections to become available.

Usage

socketSelect(socklist, write = FALSE, timeout = NULL)

Arguments

socklist  list of open socket connections
write     logical. If TRUE wait for corresponding socket to become available for writing; otherwise wait for it to become available for reading.
timeout   numeric or NULL. Time in seconds to wait for a socket to become available; NULL means wait indefinitely.

Details

The values in write are recycled if necessary to make up a logical vector the same length as socklist. Socket connections can appear more than once in socklist; this can be useful if you want to determine whether a socket is available for reading or writing.

Value

Logical the same length as socklist indicating whether the corresponding socket connection is available for output or input, depending on the corresponding value of write.

Examples

## Not run:
## test whether socket connection s is available for writing or reading
socketSelect(list(s,s),c(TRUE,FALSE),timeout=0)
## End(Not run)

solve

Solve a System of Equations

Description

This generic function solves the equation \( a \times x = b \) for \( x \), where \( b \) can be either a vector or a matrix.

Usage

solve(a, b, ...)

## Default S3 method:
solve(a, b, tol, LINPACK = FALSE, ...)

saveState

Save the Current Workspace Environment

Description

This function saves a copy of the current environment as an R object

Usage

saveState(character = NULL, file = NULL, incremental = FALSE, directory = NULL, pattern = NULL, force = FALSE, all = TRUE, verbose = TRUE)

Arguments

character    character string
file         file name
incremental  logical
directory    directory name
pattern      character string
force        logical
all          logical
verbose      logical
Arguments

- **a**: a square numeric or complex matrix containing the coefficients of the linear system.
- **b**: a numeric or complex vector or matrix giving the right-hand side(s) of the linear system. If missing, `b` is taken to be an identity matrix and `solve` will return the inverse of `a`.
- **tol**: the tolerance for detecting linear dependencies in the columns of `a`. If `LINPACK` is `TRUE` the default is `1e-7`, otherwise it is `.Machine$double.eps`. Future versions of R may use a tighter tolerance. Not presently used with complex matrices `a`.
- **LINPACK**: logical. Should LINPACK be used (for compatibility with R < 1.7.0)? Otherwise LAPACK is used.
- **...**: further arguments passed to or from other methods

Details

- `a` or `b` can be complex, but this uses double complex arithmetic which might not be available on all platforms and LAPACK will always be used.
- The row and column names of the result are taken from the column names of `a` and of `b` respectively. As from R 1.7.0 if `b` is missing the column names of the result are the row names of `a`. No check is made that the column names of `a` and the row names of `b` are equal.
- For back-compatibility `a` can be a (real) QR decomposition, although `qr.solve` should be called in that case. `qr.solve` can handle non-square systems.

References

See Also

- `solve.qr` for the `qr` method, `chol2inv` for inverting from the Choleski factor `backsolve`, `qr.solve`.

Examples

```r
hilbert <- function(n) { i <- 1:n; 1 / outer(i - 1, i, "+") }

h8 <- hilbert(8); h8
sh8 <- solve(h8)
round(sh8 %*% h8, 3)

A <- hilbert(4)
A[] <- as.complex(A)
## might not be supported on all platforms
try(solve(A))
```
sort

Description

Sort (or order) a vector or factor (partially) into ascending (or descending) order. For ordering along more than one variable, e.g., for sorting data frames, see order.

Usage

sort(x, decreasing = FALSE, ...)  
## Default S3 method:  
sort(x, decreasing = FALSE, na.last = NA, ...)  

sort.int(x, partial = NULL, na.last = NA, decreasing = FALSE,  
method = c("shell", "quick"), index.return = FALSE)  

is.unsorted(x, na.rm = FALSE)

Arguments

x  
for sort, an R object with a class or a numeric, complex, character or logical vector. For sort.int, a numeric, complex, character or logical vector, or a factor.

decreasing  
logical. Should the sort be increasing or decreasing? Not available for partial sorting.

...  
arguments to be passed to or from methods or (for the default methods and objects without a class) to sim.int.

na.last  
for controlling the treatment of NAs. If TRUE, missing values in the data are put last; if FALSE, they are put first; if NA, they are removed.

partial  
NULL or an integer vector of indices for partial sorting.

method  
character string specifying the algorithm used.

index.return  
logical indicating if the ordering index vector should be returned as well; this is only available for a few cases, the default na.last = NA and full sorting of non-factors.

na.rm  
logical. Should missing values be removed?

Details

sort is a generic function for which methods can be written, and sort.int is the internal method which is compatible with S if only the first three arguments are used.

If partial is not NULL, it is taken to contain indices of elements of x which are to be placed in their correct positions by partial sorting. After the sort, the values specified in partial are in their correct position in the sorted array. Any values smaller than these values are guaranteed to have a smaller index in the sorted array and any values which are greater are guaranteed to have a bigger index in the sorted array. (This is included for efficiency, and many of the options are not available for partial sorting. It is only substantially more efficient if partial has a handful of elements, and a full sort is done if there are more than 10.) Names are discarded for partial sorting.
Complex values are sorted first by the real part, then the imaginary part.

The sort order for character vectors will depend on the collating sequence of the locale in use: see `Comparison`. The sort order for factors is the order of their levels (which is particularly appropriate for ordered factors).

`is.unsorted` returns a logical indicating if `x` is sorted increasingly, i.e., `is.unsorted(x)` is true if any `x != sort(x)` (and there are no NAs).

Method "shell" uses Shellsort (an $O(n^{4/3})$ variant from Sedgewick (1996)). If `x` has names a stable sort is used, so ties are not reordered. (This only matters if names are present.)

Method "quick" uses Singleton’s Quicksort implementation and is only available when `x` is numeric (double or integer) and `partial` is `NULL`. (For other types of `x` Shellsort is used, silently.) It is normally somewhat faster than Shellsort (perhaps twice as fast on vectors of length a million) but has poor performance in the rare worst case. (Peto’s modification using a pseudo-random midpoint is used to make the worst case rarer.) This is not a stable sort, and ties may be reordered.

**Value**

For `sort`, the result depends on the S3 method which is dispatched. If `x` does not have a class the rest of this section applies. For classed objects which do not have a specific method the default method will be used and is equivalent to `x[order(x, ...)]`: this depends on the class having a suitable method for `order` (and also that `order` will work, which is not the case for a class based on a list).

For `sort.int` the sorted vector unless `index.return` is true, when the result is a list with components named `x` and `ix` containing the sorted numbers and the ordering index vector. In the latter case, if `method == "quick"` ties may be reversed in the ordering, unlike `sort.list`, as quicksort is not stable.

All attributes are removed from the return value (see Becker et al., 1988, p.146) except names, which are sorted. (If `partial` is specified even the names are removed.) Note that this means that the returned value has no class, except for factors and ordered factors (which are treated specially and whose result is transformed back to the original class).

**References**

**See Also**

`order` for sorting on or reordering multiple variables.

`rank`.

**Examples**

```r
require(stats)
x <- swiss$Education[1:25]
x; sort(x); sort(x, partial = c(10, 15))
stats:::median.default # shows you another example for 'partial'
```

```r
## illustrate 'stable' sorting (of ties):
```
source

```r
sort(c(10:3,2:12), method = "sh", index=TRUE) # is stable
## $x : 2 3 3 4 4 5 5 6 6 7 7 8 8 9 9 10 10 11 12
## $ix: 9 8 10 7 11 6 12 5 13 4 14 3 15 2 16 1 17 18 19

sort(c(10:3,2:12), method = "qu", index=TRUE) # is not
## $x : 2 3 3 4 4 5 5 6 6 7 7 8 8 9 9 10 10 11 12
## $ix: 9 10 8 7 11 6 12 5 13 4 14 3 15 16 2 17 1 18 19

## Not run: ## Small speed comparison simulation:
N <- 2000
Sim <- 20
rep <- 1000 # << adjust to your CPU
cl <- c2 <- numeric(Sim)
for(is in 1:Sim){
x <- rnorm(N)
c1[is] <- system.time(for(i in 1:rep) sort(x, method = "shell"))[1]
c2[is] <- system.time(for(i in 1:rep) sort(x, method = "quick"))[1]
stopifnot(sort(x, method = "s") == sort(x, method = "q"))
}
rbind(ShellSort = c1, QuickSort = c2)
cat("Speedup factor of quick sort():\n")
summary({qq <- c1 / c2; qq[is.finite(qq)]})

## A larger test
x <- rnorm(1e7)
system.time(x1 <- sort(x, method = "shell"))
system.time(x2 <- sort(x, method = "quick"))
stopifnot(identical(x1, x2))
```

source

Read R Code from a File or a Connection

Description

source causes \texttt{R} to accept its input from the named file or URL (the name must be quoted) or connection. Input is read and \texttt{parsed} by from that file until the end of the file is reached, then the parsed expressions are evaluated sequentially in the chosen environment.

Usage

```r
source(file, local = FALSE, echo = verbose, print.eval = echo,
       verbose = getOption("verbose"),
       prompt.echo = getOption("prompt"),
       max.deparse.length = 150, chdir = FALSE,
       encoding = getOption("encoding"),
       continue.echo = getOption("continue"),
       skip.echo = 0)
```

Arguments

- `file` a connection or a character string giving the pathname of the file or URL to read from.
local if local is FALSE, the statements scanned are evaluated in the user’s workspace (the global environment), otherwise in the environment calling source.

echo logical; if TRUE, each expression is printed after parsing, before evaluation.

print.eval logical; if TRUE, the result of eval(i) is printed for each expression i; defaults to echo.

verbose if TRUE, more diagnostics (than just echo = TRUE) are printed during parsing and evaluation of input, including extra info for each expression.

prompt.echo character; gives the prompt to be used if echo = TRUE.

max.deparse.length integer; is used only if echo is TRUE and gives the maximal length of the “echo” of a single expression.

chdir logical; if TRUE and file is a pathname, the R working directory is temporarily changed to the directory containing file for evaluating.

encoding character string. The encoding to be assumed when file is a character string: see file. A possible value is "unknown": see the Details.

continue.echo character; gives the prompt to use on continuation lines if echo = TRUE.

skip.echo integer; how many comment lines at the start of the file to skip if echo = TRUE.

Details

All versions of R accept input from a connection with end of line marked by LF (as used on Unix), CRLF (as used on DOS/Windows) or CR (as used on classic MacOS). The final line can be incomplete, that is missing the final EOL marker.

If options("keep.source") is true (the default), the source of functions is kept so they can be listed exactly as input. This imposes a limit of 128K bytes on the function size and a nesting limit of 265. Use option(keep.source = FALSE) when these limits might take effect: if exceeded they generate an error.

This paragraph applies if file is a filename (rather than a connection). If encoding = "unknown", an attempt is made to guess the encoding. The result of localeToCharset() is used a guide. If encoding has two or more elements, they are tried in turn until the file/URL can be read without error in the trial encoding.

Unlike input from a console, lines in the file or on a connection can contain an unlimited number of characters. However, there is a limit of 8192 bytes on the size of character strings.

When skip.echo > 0, that many comment lines at the start of the file will not be echoed. This does not affect the execution of the code at all. If there are executable lines within the first skip.echo lines, echoing will start with the first of them.

References

See Also
demo which uses source; eval, parse and scan; options("keep.source").
sys.source which is a streamlined version to source a file into an environment.
Examples

```r
## If you want to source() a bunch of files, something like
## the following may be useful:
sourcDir <- function(path, trace = TRUE, ...) {
  for (nm in list.files(path, pattern = ".*\.[RrSsQq]$")) {
    if(trace) cat(nm,":")
    source(file.path(path, nm), ...)
    if(trace) cat("\n")
  }
}
```

Special Functions of Mathematics

Description

Special mathematical functions related to the beta and gamma functions.

Usage

- `beta(a, b)`
- `lbeta(a, b)`
- `gamma(x)`
- `lgamma(x)`
- `psigamma(x, deriv = 0)`
- `digamma(x)`
- `trigamma(x)`
- `choose(n, k)`
- `lchoose(n, k)`
- `factorial(x)`
- `lfactorial(x)`

Arguments

- `a, b, x, n` numeric vectors.
- `k, deriv` integer vectors.

Details

The functions `beta` and `lbeta` return the beta function and the natural logarithm of the beta function,

\[
B(a, b) = \frac{\Gamma(a)\Gamma(b)}{\Gamma(a + b)}.
\]

The formal definition is

\[
B(a, b) = \int_0^1 t^{a-1}(1 - t)^{b-1} dt
\]

(Abramowitz and Stegun (6.2.1), page 258).

The functions `gamma` and `lgamma` return the gamma function \(\Gamma(x)\) and the natural logarithm of the absolute value of the gamma function. The gamma function is defined by (Abramowitz and Stegun (6.1.1), page 255)

\[
\Gamma(x) = \int_0^\infty t^{a-1}e^{-t} dt
\]
factorial(x) is x! and identical to gamma(x+1) and lfactorial is lgamma(x+1).

The functions digamma and trigamma return the first and second derivatives of the logarithm of the gamma function. psigamma(x, deriv) (deriv >= 0) is more generally computing the deriv-th derivative of ψ(x).

\[
digamma(x) = \psi(x) = \frac{d}{dx} \ln \Gamma(x) = \frac{\Gamma'(x)}{\Gamma(x)}
\]

The functions choose and lchoose return binomial coefficients and their logarithms. Note that choose(n,k) is defined for all real numbers n and integer k. For k ≥ 1 as n(n−1)⋯(n−k+1)/k!, as 1 for k = 0 and as 0 for negative k. choose(*,k) uses direct arithmetic (instead of [l]gamma calls) for small k, for speed and accuracy reasons. Note the function combn (package utils) for enumeration of all possible combinations.

The gamma, lgamma, digamma and trigamma functions are generic: methods can be defined for them individually or via the Math group generic.

References

sqrt(1.25)
sum(choose(1/2, k)* .25^k)

---

**split** 375

*Divide into Groups*

**Description**

*split* divides the data in the vector *x* into the groups defined by *f*. The replacement forms replace values corresponding to such a division. *unsplit* reverses the effect of *split*.

**Usage**

```r
split(x, f, drop = FALSE, ...)
unsplit(value, f, drop = FALSE)
```

**Arguments**

- **x**
  - vector or data frame containing values to be divided into groups.
- **f**
  - a “factor” in the sense that `as.factor(f)` defines the grouping, or a list of such factors in which case their interaction is used for the grouping.
- **drop**
  - logical indicating if levels that do not occur should be dropped (if *f* is a factor or a list).
value: a list of vectors or data frames compatible with a splitting of \( x \). Recycling applies if the lengths do not match.

... further potential arguments passed to methods.

Details

`split` and `split<-` are generic functions with default and `data.frame` methods.

\( f \) is recycled as necessary and if the length of \( x \) is not a multiple of the length of \( f \) a warning is printed. `unsplit` works only with lists of vectors. The data frame method can also be used to split a matrix into a list of matrices, and the replacement form likewise, provided they are invoked explicitly.

Any missing values in \( f \) are dropped together with the corresponding values of \( x \).

Value

The value returned from `split` is a list of vectors containing the values for the groups. The components of the list are named by the used factor levels given by \( f \). (If \( f \) is longer than \( x \) then some of the components will be of zero length.)

The replacement forms return their right hand side. `unsplit` returns a vector for which `split(x, f)` equals `value`.

`cut`

Examples

```r
require(stats)
n <- 10; nn <- 100
g <- factor(round(n * runif(n * nn)))
x <- rnorm(n * nn) + sqrt(as.numeric(g))
xg <- split(x, g)
boxplot(xg, col = "lavender", notch = TRUE, varwidth = TRUE)
sapply(xg, length)
sapply(xg, mean)
## Calculate z-scores by group
z <- unsplit(lapply(split(x, g), scale), g)
tapply(z, g, mean)
# or
z <- x
split(z, g) <- lapply(split(x, g), scale)
tapply(z, g, sd)
## Split a matrix into a list by columns
ma <- cbind(x = 1:10, y = (-4:5)^2)
```
### Use C-style String Formatting Commands

**Description**

A wrapper for the C function `sprintf`, that returns a character vector containing a formatted combination of text and variable values.

**Usage**

```r
sprintf(fmt, ...)  
gettextf(fmt, ..., domain = NULL)
```

**Arguments**

- `fmt` a format string.
- `...` values to be passed into `fmt`. Only logical, integer, real and character vectors are supported, but some coercion will be done: see the Details section.
- `domain` see `gettext`.

**Details**

`sprintf` is a wrapper for the system `sprintf` C-library function. Attempts are made to check that the mode of the values passed match the format supplied, and R’s special values (NA, Inf, -Inf and NaN) are handled correctly.

`gettextf` is a convenience function which provides C-style string formatting with possible translation of the format string.

The arguments (including `fmt`) are recycled if possible a whole number of times to the length of the longest, and then the formatting is done in parallel.

The following is abstracted from Kernighan and Ritchie (see References). The string `fmt` contains normal characters, which are passed through to the output string, and also special characters that operate on the arguments provided through `...`. Special characters start with a `%` and end with one of the letters in the set `difeEgGsxX%`. These letters denote the following types:

- **d, i, x, X** Integer value, **x** and **X** being hexadecimal (using the same case for a-f as the code). Numeric variables with exactly integer values will be coerced to integer.
- **f** Double precision value, in decimal notation of the form "[-]mmm.ddd". The number of decimal places is specified by the precision: the default is 6; a precision of 0 suppresses the decimal point.
- **e, E** Double precision value, in decimal notation of the form [-]m.ddde[+-]xx or [-]m.dddE[+-]xx.
- **g, G** Double precision value, in %e or %E format if the exponent is less than -4 or greater than or equal to the precision, and %f format otherwise.
- **s** Character string.
- **%** Literal % (none of the formatting characters given below are permitted in this case).
**as.character** is used for non-character arguments with *s* and **as.double** for non-double arguments with *f*, *e*, *E*, *g*, *G*. NB: the length is determined before conversion, so do not rely on the internal coercion if this would change the length.

In addition, between the initial `%` and the terminating conversion character there may be, in any order:

- **m.n** Two numbers separated by a period, denoting the field width (*m*) and the precision (*n*)
- − Left adjustment of converted argument in its field
- + Always print number with sign
- **a space** Prefix a space if the first number is not a sign
- 0 For numbers, pad to the field width with leading zeros

Further, immediately after `%` may come 1$ to 99$ to refer to the numbered argument: this allows arguments to be referenced out of order and is mainly intended for translators of error messages. If this is done it is best if all formats are numbered: if not the unnumbered ones process the arguments in order. See the examples.

A field width or precision (but not both) may be indicated by an asterisk *1. In this case an argument specifies the desired number. A negative field width is taken as a '-' flag followed by a positive field width. A negative precision is taken as if the precision were omitted. The *1$ to *99$ notation for arguments referenced out of order is also supported.

The result has a length limit, probably 8192 bytes, and attempts to exceed this may result in an error, or truncation with a warning.

**Value**

A character vector of length that of the longest input. Character **NA**s are converted to "**NA**".

**Author(s)**

Original code by Jonathan Rougier, ⟨J.C.Rougier@durham.ac.uk⟩.

**References**

**See Also**

**formatC** for a way of formatting vectors of numbers in a similar fashion.

**paste** for another way of creating a vector combining text and values.

**gettext** for the mechanisms for the automated translation of text.

**Examples**

```r
## be careful with the format: most things in R are floats
## only integer-valued reals get coerced to integer.

sprintf("%s is %f feet tall
", "Sven", 7.1)  # OK
try(sprintf("%s is %f feet tall
", "Sven", 7.1))  # not OK
try(sprintf("%s is %i feet tall
", "Sven", 7))  # OK

## use a literal % :
```
sprintf("%.0f%% said yes (out of a sample of size %.0f)", 66.666, 3)

## various formats of pi :

```r
sprintf("%f", pi)
sprintf("%.3f", pi)
sprintf("%1.0f", pi)
sprintf("%5.1f", pi)
sprintf("%05.1f", pi)
sprintf("%+f", pi)
sprintf("% f", pi)
sprintf("%-10f", pi) # left justified
sprintf("%e", pi)
sprintf("%E", pi)
sprintf("%g", pi)
sprintf("%g", le6 * pi) # -> exponential
sprintf("%.9g", le6 * pi) # -> "fixed"
sprintf("%G", le-6 * pi)
```

## no truncation:

```r
sprintf("%1.f",101)
```

## re-use one argument three times, show difference between %x and %X

```r
xx <- sprintf("%1$d %1$x %1$X", 0:15)
xx <- matrix(xx, dimnames=list(rep("", 16), "%d%x%X"))
noquote(format(xx, justify="right"))
```

## More sophisticated:

```r
sprintf("min 10-char string '%10s'",
    c("a", "ABC", "and an even longer one"))
```

```r
n <- 1:18
sprintf(paste("e with %2d digits = %.",n,"g",sep=""), n, exp(1))
```

## Using arguments out of order

```r
sprintf("second %2$1.0f, first %1$5.2f, third %3$1.0f", pi, 2, 3)
```

## Using asterisk for width or precision

```r
sprintf("precision %. *f, width '% *.3f'", 3, pi, 8, pi)
```

## Asterisk and argument re-use, 'e' example reiterated:

```r
sprintf("e with %1$2d digits = %2$. *1$g", n, exp(1))
```

## re-cycle arguments

```r
sprintf("%s %d", "test", 1:3)
```

---

### Description

Single or double quote text by combining with appropriate single or double left and right quotation marks.
Usage

sQuote(x)
dQuote(x)

Arguments

x

an R object, to be coerced to a character vector.

Details

The purpose of the functions is to provide a simple means of markup for quoting text to be used in the R output, e.g., in warnings or error messages. Note that English quoting conventions are used, whatever the locale in use.

The choice of the appropriate quotation marks depends on both the locale and the available character sets. Older Unix/X11 fonts displayed the grave accent (0x60) and the apostrophe (0x27) in a way that they could also be used as matching open and close single quotation marks. Using modern fonts, or non-Unix systems, these characters no longer produce matching glyphs. Unicode provides left and right single quotation mark characters (U+2018 and U+2019); if Unicode cannot be assumed, it seems reasonable to use the apostrophe as an undirectional single quotation mark.

Similarly, Unicode has left and right double quotation mark characters (U+201C and U+201D); if only ASCII’s typewriter characteristics can be employed, than the ASCII quotation mark (0x22) should be used as both the left and right double quotation mark.

By default, sQuote and dQuote employ undirectional ASCII quotation style. In a UTF-8 locale (see l10n_info), the Unicode directional quotes are used.

See Also

Quotes for quoting R code.

shQuote for quoting OS commands.

Examples

paste("argument", sQuote("x"), "must be non-zero")

Description

These functions are for working with source files.
Usage

```r
srcfile(filename, encoding = getOption("encoding"))
srcfilecopy(filename, lines)
getSrcLines(srcfile, first, last)
srcref(srcfile, lloc)
## S3 method for class 'srcfile':
  print(x, ...)
## S3 method for class 'srcfile':
  open(con, line, ...)
## S3 method for class 'srcfile':
  close(con, ...)
## S3 method for class 'srcref':
  print(x, useSource = TRUE, ...)
## S3 method for class 'srcref':
  as.character(x, useSource = TRUE, ...)
.isOpen(srcfile)
```

Arguments

- `filename` The name of a file
- `encoding` The character encoding to assume for the file
- `lines` A character vector of source lines. Other R objects will be coerced to character.
- `srcfile` A `srcfile` object
- `first, last, line` Line numbers
- `lloc` A vector of four values giving a source location; see Details
- `x, con` An object of the appropriate type
- `useSource` Whether to read the `srcfile` to obtain the text of a `srcref`
- `...` Additional arguments to the methods; these will be ignored

Details

These functions and classes handle source code references.

The `srcfile` function produces an object of class `srcfile`, which contains the name and directory of a source code file, along with its timestamp, for use in source level debugging (not yet implemented) and source echoing. The encoding of the file is saved; see `file` for a discussion of encodings, and `iconvlist` for a list of allowable encodings on your platform.

The `srcfilecopy` function produces an object of the descendant class `srcfilecopy`, which saves the source lines in a character vector.

The `getSrcLines` function reads the specified lines from `srcfile`. The `srcref` function produces an object of class `srcref`, which describes a range of characters in a `srcfile`. The `lloc` value gives the following values: `c(first_line, first_column, last_line, last_column)`.

Methods are defined for `print`, `open`, and `close` for classes `srcfile` and `srcfilecopy`. The `open` method opens its internal file connection at a particular line; if it was already open, it will be repositioned to that line.

Methods are defined for `print` and `as.character` for class `srcref`. The `as.character` method will read the associated source file to obtain the text corresponding to the reference. If
an error occurs (e.g. the file no longer exists), text like `<srcref: "file" chars 1:1 to 2:10>` will be returned instead, indicating the line:column ranges of the first and last character.

Lists of `srcref` objects may be attached to expressions as the "srcref" attribute. (The list of `srcref` objects should be the same length as the expression.) By default, expressions are printed by `print.default` using the associated `srcref`. To see deparsed code instead, call `print` with argument `useSource = FALSE`. If a `srcref` object is printed with `useSource = FALSE`, the `<srcref: ...>` record will be printed.

`.is_open` is intended for internal use: it checks whether the connection associated with a `srcfile` object is open.

**Value**

srcfile returns a `srcfile` object.

srcfilecopy returns a `srcfilecopy` object.

getSrcLines returns a character vector of source code lines.

`srcref` returns a `srcref` object.

**Author(s)**

Duncan Murdoch

**Examples**

```r
src <- srcfile(system.file("DESCRIPTION", package = "base"))
getSrcLines(src, 1, 4)
ref <- srcref(src, c(1, 1, 2, 1000))
ref
print(ref, useSource = FALSE)
```

---

**Startup**

**Initialization at Start of an R Session**

**Description**

In R, the startup mechanism is as follows.

Unless ` '--no-environ' ` was given on the command line, R searches for user and site files to process for setting environment variables. The name of the site file is the one pointed to by the environment variable `R_ENVIRON`; if this is unset or empty, `$R_HOME/etc/Renviron.site` is used (if it exists, which it does not in a “factory-fresh” installation). The user files searched for are `.Renviron` in the current or in the user’s home directory (in that order). See **Details** for how the files are read.

Then R searches for the site-wide startup profile unless the command line option ` '--no-site-file' ` was given. The name of this file is taken from the value of the `R_PROFILE` environment variable. If this variable is unset, the default is `$R_HOME/etc/Rprofile.site`, which is used if it exists (which it does not in a “factory-fresh” installation). This code is loaded into package `base`. Users need to be careful not to unintentionally overwrite objects in base, and it is normally advisable to use `local` if code needs to be executed: see the examples.

Then, unless ` '--no-init-file' ` was given, R searches for a file called `.Rprofile` in the current directory or in the user’s home directory (in that order) and sources it into the user workspace.
It then loads a saved image of the user workspace from `.RData` if there is one (unless `--no-restore-data` was specified, or `--no-restore`, on the command line).

Next, if a function `.First` is found on the search path, it is executed as `.First()`. Finally, function `.First.sys()` in the `base` package is run. This calls `require` to attach the default packages specified by `options("defaultPackages")`. If the `methods` package is included, this will have been attached earlier (by function `.OptRequireMethods()`) so that name space initializations such as those from the user workspace will proceed correctly.

A function `.First` (and `.Last`) can be defined in appropriate `.Rprofile` or `Rprofile.site` files or have been saved in `.RData`. If you want a different set of packages than the default ones when you start, insert a call to `options` in the `.Rprofile` or `Rprofile.site` file. For example, `options(defaultPackages = character())` will attach no extra packages on startup (only the `base` package) (or set `R_DEFAULT_PACKAGES=NULL` as an environment variable before running R). Using `options(defaultPackages = "")` or `R_DEFAULT_PACKAGES=""` enforces the R system default.

The commands history is read from the file specified by the environment variable `R_HISTFILE` (default `.Rhistory`) unless `--no-restore-history` was specified (or `--no-restore`).

The command-line flag `--vanilla` implies `--no-site-file`, `--no-init-file`, `--no-restore` and `--no-environ`.

**Usage**

```
.First <- function() { ...... }

.Rprofile <startup file>
```

**Details**

Note that there are two sorts of files used in startup: *environment files* which contain lists of environment variables to be set, and *profile files* which contain R code.

Lines in a site or user environment file should be either comment lines starting with #, or lines of the form name=value. The latter sets the environmental variable name to value, overriding an existing value. If value contains an expression of the form `${foo-bar}`, the value is that of the environmental variable `foo` if that exists and is set to a non-empty value, otherwise `bar`. (If it is of the form `${foo}`, the default is "".) This construction can be nested, so `bar` can be of the same form (as in `${foo-$(bar-blah))`). Note that the braces are essential: `$HOME` will not be interpreted.

Leading and trailing white space in `value` are stripped. `value` is processed in a similar way to a Unix shell. In particular the outermost level of (single or double) quotes is stripped, and backslashes are removed except inside quotes.

**Note**

The file `$R_HOME/etc/Renviron` is always read very early in the start-up processing. It contains environment variables set by R in the configure process. Values in that file can be overridden in site or user environment files: do not change `$R_HOME/etc/Renviron` itself. Note that this is distinct from `$R_HOME/etc/Renviron.site`.

**See Also**

`.Last` for final actions before termination. `commandArgs` for accessing the command line arguments.
An Introduction to R for more command-line options: those affecting memory management are covered in the help file for Memory.

For profiling code, see Rprof.

Examples

## Not run:
# Example ~/.Renviron on Unix
R_LIBS=~/.R/library
PAGER=~/.local/bin/less

# Example .Renviron on Windows
R_LIBS=C:/R/library
MY_TCLTK=yes
TCL_LIBRARY=c:/packages/Tcl/lib/tcl8.4

# Example of setting R_DEFAULT_PACKAGES (from R CMD check)
R_DEFAULT_PACKAGES='utils,grDevices,graphics,stats'
# this loads the packages in the order given, so they appear on
# the search path in reverse order.

# Example of .Rprofile
options(width=65, digits=5)
options(show.signif.stars=FALSE)
setHook(packageEvent("grDevices", "onLoad"),
  function(...) grDevices::ps.options(horizontal=FALSE))
set.seed(1234)
.First <- function() cat("\n Welcome to R!\n\n")
.Last <- function() cat("\n Goodbye!\n\n")

# Example of Rprofile.site
local({
  old <-getOption("defaultPackages")
  options(defaultPackages = c(old, "MASS"))
})

## if .Renviron contains
FOOBAR="coo\bar"doh\ex"abc"def'"

## then we get
> cat(Sys.getenv("FOOBAR"), "\n")
coo\bardoh\exabc"def'
## End(Not run)

---

**stop**

Stop Function Execution

Description

stop stops execution of the current expression and executes an error action.

geterrmessage gives the last error message.
Usage

```
stop(..., call. = TRUE, domain = NULL)
geterrmessage()
```

Arguments

- ...: zero or more objects which can be coerced to character (and which are pasted together with no separator) or a single condition object.
- call.: logical, indicating if the call should become part of the error message.
- domain: see `gettext`. If NA, messages will not be translated.

Details

The error action is controlled by error handlers established within the executing code and by the current default error handler set by `options(error=)`. The error is first signaled as if using `signalCondition()`. If there are no handlers or if all handlers return, then the error message is printed (if `options("show.error.messages")` is true) and the default error handler is used. The default behaviour (the NULL error-handler) in interactive use is to return to the top level prompt or the top level browser, and in non-interactive use to (effectively) call `q("no", status=1, runLast=FALSE)`. The default handler stores the error message in a buffer; it can be retrieved by `geterrmessage()`. It also stores a trace of the call stack that can be retrieved by `traceback()`.

Errors will be truncated to `getOption("warning.length")` characters, default 1000.

If a condition object is supplied it should be the only argument, and further arguments will be ignored, with a warning.

Value

`geterrmessage` gives the last error message, as a character string ending in "\n".

References

See Also

`warning, try` to catch errors and retry, and `options` for setting error handlers. `stopifnot` for validity testing. `tryCatch` and `withCallingHandlers` can be used to establish custom handlers while executing an expression.

`gettext` for the mechanisms for the automated translation of messages.

Examples

```
options(error = expression(NULL))
# don't stop on stop(.)  << Use with CARE! >>

iter <- 12
if(iter > 10) stop("too many iterations")

tst1 <- function(...) stop("dummy error")
tst1(1:10, long, calling, expression)
```
stopifnot <- function(...) stop("dummy error", call. = FALSE)
tst2 <- function(...) stop("dummy error", call. = FALSE)
tst2(1:10, longcalling, expression, but.not.seen.in.Error)
options(error = NULL)# revert to default

---

**stopifnot**

Ensure the ‘Truth’ of R Expressions

**Description**

If any of the expressions in ... are not all TRUE, stop is called, producing an error message indicating the first of the elements of ... which were not true.

**Usage**

stopifnot(...)

**Arguments**

... any number of (logical) R expressions.

which should evaluate to TRUE.

**Details**

This function is intended for use in regression tests or also argument checking of functions, in particular to make them easier to read.

stopifnot(A, B) is conceptually equivalent to { if(any(is.na(A)) || !all(A)) stop(...) ; if(any(is.na(B)) || !all(B)) stop(...) }.

**Value**

(NULL if all statements in ... are TRUE.)

**See Also**

stop, warning.

**Examples**

```r
stopifnot(1 == 1, all.equal(pi, 3.14159265), 1 < 2) # all TRUE
m <- matrix(c(1,3,3,1), 2,2)
stopifnot(m == t(m), diag(m) == rep(1,2)) # all(.) |=> TRUE

# disable stop(.)" << Use with CARE! >>

op <- options(error = expression(NULL))

stopifnot(all.equal(pi, 3.141593), 2 < 2, all(l:10 < 12), "a" < "b")

options(op)# revert to previous error handler
```
strptime

387

Date-time Conversion Functions to and from Character

strptime

Description
Functions to convert between character representations and objects of classes "POSIXlt" and
"POSIXct" representing calendar dates and times.
Usage
## S3 method for
format(x, format
## S3 method for
format(x, format

class
= "",
class
= "",

'POSIXct':
tz = "", usetz = FALSE, ...)
'POSIXlt':
usetz = FALSE, ...)

## S3 method for class 'POSIXt':
as.character(x, ...)
strftime(x, format="", usetz = FALSE, ...)
strptime(x, format, tz = "")
ISOdatetime(year, month, day, hour, min, sec, tz = "")
ISOdate(year, month, day, hour = 12, min = 0, sec = 0, tz = "GMT")
Arguments
x

An object to be converted.

tz

A timezone specification to be used for the conversion. System-specific (see
as.POSIXlt), but "" is the current time zone, and "GMT" is UTC.

format

A character string. The default is "%Y-%m-%d %H:%M:%S" if any component
has a time component which is not midnight, and "%Y-%m-%d" otherwise. If
options("digits.secs") is set, up to the specified number of digits will
be printed for seconds.

...

Further arguments to be passed from or to other methods.

logical. Should the timezone be appended to the output? This is used in printing times, and as a workaround for problems with using "%Z" on most Linux
systems.
year, month, day
numerical values to specify a day.
hour, min, sec
numerical values for a time within a day. Fractional seconds are allowed.
usetz

Details
The format and as.character methods and strftime convert objects from the classes
"POSIXlt" and "POSIXct" (not strftime) to character vectors.
strptime converts character strings to class "POSIXlt": its input x is first coerced to character
if necessary. Each string is processed as far as necessary for the format specified: any trailing
characters are ignored.


strptime is an alias for format.POSIXlt, and format.POSIXct first converts to class "POSIXlt" by calling as.POSIXlt. Note that only that conversion depends on the time zone.

The usual vector re-cycling rules are applied to x and format so the answer will be of length that of the longer of the vectors.

Locale-specific conversions to and from character strings are used where appropriate and available. This affects the names of the days and months, the AM/PM indicator (if used) and the separators in formats such as %x and %X.

The details of the formats are system-specific, but the following are defined by the ISO C / POSIX standard for strftime and are likely to be widely available. A conversion specification is introduced by %, usually followed by a single letter or O or E and then a single letter. Any character in the format string not part of a conversion specification is interpreted literally (and %% gives %).

Widely implemented conversion specifications include

- %a Abbreviated weekday name in the current locale. (Also matches full name on input.)
- %A Full weekday name in the current locale. (Also matches abbreviated name on input.)
- %b Abbreviated month name in the current locale. (Also matches full name on input.)
- %B Full month name in the current locale. (Also matches abbreviated name on input.)
- %c Date and time, locale-specific.
- %d Day of the month as decimal number (01–31).
- %H Hours as decimal number (00–23).
- %I Hours as decimal number (01–12).
- %j Day of year as decimal number (001–366).
- %m Month as decimal number (01–12).
- %M Minute as decimal number (00–59).
- %p AM/PM indicator in the locale. Used in conjunction with %I and not with %H.
- %S Second as decimal number (00–61), allowing for up to two leap-seconds (but POSIX-compliant OSes will ignore leap seconds).
- %U Week of the year as decimal number (00–53) using the first Sunday as day 1 of week 1.
- %w Weekday as decimal number (0–6, Sunday is 0).
- %W Week of the year as decimal number (00–53) using the first Monday as day 1 of week 1.
- %x Date, locale-specific.
- %X Time, locale-specific.
- %y Year without century (00–99). If you use this on input, which century you get is system-specific. So don’t! Often values up to 69 (or 68) are prefixed by 20 and 70(or 69) to 99 by 19.
- %Y Year with century.
- %z (output only.) Offset from Greenwich, so -0800 is 8 hours west of Greenwich.
- %Z (output only.) Time zone as a character string (empty if not available).

Where leading zeros are shown they will be used on output but are optional on input.

Also defined in the current standards but less widely implemented (e.g. not for output on Windows) are

- %C Century (00–99): the integer part of the year divided by 100.
- %D Locale-specific date format such as %m/%d/%y: ISO C99 says it should be that exact format.
- %e Day of the month as decimal number (1–31), with a leading space for a single-digit number.
strptime

%F Equivalent to %Y-%m-%d (the ISO 8601 date format).
%g The last two digits of the week-based year (see %V). (Typically accepted but ignored on input.)
%G The week-based year (see %V) as a decimal number. (Typically accepted but ignored on input.)
%h Equivalent to %b.
%k The 24-hour clock time with single digits preceded by a blank.
%l The 12-hour clock time with single digits preceded by a blank.
%n Newline on output, arbitrary whitespace on input.
%r The 12-hour clock time (using the locale’s AM or PM).
%R Equivalent to %H:%M.
%t Tab on output, arbitrary whitespace on input.
%T Equivalent to %H:%M:%S.
%u Weekday as a decimal number (1–7, Monday is 1).
%V Week of the year as decimal number (00–53). If the week (starting on Monday) containing 1 January has four or more days in the new year, then it is considered week 1. Otherwise, it is the last week of the previous year, and the next week is week 1. (Typically accepted but ignored on input.)

For output (and possibly input) there are also %O[dHImUvWs] which may emit numbers in an alternative locale-dependent format (e.g. roman numerals), and %E[cCyxX] which can use an alternative ‘era’ (e.g. a different religious calendar). Which of these are supported is OS-dependent.

Specific to R is %OSn, which for output gives the seconds to 0 <= n <= 6 decimal places (and if %OS is not followed by a digit, it uses the setting of getOption("digits.secs"), or if that is unset, n = 3). Further, for strptime %OS will input seconds including fractional seconds.

The behaviour of other conversion specifications (and even if other character sequences commencing with % are conversion specifications) is system-specific.

ISOdatetime and ISOdate are convenience wrappers for strptime, that differ only in their defaults and that ISOdate sets a timezone. (For dates without times it would be better to use the "Date" class.)

Value

The format methods and strftime return character vectors representing the time.

strptime turns character representations into an object of class "POSIXlt". The timezone is used to set the isdst component and (as from R 2.5.0) to set the "tzone" attribute if tz != "".

ISOdatetime and ISOdate return an object of class "POSIXct".

Note

The default formats follow the rules of the ISO 8601 international standard which expresses a day as "2001-02-28" and a time as "14:01:02" using leading zeroes as here. The ISO form uses no space to separate dates and times.

If the date string does not specify the date completely, the returned answer may be system-specific. The most common behaviour is to assume that unspecified seconds, minutes or hours are zero, and a missing year, month or day is the current one. If it specifies a date incorrectly, reliable implementations will give an error and the date is reported as NA. Unfortunately some common implementations (such as glibc’) are unreliable and guess at the intended meaning.
If the timezone specified is invalid on your system, what happens is system-specific but it will probably be ignored.

OS facilities will probably not print years before 1CE (aka 1AD) correctly.

Remember that in most timezones some times do not occur and some occur twice because of transitions to/from summer time. What happens in those cases is OS-specific.

References

See Also

DateTimeClasses for details of the date-time classes; locales to query or set a locale.

Your system’s help pages on strftime and strptime to see how to specify their formats. (On some systems strptime is replaced by corrected code from ‘glibc’, when all the conversion specifications described here are supported, but with no alternative number representation nor era available in any locale.)

Examples

```r
## locale-specific version of date()
format(Sys.time(), "%a %b %d %X %Y %Z")

## time to sub-second accuracy (if supported by the OS)
format(Sys.time(), "%H:%M:%OS3")

## read in date info in format 'ddmmmyyyy'
## This will give NA(s) in some locales; setting the C locale
## as in the commented lines will overcome this on most systems.
## lct <- Sys.getlocale("LC_TIME"); Sys.setlocale("LC_TIME", "C")
x <- c("1jan1960", "2jan1960", "31mar1960", "30jul1960")
z <- strptime(x, "%d%b%Y")
## Sys.setlocale("LC_TIME", lct)
z

## read in date/time info in format 'm/d/y h:m:s'
dates <- c("02/27/92", "02/27/92", "01/14/92", "02/28/92", "02/01/92")
x <- paste(dates, times)
strptime(x, "%m/%d/%y %H:%M:%S")

## time with fractional seconds
z <- strptime("20/2/06 11:16:16.683", "%d/%m/%y %H:%M:%OS")
z # prints without fractional seconds
op <- options(digits.secs=3)
z
options(op)

## timezones are not portable, but 'EST5EDT' comes pretty close.
(x <- strptime(c("2006-01-08 10:07:52", "2006-08-07 19:33:02"),
"%Y-%m-%d %H:%M:%S", tz="EST5EDT"))
```
strsplit

Split the Elements of a Character Vector

Description

Split the elements of a character vector \( x \) into substrings according to the presence of substring \( \text{split} \) within them.

Usage

\[
\text{strsplit}(x, \text{split}, \text{extended} = \text{TRUE}, \text{fixed} = \text{FALSE}, \text{perl} = \text{FALSE})
\]

Arguments

- **x**: character vector, each element of which is to be split. Other inputs, including a factor, will give an error.
- **split**: character vector (or object which can be coerced to such) containing regular expression(s) (unless \( \text{fixed} = \text{TRUE} \)) to use as “split”. If empty matches occur, in particular if \( \text{split} \) has length 0, \( x \) is split into single characters. If \( \text{split} \) has length greater than 1, it is re-cycled along \( x \).
- **extended**: logical. If \( \text{TRUE} \), extended regular expression matching is used, and if \( \text{FALSE} \) basic regular expressions are used.
- **fixed**: logical. If \( \text{TRUE} \) match string exactly, otherwise use regular expressions. Has priority over \( \text{perl} \) and \( \text{extended} \).
- **perl**: logical. Should perl-compatible regexps be used? Has priority over \( \text{extended} \).

Details

Argument \( \text{split} \) will be coerced to character, so you will see uses with \( \text{split} = \text{NULL} \) to mean \( \text{split} = \text{character}(0) \), including in the examples below.

Note that splitting into single characters can be done via \( \text{split}=\text{character}(0) \) or \( \text{split}="" \); the two are equivalent. The definition of ‘character’ here depends on the locale (and perhaps OS): in a single-byte locale it is a byte, and in a multi-byte locale it is the unit represented by a ‘wide character’ (almost always a Unicode point).

A missing value of \( \text{split} \) does not split the corresponding element(s) of \( x \) at all.

The algorithm applied to each input string is

\[
\text{repeat} \{ \\
\hspace{1em} \text{if the string is empty} \\
\hspace{2em} \text{break}. \\
\hspace{1em} \text{if there is a match} \\
\hspace{2em} \text{add the string to the left of the match to the output.} \\
\hspace{2em} \text{remove the match and all to the left of it.} \\
\hspace{1em} \text{else} \\
\hspace{2em} \text{add the string to the output.} \\
\hspace{1.5em} \text{break.} \\
\}
\]
Note that this means that if there is a match at the beginning of a (non-empty) string, the first element of the output is "", but if there is a match at the end of the string, the output is the same as with the match removed.

**Value**

A list of length \(\text{length}(x)\) the \(i\)-th element of which contains the vector of splits of \(x[i]\).

**Warning**

The standard regular expression code has been reported to be very slow when applied to extremely long character strings (tens of thousands of characters or more): the code used when `perl = TRUE` seems much faster and more reliable for such usages.

The `perl = TRUE` option is only implemented for single-byte and UTF-8 encodings, and will warn if used in a non-UTF-8 multibyte locale.

**See Also**

`paste` for the reverse, `grep` and `sub` for string search and manipulation; further `nchar`, `substr`.

`regular expression` for the details of the pattern specification.

**Examples**

```r
noquote(strsplit("A text I want to display with spaces", NULL)[[1]])
```

```r
x <- c(as = "asfef", qu = "qwerty", "yuiop[", "b", "stuff.blah.yech")
# split x on the letter e
strsplit(x,"e")

unlist(strsplit("a.b.c", "."))
## [1] "a" "b" "c"

## or
unlist(strsplit("a.b.c", ".", fixed = TRUE))

## a useful function: rev() for strings
strReverse <- function(x)
    sapply(lapply(strsplit(x, NULL), rev), paste, collapse="")
strReverse(c("abc", "Statistics"))

## get the first names of the members of R-core
a <- readLines(file.path(R.home("doc"),"AUTHORS"))[-(1:8)]
a <- a[(0:2)-length(a)]
(a <- sub(" . *","", a))
# and reverse them
strReverse(a)

## Note that final empty strings are not produced:
strsplit(paste(c("","a",""), collapse="#"), split="#")[[1]]
## [1] "a"

## and also an empty string is only produced before a definite match:
```
**strtrim**

Trim Character Strings to Specified Widths

**Description**

Trim character strings to specified display widths.

**Usage**

`strtrim(x, width)`

**Arguments**

- `x` a character vector, or an object which can be coerced to a character vector by `as.character`.
- `width` Positive integer values: recycled to the length of `x`.

**Details**

'Width' is interpreted as the display width in a monospaced font. What happens with non-printable characters (such as backspace, tab) is implementation-dependent and may depend on the locale (e.g. they may be included in the count or they may be omitted).

Using this function rather than `substr` is important when there might be double-width characters in character vectors.

**Value**

A character vector of the same length and with the same attributes as `x` (after possible coercion).

**Examples**

`strtrim(c("abcdef", "abcdef", "abcdef"), c(1,5,10))`

<table>
<thead>
<tr>
<th><strong>structure</strong></th>
<th>Attribute Specification</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Description</strong></td>
<td><code>structure</code> returns the given object with further <code>attributes</code> set.</td>
</tr>
<tr>
<td><strong>Usage</strong></td>
<td><code>structure(.Data, ...)</code></td>
</tr>
<tr>
<td><strong>Arguments</strong></td>
<td><code>.Data</code> an object which will have various attributes attached to it.</td>
</tr>
<tr>
<td></td>
<td><code>...</code> attributes, specified in <code>tag=value</code> form, which will be attached to data.</td>
</tr>
</tbody>
</table>

```r
strsplit("", "")[1]  # character(0)
strsplit(" ", "")[1]  # [1] ""
```
Details

Adding a class "factor" will ensure that numeric codes are given integer storage mode.

For historical reasons (these names are used when deparsing), attributes ".Dim", ".Dimnames", ".Names", ".Tsp" and ".Label" are renamed to "dim", "dimnames", "names", "tsp" and "levels".

It is possible to give the same tag more than once, in which case the last value assigned wins. As with other ways of assigning attributes, using tag=NULL removes attribute tag from .Data if it is present.

---

strwrap

Wrap Character Strings to Format Paragraphs

Description

Each character string in the input is first split into paragraphs (on lines containing whitespace only). The paragraphs are then formatted by breaking lines at word boundaries. The target columns for wrapping lines and the indentation of the first and all subsequent lines of a paragraph can be controlled independently.

Usage

strwrap(x, width = 0.9 *getOption("width"), indent = 0, exdent = 0, prefix = "", simplify = TRUE)

Arguments

x

width

indent

exdent

prefix

simplify

- a character vector, or an object which can be converted to a character vector by as.character.
- a positive integer giving the target column for wrapping lines in the output.
- a non-negative integer giving the indentation of the first line in a paragraph.
- a non-negative integer specifying the indentation of subsequent lines in paragraphs.
- a character string to be used as prefix for each line.
- a logical. If TRUE, the result is a single character vector of line text; otherwise, it is a list of the same length as x the elements of which are character vectors of line text obtained from the corresponding element of x. (Hence, the result in the former case is obtained by unlisting that of the latter.)
Details

Whitespace in the input is destroyed. Double spaces after periods (thought as representing sentence ends) are preserved. Currently, possible sentence ends at line breaks are not considered specially.

Indentation is relative to the number of characters in the prefix string.

Examples

```r
## Read in file 'THANKS'.
x <- paste(readLines(file.path(R.home("doc"), "THANKS")), collapse = "\n")
## Split into paragraphs and remove the first three ones
x <- unlist(strsplit(x, "\n\[ \t\n\] \n")[-(1:3)])
## Join the rest
x <- paste(x, collapse = "\n\n")
## Now for some fun:
writeLines(strwrap(x, width = 60))
writeLines(strwrap(x, width = 60, indent = 5))
writeLines(strwrap(x, width = 60, exdent = 5))
writeLines(strwrap(x, prefix = "THANKS> "))

## Note that messages are wrapped AT the target column indicated by
## 'width' (and not beyond it).
## From an R-devel posting by J. Hosking <jh910@juno.com>.
x <- paste(sapply(sample(10, 100, rep=TRUE),
  function(x) substring("aaaaaaaaaa", 1, x)), collapse = " ")
sapply(10:40, function(m)
  c(target = m, actual = max(nchar(strwrap(x, m)))))
```

subset 395

Subsetting Vectors, Matrices and Data Frames

Description

Return subsets of vectors, matrices or data frames which meet conditions.

Usage

```r
subset(x, ...)

## Default S3 method:
subset(x, subset, ...)

## S3 method for class 'matrix':
subset(x, subset, select, drop = FALSE, ...)

## S3 method for class 'data.frame':
subset(x, subset, select, drop = FALSE, ...)
```
Arguments

x  object to be subsetted.
subset logical expression indicating elements or rows to keep: missing values are taken as false.
select expression, indicating columns to select from a data frame.
drop passed on to \[ indexing operator.
... further arguments to be passed to or from other methods.

Details

This is a generic function, with methods supplied for matrices, data frames and vectors (including lists). Packages and users can add further methods.

For ordinary vectors, the result is simply \( x[\text{subset} \ & \ !\text{is.na(subset)}] \).

For data frames, the \text{subset} argument works on the rows. Note that \text{subset} will be evaluated in the data frame, so columns can be referred to (by name) as variables in the expression (see the examples).

The \text{select} argument exists only for the methods for data frames and matrices. It works by first replacing column names in the selection expression with the corresponding column numbers in the data frame and then using the resulting integer vector to index the columns. This allows the use of the standard indexing conventions so that for example ranges of columns can be specified easily, or single columns can be dropped (see the examples).

The \text{drop} argument is passed on to the indexing method for matrices and data frames: note that the default for matrices is different from that for indexing.

Value

An object similar to \( x \) contain just the selected elements (for a vector), rows and columns (for a matrix or data frame), and so on.

Examples

\begin{verbatim}
subset(airquality, Temp > 80, select = c(Ozone, Temp))
subset(airquality, Day == 1, select = -Temp)
subset(airquality, select = Ozone:Wind)
with(airquality, subset(Ozone, Temp > 80))
\end{verbatim}

## sometimes requiring a logical 'subset' argument is a nuisance
nm <- rownames(state.x77)
start_with_M <- nm %in% grep("^M", nm, value=TRUE)
subset(state.x77, start_with_M, Illiteracy:Murder)
Description

`substitute` returns the parse tree for the (unevaluated) expression `expr`, substituting any variables bound in `env`.

`quote` simply returns its argument. The argument is not evaluated and can be any R expression.

Usage

```r
substitute(expr, env)
quote(expr)
```

Arguments

- `expr` Any syntactically valid R expression
- `env` An environment or a list object. Defaults to the current evaluation environment.

Details

The typical use of `substitute` is to create informative labels for data sets and plots. The `myplot` example below shows a simple use of this facility. It uses the functions `deparse` and `substitute` to create labels for a plot which are character string versions of the actual arguments to the function `myplot`.

Substitution takes place by examining each component of the parse tree as follows: If it is not a bound symbol in `env`, it is unchanged. If it is a promise object, i.e., a formal argument to a function or explicitly created using `delayedAssign()`, the expression slot of the promise replaces the symbol. If it is an ordinary variable, its value is substituted, unless `env` is `.GlobalEnv` in which case the symbol is left unchanged.

`substitute` is a primitive function so positional matching is used and names of supplied arguments are ignored.

Value

The mode of the result is generally "call" but may in principle be any type. In particular, single-variable expressions have mode "name" and constants have the appropriate base mode.

Note

Substitute works on a purely lexical basis. There is no guarantee that the resulting expression makes any sense.

Substituting and quoting often causes confusion when the argument is `expression(...)`.

The result is a call to the `expression` constructor function and needs to be evaluated with `eval` to give the actual expression object.

References

See Also

`missing` for argument “missingness”, `bquote` for partial substitution, `sQuote` and `dQuote` for adding quotation marks to strings.

Examples

```r
(s.e <- substitute(expression(a + b), list(a = 1))) #> expression(l + b)
(s.s <- substitute(a + b, list(a = 1))) #> l + b
c(mode(s.e), typeof(s.e)) # "call", "language"
c(mode(s.s), typeof(s.s)) # (the same)
# but:
(e.s.e <- eval(s.e)) #> expression(l + b)
c(mode(e.s.e), typeof(e.s.e)) # "expression", "expression"

substr(x <- x + 1, list(x=1)) # nonsense

myplot <- function(x, y)
  plot(x, y, xlab=deparse(substitute(x)),
       ylab=deparse(substitute(y)))
## Simple examples about lazy evaluation, etc:

f1 <- function(x, y = x) { x <- x + 1; y }
s1 <- function(x, y = substitute(x)) { x <- x + 1; y }
s2 <- function(x, y) { if(missing(y)) y <- substitute(x); x <- x + 1; y }
a <- 10
f1(a)# 11
s1(a)# 11
s2(a)# a
typeof(s2(a))# "symbol"
```

---

**substr**

*Substrings of a Character Vector*

**Description**

Extract or replace substrings in a character vector.

**Usage**

```r
substr(x, start, stop)
substring(text, first, last = 1000000)
substr(x, start, stop) <- value
substring(text, first, last = 1000000) <- value
```

**Arguments**

- `x, text` a character vector.
- `start, first` integer. The first element to be replaced.
- `stop, last` integer. The last element to be replaced.
- `value` a character vector, recycled if necessary.
Details

substring is compatible with S, with first and last instead of start and stop. For vector arguments, it expands the arguments cyclically to the length of the longest provided none are of zero length.

When extracting, if start is larger than the string length then "" is returned.

For the extraction functions, x or text will be converted to a character vector by as.character if it is not already one.

For the replacement functions, if start is larger than the string length then no replacement is done. If the portion to be replaced is longer than the replacement string, then only the portion the length of the string is replaced.

If any argument is an NA element, the corresponding element of the answer is NA.

Value

For substr, a character vector of the same length and with the same attributes as x (after possible coercion).

For substring, a character vector of length the longest of the arguments. This will have names taken from x (if it has any after coercion, repeated as needed), and other attributes copied from x if it is the longest of the arguments).

Note

The S4 version of substring<- ignores last; this version does not.

These functions are often used with nchar to truncate a display. That does not really work (you want to limit the width, not the number of characters, so it would be better to use strtrim), but at least make sure you use nchar(type="c").

Examples

substr("abcdef",2,4)
substring("abcdef",1:6,1:6)
## strsplit is more efficient ...

substr(rep("abcdef",4),1:4,4:5)
x <- c("asfef", "qwerty", "yuiop", "b", "stuff.blah.yech")
substring(x, 2, 5)
substring(x, 2, 4:6)

substring(x, 2) <- c("..", "+++")
x
**sum**  
*Sum of Vector Elements*

**Description**

`sum` returns the sum of all the values present in its arguments.

**Usage**

`sum(..., na.rm = FALSE)`

**Arguments**

... numeric or complex or logical vectors.

na.rm logical. Should missing values be removed?

**Details**

This is a generic function: methods can be defined for it directly or via the `Summary` group generic. For this to work properly, the arguments ... should be unnamed, and dispatch is on the first argument.

If `na.rm` is `FALSE` an `NA` value in any of the arguments will cause a value of `NA` to be returned, otherwise `NA` values are ignored.

Logical true values are regarded as one, false values as zero. For historical reasons, `NULL` is accepted and treated as if it were `integer(0)`.

**Value**

The sum. If all of ... are of type integer or logical, then the sum is integer, and in that case the result will be `NA` (with a warning) if integer overflow occurs. Otherwise it is a length-one numeric or complex vector.

**NB:** the sum of an empty set is zero, by definition.

**References**

---

**summary**  
*Object Summaries*

**Description**

`summary` is a generic function used to produce result summaries of the results of various model fitting functions. The function invokes particular `methods` which depend on the `class` of the first argument.
Usage

summary(object, ...)

## Default S3 method:
summary(object, ..., digits = max(3, getOption("digits")-3))
## S3 method for class 'data.frame':
summary(object, maxsum = 7,
        digits = max(3, getOption("digits")-3), ...)
## S3 method for class 'factor':
summary(object, maxsum = 100, ...)
## S3 method for class 'matrix':
summary(object, ...)

Arguments

object  an object for which a summary is desired.
maxsum  integer, indicating how many levels should be shown for factors.
digits  integer, used for number formatting with signif() (for summary.default) or format() (for summary.data.frame).
...  additional arguments affecting the summary produced.

Details

For factors, the frequency of the first maxsum - 1 most frequent levels is shown, where the less frequent levels are summarized in "(Others)" (resulting in maxsum frequencies).

The functions summary.lm and summary.glm are examples of particular methods which summarize the results produced by lm and glm.

Value

The form of the value returned by summary depends on the class of its argument. See the documentation of the particular methods for details of what is produced by that method.

summary(attenu $ station, maxsum = 20) #-> summary.factor(...)

lst <- unclass(attenu$station) > 20 # logical with NAs
## summary.default() for logsicals -- different from *.factor:
summary(lst)
summary(as.factor(lst))
Singular Value Decomposition of a Matrix

Description

Compute the singular-value decomposition of a rectangular matrix.

Usage

svd(x, nu = min(n, p), nv = min(n, p), LINPACK = FALSE)

La.svd(x, nu = min(n, p), nv = min(n, p))

Arguments

x a real or complex matrix whose SVD decomposition is to be computed.

nu the number of left singular vectors to be computed. This must between 0 and n = nrow(x).

nv the number of right singular vectors to be computed. This must be between 0 and p = ncol(x).

LINPACK logical. Should LINPACK be used (for compatibility with R < 1.7.0)? In this case nu must be 0, nrow(x) or ncol(x).

Details

The singular value decomposition plays an important role in many statistical techniques. svd and La.svd provide two slightly different interfaces. The main functions used are the LAPACK routines DGESDD and ZGESVD; svd(LINPACK = TRUE) provides an interface to the LINPACK routine DSVDC, purely for backwards compatibility.

Computing the singular vectors is the slow part for large matrices. The computation will be more efficient if nu <= min(n, p) and nv <= min(n, p), and even more efficient if one or both are zero.

Unsuccessful results from the underlying LAPACK code will result in an error giving a positive error code: these can only be interpreted by detailed study of the FORTRAN code.

Value

The SVD decomposition of the matrix as computed by LAPACK/LINPACK,

\[ X = UDV', \]

where \( U \) and \( V \) are orthogonal, \( V' \) means \( V \) transposed, and \( D \) is a diagonal matrix with the singular values \( D_{ii} \). Equivalently, \( D = U'XV \), which is verified in the examples, below.

The returned value is a list with components

\[ \begin{align*}
d & \text{ a vector containing the singular values of } x, \text{ of length min}(n, \ p). \\
u & \text{ a matrix whose columns contain the left singular vectors of } x, \text{ present if } nu > 0. \text{ Dimension c}(n, \ nu). \\
v & \text{ a matrix whose columns contain the right singular vectors of } x, \text{ present if } nv > 0. \text{ Dimension c}(p, \ nv). \\
\end{align*} \]

For La.svd the return value replaces \( v \) by \( v^t \), the (conjugated if complex) transpose of \( v \).

t(s$su) %*% X %*% s$s # D = U' X V

sweep

Sweep out Array Summaries

Description

Return an array obtained from an input array by sweeping out a summary statistic.

Usage

sweep(x, MARGIN, STATS, FUN="-", ...)

Arguments

x
an array.

MARGIN
a vector of indices giving the extents of x which correspond to STATS.

STATS
the summary statistic which is to be swept out.

FUN
the function to be used to carry out the sweep. In the case of binary operators such as "/" etc., the function name must be backquoted or quoted. (FUN is found by a call to match.fun.)

...
optional arguments to FUN.

Value

An array with the same shape as x, but with the summary statistics swept out.

References

switch

Select One of a List of Alternatives

Description

switch evaluates EXPR and accordingly chooses one of the further arguments (in ...).

Usage

switch(EXPR, ...)

Arguments

EXPR an expression evaluating to a number or a character string.
...
... the list of alternatives, given explicitly.

Details

If the value of EXPR is an integer between 1 and nargs()-1 then the corresponding element of...

If EXPR returns a character string then that string is used to match the names of the elements in...

If there is an exact match then that element is evaluated and returned if there is one, otherwise the next element is chosen, e.g., switch("cc", a=1, cc=, d=2) evaluates to 2.

In the case of no match, if there's a further argument in switch that one is returned, otherwise NULL.

Warning

Beware of partial matching: an alternative E = foo will match the first argument EXPR unless that is named. See the examples for good practice in naming the first argument.

References

Examples

```r
require(stats)
centre <- function(x, type) {
  switch(type,
    mean = mean(x),
    median = median(x),
    trimmed = mean(x, trim = .1))
}
```

```r
x <- rcauchy(10)
centre(x, "mean")
centre(x, "median")
centre(x, "trimmed")
```

```r
ccc <- c("b","QQ","a","A","bb")
for(ch in ccc)
cat(ch,":",switch(EXPR = ch, a=1, b=2:3), "\n")
```

```r
cccc <- c("b","QQ","a","A","bb")
for(ch in ccc)
cat(ch,":",switch(EXPR = ch, a=, A=1, b=2:3, "Otherwise: last"),"\n")
```

```r
## Numeric EXPR don't allow an 'otherwise':
for(i in c(-1:3,9)) print(switch(i, 1,2,3,4))
```

---

Syntax

Operator Syntax and Precedence

Description

Outlines R syntax and gives the precedence of operators

Details

The following unary and binary operators are defined. They are listed in precedence groups, from highest to lowest.

```r
[[ [       indexing
:: :::     access variables in a name space
$ @       component / slot extraction
^         exponentiation (right to left)
- +       unary minus and plus
:         sequence operator
%any%     special operators
* /       multiply, divide
+ -       (binary) add, subtract
< > <= >= == != ordering and comparison
!         negation
& & &     and
| || |     or
~          as in formulae
-< ->>    rightwards assignment
=          assignment (right to left)
<- <<-    assignment (right to left)
?          help (unary and binary)
```
Within an expression operators of equal precedence are evaluated from left to right except where indicated.
The links in the See Also section covers most other aspects of the basic syntax.

Note

There are substantial precedence differences between R and S. In particular, in S ? has the same precedence as (binary) + - and & && | || have equal precedence.

The R Language Definition manual.

Sys.getenv

Get Environment Variables

Description

Sys.getenv obtains the values of the environment variables.

Usage

Sys.getenv(x = NULL, unset = "")

Arguments

x       a character vector, or NULL.
unset   a character string.

Details

Both arguments will be coerced to character if necessary.

Setting unset = NA will enable unset variables and those set to the value "" to be distinguished, if the OS does.

Value

A vector of the same length as x, with the variable names as its names attribute. Each element holds the value of the environment variable named by the corresponding component of x (or the value of unset if no environment variable with that name was found).

On most platforms Sys.getenv() will return a named vector giving the values of all the environment variables, collated in the current locale. (It may be confused by names containing "=" which some platforms allow but POSIX does not.)
**Sys.glob**

**Wildcard Expansion on File Paths**

**Description**

Function to do wildcard expansion (also known as ‘globbing’) on file paths.

Not all platforms support this.

**Usage**

```r
Sys.glob(paths, dirmark = FALSE)
```

**Arguments**

- `paths`: character vector of patterns for relative or absolute filepaths.
- `dirmark`: logical: should matches to directories from patterns that do not already end in / have a slash appended? May not be supported on all platforms.

**Details**

This expands wildcards in file paths. For precise details, see your system’s documentation on the `glob` system call. There is a POSIX 1003.2 standard (see [http://www.opengroup.org/onlinepubs/009695399/functions/glob.html](http://www.opengroup.org/onlinepubs/009695399/functions/glob.html)) but some OSes will go beyond this (in particular some BSD-based OSes also do tilde expansion, see `path.expand`).

All systems should interpret * (match one of more characters), ? (match a single character) and [ (begin a character class or range). If a filename starts with . this must be matched explicitly. Normally paths ending in / will be accepted and matched only to directories.

The rest of these details are indicative (and based on the POSIX standard).

[ begins a character class. If the first character in [...] is not !, this is a character class which matches a single character against any of the characters specified. The class cannot be empty, so ] can be included provided it is first. If the first character is !, the character class matches a single character which is none of the specified characters.

Character classes can include ranges such as [A–Z]: include – as a character by having it first or last in a class. (The interpretation of ranges should be locale-specific.)

One can remove the special meaning of ?, * and [ by preceding them by a backslash (except within a character class).

**Examples**

```r
## whether HOST is set will be shell-dependent e.g. Solaris' csh does not.
Sys.getenv(c("R_HOME", "R_PAPERSIZE", "R_PRINTCMD", "HOST"))

names(s <- Sys.getenv()) # all settings (the values could be very long)

## Language and Locale settings -- but rather use Sys.getlocale()
# grep("^L(C|ANG)", names(s))
```

**See Also**

- `Sys.putenv`, `Sys.getlocale` for the locale “environment”, `getwd` for the working directory.
Sys.info

Value
A character vector of matched file paths. The order is system-specific (but in the order of the elements of paths): it is normally collated in the current locale or in byte (ASCII) order.
Directory errors are normally ignored, so the matches are to accessible file paths (but not necessarily accessible files).
On platforms which do not have the glob system call, paths is returned unchanged.

See Also
path.expand.
Quotes for handling backslashes in character strings.

Examples
   ## Not run:
   Sys.glob(file.path(R.home(), "library", ",", "R", ",*.rdx"))
   ## End(Not run)

Sys.info

Description
Reports system and user information.

Usage
Sys.info()

Details
This function is not implemented on all R platforms, and returns NULL when not available. Where possible it is based on POSIX system calls.
Sys.info() returns details of the platform R is running on, whereas R.version gives details of the platform R was built on: they may well be different.

Value
A character vector with fields

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sysname</td>
<td>The operating system.</td>
</tr>
<tr>
<td>release</td>
<td>The OS release.</td>
</tr>
<tr>
<td>version</td>
<td>The OS version.</td>
</tr>
<tr>
<td>nodename</td>
<td>A name by which the machine is known on the network (if any).</td>
</tr>
<tr>
<td>machine</td>
<td>A concise description of the hardware.</td>
</tr>
<tr>
<td>login</td>
<td>The user’s login name, or &quot;unknown&quot; if it cannot be ascertained.</td>
</tr>
<tr>
<td>user</td>
<td>The name of the real user ID, or &quot;unknown&quot; if it cannot be ascertained.</td>
</tr>
</tbody>
</table>

The first five fields come from the uname(2) system call. The login name comes from getlogin(2), and the user name from getpwuid(getuid())
Note

The meaning of OS “release” and “version” is highly system-dependent and there is no guarantee that the node or login or user names will be what you might reasonably expect. (In particular on some Linux distributions the login name is unknown from sessions with re-directed inputs.)

See Also

Examples

Sys.info()
## An alternative (and probably better) way to get the login name on Unix
Sys.getenv("LOGNAME")

sys.parent

Functions to Access the Function Call Stack

Description

These functions provide access to environments (“frames” in S terminology) associated with functions further up the calling stack.

Usage

sys.call(which = 0)
sys.frame(which = 0)
sys.nframe()
sys.function(which = 0)
sys.parent(n = 1)

calls()
sys.frames()
sys.parents()
sys.on.exit()
sys.status()
parent.frame(n = 1)

Arguments

which            the frame number if non-negative, the number of frames to go back if negative.
n               the number of generations to go back. (See the Details section.)

Details

.GlobalEnv is given number 0 in the list of frames. Each subsequent function evaluation increases the frame stack by 1 and the call, function definition and the environment for evaluation of that function are returned by sys.call, sys.function and sys.frame with the appropriate index.
sys.call, sys.frame and sys.function accept integer values for the argument which. Non-negative values of which are frame numbers whereas negative values are counted back from the frame number of the current evaluation.

The parent frame of a function evaluation is the environment in which the function was called. It is not necessarily numbered one less than the frame number of the current evaluation, nor is it the environment within which the function was defined. sys.parent returns the number of the parent frame if n is 1 (the default), the grandparent if n is 2, and so on.

sys.nframe returns an integer, the number of the current frame as described in the first paragraph.
sys.calls and sys.frames give a pairlist of all the active calls and frames, respectively, and sys.parents returns an integer vector of indices of the parent frames of each of those frames.

Notice that even though the sys.xxx functions (except sys.status) are interpreted, their contexts are not counted nor are they reported. There is no access to them.

sys.status() returns a list with components sys.calls, sys.parents and sys.frames, the results of calls to those three functions (which this will include the call to sys.status: see the first example).

sys.on.exit() returns the expression stored for use by on.exit in the function currently being evaluated. (Note that this differs from S, which returns a list of expressions for the current frame and its parents.)

parent.frame(n) is a convenient shorthand for sys.frame(sys.parent(n)) (implemented slightly more efficiently).

Value

sys.call returns a call, sys.function a function definition, and sys.frame and parent.frame return an environment.

For the other functions, see the Details section.

References

See Also

eval for a usage of sys.frame and parent.frame.

Examples

```r
## Note: the first two examples will give different results
## if run by example().
ff <- function(x) gg(x)
gg <- function(y) sys.status()
str(ff(1))

gg <- function(y) {
  ggg <- function() {
    cat("current frame is", sys.nframe(), "\n")
    cat("parents are", sys.parents(), "\n")
    print(sys.function(0)) # ggg
    print(sys.function(2)) # gg
  }
  if(y > 0) gg(y-1) else ggg()
}
```
Sys.setenv

Set or Unset Environment Variables

Description

Sys.setenv sets environment variables (for other processes called from within R or future calls to Sys.getenv from this R process).

Sys.unsetenv removes environment variables.

Usage

Sys.setenv(...)

Sys.unsetenv(x)
Sys.sleep

Suspend Execution for a Time Interval

Description

Suspend execution of R expressions for a given number of seconds

Usage

Sys.sleep(time)

Arguments

time The time interval to suspend execution for, in seconds.

Details

The names setenv and putenv come from different Unix traditions: R also has Sys.putenv, but this is now deprecated. The internal code uses setenv if available, otherwise putenv.

Non-standard R names must be quoted in Sys.setenv: see the examples. Most platforms (and POSIX) do not allow names containing "=".

Value

A logical vector, with elements being true if (un)setting the corresponding variable succeeded. (For Sys.unsetenv this includes attempting to remove a non-existent variable.)

Note

Not all systems need support Sys.setenv (although all known current platforms do) nor Sys.unsetenv.

See Also

Sys.getenv, Startup for ways to set environment variables for the R session.

setwd for the working directory.

Examples

print(Sys.setenv(R_TEST="testit", "A+C"=123))  # `A+C` could also be used
Sys.getenv("R_TEST")
try(Sys.unsetenv("R_TEST"))  # may not be implemented
Sys.getenv("R_TEST", unset=NA)
Details
Using this function allows \( \mathcal{R} \) to be given very low priority and hence not to interfere with more important foreground tasks. A typical use is to allow a process launched from \( \mathcal{R} \) to set itself up and read its input files before \( \mathcal{R} \) execution is resumed.

The intention is that this function suspends execution of \( \mathcal{R} \) expressions but wakes the process up often enough to respond to GUI events, typically every 0.5 seconds.

There is no guarantee that the process will sleep for the whole of the specified interval, and it may well take slightly longer in real time to resume execution. The resolution of the time interval is system-dependent, but will normally be down to 0.02 secs or better. (On modern Unix-alikes it will be better than 1ms.)

Value
Invisible NULL.

Note
This function may not be implemented on all systems.

Examples
```r
testit <- function(x)
{
  p1 <- proc.time()
  Sys.sleep(x)
  proc.time() - p1 # The cpu usage should be negligible
}
testit(3.7)
```

---

**sys.source**  
*Parse and Evaluate Expressions from a File*

Description
Parses expressions in the given file, and then successively evaluates them in the specified environment.

Usage
```r
sys.source(file, envir = baseenv(), chdir = FALSE,
          keep.source = getOption("keep.source.pkgs"))
```

Arguments
- **file**  
a character string naming the file to be read from
- **envir**  
an \( \mathcal{R} \) object specifying the environment in which the expressions are to be evaluated. May also be a list or an integer. The default value NULL corresponds to evaluation in the base environment. This is probably not what you want; you should typically supply an explicit envir argument.
- **chdir**  
logical; if TRUE, the \( \mathcal{R} \) working directory is changed to the directory containing file for evaluating.
keep.source  logical. If TRUE, functions “keep their source” including comments, see
options(keep.source = *) for more details.

Details

For large files, keep.source = FALSE may save quite a bit of memory. In order for the code
being evaluated to use the correct environment (for example, in global assignments), source code in
packages should call toopenv(), which will return the name space, if any, the environment set up
by sys.source, or the global environment if a saved image is being used.

See Also

source, and library which uses sys.source.

Examples

## a simple way to put some objects in an environment high on the search path
tmp <- tempfile()
writeLines("aaa <- pi", tmp)
env <- attach(NULL, name = "myenv")
sys.source(tmp, env)
unlink(tmp)
search()
aaa
detach("myenv")

Sys.time  Get Current Date, Time and Timezone

Description

Sys.time and Sys.Date returns the system’s idea of the current date with and without time,
and Sys.timezone returns the current time zone.

Usage

Sys.time()
Sys.Date()
Sys.timezone()

Details

Sys.time returns an absolute date-time value which can be converted in various time zones and
may return different days.
Sys.Date returns the day in the current time zone.

Value

Sys.time returns an object of class "POSIXct" (see DateTimeClasses). On some systems it
will have sub-second accuracy, but on others it will increment in seconds. On systems conforming
to POSIX 1003.1-2001 the time will be reported in microsecond increments.
Sys.Date returns an object of class "Date" (see Date).
Sys.timezone returns an OS-specific character string, possibly an empty string. It may be
possible to set the timezone via the environment variable "TZ": see as.POSIXlt.
system

See Also

date for the system time in a fixed-format character string; the elapsed time component of
proc.time for possibly finer resolution in changes in time.

Examples

Sys.time()
## print with possibly greater accuracy:
op <- options(digits.secs=6)
Sys.time()
options(op)

## locale-specific version of date()
format(Sys.time(), "%a %b %d %X %Y")

Sys.Date()
Sys.timezone()
Details

command is parsed as a command plus arguments separated by spaces. So if the path to the command (or a filepath argument) contains spaces, it must be quoted e.g. by shQuote.

How the command is run differs by platform: Unix-alikes use a shell (`/bin/sh` by default), and Windows executes the command directly (extensions .exe, .com) or as a batch file (extensions .cmd and .bat).

If intern is TRUE then popen is used to invoke the command and the output collected, line by line, into an R character vector. If intern is FALSE then the C function system is used to invoke the command.

The ordering of arguments after the first two has changed from time to time: it is recommended to name all arguments after the first.

Value

If intern = TRUE, a character vector giving the output of the command, one line per character string. (Output lines of more than 8095 characters will be split.) If the command could not be run or gives an error this will be reported on the shell’s `stderr` (unless popen is not supported, when there is an R error).

If intern = FALSE, the return value is an error code (0 for success), given the invisible attribute (so needs to be printed explicitly). If the command could not be run for any reason, the value is 256*127 = 52512. Otherwise if wait = TRUE the value is 256 times the error code returned by the command, and if wait = FALSE it is 0 (the conventional success value).

Stdout and stderr

Error messages written to `stderr` will be sent by the shell to the terminal unless ignore.stderr = TRUE. They can be captured (in the most likely shells) by

    system("some command 2>&1", intern=TRUE)

What happens to output sent to `stdout` and `stderr` if intern = FALSE is interface-specific, and it is unsafe to assume that such messages will appear on the console (they do on the MacOS X console but not on the gnomeGUI console, for example).

Note

wait is implemented by appending & to the command: this is shell-dependent, but required by POSIX and so widely supported.

See Also

.Platform for platform-specific variables.

Examples

    # list all files in the current directory using the -F flag
    ## Not run: system("ls -F")

    # t1 is a character vector, each one
    # representing a separate line of output from who
    # (if the platform has popen and who)
    t1 <- try(system("who", intern = TRUE))
try(system("ls fizzlipuzzli", intern = TRUE, ignore.stderr = TRUE))
# empty since file doesn't exist

---

**system.file**  
*Find Names of R System Files*

**Description**

Finds the full file names of files in packages etc.

**Usage**

```r
system.file(..., package = "base", lib.loc = NULL)
```

**Arguments**

- `...`: character strings, specifying subdirectory and file(s) within some package. The default, none, returns the root of the package. Wildcards are not supported.
- `package`: a character string with the name of a single package. An error occurs if more than one package name is given.
- `lib.loc`: a character vector with path names of R libraries, or `NULL`. The default value of `NULL` corresponds to all libraries currently known. If the default is used, the loaded packages are searched before the libraries.

**Value**

A character vector of positive length, containing the file names that matched `...`, or the empty string, `""`, if none matched. If matching the root of a package, there is no trailing separator.

As a special case, `system.file()` gives the root of the `base` package only.

**See Also**

- `list.files`

**Examples**

```r
system.file()  # The root of the 'base' package
system.file(package = "stats")  # The root of package 'stats'
system.file("INDEX")
system.file("help", "AnIndex", package = "splines")
```
system.time

**CPU Time Used**

**Description**

Return CPU (and other) times that expr used.

**Usage**

```r
system.time(expr, gcFirst = TRUE)
unix.time(expr, gcFirst = TRUE)
```

**Arguments**

- `expr`: Valid R expression to be “timed”
- `gcFirst`: Logical - should a garbage collection be performed immediately before the timing? Default is `TRUE`.

**Details**

`system.time` calls the function `proc.time`, evaluates `expr`, and then calls `proc.time` once more, returning the difference between the two `proc.time` calls.

`unix.time` is an alias of `system.time`, for compatibility with S.

Timings of evaluations of the same expression can vary considerably depending on whether the evaluation triggers a garbage collection. When `gcFirst` is `TRUE` a garbage collection (`gc`) will be performed immediately before the evaluation of `expr`. This will usually produce more consistent timings.

**Value**

A object of class "proc_time": see `proc.time` for details.

**Note**

It is possible to compile R without support for `system.time`, when the function will throw an error.

**See Also**

`proc.time`, `time` which is for time series.

**Examples**

```r
require(stats)
system.time(for(i in 1:100) mad(runif(1000)))
```

```r
## Not run:
exT <- function(n = 1000) {
  # Purpose: Test if system.time works ok; n: loop size
  system.time(for(i in 1:n) x <- mean(rt(1000, df=4)))
}
#-- Try to interrupt one of the following (using Ctrl-C / Escape):
exT()  #-- about 3 secs on a 1GHz PIII
```
Given a matrix or data.frame `x`, `t` returns the transpose of `x`.

**Usage**

`t(x)`

**Arguments**

`x`  
a matrix or data frame, typically.

**Details**

This is a generic function for which methods can be written. The description here applies to the default and "data.frame" methods.

A data frame is first coerced to a matrix: see `as.matrix`. When `x` is a vector, it is treated as "column", i.e., the result is a 1-row matrix.

**Value**

A matrix, with `dim` and `dimnames` constructed appropriately from those of `x`, and other attributes except names copied across.

**References**

**See Also**

`aperm` for permuting the dimensions of arrays.

**Examples**

```r
a <- matrix(1:30, 5, 6)
ta <- t(a)  #== i.e., a[i, j] == ta[j, i] for all i, j:
for(j in seq(ncol(a)))
  if(! all(a[, j] == ta[j, ])) stop("wrong transpose")
```
Cross Tabulation and Table Creation

Description

table uses the cross-classifying factors to build a contingency table of the counts at each combination of factor levels.

Usage

table(..., exclude = c(NA, NaN), dnn = list.names(...),
       deparse.level = 1)
as.table(x, ...)
is.table(x)

## S3 method for class 'table':
as.data.frame(x, row.names = NULL, ...,
               responseName = "Freq")

Arguments

... objects which can be interpreted as factors (including character strings), or a list (or data frame) whose components can be so interpreted. (For as.table and as.data.frame, arguments passed to specific methods.)
exclude values to use in the exclude argument of factor when interpreting non-factor objects; if specified, levels to remove from all factors in ... .
dnn the names to be given to the dimensions in the result (the dimnames names).
deparse.level controls how the default dnn is constructed. See details.
x an arbitrary R object, or an object inheriting from class "table" for the as.data.frame method.
row.names a character vector giving the row names for the data frame.
responseName The name to be used for the column of table entries, usually counts.

Details

If the argument dnn is not supplied, the internal function list.names is called to compute the ‘dimname names’. If the arguments in ... are named, those names are used. For the remaining arguments, deparse.level = 0 gives an empty name, deparse.level = 1 uses the supplied argument if it is a symbol, and deparse.level = 2 will deparse the argument.

Only when exclude is specified (i.e., not by default), will table drop levels of factor arguments potentially.

Value

table() returns a contingency table, an object of class "table", an array of integer values. There is a summary method for objects created by table or xtabs, which gives basic information and performs a chi-squared test for independence of factors (note that the function chisq.test currently only handles 2-d tables).
as.table and is.table coerce to and test for contingency table, respectively. The as.data.frame method for objects inheriting from class "table" can be used to convert the array-based representation of a contingency table to a data frame containing the classifying factors and the corresponding entries (the latter as component named by responseName). This is the inverse of xtabs.

References

See Also

Use ftable for printing (and more) of multidimensional tables. margin.table, prop.table, addmargins.

Examples

require(stats) # for rpois and xtabs
## Simple frequency distribution
table(rpois(100,5))
## Check the design:
with(warpbreaks, table(wool, tension))
table(state.division, state.region)

# simple two-way contingency table
with(airquality, table(cut(Temp, quantile(Temp)), Month))

a <- letters[1:3]
table(a, sample(a))  # dnn is c("a", "")
table(a, sample(a), deparse.level = 0)  # dnn is c("", "")
table(a, sample(a), deparse.level = 2)  # dnn is c("a", "sample(a)"

## xtabs() <-> as.data.frame.table() :
UCBAdmissions ## already a contingency table
DF <- as.data.frame(UCBAdmissions)
class(tab <- xtabs(Freq ~ ., DF))  # xtabs & table
## tab *is* "the same" as the original table:
all(tab == UCBAdmissions)
all.equal(dimnames(tab), dimnames(UCBAdmissions))

# NA counting:
is.na(d) <- 3:4
d <- factor(d, exclude=NULL)
d[1:7]
table(d, exclude = NULL)
tabulate  

Tabulation for Vectors

Description

`tabulate` takes the integer-valued vector `bin` and counts the number of times each integer occurs in it.

Usage

`tabulate(bin, nbins = max(1, bin))`

Arguments

- `bin`: a numeric vector (of positive integers), or a factor.
- `nbins`: the number of bins to be used.

Details

`tabulate` is used as the basis of the `table` function.

If `bin` is a factor, its internal integer representation is tabulated.

If the elements of `bin` are numeric but not integers, they are truncated to the nearest integer.

Value

An integer vector (without names). There is a bin for each of the values 1, ..., `nbins`; values outside that range are (silently) ignored.

See Also

`table`, `factor`.

Examples

```r
tabulate(c(2,3,5))
tabulate(c(2,3,3,5), nbins = 10)
tabulate(c(-2,0,2,3,3,5))  # -2 and 0 are ignored
tabulate(c(-2,0,2,3,3,5), nbins = 3)
tabulate(factor(letters[1:10]))
```
**tapply**

*Apply a Function Over a “Ragged” Array*

**Description**

Apply a function to each cell of a ragged array, that is to each (non-empty) group of values given by a unique combination of the levels of certain factors.

**Usage**

```r
tapply(X, INDEX, FUN = NULL, ..., simplify = TRUE)
```

**Arguments**

- `X` an atomic object, typically a vector.
- `INDEX` list of factors, each of same length as `X`.
- `FUN` the function to be applied. In the case of functions like `+`, `%*%`, etc., the function name must be quoted. If `FUN` is `NULL`, `tapply` returns a vector which can be used to subscript the multi-way array `tapply` normally produces.
- `...` optional arguments to `FUN`.
- `simplify` If `FALSE`, `tapply` always returns an array of mode "list". If `TRUE` (the default), then if `FUN` always returns a scalar, `tapply` returns an array with the mode of the scalar.

**Value**

When `FUN` is present, `tapply` calls `FUN` for each cell that has any data in it. If `FUN` returns a single atomic value for each cell (e.g., functions `mean` or `var`) and when `simplify` is `TRUE`, `tapply` returns a multi-way array containing the values. The array has the same number of dimensions as `INDEX` has components; the number of levels in a dimension is the number of levels (`nlevels()`) in the corresponding component of `INDEX`.

Note that contrary to S, `simplify = TRUE` always returns an array, possibly 1-dimensional.

If `FUN` does not return a single atomic value, `tapply` returns an array of mode `list` whose components are the values of the individual calls to `FUN`, i.e., the result is a list with a `dim` attribute.

Note that optional arguments to `FUN` supplied by the `...` argument are not divided into cells. It is therefore inappropriate for `FUN` to expect additional arguments with the same length as `X`.

the convenience functions `by` and `aggregate` (using `tapply`); `apply`, `lapply` with its versions `sapply` and `mapply`. 
**Examples**

```r
require(stats)
groups <- as.factor(rbinom(32, n = 5, p = .4))
tapply(groups, groups, length) # is almost the same as
table(groups)

## contingency table from data.frame : array with named dimnames
tapply(warpbreaks$breaks, warpbreaks[, -1], sum)
tapply(warpbreaks$breaks, warpbreaks[, 3, drop = FALSE], sum)

n <- 17; fac <- factor(rep(1:3, len = n), levels = 1:5)
table(fac)
tapply(l1:n, fac, sum)
tapply(l1:n, fac, sum, simplify = FALSE)
tapply(l1:n, fac, range)
tapply(l1:n, fac, quantile)

## example of ... argument: find quarterly means
tapply(presidents, cycle(presidents), mean, na.rm = TRUE)

ind <- list(c(1, 2, 2), c("A", "A", "B"))
table(ind)
tapply(1:3, ind) #-> the split vector
tapply(1:3, ind, sum)
```

---

**taskCallback**

*Add or remove a top-level task callback*

**Description**

`addTaskCallback` registers an R function that is to be called each time a top-level task is completed.

`removeTaskCallback` un-registers a function that was registered earlier via `addTaskCallback`.

These provide low-level access to the internal/native mechanism for managing task-completion actions. One can use `taskCallbackManager` at the S-language level to manage S functions that are called at the completion of each task. This is easier and more direct.

**Usage**

```r
addTaskCallback(f, data = NULL, name = character(0))
removeTaskCallback(id)
```

**Arguments**

- `f` the function that is to be invoked each time a top-level task is successfully completed. This is called with 5 or 4 arguments depending on whether `data` is specified or not, respectively. The return value should be a logical value indicating whether to keep the callback in the list of active callbacks or discard it.
- `data` if specified, this is the 5-th argument in the call to the callback function `f`. 

taskCallback

id

A string or an integer identifying the element in the internal callback list to be removed. Integer indices are 1-based, i.e. the first element is 1. The names of currently registered handlers is available using `getTaskCallbackNames` and is also returned in a call to `addTaskCallback`.

name

Character: names to be used.

Details

Top-level tasks are individual expressions rather than entire lines of input. Thus an input line of the form `expression1 ; expression2` will give rise to 2 top-level tasks.

A top-level task callback is called with the expression for the top-level task, the result of the top-level task, a logical value indicating whether it was successfully completed or not (always TRUE at present), and a logical value indicating whether the result was printed or not. If the `data` argument was specified in the call to `addTaskCallback`, that value is given as the fifth argument.

The callback function should return a logical value. If the value is FALSE, the callback is removed from the task list and will not be called again by this mechanism. If the function returns TRUE, it is kept in the list and will be called on the completion of the next top-level task.

Value

`addTaskCallback` returns an integer value giving the position in the list of task callbacks that this new callback occupies. This is only the current position of the callback. It can be used to remove the entry as long as no other values are removed from earlier positions in the list first.

`removeTaskCallback` returns a logical value indicating whether the specified element was removed. This can fail (i.e., return FALSE) if an incorrect name or index is given that does not correspond to the name or position of an element in the list.

Note

This is an experimental feature and the interface may be changed in the future.

There is also C-level access to top-level task callbacks to allow C routines rather than R functions be used.

Examples

```r
times <- function(total = 3, str="Task a") {
  ctr <- 0

  function(expr, value, ok, visible) {
    ctr <<- ctr + 1
    cat(str, ctr, "\n")
    if(ctr == total) {
      cat("handler removing itself\n")
    }
    return(ctr < total)
  }
}
```
# add the callback that will work for
# 4 top-level tasks and then remove itself.
n <- addTaskCallback(times(4))

# now remove it, assuming it is still first in the list.
removeTaskCallback(n)

## Not run:
# There is no point in running this
# as
# addTaskCallback(times(4))

    sum(1:10)
    sum(1:10)
    sum(1:10)
    sum(1:10)
    sum(1:10)

## End(Not run)

---

**taskCallbackManager**

*Create an R-level task callback manager*

**Description**

This provides an entirely S-language mechanism for managing callbacks or actions that are invoked at the conclusion of each top-level task. Essentially, we register a single R function from this manager with the underlying, native task-callback mechanism and this function handles invoking the other R callbacks under the control of the manager. The manager consists of a collection of functions that access shared variables to manage the list of user-level callbacks.

**Usage**

```r
taskCallbackManager(handlers = list(), registered = FALSE, verbose = FALSE)
```

**Arguments**

- `handlers` this can be a list of callbacks in which each element is a list with an element named "f" which is a callback function, and an optional element named "data" which is the 5-th argument to be supplied to the callback when it is invoked. Typically this argument is not specified, and one uses `add` to register callbacks after the manager is created.

- `registered` a logical value indicating whether the evaluate function has already been registered with the internal task callback mechanism. This is usually `FALSE` and the first time a callback is added via the `add` function, the `evaluate` function is automatically registered. One can control when the function is registered by specifying `TRUE` for this argument and calling `addTaskCallback` manually.

- `verbose` a logical value, which if `TRUE`, causes information to be printed to the console about certain activities this dispatch manager performs. This is useful for debugging callbacks and the handler itself.
Value

A list containing 6 functions:

add: register a callback with this manager, giving the function, an optional 5-th argument, an optional name by which the callback is stored in the list, and a register argument which controls whether the evaluate function is registered with the internal C-level dispatch mechanism if necessary.

remove: remove an element from the manager’s collection of callbacks, either by name or position/index.

evaluate: the ‘real’ callback function that is registered with the C-level dispatch mechanism and which invokes each of the R-level callbacks within this manager’s control.

suspend: a function to set the suspend state of the manager. If it is suspended, none of the callbacks will be invoked when a task is completed. One sets the state by specifying a logical value for the status argument.

register: a function to register the evaluate function with the internal C-level dispatch mechanism. This is done automatically by the add function, but can be called manually.

callbacks: returns the list of callbacks being maintained by this manager.

Note

This is an experimental feature and the interface may be changed in the future.

addTaskCallback, removeTaskCallback, getTaskCallbackNames

http://developer.r-project.org/TaskHandlers.pdf

Examples

# create the manager
h <- taskCallbackManager()

# add a callback
h$add(function(expr, value, ok, visible) {
  cat("In handler\n")
  return(TRUE)
}, name = "simpleHandler")

# look at the internal callbacks.
getTaskCallbackNames()

# look at the R-level callbacks
names(h$callback())

getchTaskCallbackNames()
removeTaskCallback("R-taskCallbackManager")
**taskCallbackNames**  
*Query the names of the current internal top-level task callbacks*

**Description**

This provides a way to get the names (or identifiers) for the currently registered task callbacks that are invoked at the conclusion of each top-level task. These identifiers can be used to remove a callback.

**Usage**

```r
getTaskCallbackNames()
```

**Value**

A character vector giving the name for each of the registered callbacks which are invoked when a top-level task is completed successfully. Each name is the one used when registering the callbacks and returned as the in the call to `addTaskCallback`.

**Note**

One can use `taskCallbackManager` to manage user-level task callbacks, i.e., S-language functions, entirely within the S language and access the names more directly.

cat("In handler\n")
return(TRUE)
}, name = "simpleHandler")

getTaskCallbackNames()

# now remove it by name
removeTaskCallback("simpleHandler")

h <- taskCallbackManager()
h$add(function(expr, value, ok, visible) {
cat("In handler\n")
return(TRUE)
}, name = "simpleHandler")

getTaskCallbackNames()
removeTaskCallback("R-taskCallbackManager")
```
Create Names for Temporary Files

Description

tempfile returns a vector of character strings which can be used as names for temporary files.

Usage

tempfile(pattern = "file", tmpdir = tempdir())
tempdir()

Arguments

pattern a non-empty character vector giving the initial part of the name.
tmpdir a non-empty character vector giving the directory name

Details

If pattern has length greater than one then the result is of the same length giving a temporary file name for each component of pattern.

The names are very likely to be unique among calls to tempfile in an R session and across simultaneous R sessions. The filenames are guaranteed not to be currently in use.

The file name is made of the pattern and a random suffix in hex. By default, the filenames will be in the directory given by tempdir(). This will be a subdirectory of the temporary directory found by the following rule. The environment variables TMPDIR, TMP and TEMP are checked in turn and the first found which points to a writable directory is used: if none succeeds '/tmp' is used.

Value

For tempfile a character vector giving the names of possible (temporary) files. Note that no files are generated by tempfile.

For tempdir, the path of the per-session temporary directory.

References

See Also

unlink for deleting files.

Examples

tempfile(c("ab", "a b c")) # give file name with spaces in!
tempdir() # working on all platforms with quite platform dependent result
Description

Input and output text connections.

Usage

```r
textConnection(object, open = "r", local = FALSE)
textConnectionValue(con)
```

Arguments

- `object` character. A description of the connection. For an input this is an R character vector object, and for an output connection the name for the R character vector to receive the output, or `NULL` (for none).
- `open` character. Either "r" (or equivalently "") for an input connection or "w" or "a" for an output connection.
- `local` logical. Used only for output connections. If `TRUE`, output is assigned to a variable in the calling environment. Otherwise the global environment is used.
- `con` An output text connection.

Details

An input text connection is opened and the character vector is copied at time the connection object is created, and `close` destroys the copy.

An output text connection is opened and creates an R character vector of the given name in the user's workspace or in the calling environment, depending on the value of the `local` argument. This object will at all times hold the completed lines of output to the connection, and `isIncomplete` will indicate if there is an incomplete final line. Closing the connection will output the final line, complete or not. (A line is complete once it has been terminated by end-of-line, represented by "\n" in R.) The output character vector has locked bindings (see `lockBinding`) until `close` is called on the connection. The character vector can also be retrieved via `textConnectionValue`, which is the only way to do so if `object = NULL`.

Opening a text connection with `mode = "a"` will attempt to append to an existing character vector with the given name in the user's workspace or the calling environment. If none is found (even if an object exists of the right name but the wrong type) a new character vector will be created, with a warning.

You cannot `seek` on a text connection, and `seek` will always return zero as the position.

Value

For `textConnection`, a connection object of class "textConnection" which inherits from class "connection".

For `textConnectionValue`, a character vector.
Note

As output text connections keep the character vector up to date line-by-line, they are relatively expensive to use, and it is often better to use an anonymous \texttt{file()} connection to collect output.

On platforms where \texttt{vsnprintf} does not return the needed length of output (e.g., Windows) there is a 100,000 character limit on the length of line for output connections: longer lines will be truncated with a warning.

scan(zz, "", 4)
close(zz)

zz <- textConnection("foo", "w")
writeLines(c("testit1", "testit2"), zz)
cat("testit3 ", file=zz)
isIncomplete(zz)
cat("testit4\n", file=zz)
isIncomplete(zz)
close(zz)
foo

## Not run:
# capture R output: use part of example from help(lm)
zz <- textConnection("foo", "w")
ctl <- c(4.17, 5.58, 5.18, 6.11, 4.5, 4.61, 5.17, 4.53, 5.33, 5.14)
trt <- c(4.81, 4.17, 4.41, 3.59, 5.87, 3.83, 6.03, 4.89, 4.32, 4.69)
group <- gl(2, 10, 20, labels = c("Ctl", "Trt"))
weight <- c(ctl, trt)
sink(zz)
anova(lm.D9 <- lm(weight ~ group))
cat("\nSummary of Residuals:\n\n")
summary(resid(lm.D9))
sink()
close(zz)
cat(foo, sep = "\n")
## End(Not run)
\end{verbatim}
tilde  

**Tilde Operator**

**Description**

Tilde is used to separate the left- and right-hand sides in model formula.

**Usage**

\[ y \sim \text{model} \]

**Arguments**

- `y`, `model`  symbolic expressions.

**Details**

The left-hand side is optional, and one-sided formulae are used in some contexts.

**References**

**See Also**

`formula`

toString  

**Convert an R Object to a Character String**

**Description**

This is a helper function for `format` to produce a single character string describing an R object.

**Usage**

```
toString(x, ...)  
```

```
## Default S3 method:  
toString(x, width = NULL, ...)  
```

**Arguments**

- `x`  The object to be converted.
- `width`  Suggestion for the maximum field width. Values of `NULL` or 0 indicate no maximum. The minimum value accepted is 6 and smaller values are taken as 6.
- `...`  Optional arguments passed to or from methods.
Details

This is a generic function for which methods can be written: only the default method is described here. Most methods should honor the `width` argument to specify the maximum display width (as measured by `nchar(type = "width")`) of the result.

The default method first converts \( x \) to character and then concatenates the elements separated by ", "\). If `width` is supplied and is not `NULL`, the default method returns the first `width - 4` characters of the result with `....` appended, if the full result would use more than `width` characters.

Value

A character vector of length 1 is returned.

trace

Interactive Tracing and Debugging of Calls to a Function or Method

Description

A call to \texttt{trace} allows you to insert debugging code (e.g., a call to \texttt{browser} or \texttt{recover}) at chosen places in any function. A call to \texttt{untrace} cancels the tracing. Specified methods can be traced the same way, without tracing all calls to the function. Trace code can be any \texttt{R} expression. Tracing can be temporarily turned on or off globally by calling \texttt{tracingState}.

Usage

\[
\text{trace}(\text{what}, \text{tracer}, \text{exit}, \text{at}, \text{print}, \text{signature},
\phantom{\text{signature}}\text{where} = \text{topenv(\text{parent.frame}())}, \text{edit} = \text{FALSE})
\]

\[
\text{untrace}(\text{what}, \text{signature} = \text{NULL}, \text{where} = \text{topenv(\text{parent.frame}())})
\]

\[
\text{tracingState(on} = \text{NULL})
\]

\[
\text{.doTrace(expr, msg})
\]
Arguments

what
The name (quoted or not) of a function to be traced or untraced. For untrace or for trace with more than one argument, more than one name can be given in the quoted form, and the same action will be applied to each one.

tracer
Either a function or an unevaluated expression. The function will be called or the expression will be evaluated either at the beginning of the call, or before those steps in the call specified by the argument at. See the details section.

exit
Either a function or an unevaluated expression. The function will be called or the expression will be evaluated on exiting the function. See the details section.

at
optional numeric vector. If supplied, tracer will be called just before the corresponding step in the body of the function. See the details section.

print
If TRUE (as per default), a descriptive line is printed before any trace expression is evaluated.

signature
If this argument is supplied, it should be a signature for a method for function what. In this case, the method, and not the function itself, is traced.

edit
For complicated tracing, such as tracing within a loop inside the function, you will need to insert the desired calls by editing the body of the function. If so, supply the edit argument either as TRUE, or as the name of the editor you want to use. Then trace() will call edit and use the version of the function after you edit it. See the details section for additional information.

where
where to look for the function to be traced; by default, the top-level environment of the call to trace.

An important use of this argument is to trace a function when it is called from a package with a name space. The current name space mechanism imports the functions to be called (with the exception of functions in the base package). The functions being called are not the same objects seen from the top-level (in general, the imported packages may not even be attached). Therefore, you must ensure that the correct versions are being traced. The way to do this is to set argument where to a function in the name space. The tracing computations will then start looking in the environment of that function (which will be the name space of the corresponding package). (Yes, it’s subtle, but the semantics here are central to how name spaces work in R.)

on
logical; a call to the support function tracingState returns TRUE if tracing is globally turned on, FALSE otherwise. An argument of one or the other of those values sets the state. If the tracing state is FALSE, none of the trace actions will actually occur (used, for example, by debugging functions to shut off tracing during debugging).

expr, msg
arguments to the support function .doTrace, calls to which are inserted into the modified function or method: expr is the tracing action (such as a call to browser()), and msg is a string identifying the place where the trace action occurs.

Details

The trace function operates by constructing a revised version of the function (or of the method, if signature is supplied), and assigning the new object back where the original was found. If only the what argument is given, a line of trace printing is produced for each call to the function (back compatible with the earlier version of trace).
The object constructed by `trace` is from a class that extends "function" and which contains the original, untraced version. A call to `untrace` re-assigns this version.

If the argument `tracer` or `exit` is the name of a function, the tracing expression will be a call to that function, with no arguments. This is the easiest and most common case, with the functions `browser` and `recover` the likeliest candidates; the former browses in the frame of the function being traced, and the latter allows browsing in any of the currently active calls.

The `tracer` or `exit` argument can also be an unevaluated expression (such as returned by a call to `quote` or `substitute`). This expression itself is inserted in the traced function, so it will typically involve arguments or local objects in the traced function. An expression of this form is useful if you only want to interact when certain conditions apply (and in this case you probably want to supply `print=FALSE` in the call to `trace` also).

When the `at` argument is supplied, it should be a vector of integers referring to the substeps of the body of the function (this only works if the body of the function is enclosed in `{ ...}`). In this case `tracer` is not called on entry, but instead just before evaluating each of the steps listed in `at`. (Hint: you don’t want to try to count the steps in the printed version of a function; instead, look at `as.list(body(f))` to get the numbers associated with the steps in function `f`.)

An intrinsic limitation in the `exit` argument is that it won’t work if the function itself uses `on.exit`, since the existing calls will override the one supplied by `trace`.

Tracing does not nest. Any call to `trace` replaces previously traced versions of that function or method (except for edited versions as discussed below), and `untrace` always restores an untraced version. (Allowing nested tracing has too many potentials for confusion and for accidentally leaving traced versions behind.)

When the `edit` argument is used repeatedly with no call to `untrace` on the same function or method in between, the previously edited version is retained. If you want to throw away all the previous tracing and then edit, call `untrace` before the next call to `trace`. Editing may be combined with automatic tracing; just supply the other arguments such as `tracer`, and the `edit` argument as well. The `edit=TRUE` argument uses the default editor (see `edit`).

Tracing primitive functions (builtns and specials) from the base package works, but only by a special mechanism and not very informatively. Tracing a primitive causes the primitive to be replaced by a function with argument ... (only). You can get a bit of information out, but not much. A warning message is issued when `trace` is used on a primitive.

The practice of saving the traced version of the function back where the function came from means that tracing carries over from one session to another, if the traced function is saved in the session image. (In the next session, `untrace` will remove the tracing.) On the other hand, functions that were in a package, not in the global environment, are not saved in the image, so tracing expires with the session for such functions.

Tracing a method is basically just like tracing a function, with the exception that the traced version is stored by a call to `setMethod` rather than by direct assignment, and so is the untraced version after a call to `untrace`.

The version of `trace` described here is largely compatible with the version in S-Plus, although the two work by entirely different mechanisms. The S-Plus `trace` uses the session frame, with the result that tracing never carries over from one session to another (R does not have a session frame). Another relevant distinction has nothing directly to do with `trace`: The browser in S-Plus allows changes to be made to the frame being browsed, and the changes will persist after exiting the browser. The R browser allows changes, but they disappear when the browser exits. This may be relevant in that the S-Plus version allows you to experiment with code changes interactively, but the R version does not. (A future revision may include a “destructive” browser for R.)
Value
In the simple version (just the first argument), invisible NULL. Otherwise, the traced function(s) name(s). The relevant consequence is the assignment that takes place.

Note
The version of function tracing that includes any of the arguments except for the function name requires the methods package (because it uses special classes of objects to store and restore versions of the traced functions).
If methods dispatch is not currently on, \texttt{trace} will load the methods name space, but will not put the methods package on the search list.

References

See Also
\texttt{browser} and \texttt{recover}, the likeliest tracing functions; also, \texttt{quote} and \texttt{substitute} for constructing general expressions.

Examples
## Very simple use
\texttt{trace(sum)}
\texttt{hist(rnorm(100)) \# shows about 3-4 calls to sum()} \texttt{untrace(sum)}

\texttt{if(.isMethodsDispatchOn()) \{ \# non-simple use needs 'methods' package}
\texttt{f <- function(x, y) \{
  y <- pmax(y, .001)
  x ^ y
\}}
\texttt{## arrange to call the browser on entering and exiting}
\texttt{## function f}
\texttt{trace("f", browser, exit = browser)}
\texttt{## instead, conditionally assign some data, and then browse}
\texttt{## on exit, but only then. Don't bother me otherwise}
\texttt{trace("f", quote(if(any(y < 0)) yOrig <- y),}
\texttt{  exit = quote(if(exists("yOrig")) browser()),}
\texttt{  print = FALSE)}
\texttt{## trace a utility function, with recover so we}
\texttt{## can browse in the calling functions as well.}
\texttt{trace("as.matrix", recover)}
\texttt{## turn off the tracing}
\texttt{untrace(c("f", "as.matrix"))}
## Not run:
## trace calls to the function \texttt{lm()} that come from the \texttt{nlme} package
## (The function \texttt{nlme} is in that package, and the package has a name space, so the where- argument must be used to get the right version of \texttt{lm})

\begin{verbatim}
trace(lm, exit = recover, where = nlme)
## End(Not run)
\end{verbatim}

\section*{Description}
By default \texttt{traceback()} prints the call stack of the last uncaught error, i.e., the sequence of calls that lead to the error. This is useful when an error occurs with an unidentifiable error message. It can also be used to print arbitrary lists of deparsed calls.

\section*{Usage}

\begin{verbatim}
traceback(x = NULL, max.lines = getOption("deparse.max.lines"))
\end{verbatim}

\section*{Arguments}

\begin{itemize}
\item \texttt{x} \hspace{1cm} \texttt{NULL} (default, meaning \texttt{.Traceback}), or a list or pairlist of deparsed calls.
\item \texttt{max.lines} \hspace{1cm} The maximum number of lines to be printed \textit{per call}. The default is unlimited.
\end{itemize}

\section*{Details}
The stack of the last uncaught error is stored as a list of deparsed calls in \texttt{.Traceback}, which \texttt{traceback} prints in a user-friendly format. The stack of deparsed calls always contains all function calls and all foreign function calls (such as \texttt{.Call}): if profiling is in progress it will include calls to some primitive functions. (Calls to builtins are included, but not to specials.) Errors which are caught via \texttt{try} or \texttt{tryCatch} do not generate a traceback, so what is printed is the call sequence for the last uncaught error, and not necessarily for the last error.

\section*{Value}
\texttt{traceback()} returns nothing, but prints the deparsed call stack deepest call first. The calls may print on more than one line, and the first line for each call is labelled by the frame number. The number of lines printed per call can be limited via \texttt{max.lines}.

\section*{Warning}
It is undocumented where \texttt{.Traceback} is stored nor that it is visible, and this is subject to change. Prior to R 2.4.0 it was stored in the workspace, but no longer.

\section*{References}
Examples

```r
foo <- function(x) { print(1); bar(2) }
bar <- function(x) { x + a.variable.which.does.not.exist }
## Not run:
foo(2) # gives a strange error
traceback()
## End(Not run)
## 2: bar(2)
## 1: foo(2)
bar
## Ah, this is the culprit ...
```

---

**tracemem**

*Trace Copying of Objects*

Description

This function marks an object so that a message is printed whenever the internal function `duplicate` is called. This happens when two objects share the same memory and one of them is modified. It is a major cause of hard-to-predict memory use in R.

Usage

```r
tracemem(x)
untracemem(x)
retracemem(x, previous = NULL)
```

Arguments

- `x`: An R object, not a function or environment or `NULL`.
- `previous`: A value as returned by `tracemem` or `retracemem`.

Details

This functionality is optional, determined at compilation, because it makes R run a little more slowly even when no objects are being traced. `tracemem` and `untracemem` give errors when R is not compiled with memory profiling; `retracemem` does not (so it can be left in code during development).

When an object is traced any copying of the object by the C function `duplicate` or by arithmetic or mathematical operations produces a message to standard output. The message consists of the string `tracemem`, the identifying strings for the object being copied and the new object being created, and a stack trace showing where the duplication occurred. `retracemem()` is used to indicate that a variable should be considered a copy of a previous variable (e.g. after subscripting). The messages can be turned off with `tracingState`.

It is not possible to trace functions, as this would conflict with `trace` and it is not useful to trace `NULL`, environments, promises, weak references, or external pointer objects, as these are not duplicated.

Value

A character string for identifying the object in the trace output (an address in hex enclosed in angle brackets), or `NULL` (invisibly for `untracemem`).
transform

trace.Rprofmem

http://developer.r-project.org/memory-profiling.html

Examples

## Not run:
a <- 1:10
tracemem(a)
## b and a share memory
b <- a
b[1] <- 1
untracemem(a)

## copying in lm
d <- rnorm(10)
tracemem(d)
lm(d ~ a+log(b))

## f is not a copy and is not traced
f <- d[-1]
f+1
## indicate that f should be traced as a copy of d
retracemem(f, retracemem(d))
f+1
## End(Not run)

transform

Transform an Object, for Example a Data Frame

Description

transform is a generic function, which—at least currently—only does anything useful with data frames. transform.default converts its first argument to a data frame if possible and calls transform.data.frame.

Usage

transform(`_data`, ...)

Arguments

_data The object to be transformed
...

Further arguments of the form tag=value

Details

The ... arguments to transform.data.frame are tagged vector expressions, which are evaluated in the data frame _data. The tags are matched against names(_data), and for those that match, the value replace the corresponding variable in _data, and the others are appended to _data.
Trig

Value

The modified value of _data.

Note

Prior to R 2.3.0, the first argument was named x, but this caused trouble if people wanted to create a variable of that name. Names starting with an underscore are syntactically invalid, so the current choice should be less problematic.

If some of the values are not vectors of the appropriate length, you deserve whatever you get!

subset, list, data.frame

Examples

transform(airquality, Ozone = -Ozone)
transform(airquality, new = -Ozone, Temp = (Temp-32)/1.8)

attach(airquality)
transform(Ozone, logOzone = log(Ozone)) # marginally interesting ...
detach(airquality)

Trig

Trigonometric Functions

Description

These functions give the obvious trigonometric functions. They respectively compute the cosine, sine, tangent, arc-cosine, arc-sine, arc-tangent, and the two-argument arc-tangent.

Usage

cos(x)
sin(x)
tan(x)
acos(x)
asin(x)
atan(x)
atan2(y, x)

Arguments

x, y numeric or complex vectors.
try

Details

The arc-tangent of two arguments \( \text{atan2}(y, x) \) returns the angle between the x-axis and the vector from the origin to \((x, y)\), i.e., for positive arguments \( \text{atan2}(y, x) = \text{atan}(y/x) \).

Angles are in radians, not degrees (i.e., a right angle is \( \pi/2 \)).

All except \( \text{atan2} \) are generic functions: methods can be defined for them individually or via the Math group generic.

Complex values

For the inverse trigonometric functions, branch cuts are defined as in Abramowitz and Stegun, figure 4.4, page 79. Continuity on the branch cuts is standard.

For \( \text{asin()} \) and \( \text{acos()} \), there are two cuts, both along the real axis: \((-\infty, -1] \) and \([1, \infty) \).

Functions \( \text{asin()} \) and \( \text{acos()} \) are continuous from above on the interval \((-\infty, -1] \) and continuous from below on \([1, \infty) \).

For \( \text{atan()} \) there are two cuts, both along the pure imaginary axis: \((-\infty i, -1i] \) and \([1i, \infty i) \). It is continuous from the left on the interval \((-\infty i, -1i] \) and from the right on the interval \([1i, \infty i) \).

References

try

Try an Expression Allowing Error Recovery

Description

\text{try} \) is a wrapper to run an expression that might fail and allow the user’s code to handle error-recovery.

Usage

\text{try}(\text{expr}, \text{silent} = \text{FALSE})

Arguments

\text{expr} \quad \text{an R expression to try.}

\text{silent} \quad \text{logical: should the report of error messages be suppressed?}

Details

\text{try} \) evaluates an expression and traps any errors that occur during the evaluation. If an error occurs then the error message is printed to the stderr connection unless \text{options("show.error.messages")} is false or the call includes silent = \text{TRUE}. The error message is also stored in a buffer where it can be retrieved by geterrmessage. (This should not be needed as the value returned in case of an error contains the error message.) \text{try} \) is implemented using \text{tryCatch}.
The value of the expression if `expr` is evaluated without error, but an invisible object of class "try-error" containing the error message if it fails.

See Also

`options` for setting error handlers and suppressing the printing of error messages; `geterrmessage` for retrieving the last error message. `tryCatch` provides another means of catching and handling errors.

Examples

```r
## this example will not work correctly in example(try), but
## it does work correctly if pasted in
options(show.error.messages = FALSE)
try(log("a"))
print(.Last.value)
options(show.error.messages = TRUE)

## alternatively,
print(try(log("a"), TRUE))

## run a simulation, keep only the results that worked.
set.seed(123)
x <- rnorm(50)
doit <- function(x)
{
  x <- sample(x, replace=TRUE)
  if(length(unique(x)) > 30) mean(x)
  else stop("too few unique points")
}
## alternative 1
res <- lapply(1:100, function(i) try(doit(x), TRUE))
## alternative 2
## Not run:
res <- vector("list", 100)
for(i in 1:100) res[[i]] <- try(doit(x), TRUE)
## End(Not run)
unlist(res[sapply(res, function(x) !inherits(x, "try-error"))])
```

`typeof` The Type of an Object

determines the (R internal) type or storage mode of any object

Usage

`typeof(x)`

Arguments

`x` any R object.
Value

A character string. The possible values are listed in the structure `TypeTable` in `src/main/util.c`. Current values are the vector types "logical", "integer", "double", "complex", "character", "raw" and "list", "NULL", "closure" (function), "special" and "builtin" (basic functions and operators), "environment", and others that are unlikely to be seen at user level ("symbol", "pairlist", "promise", "language", "char", ".", "any", "expression", "externalptr", "bytecode" and "weakref").

As from R 2.4.0, "S4" can occur to refer to some objects with formal (S4) classes.

See Also

`mode`, `storage.mode`.

Examples

```r
typeof(2)
mode(2)
```

---

**unique**

**Extract Unique Elements**

Description

`unique` returns a vector, data frame or array like `x` but with duplicate elements removed.

Usage

```r
unique(x, incomparables = FALSE, ...)  
## S3 method for class 'matrix':  
unique(x, incomparables = FALSE, MARGIN = 1, ...)  
## S3 method for class 'array':  
unique(x, incomparables = FALSE, MARGIN = 1, ...)
```

Arguments

- `x` a vector or a data frame or an array or `NULL`.
- `incomparables` a vector of values that cannot be compared. Currently, `FALSE` is the only possible value, meaning that all values can be compared.
- `...` arguments for particular methods.
- `MARGIN` the array margin to be held fixed: a single integer.

Details

This is a generic function with methods for vectors, data frames and arrays (including matrices). The array method calculates for each element of the dimension specified by `MARGIN` if the remaining dimensions are identical to those for an earlier element (in row-major order). This would most commonly be used for matrices to find unique rows (the default) or columns (with `MARGIN = 2`).
Value

For a vector, an object of the same type of \( x \), but with only one copy of each duplicated element. No attributes are copied (so the result has no names).

For a data frame, a data frame is returned with the same columns but possibly fewer rows (and with row names from the first occurrences of the unique rows).

A matrix or array is subsetted by \([, \text{drop} = \text{FALSE}]\), so dimensions and dimnames are copied appropriately, and the result always has the same number of dimensions as \( x \).

Warning

Using this for lists is potentially slow, especially if the elements are not atomic vectors (see \texttt{vector}) or differ only in their attributes. In the worst case it is \( O(n^2) \).

References

See Also

duplicated which gives the indices of duplicated elements.

Examples

\begin{verbatim}
unique(c(3:5, 11:8, 8 + 0:5))
length(unique(sample(100, 100, replace=TRUE)))
## approximately 100(1 - 1/e) = 63.21
unique(iris)
\end{verbatim}

\textbf{unlink}

Delete Files and Directories

Description

\texttt{unlink} deletes the file(s) or directories specified by \( x \).

Usage

\texttt{unlink(x, recursive = FALSE)}

Arguments

\begin{itemize}
  \item \texttt{x} \hspace{1cm} a character vector with the names of the file(s) or directories to be deleted. Wildcards (normally ‘*’ and ‘?’) are allowed.
  \item \texttt{recursive} \hspace{1cm} logical. Should directories be deleted recursively?
\end{itemize}

Details

If \texttt{recursive = FALSE} directories are not deleted, not even empty ones.

\texttt{file.remove} can only remove files, but gives more detailed error information.
unlist

Value

The return value of the corresponding system command, `rm -f`, normally 0 for success, 1 for failure. Not deleting a non-existent file is not a failure.

Note

Prior to R version 1.2.0 the default on Unix was `recursive = TRUE`, and on Windows empty directories could be deleted.

References

See Also

`file.remove`.

unlist

Flatten Lists

Description

Given a list structure `x`, `unlist` simplifies it to produce a vector which contains all the atomic components which occur in `x`.

Usage

`unlist(x, recursive = TRUE, use.names = TRUE)`

Arguments

- `x` An R object, typically a list or vector.
- `recursive` logical. Should unlisting be applied to list components of `x`?
- `use.names` logical. Should names be preserved?

Details

`unlist` is generic: you can write methods to handle specific classes of objects, see `InternalMethods`.

If `x` has length zero the result is `NULL`.

If `recursive = FALSE`, the function will not recurse beyond the first level items in `x`.

Factors are treated specially. If all non-list elements of `x` are factors (or ordered factors) then the result will be a factor with levels the union of the level sets of the elements, in the order the levels occur in the level sets of the elements (which means that if all the elements have the same level set, that is the level set of the result).

`x` can be an atomic vector, but then `unlist` does nothing useful, not even drop names.

By default, `unlist` tries to retain the naming information present in `x`. If `use.names = FALSE` all naming information is dropped.
Where possible the list elements are coerced to a common mode during the unlisting, and so the result often ends up as a character vector. Vectors will be coerced to the highest type of the components in the hierarchy `NULL < raw < logical < integer < real < complex < character < list < expression`: pairlists are treated as lists.

A list is a (generic) vector, and the simplified vector might still be a list (and might be unchanged). Non-vector elements of the list (for example language elements such as names, formulas and calls) are not coerced, and so a list containing one or more of these remains a list. (The effect of unlisting an `lm` fit is a list which has individual residuals as components.)

**Value**

`NULL` or an expression or a vector of an appropriate mode to hold the list components.

The output type is determined from the highest type of the components in the hierarchy `raw < logical < integer < real < complex < character < list < expression`, after coercion of pairlists to lists.

**References**

**See Also**

`c`, `as.list`.

**Examples**

```r
unlist(options())
unlist(options(), use.names=FALSE)

l.ex <- list(a = list(1:5, LETTERS[1:5]), b = "Z", c = NA)
unlist(l.ex, recursive = FALSE)
unlist(l.ex, recursive = TRUE)

l1 <- list(a="a", b=2, c=pi+2i)
unlist(l1) # a character vector
l2 <- list(a="a", b=as.name("b"), c=pi+2i)
unlist(l2) # remains a list
```

**unnamed**

Remove ‘names’ or ‘dimnames’

**Description**

Remove the `names` or `dimnames` attribute of an `R` object.

**Usage**

```r
uname(obj, force = FALSE)
```
UseMethod

Arguments

obj   the R object which is wanted “nameless”.
force   logical; if true, the dimnames are even removed from data.frames. This argument is currently experimental and hence might change!

Value

Object as obj but without names or dimnames.

Examples

## Answering a question on R-help (14 Oct 1999):
col3 <- 750+ 100* rt(1500, df = 3)
b breaks <- factor(cut(col3,breaks=360+5*(0:155)))
z <- table(breaks)
z[1:5] # The names are larger than the data ...
barplot(unname(z), axes= FALSE)

UseMethod   Class Methods

Description

R possesses a simple generic function mechanism which can be used for an object-oriented style of programming. Method dispatch takes place based on the class(es) of the first argument to the generic function or of the object supplied as an argument to UseMethod or NextMethod.

Usage

UseMethod(generic, object)
NextMethod(generic = NULL, object = NULL, ...)

Arguments

generic   a character string naming a function (and not a built-in operator). Required for UseMethod.
object   for UseMethod: an object whose class will determine the method to be dispatched. Defaults to the first argument of the enclosing function.
...   further arguments to be passed to the next method.

Details

An R “object” is a data object which has a class attribute (and this can be tested by is.object). A class attribute is a character vector giving the names of the classes which the object “inherits” from. If the object does not have a class attribute, it has an implicit class. Matrices and arrays have class "matrix" or"array" followed by the class of the underlying vector. Most vectors have class the result of mode(x), except that integer vectors have class c("integer", "numeric") and real vectors have class c("double", "numeric").

When a function calling UseMethod("fun") is applied to an object with class attribute c("first", "second"), the system searches for a function called fun.first and, if it
finds it, applies it to the object. If no such function is found a function called fun.second is tried. If no class name produces a suitable function, the function fun.default is used, if it exists, or an error results.

Function methods can be used to find out about the methods for a particular generic function or class.

UseMethod is a primitive function so positional matching is used and names of supplied arguments are ignored. It is not the only means of dispatch of methods, for there are internal generic and group generic functions. UseMethod currently dispatches on the implicit class even for arguments that are not objects, but the other means of dispatch do not.

NextMethod invokes the next method (determined by the class vector, either of the object supplied to the generic, or of the first argument to the function containing NextMethod if a method was invoked directly). Normally NextMethod is used with only one argument, generic, but if further arguments are supplied these modify the call to the next method.

NextMethod should not be called except in methods called by UseMethod or from internal generics (see InternalGenerics). In particular it will not work inside anonymous calling functions (e.g. get("print.ts")(AirPassengers)).

Name spaces can register methods for generic functions. To support this, UseMethod and NextMethod search for methods in two places: first in the environment in which the generic function is called, and then in the registration data base for the environment in which the generic is defined (typically a namespace). So methods for a generic function need to be available in the environment of the call to the generic, or they must be registered. (It does not matter whether they are visible in the environment in which the generic is defined.)

Technical Details

Now for some obscure details that need to appear somewhere. These comments will be slightly different than those in Chambers(1992). (See also the draft ‘R Language Definition’.) UseMethod creates a “new” function call with arguments matched as they came in to the generic. Any local variables defined before the call to UseMethod are retained (unlike S). Any statements after the call to UseMethod will not be evaluated as UseMethod does not return. UseMethod can be called with more than two arguments: a warning will be given and additional arguments ignored. (They are not completely ignored in S.) If it is called with just one argument, the class of the first argument of the enclosing function is used as object: unlike S this is the first actual argument passed and not the current value of the object of that name.

NextMethod works by creating a special call frame for the next method. If no new arguments are supplied, the arguments will be the same in number, order and name as those to the current method but their values will be promises to evaluate their name in the current method and environment. Any named arguments matched to ... are handled specially: they either replace existing arguments of the same name or are appended to the argument list. They are passed on as the promise that was supplied as an argument to the current environment. (S does this differently!) If they have been evaluated in the current (or a previous environment) they remain evaluated. (This is a complex area, and subject to change: see the draft ‘R Language Definition’.)

The search for methods for NextMethod is slightly different from that for UseMethod. Finding no fun.default is not necessarily an error, as the search continues to the generic itself. This is to pick up an internal generic like [ which has no separate default method, and succeeds only if the generic is a primitive function or a wrapper for a .Internal function of the same name. (When a primitive is called as the default method, argument matching may not work as described above due to the different semantics of primitives.)

You will see objects such as .Generic, .Method, and .Class used in methods. These are set in the environment within which the method is evaluated by the dispatch mechanism, which is as follows:
1. Find the context for the calling function (the generic): this gives us the unevaluated arguments for the original call.

2. Evaluate the object (usually an argument) to be used for dispatch, and find a method (possibly the default method) or throw an error.

3. Create an environment for evaluating the method and insert special variables (see below) into that environment. Also copy any variables in the environment of the generic that are not formal (or actual) arguments.

4. Fix up the argument list to be the arguments of the call matched to the formals of the method.

**.Generic** is a length-one character vector naming the generic function.

**.Method** is a character vector (normally of length one) naming the method function. (For functions in the group generic **Ops** it is of length two.)

**.Class** is a character vector of classes used to find the next method. **NextMethod** adds an attribute "previous" to **.Class** giving the **.Class** last used for dispatch, and shifts **.Class** along to that used for dispatch.

**.GenericCallEnv** and **.GenericDefEnv** are the environments of the call to be generic and defining the generic respectively. (The latter is used to find methods registered for the generic.)

Note that **.Class** is set when the generic is called, and is unchanged if the class of the dispatching argument is changed in a method. It is possible to change the method that **NextMethod** would dispatch by manipulating **.Class**, but ‘this is not recommended unless you understand the inheritance mechanism thoroughly’ (Chambers & Hastie, 1992, p. 469).

**Historical note**

Prior to R 2.1.0 **UseMethod** accepted a call with no arguments and tried to deduce the generic from the context. This was undocumented on the help page. It is allowed but ‘strongly discouraged’ in S-PLUS, and is no longer allowed in R.

**Note**

This scheme is called **S3** (S version 3). For new projects, it is recommended to use the more flexible and robust **S4** scheme provided in the **methods** package.

**References**

The draft ‘R Language Definition’.

*methods, class, getS3method, is.object.*
UserHooks

**Functions to Get and Set Hooks for Load, Attach, Detach and Unload**

**Description**

These functions allow users to set actions to be taken before packages are attached/detached and name spaces are (un)loaded.

**Usage**

```
getHook(hookName)
setHook(hookName, value, action = c("append", "prepend", "replace"))
packageEvent(pkgname, event = c("onLoad", "attach", "detach", "onUnload"))
```

**Arguments**

- **hookName**: character string: the hook name
- **pkgname**: character string: the package/name space name. If versioned install has been used, pkgname should be the unversioned name of the package (but any version information will be stripped).
- **event**: character string: an event for the package
- **value**: A function, or for action= "replace", NULL.
- **action**: The action to be taken. The names can be abbreviated.

**Details**

`setHook` provides a general mechanism for users to register hooks, a list of functions to be called from system (or user) functions. The initial set of hooks is associated with events on packages/name spaces: these hooks are named via calls to `packageEvent`.

To remove a hook completely, call `setHook(hookName, NULL, "replace")`.

When an R package is attached by `library`, it can call initialization code via a function `.First.lib` and when it is detached it can tidy up via a function `.Last.lib`. Users can add their own initialization code via these functions, functions which will be called as `funname(pkgname, pkgpath)` inside a `try` call. (The attach hook is called after `.First.lib` and the detach hook before `.Last.lib`.)

If a package has a name space, there are two further actions, when the name space is loaded (before being attached and after `onLoad` is called ) and when it is unloaded (after being detached and before `onUnload`). Note that code in these hooks is run without the package being on the search path, so objects in the package need to be referred to using the double colon operator as in the example. (Unlike `onLoad`, the user hook is run after the name space has been sealed.)

Hooks are normally run in the order shown by `getHook`, but the "detach" and "onUnload" hooks are run in reverse order so the default for package events is to add hooks ‘inside’ existing ones.

Note that when an R session is finished, packages are not detached and name spaces are not unloaded, so the corresponding hooks will not be run.

The hooks are stored in the environment `.userHooksEnv` in the base package, with ‘mangled’ names.
**utf8Conversion**  

_Convert to or from UTF-8-encoded Character Vectors_

**Description**

Conversion of UTF-8 encoded character vectors to and from integer vectors.

**Usage**

```r
utf8ToInt(x)
intToUtf8(x, multiple = FALSE)
```

**Arguments**

- **x** object to be converted.
- **multiple** logical: should the conversion be to a single character string or multiple individual characters?

**Details**

These will work in any locale, including on machines that do not otherwise support multi-byte character sets.

**Value**

- `utf8ToInt` converts a length-one character string encoded in UTF-8 to an integer vector of (numeric) UTF-8 code points.
- `intToUtf8` converts a vector of (numeric) UTF-8 code points either to a single character string or a character vector of single characters. (Note that a single character string could contain embedded nuls.)

**See Also**

- `library`, `detach`, `loadNamespace`.

Other hooks may be added later: `plot.new` and `persp` already have them.
Description

`vector` produces a vector of the given length and mode.

`as.vector`, a generic, attempts to coerce its argument into a vector of mode `mode` (the default is to coerce to whichever mode is most convenient).

`is.vector` returns `TRUE` if `x` is a vector (of mode logical, integer, real, complex, character, raw or list if not specified) or expression and `FALSE` otherwise.

Usage

```r
vector(mode = "logical", length = 0)
as.vector(x, mode = "any")
is.vector(x, mode = "any")
```

Arguments

- `mode` A character string giving an atomic mode or "list", or (not for `vector") "any".
- `length` A non-negative integer specifying the desired length.
- `x` An object.

Details

The atomic modes are "logical", "integer", "numeric", "complex", "character" and "raw".

`is.vector` returns `FALSE` if `x` has any attributes except names. (This is incompatible with S.) On the other hand, `as.vector` removes all attributes including names for results of atomic mode.

Note that factors are not vectors; `is.vector` returns `FALSE` and `as.vector` converts to a character vector for `mode = "any"`.

Value

For `vector`, a vector of the given length and mode. Logical vector elements are initialized to `FALSE`, numeric vector elements to `0`, character vector elements to "", raw vector elements to null bytes and list elements to `NULL`

All attributes are removed from the answer if it is of an atomic mode.

Note

`as.vector` and `is.vector` are quite distinct from the meaning of the formal class "vector" in the `methods` package, and hence `as(x, "vector")` and `is(x, "vector")`.

Modes of "symbol", "pairlist" and "expression" are allowed but have long been undocumented.
warning

References

See Also

c, is.numeric, is.list, etc.

Examples

df <- data.frame(x=1:3, y=5:7)
## Not run:
## Error:
## as.vector(data.frame(x=1:3, y=5:7), mode="numeric")
## End(Not run)

x <- c(a = 1, b = 2)
is.vector(x)
as.vector(x)
all.equal(x, as.vector(x)) ## FALSE

###-- All the following are TRUE:
is.list(df)
! is.vector(df)
! is.vector(df, mode="list")
is.vector(list(), mode="list")
is.vector(NULL, mode="NULL")

Description

Generates a warning message that corresponds to its argument(s) and (optionally) the expression or function from which it was called.

Usage

```
warning(..., call. = TRUE, immediate. = FALSE, domain = NULL)
suppressWarnings(expr)
```

Arguments

```
... zero or more objects which can be coerced to character (and which are pasted together with no separator) or a single condition object.
call. logical, indicating if the call should become part of the warning message.
immediate. logical, indicating if the call should be output immediately, even if `getOption`(warn) <= 0.
expr expression to evaluate.
domain see `gettext`. If NA, messages will not be translated.
```
Details

The result depends on the value of `options("warn")` and on handlers established in the executing code.

If a condition object is supplied it should be the only argument, and further arguments will be ignored, with a message.

`warning` signals a warning condition by (effectively) calling `signalCondition`. If there are no handlers or if all handlers return, then the value of `warn = getOption("warn")` is used to determine the appropriate action. If `warn` is negative warnings are ignored; if it is zero they are stored and printed after the top–level function has completed; if it is one they are printed as they occur and if it is 2 (or larger) warnings are turned into errors. Calling `warning(immediate. = TRUE)` turns `warn <= 0` into `warn = 1` for this call only.

If `warn` is zero (the default), a read-only variable `last.warning` is created. It contains the warnings which can be printed via a call to `warnings`.

Warnings will be truncated to `getOption("warning.length")` characters, default 1000, indicated by `[... truncated]`.

While the warning is being processed, a `muffleWarning` restart is available. If this restart is invoked with `invokeRestart`, then `warning` returns immediately.

An attempt is made to coerce other types of inputs to `warning` to character vectors.

`suppressWarnings` evaluates its expression in a context that ignores all warnings.

References

See Also

`stop` for fatal errors, `message` for diagnostic messages, `warnings`, and `options` with argument `warn`.

`gettext` for the mechanisms for the automated translation of messages.

Examples

```r
testit <- function() warning("testit")
testit() ## shows call

suppressWarnings(warning("testit"))
```

## Print Warning Messages

### Description

`warnings` and its `print` method print the variable `last.warning` in a pleasing form.

### Usage

```r
warnings(...)
```
Arguments

... arguments to be passed to cat.

Details

See the description of options("warn") for the circumstances under which there is a last.warning object and warnings() is used. In essence this is if options(warn = 0) and warning has been called at least once.

It is possible that last.warning refers to the last recorded warning and not to the last warning, for example if options(warn) has been changed or if a catastrophic error occurred.

Warning

It is undocumented where last.warning is stored nor that it is visible, and this is subject to change. Prior to R 2.4.0 it was stored in the workspace, but no longer.

References

See Also

warning.

Examples

## NB this example is intended to be pasted in,
## rather than run by example()
ow <- options("warn")

}
warnings()
options(ow) # reset

weekdays

Extract Parts of a POSIXt or Date Object

Description

Extract the weekday, month or quarter, or the Julian time (days since some origin). These are generic functions: the methods for the internal date-time classes are documented here.
Usage

weekdays(x, abbreviate)
## S3 method for class 'POSIXt':
weekdays(x, abbreviate = FALSE)
## S3 method for class 'Date':
weekdays(x, abbreviate = FALSE)

months(x, abbreviate)
## S3 method for class 'POSIXt':
months(x, abbreviate = FALSE)
## S3 method for class 'Date':
months(x, abbreviate = FALSE)

quarters(x, abbreviate)
## S3 method for class 'POSIXt':
quarters(x, ...)
## S3 method for class 'Date':
quarters(x, ...)

julian(x, ...)
## S3 method for class 'POSIXt':
julian(x, origin = as.POSIXct("1970-01-01", tz="GMT"), ...)
## S3 method for class 'Date':
julian(x, origin = as.Date("1970-01-01"), ...)

Arguments

x an object inheriting from class "POSIXt" or "Date".
abbreviate logical. Should the names be abbreviated?
origin an length-one object inheriting from class "POSIXt" or "Date".
... arguments for other methods.

Value

weekdays and months return a character vector of names in the locale in use.
quarters returns a character vector of "Q1" to "Q4".
julian returns the number of days (possibly fractional) since the origin, with the origin as a "origin" attribute.

Note

Other components such as the day of the month or the year are very easy to compute: just use as.POSIXlt and extract the relevant component.

DateTimeClasses, Date
which

Examples

weekdays(.leap.seconds)
months(.leap.seconds)
quarters(.leap.seconds)

which

Which indices are TRUE?

Description

Give the TRUE indices of a logical object, allowing for array indices.

Usage

which(x, arr.ind = FALSE)

Arguments

x

a logical vector or array. NAs are allowed and omitted (treated as if FALSE).

arr.ind

logical; should array indices be returned when x is an array?

Value

If arr.ind == FALSE (the default), an integer vector with length equal to sum(x), i.e., to the number of TRUEs in x; Basically, the result is (1:length(x))[x].

If arr.ind == TRUE and x is an array (has a dim attribute), the result is a matrix whose rows each are the indices of one element of x; see Examples below.

Author(s)

Werner Stahel and Peter Holzer (holzer@stat.math.ethz.ch), for the array case.

See Also

Logic, which.min for the index of the minimum or maximum, and match for the first index of an element in a vector, i.e., for a scalar a, match(a,x) is equivalent to min(which(x == a)) but much more efficient.

Examples

which(LETTERS == "R")
which(ll <- c(TRUE,FALSE,TRUE,NA,FALSE,FALSE,TRUE))#> 1 3 7
names(ll) <- letters[seq(ll)]
which(ll)
which((1:12)%%2 == 0) # which are even?
which(1:10 > 3, arr.ind=TRUE)

( m <- matrix(1:12,3,4) )
which(m %% 3 == 0)
which(m %% 3 == 0, arr.ind=TRUE)
rownames(m) <- paste("Case",1:3, sep="_")
which(m %% 5 == 0, arr.ind=TRUE)
dim(m) <- c(2,2,3); m
which(m %% 3 == 0, arr.ind=FALSE)
which(m %% 3 == 0, arr.ind=TRUE)

vm <- c(m)
dim(vm) <- length(vm) #-- funny thing with length(dim(...)) == 1
which(vm %% 3 == 0, arr.ind=TRUE)

\textit{which.min} \\
\textit{Where is the Min() or Max()?}

\textbf{Description}

Determines the location, i.e., index of the (first) minimum or maximum of a numeric vector.

\textbf{Usage}

\begin{verbatim}
which.min(x)
which.max(x)
\end{verbatim}

\textbf{Arguments}

\begin{itemize}
\item {\textbf{x}} \\
\end{itemize}

\textit{numeric (integer or double) vector, whose min or max is searched for.}

\textbf{Value}

Missing and NaN values are discarded.

an \textbf{integer} of length 1 or 0 (iff \textbf{x} has no non-NAs), giving the index of the first minimum or maximum respectively of \textbf{x}.

If this extremum is unique (or empty), the results are the same as (but more efficient than) \textbf{which}(\textbf{x} == min(\textbf{x})) or \textbf{which}(\textbf{x} == max(\textbf{x})) respectively.

\textbf{Author(s)}

Martin Maechler

\textbf{See Also}

\begin{verbatim}
which, max.col, max, etc.
which.is.max in package nnet differs in breaking ties at random (and having a “fuzz” in the definition of ties).
\end{verbatim}

\textbf{Examples}

\begin{verbatim}
x <- c(1:4,0:5,11)
which.min(x)
which.max(x)

## it *does* work with NA's present, by discarding them:
presidents[1:30]
range(presidents, na.rm = TRUE)
which.min(presidents) # 28
which.max(presidents) # 2
\end{verbatim}
**Description**

Evaluate an R expression in an environment constructed from data.

**Usage**

```r
with(data, expr, ...)
```

**Arguments**

- `data`: data to use for constructing an environment. For the default method this may be an environment, a list, a data frame, or an integer as in `sys.call`.
- `expr`: expression to evaluate.
- `...`: arguments to be passed to future methods.

**Details**

`with` is a generic function that evaluates `expr` in a local environment constructed from `data`. The environment has the caller’s environment as its parent. This is useful for simplifying calls to modeling functions.

Note that assignments within `expr` take place in the constructed environment and not in the user’s workspace.

**See Also**

`evalq`, `attach`.

**Examples**

```r
require(stats); require(graphics)
#examples from glm:
## Not run:
library(MASS)
with(anorexia, {  
anorex.1 <- glm(Postwt ~ Prewt + Treat + offset(Prewt),  
               family = gaussian)  
               summary(anorex.1)  
})
## End(Not run)
with(data.frame(u = c(5,10,15,20,30,40,60,80,100),  
               lot1 = c(118,58,42,35,27,25,21,19,18),  
               lot2 = c(69,35,26,21,18,16,13,12,12)),  
list(summary(glm(lot1 ~ log(u), family = Gamma)),  
     summary(glm(lot2 ~ log(u), family = Gamma))))
# example from boxplot:
with(ToothGrowth, {  
   boxplot(len ~ dose, boxwex = 0.25, at = 1:3 - 0.2,
```
```r
subset = (supp == "VC"), col = "yellow",
main = "Guinea Pigs' Tooth Growth",
xlab = "Vitamin C dose mg",
ylab = "tooth length", ylim = c(0,35))
boxplot(len ~ dose, add = TRUE, boxwex = 0.25, at = 1:3 + 0.2,
subset = supp == "OJ", col = "orange")
legend(2, 9, c("Ascorbic acid", "Orange juice"),
fill = c("yellow", "orange"))
```

```r
# alternate form that avoids subset argument:
with(subset(ToothGrowth, supp == "VC"),
   boxplot(len ~ dose, boxwex = 0.25, at = 1:3 - 0.2,
   col = "yellow", main = "Guinea Pigs' Tooth Growth",
   xlab = "Vitamin C dose mg",
   ylab = "tooth length", ylim = c(0,35)))
with(subset(ToothGrowth, supp == "OJ"),
   boxplot(len ~ dose, add = TRUE, boxwex = 0.25, at = 1:3 + 0.2,
   col = "orange"))
legend(2, 9, c("Ascorbic acid", "Orange juice"),
fill = c("yellow", "orange"))
```

---

**write**

**Write Data to a File**

**Description**

The data (usually a matrix) \(x\) are written to file `file`. If \(x\) is a two-dimensional matrix you need to transpose it to get the columns in `file` the same as those in the internal representation.

**Usage**

```r
write(x, file = "data",
   ncolumns = if(is.character(x)) 1 else 5,
   append = FALSE, sep = " ")
```

**Arguments**

- \(x\) the data to be written out.
- **file** A connection, or a character string naming the file to write to. If "", print to the standard output connection. If it is "| cmd", the output is piped to the command given by `cmd`.
- **ncolumns** the number of columns to write the data in.
- **append** if TRUE the data \(x\) are appended to the connection.
- **sep** a string used to separate columns. Using sep = "t" gives tab delimited output; default is " ".

**References**

**writeLines**

Write Lines to a Connection

**Description**

Write text lines to a connection.

**Usage**

```
writeLines(text, con = stdout(), sep = "\n")
```

**Arguments**

- `text` A character vector
- `con` A connection object or a character string.
- `sep` character. A string to be written to the connection after each line of text.

**Details**

If the `con` is a character string, the function calls `file` to obtain a file connection which is opened for the duration of the function call.

If the connection is open it is written from its current position. If it is not open, it is opened for the duration of the call and then closed again.

Normally `writeLines` is used with a text connection, and the default separator is converted to the normal separator for that platform (LF on Unix/Linux, CRLF on Windows, CR on Classic MacOS). For more control, open a binary connection and specify the precise value you want written to the file in `sep`. For even more control, use `writeChar` on a binary connection.

**See Also**

`connections`, `writeChar`, `writeBin`, `readLines`, `cat`
Description

.packages returns information about package availability.

Usage

.packages(all.available = FALSE, lib.loc = NULL)

Arguments

all.available
  logical; if TRUE return a character vector of all available packages in lib.loc.

lib.loc
  a character vector describing the location of R library trees to search through, or
  NULL. The default value of NULL corresponds to all libraries currently known.

Details

.packages() returns the “base names” of the currently attached packages invisibly whereas
.packages(all.available = TRUE) gives (visibly) all packages available in the library
location path lib.loc. For a package to be regarded as being available it must have a
‘DESCRIPTION’ file containing a valid version field.

Value

A character vector of package “base names”, invisible unless all.available = TRUE.

Author(s)

R core; Guido Masarotto for the all.available=TRUE part of .packages.

See Also

library, .libPaths.

Examples

(.packages()) # maybe just "base"
.packages(all = TRUE) # return all available as character vector
require(splines) # the same
(.packages()) # "splines", too
detach("package:splines")
Description

Miscellaneous internal/programming utilities.

Usage

.standard_regexps()

Details

.standard_regexps returns a list of “standard” regexps, including elements named valid_package_name and valid_package_version with the obvious meanings. The regexps are not anchored.
Chapter 2

The datasets package

datasets-package  The R Datasets Package

Description

Base R datasets

Details

This package contains a variety of datasets. For a complete list, use library(help="datasets").

Author(s)

R Development Core Team and contributors worldwide
Maintainer: R Core Team (R-core@r-project.org)

ability.cov  Ability and Intelligence Tests

Description

Six tests were given to 112 individuals. The covariance matrix is given in this object.

Usage

ability.cov
Details

The tests are described as

**general**: a non-verbal measure of general intelligence using Cattell’s culture-fair test.

**picture**: a picture-completion test

**blocks**: block design

**maze**: mazes

**reading**: reading comprehension

**vocab**: vocabulary

Bartholomew gives both covariance and correlation matrices, but these are inconsistent. Neither are in the original paper.

Source

References

Examples

```r
require(stats)
(ability.FA <- factanal(factors = 1, covmat=ability.cov))
update(ability.FA, factors=2)
update(ability.FA, factors=2, rotation="promax")
```

---

**airmiles**  
*Passenger Miles on Commercial US Airlines, 1937–1960*

Description

The revenue passenger miles flown by commercial airlines in the United States for each year from 1937 to 1960.

Usage

```r
airmiles
```

Format

Source

F.A.A. Statistical Handbook of Aviation.
AirPassengers

Examples

```r
plot(airmiles, main = "airmiles data",
     xlab = "Passenger-miles flown by U.S. commercial airlines", col = 4)
```

**AirPassengers**

*Monthly Airline Passenger Numbers 1949-1960*

Description

The classic Box & Jenkins airline data. Monthly totals of international airline passengers, 1949 to 1960.

Usage

`AirPassengers`

Format

A monthly time series, in thousands.

Source

Examples

```r
## Not run:
## These are quite slow and so not run by example(AirPassengers)

## The classic 'airline model', by full ML
(fit <- arima(log10(AirPassengers), c(0, 1, 1),
             seasonal = list(order=c(0, 1,1), period=12)))
update(fit, method = "CSS")
update(fit, x=window(log10(AirPassengers), start = 1954))
pred <- predict(fit, n.ahead = 24)
tl <- pred$pred - 1.96 * pred$se
tu <- pred$pred + 1.96 * pred$se
ts.plot(AirPassengers, 10^tl, 10^tu, log = "y", lty = c(1,2,2))

## full ML fit is the same if the series is reversed, CSS fit is not
ap0 <- rev(log10(AirPassengers))
attributes(ap0) <- attributes(AirPassengers)
arima(ap0, c(0, 1, 1), seasonal = list(order=c(0, 1,1), period=12))
arima(ap0, c(0, 1, 1), seasonal = list(order=c(0, 1,1), period=12),
      method = "CSS")

## Structural Time Series
ap <- log10(AirPassengers) - 2
```
(fit <- StructTS(ap, type= "BSM"))
par(mfrow=c(1,2))
plot(cbind(ap, fitted(fit)), plot.type = "single")
plot(cbind(ap, tsSmooth(fit)), plot.type = "single")
## End(Not run)

### airquality

**New York Air Quality Measurements**

**Description**

**Usage**

`airquality`

**Format**

A data frame with 154 observations on 6 variables.

```
[,1] Ozone   numeric  Ozone (ppb)
[,3] Wind    numeric  Wind (mph)
[,4] Temp    numeric  Temperature (degrees F)
[,5] Month   numeric  Month (1–12)
```

**Details**

Daily readings of the following air quality values for May 1, 1973 (a Tuesday) to September 30, 1973.

- **Ozone**: Mean ozone in parts per billion from 1300 to 1500 hours at Roosevelt Island
- **Solar.R**: Solar radiation in Langley s in the frequency band 4000–7700 Angstroms from 0800 to 1200 hours at Central Park
- **Wind**: Average wind speed in miles per hour at 0700 and 1000 hours at LaGuardia Airport
- **Temp**: Maximum daily temperature in degrees Fahrenheit at LaGuardia Airport.

**Source**

The data were obtained from the New York State Department of Conservation (ozone data) and the National Weather Service (meteorological data).

**References**

**Examples**

```
pairs(airquality, panel = panel.smooth, main = "airquality data")
```
Description

Four \( x \)-\( y \) datasets which have the same traditional statistical properties (mean, variance, correlation, regression line, etc.), yet are quite different.

Usage

anscombe

Format

A data frame with 11 observations on 8 variables.

\[
\begin{align*}
x1 & \equiv x2 \equiv x3 \quad \text{the integers 4:14, specially arranged} \\
x4 & \quad \text{values 8 and 19} \\
y1, y2, y3, y4 & \quad \text{numbers in (3, 12.5) with mean 7.5 and sdev 2.03}
\end{align*}
\]

Source

References

Examples

require(stats)
summary(anscombe)

### Now some "magic" to do the 4 regressions in a loop:
ff <- y ~ x
for(i in 1:4) {
  ff[2:3] <- lapply(paste(c("y","x"), i, sep=""), as.name)
  ## or ff[[2]] <- as.name(paste("y", i, sep=""))
  ## ff[[3]] <- as.name(paste("x", i, sep=""))
  assign(paste("lm." ,i, sep=""), lmi <- lm(ff, data= anscombe))
  print(anova(lmi))
}

### See how close they are (numerically!)
sapply(objects(pat="lm\.[1-4]$"), function(n) coef(get(n)))
lapply(objects(pat="lm\.[1-4]$"), function(n) summary(get(n))$coef)

### Now, do what you should have done in the first place: PLOTS
op <- par(mfrow=c(2,2), mar=.1+c(4,4,1,1), oma= c(0,0,2,0))
for(i in 1:4) {
  ff[2:3] <- lapply(paste(c("y","x"), i, sep=""), as.name)
  plot(ff, data =anscombe, col="red", pch=21, bg = "orange", cex = 1.2, 
xlim=c(3,19), ylim=c(3,13))
attenu

The Joyner–Boore Attenuation Data

Description

This data gives peak accelerations measured at various observation stations for 23 earthquakes in California. The data have been used by various workers to estimate the attenuating affect of distance on ground acceleration.

Usage

attenu

Format

A data frame with 182 observations on 5 variables.

\[
\begin{array}{c|c|c}
& \text{variable} & \text{description} \\
1. & \text{event} & \text{numeric Event Number} \\
2. & \text{mag} & \text{numeric Moment Magnitude} \\
3. & \text{station} & \text{numeric Station Number} \\
4. & \text{dist} & \text{numeric Station-hypocenter distance (km)} \\
5. & \text{accel} & \text{numeric Peak acceleration (g)} \\
\end{array}
\]

Examples

```r
## check the data class of the variables
```
The Chatterjee–Price Attitude Data

Description

From a survey of the clerical employees of a large financial organization, the data are aggregated from the questionnaires of the approximately 35 employees for each of 30 (randomly selected) departments. The numbers give the percent proportion of favourable responses to seven questions in each department.

Usage

attitude

Format

A dataframe with 30 observations on 7 variables. The first column are the short names from the reference, the second one the variable names in the data frame:

<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Overall rating</td>
<td>Handling of employee complaints</td>
<td>Does not allow special privileges</td>
<td>Opportunity to learn</td>
<td>Raises based on performance</td>
<td>Too critical</td>
<td>Advancement</td>
</tr>
</tbody>
</table>

### beavers

**Body Temperature Series of Two Beavers**

**Description**

Reynolds (1994) describes a small part of a study of the long-term temperature dynamics of beaver *Castor canadensis* in north-central Wisconsin. Body temperature was measured by telemetry every 10 minutes for four females, but data from a one period of less than a day for each of two animals is used there.

**Usage**

beaver1
beaver2

**Format**

The `beaver1` data frame has 114 rows and 4 columns on body temperature measurements at 10 minute intervals.

The `beaver2` data frame has 100 rows and 4 columns on body temperature measurements at 10 minute intervals.

The variables are as follows:

- **day**  Day of observation (in days since the beginning of 1990), December 12–13 (`beaver1`) and November 3–4 (`beaver2`).
- **time**  Time of observation, in the form 0330 for 3:30am
- **temp**  Measured body temperature in degrees Celsius.
- **activ**  Indicator of activity outside the retreat.

**Note**

The observation at 22:20 is missing in `beaver1`. 
Source

Examples

(yl <- range(beaver1$temp, beaver2$temp))

beaver.plot <- function(bdat, ...) {
  nam <- deparse(substitute(bdat))
  with(bdat, {
    # Hours since start of day:
    hours <- time %% 100 + 24*(day - day[1]) + (time %% 100)/60
    plot (hours, temp, type = "l", ..., 
          main = paste(nam, "body temperature"))
    abline(h = 37.5, col = "gray", lty = 2)
    is.act <- activ == 1
    points(hours[is.act], temp[is.act], col = 2, cex = .8)
  })
}

  lines(d, predict(fm, data.frame(speed=d)), col = degree)
}
anova(cars.1, cars.2, cars.3, cars.4)

ChickWeight

Weight versus age of chicks on different diets

Description

The ChickWeight data frame has 578 rows and 4 columns from an experiment on the effect of diet on early growth of chicks.
Usage

ChickWeight

Format

This data frame contains the following columns:

- **weight** a numeric vector giving the body weight of the chick (gm).
- **Time** a numeric vector giving the number of days since birth when the measurement was made.
- **Chick** an ordered factor with levels 18 < . . . < 48 giving a unique identifier for the chick. The ordering of the levels groups chicks on the same diet together and orders them according to their final weight (lightest to heaviest) within diet.
- **Diet** a factor with levels 1, . . . , 4 indicating which experimental diet the chick received.

Details

The body weights of the chicks were measured at birth and every second day thereafter until day 20. They were also measured on day 21. There were four groups on chicks on different protein diets.

Source

Examples

```r
require(stats)
coplot(weight ~ Time | Chick, data = ChickWeight, type = "b", show = FALSE)
## fit a representative chick
fm1 <- nls(weight ~ SSlogis( Time, Asym, xmid, scal ),
           data = ChickWeight, subset = Chick == 1)
summary( fm1 )
```

chickwts

*Chicken Weights by Feed Type*

Description

An experiment was conducted to measure and compare the effectiveness of various feed supplements on the growth rate of chickens.

Usage

chickwts
**CO2**

**Format**

A data frame with 71 observations on 2 variables.

- **weight** a numeric variable giving the chick weight.
- **feed** a factor giving the feed type.

**Details**

Newly hatched chicks were randomly allocated into six groups, and each group was given a different feed supplement. Their weights in grams after six weeks are given along with feed types.

**Source**

**References**

**Examples**

```r
require(stats)

**CO2**

*Carbon Dioxide uptake in grass plants*

**Description**

The CO2 data frame has 84 rows and 5 columns of data from an experiment on the cold tolerance of the grass species *Echinochloa crus-galli*.

**Usage**

CO2

**Format**

This data frame contains the following columns:

- **Plant** an ordered factor with levels Qn1 < Qn2 < Qn3 < ... < Mc1 giving a unique identifier for each plant.
- **Type** a factor with levels Quebec Mississippi giving the origin of the plant
- **Treatment** a factor with levels nonchilled chilled
- **conc** a numeric vector of ambient carbon dioxide concentrations (mL/L).
- **uptake** a numeric vector of carbon dioxide uptake rates (µmol/m² sec).
Details

The CO$_2$ uptake of six plants from Quebec and six plants from Mississippi was measured at several levels of ambient CO$_2$ concentration. Half the plants of each type were chilled overnight before the experiment was conducted.

Source

Examples

```r
require(stats)
coplot(uptake ~ conc | Plant, data = CO2, show = FALSE, type = "b")
## fit the data for the first plant
fm1 <- nls(uptake ~ SSasymp(conc, Asym, lrc, c0),
        data = CO2, subset = Plant == 'Qn1')
summary(fm1)
## fit each plant separately
fmlist <- list()
for (pp in levels(CO2$Plant)) {
  fmlist[[pp]] <- nls(uptake ~ SSasymp(conc, Asym, lrc, c0),
                    data = CO2, subset = Plant == pp)
}
## check the coefficients by plant
sapply(fmlist, coef)
```

---

co2

*Mauna Loa Atmospheric CO2 Concentration*

Description

Atmospheric concentrations of CO$_2$ are expressed in parts per million (ppm) and reported in the preliminary 1997 SIO manometric mole fraction scale.

Usage

```r
c02
```

Format

A time series of 468 observations; monthly from 1959 to 1997.

Details

The values for February, March and April of 1964 were missing and have been obtained by interpolating linearly between the values for January and May of 1964.
**Source**

Keeling, C. D. and Whorf, T. P., Scripps Institution of Oceanography (SIO), University of California, La Jolla, California USA 92039-0220.

**Examples**

```r
plot(co2, ylab = expression("Atmospheric concentration of CO"[2]),
     las = 1)
title(main = "co2 data set")
```

---

**crimtab**

*Student’s 3000 Criminals Data*

**Description**

Data of 3000 male criminals over 20 years old undergoing their sentences in the chief prisons of England and Wales.

**Usage**

```r
data(crimtab)
```

**Format**

A `table` object of `integer` counts, of dimension 42 x 22 with a total count, `sum(crimtab)` of 3000.

The 42 `rownames` ("9.4", "9.5", ...) correspond to midpoints of intervals of finger lengths whereas the 22 column names (`colnames`) (code "142.24", "144.78", ...) correspond to (body) heights of 3000 criminals, see also below.

**Details**

Student is the pseudonym of William Sealy Gosset. In his 1908 paper he wrote (on page 13) at the beginning of section VI entitled *Practical Test of the foregoing Equations*:

“Before I had succeeded in solving my problem analytically, I had endeavoured to do so empirically. The material used was a correlation table containing the height and left middle finger measurements of 3000 criminals, from a paper by W. R. MacDonell (*Biometrika*, Vol. I., p. 219). The measurements were written out on 3000 pieces of cardboard, which were then very thoroughly shuffled and drawn at random. As each card was drawn its numbers were written down in a book, which thus contains the measurements of 3000 criminals in a random order. Finally, each consecutive set of 4 was taken as a sample—750 in all—and the mean, standard deviation, and correlation of each sample determined. The difference between the mean of each sample and the mean of the population was then divided by the standard deviation of the sample, giving us the $z$ of Section III.”

The table is in fact page 216 and not page 219 in MacDonell(1902). In the MacDonell table, the middle finger lengths were given in mm and the heights in feet/inches intervals, they are
both converted into cm here. The midpoints of intervals were used, e.g., where MacDonell has $4'7''9/16 - 8'9/16$, we have 142.24 which is $2.54 \times 56 = 2.54 \times (4'8'')$.

MacDonell credited the source of data (page 178) as follows: *The data on which the memoir is based were obtained, through the kindness of Dr Garson, from the Central Metric Office, New Scotland Yard...* He pointed out on page 179 that: *The forms were drawn at random from the mass on the office shelves; we are therefore dealing with a random sampling.*

**Examples**

```r
data(crimtab)
dim(crimtab)
str(crimtab)
## for nicer printing:
local({cT <- crimtab
    colnames(cT) <- substring(colnames(cT), 2,3)
    print(cT, zero = " ")
})
## Repeat Student's experiment:
# 1) Reconstitute 3000 raw data for heights in inches and rounded to
# nearest integer as in Student's paper:
(heIn <- round(as.numeric(colnames(crimtab)) / 2.54))
d.hei <- data.frame(height = rep(heIn, colSums(crimtab)))
# 2) shuffle the data:
set.seed(1)
d.hei <- d.hei[sample(1:3000), , drop = FALSE]
# 3) Make 750 samples each of size 4:
d.hei$sample <- as.factor(rep(1:750, each = 4))
# 4) Compute the means and standard deviations (n) for the 750 samples:
h.mean <- with(d.hei, tapply(height, sample, FUN = mean))
h.sd <- with(d.hei, tapply(height, sample, FUN = sd)) * sqrt(3/4)
# 5) Compute the difference between the mean of each sample and the mean of
# the population and then divide by the standard deviation of the sample:
```

**References**

**Source**

discoveries

zobs <- (h.mean - mean(d.hei[, "height"]))/h.sd

# 6) Replace infinite values by +/- 6 as in Student’s paper:

zobs[is.infinite(zobs)] <- 6 * sign(zobs[is.infinite(zobs)])

# 7) Plot the distribution:

hist(x = zobs, probab = TRUE, xlab = "Student’s z",
    col = grey(0.8), border = grey(0.5),
    main = "Distribution of Student’s z score for 'crimtab' data")

discoveries

Yearly Numbers of Important Discoveries

Description

The numbers of “great” inventions and scientific discoveries in each year from 1860 to 1959.

Usage
discoveries

Format

A time series of 100 values.

### euro

#### Description

Conversion rates between the various Euro currencies.

#### Usage

euro
euro.cross

#### Format

euro is a named vector of length 11, euro.cross a matrix of size 11 by 11, with dimnames.

#### Details

The data set euro contains the value of 1 Euro in all currencies participating in the European monetary union (Austrian Schilling ATS, Belgian Franc BEF, German Mark DEM, Spanish Peseta ESP, Finnish Markka FIM, French Franc FRF, Irish Punt IEP, Italian Lira ITL, Luxembourg Franc LUF, Dutch Guilder NLG and Portuguese Escudo PTE). These conversion rates were fixed by the European Union on December 31, 1998. To convert old prices to Euro prices, divide by the respective rate and round to 2 digits.

The data set euro.cross contains conversion rates between the various Euro currencies, i.e., the result of outer(1 / euro, euro).

#### Examples

cbind(euro)

## These relations hold:
euro == signif(euro,6) # [6 digit precision in Euro's definition]
all(euro.cross == outer(1/euro, euro))

## Convert 20 Euro to Belgian Franc
20 * euro["BEF"]

## Convert 20 Austrian Schilling to Euro
20 / euro["ATS"]

## Convert 20 Spanish Pesetas to Italian Lira
20 * euro.cross["ESP", "ITL"]
eurodist

```
require(graphics)
dotchart(euro,
    main = "euro data: 1 Euro in currency unit")
dotchart(1/euro,
    main = "euro data: 1 currency unit in Euros")
dotchart(log(euro, 10),
    main = "euro data: log10(1 Euro in currency unit)")
```

eurodist

**Distances Between European Cities**

**Description**

The data give the road distances (in km) between 21 cities in Europe. The data are taken from a table in “The Cambridge Encyclopaedia”.

**Usage**

```
eurodist
```

**Format**

A `dist` object based on 21 objects. (You must have the `stats` package loaded to have the methods for this kind of object available).

**Source**

EuStockMarkets

**Daily Closing Prices of Major European Stock Indices, 1991–1998**

**Description**

Contains the daily closing prices of major European stock indices: Germany DAX (Ibis), Switzerland SMI, France CAC, and UK FTSE. The data are sampled in business time, i.e., weekends and holidays are omitted.

**Usage**

```
EuStockMarkets
```

**Format**

A multivariate time series with 1860 observations on 4 variables. The object is of class "mts".

**Source**

The data were kindly provided by Erste Bank AG, Vienna, Austria.
Old Faithful Geyser Data

Description
Waiting time between eruptions and the duration of the eruption for the Old Faithful geyser in Yellowstone National Park, Wyoming, USA.

Usage
faithful

Format
A data frame with 272 observations on 2 variables.

\[
\begin{array}{ccc}
[,1] & eruptions & numeric \\
 & \text{Eruption time in mins} \\
[,2] & waiting & numeric \\
 & \text{Waiting time to next eruption (in mins)} \\
\end{array}
\]

Details
A closer look at faithful$eruptions reveals that these are heavily rounded times originally in seconds, where multiples of 5 are more frequent than expected under non-human measurement. For a “better” version of the eruptions times, see the example below.

There are many versions of this dataset around: Azzalini and Bowman (1990) use a more complete version.

Source
W. Härdle.

References

pplot(fm1)
par(opar)
```
freeny

Freeny’s Revenue Data

Description

Freeny’s data on quarterly revenue and explanatory variables.

Usage

freeny
freeny.x
freeny.y

Format

There are three ‘freeny’ data sets.

freeny.y is a time series with 39 observations on quarterly revenue from (1962,2Q) to (1971,4Q).

freeny.x is a matrix of explanatory variables. The columns are freeny.y lagged 1 quarter, price index, income level, and market potential.

Finally, freeny is a data frame with variables y, lag.quarterly.revenue, price.index, income.level, and market.potential obtained from the above two data objects.

Source

par(par)
**HairEyeColor**

**Hair and Eye Color of Statistics Students**

**Description**

Distribution of hair and eye color and sex in 592 statistics students.

**Usage**

`HairEyeColor`

**Format**

A 3-dimensional array resulting from cross-tabulating 592 observations on 3 variables. The variables and their levels are as follows:

<table>
<thead>
<tr>
<th>No</th>
<th>Name</th>
<th>Levels</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Hair</td>
<td>Black, Brown, Red, Blond</td>
</tr>
<tr>
<td>2</td>
<td>Eye</td>
<td>Brown, Blue, Hazel, Green</td>
</tr>
<tr>
<td>3</td>
<td>Sex</td>
<td>Male, Female</td>
</tr>
</tbody>
</table>

**Details**

This data set is useful for illustrating various techniques for the analysis of contingency tables, such as the standard chi-squared test or, more generally, log-linear modelling, and graphical methods such as mosaic plots, sieve diagrams or association plots.

**References**

**See Also**

`chisq.test`, `loglin`, `mosaicplot`

**Examples**

```r
require(graphics)

## Full mosaic
mosaicplot(HairEyeColor)

## Aggregate over sex:
x <- apply(HairEyeColor, c(1, 2), sum)
x
mosaicplot(x, main = "Relation between hair and eye color")
```
Harman23.cor  Harman Example 2.3

Description
A correlation matrix of eight physical measurements on 305 girls between ages seven and seventeen.

Usage
Harman23.cor

Source

Examples
```r
require(stats)
(Harman23.FA <- factanal(factors = 1, covmat = Harman23.cor))
for(factors in 2:4) print(update(Harman23.FA, factors = factors))
```

Harman74.cor  Harman Example 7.4

Description
A correlation matrix of 24 psychological tests given to 145 seventh and eight-grade children in a Chicago suburb by Holzinger and Swineford.

Usage
Harman74.cor

Source

Examples
```r
require(stats)
(Harman74.FA <- factanal(factors = 1, covmat = Harman74.cor))
for(factors in 2:5) print(update(Harman74.FA, factors = factors))
Harman74.FA <- factanal(factors = 5, covmat = Harman74.cor, rotation="promax")
print(Harman74.FA$loadings, sort = TRUE)
```
Description

The Indometh data frame has 66 rows and 3 columns of data on the pharmacokinetics of indomethicin.

Usage

Indometh

Format

This data frame contains the following columns:

- Subject: an ordered factor with containing the subject codes. The ordering is according to increasing maximum response.
- time: a numeric vector of times at which blood samples were drawn (hr).
- conc: a numeric vector of plasma concentrations of indomethicin (mcg/ml).

Details

Each of the six subjects were given an intravenous injection of indomethicin.

Source

Examples

```r
require(stats)
fm1 <- nls(conc ~ SSbiexp(time, A1, lrc1, A2, lrc2),
           data = Indometh, subset = Subject == 1)
summary(fm1)
```
Infertility after Spontaneous and Induced Abortion

Description

This is a matched case-control study dating from before the availability of conditional logistic regression.

Usage

infert

Format

### iris

**Edgar Anderson’s Iris Data**
Description

This famous (Fisher’s or Anderson’s) iris data set gives the measurements in centimeters of the variables sepal length and width and petal length and width, respectively, for 50 flowers from each of 3 species of iris. The species are *Iris setosa*, *versicolor*, and *virginica*.

Usage

```r
iris
iris3
```

Format

*iris* is a data frame with 150 cases (rows) and 5 variables (columns) named *Sepal.Length*, *Sepal.Width*, *Petal.Length*, *Petal.Width*, and *Species*.

*iris3* gives the same data arranged as a 3-dimensional array of size 50 by 4 by 3, as represented by S-PLUS. The first dimension gives the case number within the species subsample, the second the measurements with names *Sepal L.*, *Sepal W.*, *Petal L.*, and *Petal W.*, and the third the species.

Source

References

See Also

`matplot` some examples of which use *iris*.

Examples

```r
dni3 <- dimnames(iris3)
ii <- data.frame(matrix(aperm(iris3, c(1,3,2)), ncol=4, 
  dimnames = list(NULL, sub(" L.",".Length",
  sub(" W.",".Width", dni3[[2]])))),
  Species = gl(3, 50, 
  lab=sub("S", "s", sub("V", "v", dni3[[3]]))))
all.equal(ii, iris) # TRUE
```
islands

Areas of the World's Major Landmasses

Description
The areas in thousands of square miles of the landmasses which exceed 10,000 square miles.

Usage
islands

Format
A named vector of length 48.

Source

References

Examples

</tr>
</tbody>
</table>

Details

Under the life-cycle savings hypothesis as developed by Franco Modigliani, the savings ratio (aggregate personal saving divided by disposable income) is explained by per-capita disposable income, the percentage rate of change in per-capita disposable income, and two demographic variables: the percentage of population less than 15 years old and the percentage of the population over 75 years old. The data are averaged over the decade 1960–1970 to remove the business cycle or other short-term fluctuations.

Source

The data were obtained from Belsley, Kuh and Welsch (1980). They in turn obtained the data from Sterling (1977).

fm1 <- lm(sr ~ pop15 + pop75 + dpi + ddpi, data = LifeCycleSavings)
summary(fm1)
```
Loblolly  

*Growth of Loblolly pine trees*

**Description**

The **Loblolly** data frame has 84 rows and 3 columns of records of the growth of Loblolly pine trees.

**Usage**

Loblolly

**Format**

This data frame contains the following columns:

- **height** a numeric vector of tree heights (ft).
- **age** a numeric vector of tree ages (yr).
- **Seed** an ordered factor indicating the seed source for the tree. The ordering is according to increasing maximum height.

**Source**

**Examples**

```r
require(stats)
plot(height ~ age, data = Loblolly, subset = Seed == 329, 
     xlab = "Tree age (yr)", las = 1, 
     ylab = "Tree height (ft)"
     main = "Loblolly data and fitted curve (Seed 329 only)"

fm1 <- nls(height ~ SSasymp(age, Asym, R0, lrc), 
    data = Loblolly, subset = Seed == 329)
summary(fm1)

age <- seq(0, 30, len = 101)
lines(age, predict(fm1, list(age = age)))
```

---

longley  

*Longley’s Economic Regression Data*

**Description**

A macroeconomic data set which provides a well-known example for a highly collinear regression.

**Usage**

longley
Format

A data frame with 7 economical variables, observed yearly from 1947 to 1962 (n = 16).

**GNP.deflator:** GNP implicit price deflator (1954 = 100)

**GNP:** Gross National Product.

**Unemployed:** number of unemployed.

**Armed.Forces:** number of people in the armed forces.

**Population:** ‘noninstitutionalized’ population ≥ 14 years of age.

**Year:** the year (time).

**Employed:** number of people employed.

The regression \( \text{lm}(\text{Employed} \sim .) \) is known to be highly collinear.

Source

References

Examples

```r
## give the data set in the form it is used in S-PLUS:
longley.x <- data.matrix(longley[, 1:6])
longley.y <- longley[, "Employed"]
pairs(longley, main = "longley data")
summary(fm1 <- lm(Employed ~ ., data = longley))
par(opar <- par(mfrow = c(2, 2), oma = c(0, 0, 1.1, 0), 
mar = c(4.1, 4.1, 2.1, 1.1))
plot(fm1)
par(opar)
```

**lynx**

*Annual Canadian Lynx trappings 1821–1934*

Description

Annual numbers of lynx trappings for 1821–1934 in Canada. Taken from Brockwell & Davis (1991), this appears to be the series considered by Campbell & Walker (1977).

Usage

```r
lynx
```

Source

References

**morley**

*Michaelson-Morley Speed of Light Data*

**Description**

The classical data of Michaelson and Morley on the speed of light. The data consists of five experiments, each consisting of 20 consecutive ‘runs’. The response is the speed of light measurement, suitably coded.

**Usage**

`morley`

**Format**

A data frame contains the following components:

- **Expt**  The experiment number, from 1 to 5.
- **Run**   The run number within each experiment.
- **Speed** Speed-of-light measurement.

**Details**

The data is here viewed as a randomized block experiment with ‘experiment’ and ‘run’ as the factors. ‘run’ may also be considered a quantitative variate to account for linear (or polynomial) changes in the measurement over the course of a single experiment.

**Source**

**Examples**

```r
require(stats)
morley$Expt <- factor(morley$Expt)
morley$Run <- factor(morley$Run)
attach(morley)
plot(Expt, Speed, main = "Speed of Light Data", xlab = "Experiment No.")
fm <- aov(Speed ~ Run + Expt, data = morley)
summary(fm)
fm0 <- update(fm, . ~ . - Run)
anova(fm0, fm)
detach(morley)
```
mtcars  

*Motor Trend Car Road Tests*

**Description**

The data was extracted from the 1974 *Motor Trend* US magazine, and comprises fuel consumption and 10 aspects of automobile design and performance for 32 automobiles (1973–74 models).

**Usage**

```r
mtcars
```

**Format**

A data frame with 32 observations on 11 variables.

```
[, 1]  mpg  Miles/(US) gallon
[, 2]  cyl  Number of cylinders
[, 3]  disp Displacement (cu.in.)
[, 4]  hp  Gross horsepower
[, 5]  drat Rear axle ratio
[, 6]  wt  Weight (lb/1000)
[, 7]  qsec 1/4 mile time
[, 8]  vs  V/S
[, 9]  am  Transmission (0 = automatic, 1 = manual)
[,10]  gear Number of forward gears
[,11]  carb Number of carburetors
```

**Source**

**Examples**

```r
pairs(mtcars, main = "mtcars data")
coplot(mpg ~ disp | as.factor(cyl), data = mtcars, 
      panel = panel.smooth, rows = 1)
```

nhtemp  

*Average Yearly Temperatures in New Haven*

**Description**

The mean annual temperature in degrees Fahrenheit in New Haven, Connecticut, from 1912 to 1971.

**Usage**

```r
nhtemp
```
**Format**

A time series of 60 observations.

**Source**

**References**

**Examples**

```r
plot(nhtemp, main = "nhtemp data",
     ylab = "Mean annual temperature in New Haven, CT (deg. F)")
```

---

**Nile**

*Flow of the River Nile*

---

**Description**

**Usage**

```r
Nile
```

**Format**

A time series of length 100.

**Source**

lines(tsSmooth(fit), lty = 2, col = 4) # fixed-interval smoothing
plot(residuals(fit)); abline(h = 0, lty = 3)
## local trend model
(fit2 <- StructTS(Nile, type = "trend")) # constant trend fitted
pred <- predict(fit, n.ahead = 30)
## with 50% confidence interval
ts.plot(Nile, pred$pred, pred$pred + 0.67*pred$se, pred$pred -0.67*pred$se)
```

```r
## Now consider missing values
plot(NileNA)
(fit3 <- StructTS(NileNA, type = "level"))
lines(fitted(fit3), lty = 2)
lines(tsSmooth(fit3), lty = 3)
plot(residuals(fit3)); abline(h = 0, lty = 3)
```

---

**nottem**

*Average Monthly Temperatures at Nottingham, 1920–1939*

**Description**

A time series object containing average air temperatures at Nottingham Castle in degrees Fahrenheit for 20 years.
Usage

nottem

Source

Examples

```r
## Not run:
nott <- window(nottem, end=c(1936,12))
fit <- arima(nott,order=c(1,0,0), list(order=c(2,1,0), period=12))
nott.fore <- predict(fit, n.ahead=36)
ts.plot(nott, nott.fore$pred, nott.fore$pred+2*nott.fore$se,
        nott.fore$pred-2*nott.fore$se, gpars=list(col=c(1,1,4,4)))
## End(Not run)
```

Orange

*Growth of orange trees*

Description

The Orange data frame has 35 rows and 3 columns of records of the growth of orange trees.

Usage

Orange

Format

This data frame contains the following columns:

- **Tree** an ordered factor indicating the tree on which the measurement is made. The ordering is according to increasing maximum diameter.
- **age** a numeric vector giving the age of the tree (days since 1968/12/31)
- **circumference** a numeric vector of trunk circumferences (mm). This is probably “circumference at breast height”, a standard measurement in forestry.

Source

Examples

```r
require(stats)
coplot(circumference ~ age | Tree, data = Orange, show = FALSE)
fml <- nls(circumference ~ SSlogis(age, Asym, xmid, scal),
           data = Orange, subset = Tree == 3)
plot(circumference ~ age, data = Orange, subset = Tree == 3,
     xlab = "Tree age (days since 1968/12/31)",
     ylab = "Tree circumference (mm)", las = 1,
     main = "Orange tree data and fitted model (Tree 3 only)"
     age <- seq(0, 1600, len = 101)
lines(age, predict(fml, list(age = age)))
```

---

**OrchardSprays  Potency of Orchard Sprays**

**Description**

An experiment was conducted to assess the potency of various constituents of orchard sprays in repelling honeybees, using a Latin square design.

**Usage**

OrchardSprays

**Format**

A data frame with 64 observations on 4 variables.

<p>| | | | |</p>

</tr>
</tbody>
</table>

**Details**

Individual cells of dry comb were filled with measured amounts of lime sulphur emulsion in sucrose solution. Seven different concentrations of lime sulphur ranging from a concentration of 1/100 to 1/1,562,500 in successive factors of 1/5 were used as well as a solution containing no lime sulphur. The responses for the different solutions were obtained by releasing 100 bees into the chamber for two hours, and then measuring the decrease in volume of the solutions in the various cells.

An 8 x 8 Latin square design was used and the treatments were coded as follows:

- A  highest level of lime sulphur
- B  next highest level of lime sulphur
- .  
- .  
- .  
- G  lowest level of lime sulphur
- H  no lime sulphur

**PlantGrowth**

*Results from an Experiment on Plant Growth*

Description

Results from an experiment to compare yields (as measured by dried weight of plants) obtained under a control and two different treatment conditions.

Usage

`PlantGrowth`

Format

A data frame of 30 cases on 2 variables.

```
[, 1]  weight numeric
[, 2]  group  factor
```

The levels of `group` are ‘ctrl’, ‘trt1’, and ‘trt2’.

Source

Examples

```r
## One factor ANOVA example from Dobson's book, cf. Table 7.4:
require(stats)
boxplot(weight ~ group, data = PlantGrowth, main = "PlantGrowth data",
        ylab = "Dried weight of plants", col = "lightgray",
        notch = TRUE, varwidth = TRUE)
anova(lm(weight ~ group, data = PlantGrowth))
```

---

**precip**

*Annual Precipitation in US Cities*
presidents

Description
The average amount of precipitation (rainfall) in inches for each of 70 United States (and Puerto Rico) cities.

Usage
precip

Format
A named vector of length 70.

Source

References

Examples

require(graphics)
dotchart(precip[order(precip)], main = "precip data")

     main = "pressure data: Vapor Pressure of Mercury")
plot(pressure, xlab = "Temperature (deg C)", log = "y",
     ylab = "Pressure (mm of Hg)",
     main = "pressure data: Vapor Pressure of Mercury")
```

Puromycin  

**Reaction velocity of an enzymatic reaction**

Description

The Puromycin data frame has 23 rows and 3 columns of the reaction velocity versus substrate concentration in an enzymatic reaction involving untreated cells or cells treated with Puromycin.

Usage

Puromycin
Puromycin

Format

This data frame contains the following columns:

- **conc** a numeric vector of substrate concentrations (ppm)
- **rate** a numeric vector of instantaneous reaction rates (counts/min/min)
- **state** a factor with levels treated untreated

Details

Data on the “velocity” of an enzymatic reaction were obtained by Treloar (1974). The number of counts per minute of radioactive product from the reaction was measured as a function of substrate concentration in parts per million (ppm) and from these counts the initial rate, or “velocity,” of the reaction was calculated (counts/min/min). The experiment was conducted once with the enzyme treated with Puromycin, and once with the enzyme untreated.

Source

Examples

```r
plot(rate ~ conc, data = Puromycin, las = 1,
     xlab = "Substrate concentration (ppm)",
     ylab = "Reaction velocity (counts/min/min)",
     pch = as.integer(Puromycin$state),
     col = as.integer(Puromycin$state),
     main = "Puromycin data and fitted Michaelis-Menten curves")
## simplest form of fitting the Michaelis-Menten model to these data
fm1 <- nls(rate ~ Vm * conc/(K + conc), data = Puromycin,
           subset = state == "treated",
           start = c(Vm = 200, K = 0.05), trace = TRUE)
fm2 <- nls(rate ~ Vm * conc/(K + conc), data = Puromycin,
           subset = state == "untreated",
           start = c(Vm = 160, K = 0.05), trace = TRUE)
summary(fm1)
summary(fm2)
## using partial linearity
fm3 <- nls(rate ~ conc/(K + conc), data = Puromycin,
           subset = state == "treated",
           algorithm = "plinear", trace = TRUE)
## using a self-starting model
fm4 <- nls(rate ~ SSmicmen(conc, Vm, K), data = Puromycin,
           subset = state == "treated")
summary(fm4)
## add fitted lines to the plot
conc <- seq(0, 1.2, len = 101)
lines(conc, predict(fm1, list(conc = conc)), lty = 1, col = 1)
lines(conc, predict(fm2, list(conc = conc)), lty = 2, col = 2)
legend(0.8, 120, levels(Puromycin$state),
       col = 1:2, lty = 1:2, pch = 1:2)
```
Description

The data set gives the locations of 1000 seismic events of MB > 4.0. The events occurred in a cube near Fiji since 1964.

Usage

quakes

Format

A data frame with 1000 observations on 5 variables.

\[
\begin{array}{ccc}
[.1] & lat & numeric & \text{Latitude of event} \\
[.2] & long & numeric & \text{Longitude} \\
[.3] & depth & numeric & \text{Depth (km)} \\
[.4] & mag & numeric & \text{Richter Magnitude} \\
[.5] & stations & numeric & \text{Number of stations reporting}
\end{array}
\]

Details

There are two clear planes of seismic activity. One is a major plate junction; the other is the Tonga trench off New Zealand. These data constitute a subsample from a larger dataset containing 5000 observations.

Source

This is one of the Harvard PRIM-H project data sets. They in turn obtained it from Dr. John Woodhouse, Dept. of Geophysics, Harvard University.

Examples

pairs(quakes, main = "Fiji Earthquakes, N = 1000", cex.main=1.2, pch=".")

Description

400 triples of successive random numbers were taken from the VAX FORTRAN function RANDU running under VMS 1.5.

Usage

randu
Format

A data frame with 400 observations on 3 variables named x, y and z which give the first, second and third random number in the triple.

Details

In three dimensional displays it is evident that the triples fall on 15 parallel planes in 3-space. This can be shown theoretically to be true for all triples from the RANDU generator.

These particular 400 triples start 5 apart in the sequence, that is they are ((U[5i+1], U[5i+2], U[5i+3]), i= 0, . . . , 399), and they are rounded to 6 decimal places.

Under VMS versions 2.0 and higher, this problem has been fixed.

Source

David Donoho

Examples

```r
## Not run:
## We could re-generate the dataset by the following R code
seed <- as.double(1)
RANDU <- function() {
  seed <<- ((2^16 + 3) * seed) %% (2^31)
  seed/(2^31)
}
for(i in 1:400) {
  U <- c(RANDU(), RANDU(), RANDU(), RANDU(), RANDU())
  print(round(U[1:3], 6))
}
## End(Not run)
```

**sleep**  
*Student’s Sleep Data*

**Description**

Data which show the effect of two soporific drugs (increase in hours of sleep compared to control) on 10 patients.

**Usage**

`sleep`

**Format**

A data frame with 20 observations on 2 variables.

```
[, 1] extra numeric increase in hours of sleep
[, 2] group factor drug given
```
### stackloss

**Source**

**References**

**Examples**

```r
require(stats)
## Student's paired t-test
t.test(extra ~ group, data = sleep, paired = TRUE)
```

---

**stackloss**  
*Brownlee’s Stack Loss Plant Data*

**Description**

Operational data of a plant for the oxidation of ammonia to nitric acid.

**Usage**

```r
stackloss
```

```r
stack.x
```

```r
stack.loss
```

**Format**

`stackloss` is a data frame with 21 observations on 4 variables.

<p>| | | | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>[4]</td>
<td>stack.loss</td>
<td>Stack loss</td>
<td></td>
</tr>
</tbody>
</table>

For compatibility with S-PLUS, the data sets `stack.x`, a matrix with the first three (independent) variables of the data frame, and `stack.loss`, the numeric vector giving the fourth (dependent) variable, are provided as well.

**Details**

“Obtained from 21 days of operation of a plant for the oxidation of ammonia (NH₃) to nitric acid (HNO₃). The nitric oxides produced are absorbed in a countercurrent absorption tower”. (Brownlee, cited by Dodge, slightly reformatted by MM.)

Air Flow represents the rate of operation of the plant. Water Temp is the temperature of cooling water circulated through coils in the absorption tower. Acid Conc. is the concentration of the acid circulating, minus 50, times 10: that is, 89 corresponds to 58.9 per cent acid. stack.loss (the dependent variable) is 10 times the percentage of the ingoing ammonia to the plant that escapes
from the absorption column unabsorbed; that is, an (inverse) measure of the over-all efficiency of
the plant.

US State Facts and Figures

Description

Data sets related to the 50 states of the United States of America.

Usage

state.abb
state.area
state.center
state.division
state.name
state.region
state.x77

Details

R currently contains the following “state” data sets. Note that all data are arranged according to
alphabetical order of the state names.

state.abb: character vector of 2-letter abbreviations for the state names.
state.area: numeric vector of state areas (in square miles).
state.center: list with components named x and y giving the approximate geographic center
of each state in negative longitude and latitude. Alaska and Hawaii are placed just off the West
Coast.
state.division: factor giving state divisions (New England, Middle Atlantic, South Atlantic,
East South Central, West South Central, East North Central, West North Central, Mountain,
and Pacific).
state.name: character vector giving the full state names.
**state.region**: factor giving the region (Northeast, South, North Central, West) that each state belongs to.

**state.x77**: matrix with 50 rows and 8 columns giving the following statistics in the respective columns.

- **Population**: population estimate as of July 1, 1975
- **Income**: per capita income (1974)
- **Illiteracy**: illiteracy (1970, percent of population)
- **Life Exp**: life expectancy in years (1969–71)
- **Murder**: murder and non-negligent manslaughter rate per 100,000 population (1976)
- **HS Grad**: percent high-school graduates (1970)
- **Frost**: mean number of days with minimum temperature below freezing (1931–1960) in capital or large city
- **Area**: land area in square miles

**Source**

**References**

---

**sunspot.month**  
*Monthly Sunspot Data, 1749–1997*

**Description**

Monthly numbers of sunspots.

**Usage**

```r
sunspot.month
```

**Format**

The univariate time series **sunspot.year** and **sunspot.month** contain 289 and 2988 observations, respectively. The objects are of class "ts".

**Source**

**See Also**

**sunspot.month** is a longer version of **sunspots** that runs until 1988 rather than 1983.
Examples

```r
require(stats)
## Compare the monthly series
plot(sunspot.month, main = "sunspot.month [stats]", col = 2)
lines(sunspots) # "very barely" see something

## Now look at the difference :
all(tsp(sunspots) [c(1,3)] ==
tsp(sunspot.month)[c(1,3)]) ## Start & Periodicity are the same
n1 <- length(sunspots)
table(eq <- sunspots == sunspot.month[1:n1]) #> 132 are different !
i <- which(!eq)
rug(time(eq)[i])
s1 <- sunspots[i] ; s2 <- sunspot.month[i]
cbind(i = i, sunspots = s1, ss.month = s2,
      perc.diff = round(100*2*abs(s1-s2)/(s1+s2), 1))
```

sunspot.year

**Yearly Sunspot Data, 1700–1988**

Description

Yearly numbers of sunspots.

Usage

sunspot.year

Format

The univariate time series sunspot.year contains 289 observations, and is of class "ts".

Source

dsunspots

**Monthly Sunspot Numbers, 1749–1983**

Description

Monthly mean relative sunspot numbers from 1749 to 1983. Collected at Swiss Federal Observatory, Zurich until 1960, then Tokyo Astronomical Observatory.

Usage

sunspots

Format

A time series of monthly data from 1749 to 1983.
Source

See Also

sunspot.month has a longer (and a bit different) series.

Examples

\[
\text{plot(sunspots, main = "sunspots data", xlab = "Year", ylab = "Monthly sunspot numbers")}
\]

---

swiss

Swiss Fertility and Socioeconomic Indicators (1888) Data

Description

Standardized fertility measure and socio-economic indicators for each of 47 French-speaking provinces of Switzerland at about 1888.

Usage

swiss

Format

A data frame with 47 observations on 6 variables, each of which is in percent, i.e., in \([0, 100]\).

\[
\begin{array}{ll}
.1 & \text{Fertility } I_g, \text{"common standardized fertility measure"} \\
.2 & \text{Agriculture } \% \text{ of males involved in agriculture as occupation} \\
.3 & \text{Examination } \% \text{ "draftees" receiving highest mark on army examination} \\
.4 & \text{Education } \% \text{ education beyond primary school for "draftees".} \\
.5 & \text{Catholic } \% \text{ catholic (as opposed to "protestant").} \\
.6 & \text{Infant.Mortality } \text{live births who live less than 1 year.}
\end{array}
\]

All variables but ‘Fertility’ give proportions of the population.

Details

(paraphrasing Mosteller and Tukey):

Switzerland, in 1888, was entering a period known as the “demographic transition”; i.e., its fertility was beginning to fall from the high level typical of underdeveloped countries.

The data collected are for 47 French-speaking “provinces” at about 1888.

Here, all variables are scaled to \([0, 100]\), where in the original, all but "Catholic" were scaled to \([0, 1]\).

Note

Files for all 182 districts in 1888 and other years have been available at http://opr.princeton.edu/archive/eufert/switz.html or http://opr.
Theophylline Pharmacokinetics

Description

The Theoph data frame has 132 rows and 5 columns of data from an experiment on the pharmacokinetics of theophylline.

Usage

Theoph

Format

This data frame contains the following columns:

Subject an ordered factor with levels 1, ..., 12 identifying the subject on whom the observation was made. The ordering is by increasing maximum concentration of theophylline observed.

Wt weight of the subject (kg).

Dose dose of theophylline administered orally to the subject (mg/kg).

Time time since drug administration when the sample was drawn (hr).

conc theophylline concentration in the sample (mg/L).

Source

Project “16P5”, pages 549–551 in

col = 3 + (swiss$Catholic > 50))
summary(lm(Fertility ~ ., data = swiss))

princeton.edu/archive/pefp/switz.asp.

They state that variables Examination and Education are averages for 1887, 1888 and 1889.
Details

Boeckmann, Sheiner and Beal (1994) report data from a study by Dr. Robert Upton of the kinetics of the anti-asthmatic drug theophylline. Twelve subjects were given oral doses of theophylline then serum concentrations were measured at 11 time points over the next 25 hours.

These data are analyzed in Davidian and Giltinan (1995) and Pinheiro and Bates (2000) using a two-compartment open pharmacokinetic model, for which a self-starting model function, SSfol, is available.

Titanic

Survival of passengers on the Titanic

Description

This data set provides information on the fate of passengers on the fatal maiden voyage of the ocean liner 'Titanic', summarized according to economic status (class), sex, age and survival.

Usage

Titanic
Format

A 4-dimensional array resulting from cross-tabulating 2201 observations on 4 variables. The variables and their levels are as follows:

<table>
<thead>
<tr>
<th>No</th>
<th>Name</th>
<th>Levels</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Class</td>
<td>1st, 2nd, 3rd, Crew</td>
</tr>
<tr>
<td>2</td>
<td>Sex</td>
<td>Male, Female</td>
</tr>
<tr>
<td>3</td>
<td>Age</td>
<td>Child, Adult</td>
</tr>
<tr>
<td>4</td>
<td>Survived</td>
<td>No, Yes</td>
</tr>
</tbody>
</table>

Details

The sinking of the Titanic is a famous event, and new books are still being published about it. Many well-known facts—from the proportions of first-class passengers to the "women and children first" policy, and the fact that that policy was not entirely successful in saving the women and children in the third class—are reflected in the survival rates for various classes of passenger.

These data were originally collected by the British Board of Trade in their investigation of the sinking. Note that there is not complete agreement among primary sources as to the exact numbers on board, rescued, or lost.

Due in particular to the very successful film 'Titanic', the last years saw a rise in public interest in the Titanic. Very detailed data about the passengers is now available on the Internet, at sites such as Encyclopedia Titanica (http://www.rmplc.co.uk/eduweb/sites/phind).

Source

The source provides a data set recording class, sex, age, and survival status for each person on board of the Titanic, and is based on data originally collected by the British Board of Trade and reprinted in:

Examples

```
require(graphics)
mosaicplot(Titanic, main = "Survival on the Titanic")
## Higher survival rates in children?
apply(Titanic, c(3, 4), sum)
## Higher survival rates in females?
apply(Titanic, c(2, 4), sum)
## Use loglm() in package 'MASS' for further analysis ...
```

ToothGrowth

The Effect of Vitamin C on Tooth Growth in Guinea Pigs
turning

**Description**

The response is the length of odontoblasts (teeth) in each of 10 guinea pigs at each of three dose levels of Vitamin C (0.5, 1, and 2 mg) with each of two delivery methods (orange juice or ascorbic acid).

**Usage**

`ToothGrowth`

**Format**

A data frame with 60 observations on 3 variables.

<table>
<thead>
<tr>
<th></th>
<th>Variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>[1]</td>
<td>len</td>
<td>numeric Tooth length</td>
</tr>
<tr>
<td>[2]</td>
<td>supp</td>
<td>factor Supplement type (VC or OJ)</td>
</tr>
</tbody>
</table>

**Source**

**References**

**Examples**

```r
coplot(len ~ dose | supp, data = ToothGrowth, panel = panel.smooth,
        xlab = "ToothGrowth data: length vs dose, given type of supplement")
```

treering

**Description**

Contains normalized tree-ring widths in dimensionless units.

**Usage**

`treering`

**Format**

A univariate time series with 7981 observations. The object is of class "ts".

Each tree ring corresponds to one year.

**Details**

The data were recorded by Donald A. Graybill, 1980, from Gt Basin Bristlecone Pine 2805M, 3726-11810 in Methuselah Walk, California.
Source

References

For background on Bristlecone pines and Methuselah Walk, see http://www.sonic.net/bristlecone/; for some photos see http://www.ltrr.arizona.edu/~hallman/sitephotos/meth.html

Description

This data set provides measurements of the girth, height and volume of timber in 31 felled black cherry trees. Note that girth is the diameter of the tree (in inches) measured at 4 ft 6 in above the ground.

Usage

trees

Format

A data frame with 31 observations on 3 variables.

[,1] Girth numeric Tree diameter in inches
[,2] Height numeric Height in ft
[,3] Volume numeric Volume of timber in cubic ft

Source

References

Examples

pairs(trees, panel = panel.smooth, main = "trees data")

coplot(log(Volume) ~ log(Girth) | Height, data = trees, panel = panel.smooth)
summary(fm1 <- lm(log(Volume) ~ log(Girth), data = trees))
summary(fm2 <- update(fm1, ~ . + log(Height), data = trees))
step(fm2)
## i.e., Volume ~ c * Height * Girth^2 seems reasonable
UCBAdmissions | Student Admissions at UC Berkeley

Description

Aggregate data on applicants to graduate school at Berkeley for the six largest departments in 1973 classified by admission and sex.

Usage

UCBAdmissions

Format

A 3-dimensional array resulting from cross-tabulating 4526 observations on 3 variables. The variables and their levels are as follows:

<table>
<thead>
<tr>
<th>No</th>
<th>Name</th>
<th>Levels</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Admit</td>
<td>Admitted, Rejected</td>
</tr>
<tr>
<td>2</td>
<td>Gender</td>
<td>Male, Female</td>
</tr>
<tr>
<td>3</td>
<td>Dept</td>
<td>A, B, C, D, E, F</td>
</tr>
</tbody>
</table>

Details

This data set is frequently used for illustrating Simpson’s paradox, see Bickel et al. (1975). At issue is whether the data show evidence of sex bias in admission practices. There were 2691 male applicants, of whom 1198 (44.5%) were admitted, compared with 1835 female applicants of whom 557 (30.4%) were admitted. This gives a sample odds ratio of 1.83, indicating that males were almost twice as likely to be admitted. In fact, graphical methods (as in the example below) or log-linear modelling show that the apparent association between admission and sex stems from differences in the tendency of males and females to apply to the individual departments (females used to apply “more” to departments with higher rejection rates).

This data set can also be used for illustrating methods for graphical display of categorical data, such as the general-purpose mosaic plot or the “fourfold display” for 2-by-2-by-\( k \) tables. See the home page of Michael Friendly (http://www.math.yorku.ca/SCS/friendly.html) for further information.

References

Examples

```
UKDriverDeaths

Road Casualties in Great Britain 1969–84

Description

UKDriverDeaths is a time series giving the monthly totals of car drivers in Great Britain killed or seriously injured Jan 1969 to Dec 1984. Compulsory wearing of seat belts was introduced on 31 Jan 1983.

Seatbelts is more information on the same problem.

Usage

UKDriverDeaths
Seatbelts

Format

Seatbelts is a multiple time series, with columns

DriversKilled car drivers killed.
drivers same as UKDriverDeaths.
front front-seat passengers killed or seriously injured.
rear rear-seat passengers killed or seriously injured.
kms distance driven.
PetrolPrice petrol price.
VanKilled number of van (‘light goods vehicle’) drivers.
law 0/1: was the law in effect that month?

Source

References

UKgas

UK Quarterly Gas Consumption

Description

Quarterly UK gas consumption from 1960Q1 to 1986Q4, in millions of therms.

Usage

UKgas

Format

A quarterly time series of length 108.

Source

Examples

## maybe str(UKgas) ; plot(UKgas) ...
UKLungDeaths

Monthly Deaths from Lung Diseases in the UK

Description

Three time series giving the monthly deaths from bronchitis, emphysema and asthma in the UK, 1974–1979, both sexes (ldeaths), males (mdeaths) and females (fdeaths).

Usage

ldeaths
fdeaths
mdeaths

Source

Examples

require(stats) # for time
plot(ldeaths)
plot(mdeaths, fdeaths)
## Better labels:
yr <- floor(tt <- time(mdeaths))
plot(mdeaths, fdeaths,
   xy.labels = paste(month.abb[12*(tt - yr)], yr-1900, sep=""))

USAccDeaths

Accidental Deaths in the US 1973–1978

Description

A time series giving the monthly totals of accidental deaths in the USA. The values for the first six months of 1979 are 7798 7406 8363 8460 9217 9316.

Usage

USAccDeaths

Source

USArrests

Violent Crime Rates by US State

Description

This data set contains statistics, in arrests per 100,000 residents for assault, murder, and rape in each of the 50 US states in 1973. Also given is the percent of the population living in urban areas.

Usage

USArrests

Format

A data frame with 50 observations on 4 variables.

<table>
<thead>
<tr>
<th></th>
<th>Murder</th>
<th>Assault</th>
<th>UrbanPop</th>
<th>Rape</th>
</tr>
</thead>
<tbody>
<tr>
<td>.1</td>
<td>numeric</td>
<td>numeric</td>

USJudgeRatings

Lawyers’ Ratings of State Judges in the US Superior Court

Description

Lawyers’ ratings of state judges in the US Superior Court.

Usage

USJudgeRatings
Format

A data frame containing 43 observations on 12 numeric variables.
USPersonalExpenditure

[,1] CONT  Number of contacts of lawyer with judge.
[,2] INTG  Judicial integrity.
[,3] DMNR  Demeanor.
[,5] CFMG  Case flow managing.
[,6] DECI  Prompt decisions.
[,7] PREP  Preparation for trial.
[,8] FAMI  Familiarity with law.
[,9] ORAL  Sound oral rulings.
[.10] WRIT  Sound written rulings.
[.11] PHYS  Physical ability.
[.12] RTEN  Worthy of retention.

Source

New Haven Register, 14 January, 1977 (from John Hartigan).

Examples

pairs(USJudgeRatings, main = "USJudgeRatings data")

USPersonalExpenditure

Personal Expenditure Data

Description

This data set consists of United States personal expenditures (in billions of dollars) in the categories; food and tobacco, household operation, medical and health, personal care, and private education for the years 1940, 1945, 1950, 1955 and 1960.

Usage

USPersonalExpenditure

Format

A matrix with 5 rows and 5 columns.

Source

References

Examples

require(stats) # for medpolish
USPersonalExpenditure
medpolish(log10(USPersonalExpenditure))
uspop  
*Populations Recorded by the US Census*

**Description**

This data set gives the population of the United States (in millions) as recorded by the decennial census for the period 1790–1970.

**Usage**

`uspop`

**Format**

A time series of 19 values.

**Source**

**Examples**

```r
plot(uspop, log = "y", main = "uspop data", xlab = "Year", ylab = "U.S. Population (millions)")
```

VADeaths  
*Death Rates in Virginia (1940)*

**Description**

Death rates per 1000 in Virginia in 1940.

**Usage**

`VADeaths`

**Format**

A matrix with 5 rows and 5 columns.

**Details**

The death rates are measured per 1000 population per year. They are cross-classified by age group (rows) and population group (columns). The age groups are: 50–54, 55–59, 60–64, 65–69, 70–74 and the population groups are Rural/Male, Rural/Female, Urban/Male and Urban/Female. This provides a rather nice 3-way analysis of variance example.

**Source**

References

Examples

```r
require(stats)
n <- length(dr <- c(VADeaths))
nam <- names(VADeaths)

volcano

Topographic Information on Auckland's Maunga Whau Volcano

Description

Maunga Whau (Mt Eden) is one of about 50 volcanos in the Auckland volcanic field. This data set gives topographic information for Maunga Whau on a 10m by 10m grid.

Usage

volcano

Format

A matrix with 87 rows and 61 columns, rows corresponding to grid lines running east to west and columns to grid lines running south to north.

Source

Digitized from a topographic map by Ross Ihaka. These data should not be regarded as accurate.

See Also

`filled.contour` for a nice plot.

Examples

```r
require(graphics)
filled.contour(volcano, color = terrain.colors, asp = 1)
title(main = "volcano data: filled contour map")
```
warpbreaks  The Number of Breaks in Yarn during Weaving

Description

This data set gives the number of warp breaks per loom, where a loom corresponds to a fixed length of yarn.

Usage

warpbreaks

Format

A data frame with 54 observations on 3 variables.

[,1]  breaks  numeric  The number of breaks
[,2]  wool    factor  The type of wool (A or B)
[,3]  tension factor  The level of tension (L, M, H)

There are measurements on 9 looms for each of the six types of warp (AL, AM, AH, BL, BM, BH).

Source

References

See Also

xtabs for ways to display these data as a table.

Examples

summary(warpbreaks)
par <- par(mfrow = c(1,2), oma = c(0, 0, 1.1, 0))
plot(breaks ~ tension, data = warpbreaks, col = "lightgray",
     varwidth = TRUE, subset = wool == "A", main = "Wool A")
plot(breaks ~ tension, data = warpbreaks, col = "lightgray",

women

Average Heights and Weights for American Women

Description
This data set gives the average heights and weights for American women aged 30–39.

Usage
women

Format
A data frame with 15 observations on 2 variables.

\[
\begin{array}{ccc}
[,1] & \text{height} & \text{numeric} \\
[,2] & \text{weight} & \text{numeric}
\end{array}
\]

Height (in)  Weight (lbs)

Details
The data set appears to have been taken from the American Society of Actuaries Build and Blood Pressure Study for some (unknown to us) earlier year.

The World Almanac notes: “The figures represent weights in ordinary indoor clothing and shoes, and heights with shoes”.

Source

References

Examples
plot(women, xlab = "Height (in)", ylab = "Weight (lb)", main = "women data: American women aged 30-39")

WorldPhones
The World’s Telephones

Description
The number of telephones in various regions of the world (in thousands).

Usage
phones
WWWusage

Format
A matrix with 7 rows and 8 columns. The columns of the matrix give the figures for a given region, and the rows the figures for a year.
The regions are: North America, Europe, Asia, South America, Oceania, Africa, Central America.

Source

References

Examples
```r
matplot(rownames(WorldPhones), WorldPhones, type = "b", log = "y",
    xlab = "Year", ylab = "Number of telephones (1000's)"
legend(1951.5, 80000, colnames(WorldPhones), col = 1:6, lty = 1:5,
    pch = rep(21, 7))
title(main = "World phones data: log scale for response")
```

Chapter 3

The grDevices package

grDevices-package  The R Graphics Devices and Support for Colours and Fonts

Description

Graphics devices and support for base and grid graphics

Details

This package contains functions which support both base and grid graphics. For a complete list of functions, use library(help="grDevices").

Author(s)

R Development Core Team and contributors worldwide
Maintainer: R Core Team (R-core@r-project.org)

as.graphicsAnnot  Coerce an Object for Graphics Annotation

Description

Coerce an R object into a form suitable for graphics annotation.

Usage

as.graphicsAnnot(x)

Arguments

x  An R object
boxplot.stats

Details
Expressions, calls and names (as used by plotmath) are passed through unchanged. All other objects with an S3 class (as determined by is.object) are coerced by as.character to character vectors.

All the graphics and grid functions which use this coerce calls and names to expressions internally.

Value
A language object or a character vector.

boxplot.stats  Box Plot Statistics

Description
This function is typically called by another function to gather the statistics necessary for producing box plots, but may be invoked separately.

Usage
boxplot.stats(x, coef = 1.5, do.conf = TRUE, do.out = TRUE)

Arguments
x
a numeric vector for which the boxplot will be constructed (NAs and NaNs are allowed and omitted).

coef
this determines how far the plot “whiskers” extend out from the box. If coef is positive, the whiskers extend to the most extreme data point which is no more than coef times the length of the box away from the box. A value of zero causes the whiskers to extend to the data extremes (and no outliers be returned).

do.conf, do.out
logicals; if FALSE, the conf or out component respectively will be empty in the result.

Details
The two “hinges” are versions of the first and third quartile, i.e., close to quantile(x, c(1,3)/4). The hinges equal the quartiles for odd n (where n <- length(x)) and differ for even n. Where the quartiles only equal observations for n %% 4 == 1 (n ≡ 1 mod 4), the hinges do so additionally for n %% 4 == 2 (n ≡ 2 mod 4), and are in the middle of two observations otherwise.

The notches (if requested) extend to +/-1.58 IQR/sqrt(n). This seems to be based on same calculations as the formula with 1.57 in Chambers et al. (1983, p. 62), given in McGill et al. (1978, p. 16). They are based on asymptotic normality of the median and roughly equal sample sizes for the two medians being compared, and are said to be rather insensitive to the underlying distributions of the samples. The idea appears to be to give roughly a 95% confidence interval for the difference in two medians.
Value

List with named components as follows:

- `stats`: a vector of length 5, containing the extreme of the lower whisker, the lower “hinge”, the median, the upper “hinge” and the extreme of the upper whisker.
- `n`: the number of non-NA observations in the sample.
- `conf`: the lower and upper extremes of the “notch” (if `do.conf`). See the details.
- `out`: the values of any data points which lie beyond the extremes of the whiskers (if `do.out`).

Note that `$stats` and `$conf` are sorted in increasing order, unlike S, and that `$n` and `$out` include any `+- Inf` values.

References

See Also

- `fivenum`
- `boxplot`
- `bxp`

Examples

```r
x <- c(1:100, 1000)
(b1 <- boxplot.stats(x))
(b2 <- boxplot.stats(x, do.conf=FALSE, do.out=FALSE))
stopifnot(b1 $ stats == b2 $ stats) # do.out=F is still robust
boxplot.stats(x, coef = 3, do.conf=FALSE)
## no outlier treatment:
boxplot.stats(x, coef = 0)

boxplot.stats(c(x, NA)) # slight change : n is 101
(r <- boxplot.stats(c(x, -1:1/0)))
stopifnot(r$out == c(1000, -Inf, Inf))
```
**check.options**  
*Set Options with Consistency Checks*

**Description**

Utility function for setting options with some consistency checks. The attributes of the new settings in `new` are checked for consistency with the `model` (often default) list in `name.opt`.

**Usage**

```r
check.options(new, name.opt, reset = FALSE, assign.opt = FALSE,  
envir = .GlobalEnv,  
check.attributes = c("mode", "length"),  
override.check = FALSE)
```

**Arguments**

- `new`: a named list
- `name.opt`: character with the name of R object containing the “model” (default) list.
- `reset`: logical; if TRUE, reset the options from `name.opt`. If there is more than one R object with name `name.opt`, remove the first one in the `search()` path.
- `assign.opt`: logical; if TRUE, assign the...
- `envir`: the environment used for `get` and `assign`.
- `check.attributes`: character containing the attributes which `check.options` should check.
- `override.check`: logical vector of length `length(new)` (or 1 which entails recycling). For those `new[i]` where `override.check[i] == TRUE`, the checks are overridden and the changes made anyway.

**Value**

A list of components with the same names as the one called `name.opt`. The values of the components are changed from the new list, as long as these pass the checks (when these are not overridden according to `override.check`).

**Author(s)**

Martin Maechler

**See Also**

`ps.options` which uses `check.options`.

**Examples**

```r
(L1 <- list(a=1:3, b=pi, ch="CH"))
check.options(list(a=0:2), name.opt = "L1")
check.options(NULL, reset = TRUE, name.opt = "L1")
```
chull

Compute Convex Hull of a Set of Points

Description

Computes the subset of points which lie on the convex hull of the set of points specified.

Usage

chull(x, y = NULL)

Arguments

x, y
coordinate vectors of points. This can be specified as two vectors x and y, a
2-column matrix x, a list x with two components, etc, see xy.coords.

Details

xy.coords is used to interpret the specification of the points. The algorithm is that given by Eddy

‘Peeling’ as used in the S function chull can be implemented by calling chull recursively.

Value

An integer vector giving the indices of the points lying on the convex hull, in clockwise order.

References

**cm**  
*Unit Transformation*

**Description**  
Translates from inches to cm (centimeters).

**Usage**  
```r  
cm(x)  
```

**Arguments**  
- `x` numeric vector

**Examples**  
```r  
cm(1)# = 2.54  
```

---

**col2rgb**  
*Color to RGB Conversion*

**Description**  
“Any R color” to RGB (red/green/blue) conversion.

**Usage**  
```r  
col2rgb(col, alpha = FALSE)  
```

**Arguments**  
- `col` vector of any of the three kind of R colors, i.e., either a color name (an element of `colors()`), a hexadecimal string of the form "#rrggbb", or an integer i meaning `palette()[i]`.
- `alpha` logical value indicating whether alpha channel values should be returned.

**Details**  
For integer colors, 0 is shorthand for the current `par("bg")`, and `NA` means “nothing” which effectively does not draw the corresponding item.

For character colors, "NA" is equivalent to `NA` above.

**Value**  
an integer matrix with three or four rows and number of columns the length (and names if any) as `col`.
**Author(s)**

Martin Maechler

**See Also**

`rgb, colors, palette`, etc.

**Examples**

```r
col2rgb("peachpuff")
col2rgb(c(blue = "royalblue", reddish = "tomato")) # names kept
col2rgb(1:8)# the ones from the palette():
col2rgb(paste("gold", 1:4, sep=""))
col2rgb("#08a0ff")
## all three kind of colors mixed :
col2rgb(c(red="red", palette= 1:3, hex="#abcdef"))
```

```r
##-- NON-INTRODUCTORY examples --
grC <- col2rgb(paste("gray",0:100,sep=""))
table(print(diff(grC["red",])))## '2' or '3': almost equidistant
## The 'named' grays are in between ("slate gray" is not gray, strictly)
col2rgb(c(g66="gray66", darkg= "dark gray", g67="gray67",
g74="gray74", gray = "gray", g75="gray75",
g82="gray82", light="light gray", g83="gray83"))
```

```r
crgb <- col2rgb(cc <- colors())
colnames(crgb) <- cc
t(crgb)# The whole table
ccodes <- c(256^2:0) %% crgb)# = internal codes
## how many names are 'aliases' of each other:
table(tcc <- table(ccodes)) # 502
## All the multiply named colors:
mult <- uc[tcc >= 2]
ci <- lapply(mult, function(m) cc[ccodes == m])
names(ci) <- apply(col2rgb(sapply(ci, function(x)x[1])),
                   2, function(n)paste(n, collapse="", "))
utils::str(ci)
```
Description

These functions return functions that interpolate a set of given colors to create new color palettes (like `topo.colors`) and color ramps, functions that map the interval \([0, 1]\) to colors (like `grey`).

Usage

```r
colorRamp(colors, bias = 1, space = c("rgb", "Lab"),
    interpolate = c("linear", "spline"))
colorRampPalette(colors, ...)  
```

Arguments

- `colors` Colors to interpolate
- `bias` A positive number. Higher values give more widely spaced colors at the high end.
- `space` Interpolation in RGB or CIE Lab color spaces
- `interpolate` Use spline or linear interpolation.
- `...` arguments to pass to `colorRamp`.

Details

The CIE Lab color space is approximately perceptually uniform, and so gives smoother and more uniform color ramps. On the other hand, palettes that vary from one hue to another via white may have a more symmetrical appearance in RGB space.

The conversion formulas in this function do not appear to be completely accurate and the color ramp may not reach the extreme values in Lab space. Future changes in the R color model may change the colors produced with `space="Lab"`.

Value

- `colorRamp` returns a function that maps values between 0 and 1 to colors. `colorRampPalette` returns a function that takes an integer argument and returns that number of colors interpolating the given sequence (similar to `heat.colors` or `terrain.colors`).

See Also

Good starting points for interpolation are the "sequential" and "diverging" ColorBrewer palettes in the RColorBrewer package

Examples

```r
## Here space="rgb" gives palettes that vary only in saturation,  
## as intended.
## With space="Lab" the steps are more uniform, but the hues  
## are slightly purple.
filled.contour(volcano,
    color = colorRampPalette(c("red", "white", "blue")),  
    asp = 1)
filled.contour(volcano,
    color = colorRampPalette(c("red", "white", "blue"),  
        space = "Lab"),
    asp = 1)
```
## Interpolating a 'sequential' ColorBrewer palette

```r
YlOrBr <- c("#FFFFD4", "#FED98E", "#FE9929", "#D95F0E", "#993404")
filled.contour(volcano,
    color = colorRampPalette(YlOrBr, space = "Lab"),
    asp = 1)
filled.contour(volcano,
    color = colorRampPalette(YlOrBr, space = "Lab",
        bias = 0.5),
    asp = 1)
```

## 'jet.colors' is "as in Matlab" (and hurting the eye by over-saturation)

```r
jet.colors <-
colorRampPalette(c("#00007F", "blue", "#007FFF", "cyan",
    "#7FFF7F", "yellow", "#FF7F00", "red", "#7F0000"))
filled.contour(volcano, color = jet.colors, asp = 1)
```

## space="Lab" helps when colors don't form a natural sequence

```r
m <- outer(1:20,1:20,function(x,y) sin(sqrt(x *y)/3))
rgb.palette <- colorRampPalette(c("red", "orange", "blue"),
    space = "rgb")
Lab.palette <- colorRampPalette(c("red", "orange", "blue"),
    space = "Lab")
filled.contour(m,col = rgb.palette(20))
filled.contour(m,col = Lab.palette(20))
```

---

### colors

<table>
<thead>
<tr>
<th>Color Names</th>
</tr>
</thead>
</table>

## Description

Returns the built-in color names which R knows about.

## Usage

```r
colors()
colours()
```

## Details

These color names can be used with a `col=` specification in graphics functions.

An even wider variety of colors can be created with primitives `rgb` and `hsv` or the derived `rainbow`, `heat.colors`, etc.

## Value

A character vector containing all the built-in color names.

## See Also

- `palette` for setting the “palette” of colors for `par(col=<num>)`; `rgb`, `hsv`, `hcl`, `gray`, `rainbow` for a nice example; and `heat.colors`, `topo.colors` for images.
- `col2rgb` for translating to RGB numbers and extended examples.
contourLines

Calculate Contour Lines

Description

Calculate contour lines for a given set of data.

Usage

```r
contourLines(x = seq(0, 1, len = nrow(z)),
y = seq(0, 1, len = ncol(z)),
  z, nlevels = 10,
  levels = pretty(range(z, na.rm=TRUE), nlevels))
```

Arguments

- `x`, `y` locations of grid lines at which the values in `z` are measured. These must be in ascending order. By default, equally spaced values from 0 to 1 are used. If `x` is a list, its components `x$x` and `x$y` are used for `x` and `y`, respectively. If the list has component `z` this is used for `z`.
- `z` a matrix containing the values to be plotted (NA values are allowed). Note that `x` can be used instead of `z` for convenience.
- `nlevels` number of contour levels desired iff `levels` is not supplied.
- `levels` numeric vector of levels at which to draw contour lines.

Details

`contourLines` draws nothing, but returns a set of contour lines.

There is currently no documentation about the algorithm. The source code is in `$R_HOME/src/main/plot3d.c`.

Value

A list of contours. Each contour is a list with elements:

- `level` The contour level.
- `x` The x-coordinates of the contour.
- `y` The y-coordinates of the contour.

See Also

`options("max.countour.segments")` for the maximal complexity of a single contour line.
`contour`
Examples

```r
x <- 10*1:nrow(volcano)
y <- 10*1:ncol(volcano)
contourLines(x, y, volcano)
```

**convertColor**  
Convert between colour spaces

**Description**

Convert colours between standard colour space representations. This function is experimental.

**Usage**

```r
convertColor(color, from, to, from.ref.white, to.ref.white, 
            scale.in=1, scale.out=1, clip=TRUE)
```

**Arguments**

- `color` A matrix whose rows specify colors
- `from`, `to` Input and output color spaces. See Details below
- `from.ref.white`, `to.ref.white` Reference whites or NULL if these are built in to the definition, as for RGB spaces. D65 is the default, see Details for others
- `scale.in`, `scale.out` Input is divided by `scale.in`, output is multiplied by `scale.out`. Use NULL to suppress scaling when input or output is not numeric.
- `clip` If TRUE, truncate RGB output to [0,1], FALSE return out-of-range RGB, NA set out of range colors to NaN.

**Details**

Color spaces are specified by objects of class `colorConverter`, created by `colorConverter` or `make.rgb`. Built-in color spaces may be referenced by strings: "XYZ", "sRGB", "Apple RGB", "CIE RGB", "Lab", "Luv". The converters for these colour spaces are in the object `colorspaces`.

The "sRGB" color space is that used by standard PC monitors. "Apple RGB" is used by Apple monitors. "Lab" and "Luv" are approximately perceptually uniform spaces standardized by the Commission Internationale d’Eclairage. XYZ is a 1931 CIE standard capable of representing all visible colors (and then some), but not in a perceptually uniform way.

The Lab and Luv spaces describe colors of objects, and so require the specification of a reference “white light” color. Illuminant D65 is a standard indirect daylight, Illuminant D50 is close to direct sunlight, and Illuminant A is the light from a standard incandescent bulb. Other standard CIE illuminants supported are B, C, E and D55. RGB colour spaces are defined relative to a particular reference white, and can be only approximately translated to other reference whites. The Bradford chromatic adaptation algorithm is used for this.

The RGB color spaces are specific to a particular class of display. An RGB space cannot represent all colors, and the `clip` option controls what is done to out-of-range colors.
Value

A 3-row matrix whose columns specify the colors.

Examples

```r
par(mfrow=c(2,2))
## The displayable colors from four planes of Lab space
ab <- expand.grid(a=(-10:15)*10,b=(-15:10)*10)
Lab <- cbind(L=20,ab)
srgb <- convertColor(Lab,from="Lab",to="sRGB",clip=NA)
colored <- attr(na.omit(srgb),"na.action")
srgb[colored,] <- 0
cols <- rgb(srgb[,1],srgb[,2],srgb[,3])
image((-10:15)*10,(-15:10)*10,matrix(1:(26*26),ncol=26),col=cols,
xlab="a",ylab="b",main="Lab: L=20")

Lab <- cbind(L=40,ab)
srgb <- convertColor(Lab,from="Lab",to="sRGB",clip=NA)
colored <- attr(na.omit(srgb),"na.action")
srgb[colored,] <- 0
cols <- rgb(srgb[,1],srgb[,2],srgb[,3])
image((-10:15)*10,(-15:10)*10,matrix(1:(26*26),ncol=26),col=cols,
xlab="a",ylab="b",main="Lab: L=40")

Lab <- cbind(L=60,ab)
srgb <- convertColor(Lab,from="Lab",to="sRGB",clip=NA)
colored <- attr(na.omit(srgb),"na.action")
srgb[colored,] <- 0
cols <- rgb(srgb[,1],srgb[,2],srgb[,3])
image((-10:15)*10,(-15:10)*10,matrix(1:(26*26),ncol=26),col=cols,
xlab="a",ylab="b",main="Lab: L=60")

Lab <- cbind(L=80,ab)
srgb <- convertColor(Lab,from="Lab",to="sRGB",clip=NA)
colored <- attr(na.omit(srgb),"na.action")
srgb[colored,] <- 0
cols <- rgb(srgb[,1],srgb[,2],srgb[,3])
image((-10:15)*10,(-15:10)*10,matrix(1:(26*26),ncol=26),col=cols,
xlab="a",ylab="b",main="Lab: L=80")
(cols <- t(col2rgb(palette())))
(lab <- convertColor(cols,from="sRGB",to="Lab",scale.in=255))
round(convertColor(lab,from="Lab",to="sRGB",scale.out=255))
```
dev.interactive

**Is the Current Graphics Device Interactive?**

**Description**

Test if the current graphics device is interactive.

**Usage**

```r
dev.interactive(orNone = FALSE)
```

**Arguments**

- `orNone` logical; if TRUE, the function also returns TRUE when `.Device` == `"null device"` and `getOption("device")` is among the interactive devices.

**Details**

The X11 (Unix), windows (Windows) and quartz (MacOS X) are regarded as interactive, together with GTK and gnome (used with the GNOME GUI: GTK is available in package `gtkDevice` and gnome is expected to be in a package `gnomeDevice`) and JavaGD (from the JGR project, see http://stats.math.uni-augsburg.de/JGR/).

**Value**

`dev.interactive()` returns a logical, TRUE if and only if an interactive (screen) device is in use.

**See Also**

Devices for the available devices on your platform.

**Examples**

```r
dev.interactive # definition -> see list of "interactive" devices explicitly
```

dev.xxx

**Control Multiple Devices**

**Description**

These functions provide control over multiple graphics devices.

**Usage**

```r
dev.cur()
dev.list()
dev.next(which = dev.cur())
dev.prev(which = dev.cur())
dev.off(which = dev.cur())
dev.set(which = dev.next())
graphics.off()
```
Arguments

which  An integer specifying a device number

Details

Only one device is the ‘active’ device: this is the device in which all graphics operations occur. There is a "null device" which is always open but is really a placeholder: any attempt to use it will open a new device specified by `getOption("device")`.

Devices are associated with a name (e.g., "X11" or "postscript") and a number in the range 1 to 63; the "null device" is always device 1. Once a device has been opened the null device is not considered as a possible active device. There is a list of open devices, and this is considered as a circular list not including the null device. `dev.next` and `dev.prev` select the next open device in the appropriate direction, unless no device is open.

`dev.off` shuts down the specified (by default the current) device. If the current device is shut down and any other devices are open, the next open device is made current. It is an error to attempt to shut down device 1. `graphics.off()` shuts down all open graphics devices.

`dev.set` makes the specified device the active device. If there is no device with that number, it is equivalent to `dev.next`. If `which = 1` it opens a new device and selects that.

Value

`dev.cur` returns the number and name of the active device, or 1, the null device, if none is active.
`
dev.list` returns the numbers of all open devices, except device 1, the null device. This is a numeric vector with a names attribute giving the names, or `NULL` if there is no open device.

`dev.next` and `dev.prev` return the number and name of the next / previous device in the list of devices. This will be the null device if and only if there are no open devices.

`dev.off` returns the name and number of the new active device (after the specified device has been shut down).

`dev.set` returns the name and number of the new active device.

See Also

`Devices`, such as `postscript`, etc.
`layout` and its links for setting up plotting regions on the current device.

Examples

```r
## Not run:
## Unix-specific example
x11()
plot(1:10)
x11()
plot(rnorm(10))
de.set(dev.prev())
abline(0,1)# through the 1:10 points
de.set(dev.next())
avline(h=0, col="gray")# for the residual plot
de.set(dev.prev())
de.off(); de.off()#- close the two X devices
## End(Not run)
```
Copy Graphics Between Multiple Devices

Description

dev.copy copies the graphics contents of the current device to the device specified by which or to a new device which has been created by the function specified by device (it is an error to specify both which and device). (If recording is off on the current device, there are no contents to copy: this will result in no plot or an empty plot.) The device copied to becomes the current device.

dev.print copies the graphics contents of the current device to a new device which has been created by the function specified by device and then shuts the new device.

dev.copy2eps is similar to dev.print but produces an EPSF output file, in portrait orientation (horizontal = FALSE)

dev.control allows the user to control the recording of graphics operations in a device. If displaylist is "inhibit" ("enable") then recording is turned off (on). It is only safe to change this at the beginning of a plot (just before or just after a new page). Initially recording is on for screen devices, and off for print devices.

Usage

dev.copy(device, ..., which = dev.next())
dev.print(device = postscript, ...)
dev.copy2eps(...)
dev.control(displaylist = c("inhibit", "enable"))

Arguments

device A device function (e.g., x11, postscript,...)
... Arguments to the device function above. For dev.print, this includes which and by default any postscript arguments.
which A device number specifying the device to copy to
displaylist A character string: the only valid values are "inhibit" and "enable".

Details

For dev.copy2eps, width and height are taken from the current device unless otherwise specified. If just one of width and height is specified, the other is adjusted to preserve the aspect ratio of the device being copied. The default file name is Rplot.eps.

The default for dev.print is to produce and print a postscript copy, if options("printcmd") is set suitably.

dev.print is most useful for producing a postscript print (its default) when the following applies. Unless file is specified, the plot will be printed. Unless width, height and pointsize are specified the plot dimensions will be taken from the current device, shrunk if necessary to fit on the paper. (pointsize is rescaled if the plot is shrunk.) If horizontal is not specified and the plot can be printed at full size by switching its value this is done instead of shrinking the plot region.

If dev.print is used with a specified device (even postscript) it sets the width and height in the same way as dev.copy2eps. This will not be appropriate unless the device specifies dimensions in inches, in particular not for jpeg and (Windows only) bmp.
Value

dev.copy returns the name and number of the device which has been copied to.
dev.print and dev.copy2eps return the name and number of the device which has been
copied from.

Note

Most devices (including all screen devices) have a display list which records all of the graphics
operations that occur in the device. dev.copy copies graphics contents by copying the display list
from one device to another device. Also, automatic redrawing of graphics contents following the
resizing of a device depends on the contents of the display list.

After the command dev.control("inhibit"), graphics operations are not recorded in the
display list so that dev.copy and dev.print will not copy anything and the contents of a device
will not be redrawn automatically if the device is resized.

The recording of graphics operations is relatively expensive in terms of memory so the command
dev.control("inhibit") can be useful if memory usage is an issue.

See Also

dev.cur and other dev.xxx functions

Examples

## Not run:
x11()
plot(rnorm(10), main="Plot 1")
dev.copy(device=x11)
mtext("Copy 1", 3)
dev.print(width=6, height=6, horizontal=FALSE) # prints it
dev.off(dev.prev())
dev.off()
## End(Not run)
**Arguments**

- **file** The output file name, with an appropriate extension.
- **type** The type of bitmap, the default is "png256".
- **height** The plot height, in inches.
- **width** The plot width, in inches.
- **res** Resolution, in dots per inch.
- **pointsize** The pointsize to be used for text: defaults to something reasonable given the width and height
- ... Other parameters passed to postscript.

**Details**

`dev2bitmap` works by copying the current device to a `postscript` device, and post-processing the output file using `ghostscript`. `bitmap` works in the same way using a `postscript` device and post-processing the output as “printing”.

You will need a version of `ghostscript` (5.10 and later have been tested): the full path to the executable can be set by the environment variable `R_GSCMD`. (If this is unset the command "gs" is used, which will work if it is in your path.)

Note: despite the name of the functions they can produce PDF via `type = "pdfwrite"`, and the PDF produced is not bitmapped.

For formats which contain a single image, a file specification like `Rplots%03d.png` can be used: this is interpreted by GhostScript.

For `dev2bitmap` if just one of `width` and `height` is specified, the other is chosen to preserve aspect ratio of the device being copied.

For graphics parameters such as "cra" that need to work in pixels, the default resolution of 72dpi is always used.

**Value**

None.

**See Also**

`postscript`, `png` and `jpeg` and on Windows `bmp`.

`pdf` generate PDF directly.

To display an array of data, see `image`. 
List of Graphical Devices

Description

The following graphics devices are currently available:

- **postscript** Writes PostScript graphics commands to a file
- **pdf** Write PDF graphics commands to a file
- **pictex** Writes LaTeX/PicTeX graphics commands to a file
- **xfig** Device for XFIG graphics file format
- **bitmap** bitmap pseudo-device via GhostScript (if available).

The following devices will be available if R was compiled to use them:

- **X11** The graphics driver for the X11 Window system
- **png** PNG bitmap device
- **jpeg** JPEG bitmap device

Details

If no device is open, using a high-level graphics function will cause a device to be opened. Which device is given by `options("device")` which is initially set as the most appropriate for each platform: a screen device for most interactive use and `postscript` otherwise. The exception is interactive use under Unix if no screen device is known to be available, when `postscript()` is used for most systems; `pdf()` for Mac OS X.

See Also

The individual help files for further information on any of the devices listed here;

`dev.interactive`, `dev.cur`, `dev.print`, `graphics.off`, `image`, `dev2bitmap`, `capabilities` to see if `X11`, `jpeg` and `png` are available.

Examples

```r
## Not run:
## open the default screen device on this platform if no device is open
if(dev.cur() == 1) get(getOption("device"))()
## End(Not run)
```
Embed Fonts in PostScript and PDF

Description

Runs ghostscript to process a PDF or PostScript file and embed all fonts in the file.

Usage

`embedFonts(file, format, outfile = file, fontpaths = "", options = "")`

Arguments

- `file` a character string giving the name of the original file.
- `format` either "pswrite" or "pdfwrite". If not specified, it is guessed from the suffix of `file`.
- `outfile` the name of the new file (with fonts embedded).
- `fontpaths` a character vector giving directories that ghostscript will search for fonts.
- `options` a character string containing further options to ghostscript.

Details

This function is not necessary if you just use the standard default fonts for PostScript and PDF output.

If you use a special font, this function is useful for embedding that font in your PostScript or PDF document so that it can be shared with others without them having to install your special font.

If the special font is not installed for ghostscript, you will need to tell ghostscript where the font is, using something like `options="-sFONTPATH=path/to/font"`.

This function relies on a suitable ghostscript executable being in your path, or the environment variable `R_GSCMD` (the same as `bitmap`) being set as the full path to the ghostscript executable.

Value

The shell command used to invoke ghostscript is returned invisibly. This may be useful for debugging purposes as you can run the command by hand in a shell to look for problems.

See Also

`postscriptFonts`, `Devices`. 
extendrange  

Extend a Numerical Range by a Small Percentage

Description

Extends a numerical range by a small percentage, i.e., fraction, on both sides.

Usage

```r
extendrange(x, r = range(x, na.rm = TRUE), f = 0.05)
```

Arguments

- `x`: numeric vector; not used if `r` is specified.
- `r`: numeric vector of length 2; defaults to the `range` of `x`.
- `f`: number specifying the fraction by which the range should be extended.

Value

numeric vector of length 2, “r extended”, namely simply `r + c(-f, f) * diff(r)`.

See Also

- `range`; `pretty` which can be considered a sophisticated extension of `extendrange`.

Examples

```r
x <- 1:5
(r <- range(x)) # 1 5
extendrange(x) # 0.8 5.2
extendrange(x, f = 0.01) # 0.96 5.04
## Use 'r' if you have it already:
stopifnot(identical(extendrange(r=r),
                   extendrange(x)))
```

getGraphicsEvent  

Wait for a mouse or keyboard event from a graphics window

Description

This function waits for input from a graphics window in the form of a mouse or keyboard event.

Usage

```r
getGraphicsEvent(prompt = "Waiting for input",
                  onMouseDown = NULL, onMouseMove = NULL, onMouseUp = NULL,
                  onKeybd = NULL)
```
getGraphicsEvent

Arguments

- **prompt**: prompt to be displayed to the user
- **onMouseDown**: a function to respond to mouse clicks
- **onMouseMove**: a function to respond to mouse movement
- **onMouseUp**: a function to respond to mouse button releases
- **onKeybd**: a function to respond to key presses

Details

This function allows user input from some graphics devices (currently only the Windows screen display). When called, event handlers may be installed to respond to events involving the mouse or keyboard.

The mouse event handlers should be functions with header `function(buttons, x, y)`. The coordinates `x` and `y` will be passed to mouse event handlers in device independent coordinates (i.e. the lower left corner of the window is `(0,0)`, the upper right is `(1,1)`). The `buttons` argument will be a vector listing the buttons that are pressed at the time of the event, with 0 for left, 1 for middle, and 2 for right.

The keyboard event handler should be a function with header `function(key)`. A single element character vector will be passed to this handler, corresponding to the key press. Shift and other modifier keys will have been processed, so `shift-a` will be passed as "A". The following special keys may also be passed to the handler:

- Control keys, passed as "Ctrl-A", etc.
- Navigation keys, passed as one of "Left", "Up", "Right", "Down", "PgUp", "PgDn", "End", "Home"
- Edit keys, passed as one of "Ins", "Del"
- Function keys, passed as one of "F1", "F2", ...

The event handlers are standard R functions, and will be executed in an environment as though they had been called directly from `getGraphicsEvent`.

Events will be processed until

- one of the event handlers returns a non-NULL value which will be returned as the value of `getGraphicsEvent`, or
- the user interrupts the function from the console.

Value

A non-NULL value returned from one of the event handlers.

## End(Not run)

gray

Gray Level Specification

Description
Create a vector of colors from a vector of gray levels.
Usage
gray(level)
grey(level)
Arguments
level

a vector of desired gray levels between 0 and 1; zero indicates "black" and
one indicates "white".

Details
The values returned by gray can be used with a col= specification in graphics functions or in
par.
grey is an alias for gray.
Value
A vector of “colors” of the same length as level.
See Also
rainbow, hsv, hcl, rgb.
Examples
gray(0:8 / 8)


gray.colors  Gray Color Palette

Description

Create a vector of n gamma-corrected gray colors.

Usage

gray.colors(n, start = 0.3, end = 0.9, gamma = 2.2)
grey.colors(n, start = 0.3, end = 0.9, gamma = 2.2)

Arguments

n     the number of gray colors (≥ 1) to be in the palette.
start starting gray level in the palette (should be between 0 and 1 where zero indicates "black" and one indicates "white").
end   ending gray level in the palette.
gamma the gamma correction.

Details

The function gray.colors chooses a series of n gamma-corrected gray levels between start and end: (startγ, ..., endγ)1/γ. The returned palette contains the corresponding gray colors. This palette is used in barplot.default.

grey.colors is an alias for gray.colors.

Value

A vector of n gray colors.

See Also

gray, rainbow, palette.

Examples

pie(rep(1,12), col = gray.colors(12))
barplot(1:12, col = gray.colors(12))
Description
Create a vector of colors from vectors specifying hue, chroma and luminance.

Usage
hcl(h = 0, c = 35, l = 85, alpha, fixup = TRUE)

Arguments
h The hue of the color specified as an angle in the range [0,360]. 0 yields red, 120 yields green 240 yields blue, etc.
c The chroma of the color. The upper bound for chroma depends on hue and luminance.
l A value in the range [0,100] giving the luminance of the colour. For a given combination of hue and chroma, only a subset of this range is possible.
alpha numeric vector of values in the range [0,1] for alpha transparency channel (0 means transparent and 1 means opaque).
fixup a logical value which indicates whether the resulting RGB values should be corrected to ensure that a real color results. If fixup is FALSE RGB components lying outside the range [0,1] will result in an NA value.

Details
This function corresponds to polar coordinates in the CIE-LUV color space. Steps of equal size in this space correspond to approximately equal perceptual changes in color. Thus, hcl can be thought of as a perceptually based version of hsv.
The function is primarily intended as a way of computing colors for filling areas in plots where area corresponds to a numerical value (pie charts, bar charts, mosaic plots, histograms, etc). Choosing colors which have equal chroma and luminance provides a way of minimising the irradiation illusion which would otherwise produce a misleading impression of how large the areas are.
The default values of chroma and luminance make it possible to generate a full range of hues and have a relatively pleasant pastel appearance.
The RGB values produced by this function correspond to the sRGB color space used on most PC computer displays. There are other packages which provide more general color space facilities.
Semi-transparent colors (0 < alpha < 1) are supported only on a few devices: at the time of writing only on the pdf and (on MacOS X) quartz devices.

Value
A vector of character strings which can be used as color specifications by R graphics functions.

Note
At present there is no guarantee that the colours rendered by R graphics devices will correspond to their sRGB description. It is planned to adopt sRGB as the standard R color description in future.

### Hershey Vector Fonts in R

#### Description

If the `family` graphical parameter (see `par`) has been set to one of the Hershey fonts (see below) Hershey vector fonts are used to render text.

These fonts have two advantages:

1. Vector fonts describe each character in terms of a set of points; R renders the character by joining up the points with straight lines. This intimate knowledge of the outline of each character means that R can arbitrarily transform the characters, which can mean that the vector fonts look better for rotated and 3d text. This works for Latin-1 and Cyrillic characters, only.

2. This implementation was adapted from the GNU libplot library which provides support for non-ASCII and non-English fonts. This means that it is possible, for example, to produce weird plotting symbols and Japanese characters.

For historical reasons, when using the `text` function, Hershey fonts may also be selected via the `vfont` argument, which is a character vector of length 2 (see below for valid values).

**Drawback:**
You cannot use mathematical expressions (`plotmath`) with Hershey fonts.

#### Usage

Hershey

#### Details

The Hershey characters are organised into a set of fonts. A particular font is selected by specifying one of the following font families via `par(family)` and specifying the desired font face (plain, bold, italic, bold-italic) via `par(font)`.

<table>
<thead>
<tr>
<th>family</th>
<th>faces available</th>
</tr>
</thead>
<tbody>
<tr>
<td>&quot;HersheySerif&quot;</td>
<td>plain, bold, italic, bold-italic</td>
</tr>
<tr>
<td>&quot;HersheySans&quot;</td>
<td>plain, bold, italic, bold-italic</td>
</tr>
<tr>
<td>&quot;HersheyScript&quot;</td>
<td>plain, bold</td>
</tr>
<tr>
<td>&quot;HersheyGothicEnglish&quot;</td>
<td>plain</td>
</tr>
<tr>
<td>&quot;HersheyGothicGerman&quot;</td>
<td>plain</td>
</tr>
<tr>
<td>&quot;HersheyGothicItalian&quot;</td>
<td>plain</td>
</tr>
<tr>
<td>&quot;HersheySymbol&quot;</td>
<td>plain, bold, italic, bold-italic</td>
</tr>
<tr>
<td>&quot;HersheySansSymbol&quot;</td>
<td>plain, italic</td>
</tr>
</tbody>
</table>

In the old, `vfont` specification for the `text` function, the Hershey font is specified by a typeface (e.g., serif or sans serif) and a fontindex or "style" (e.g., plain or italic). The first element of `vfont` specifies the typeface and the second element specifies the fontindex. The first table produced by `demo(Hershey)` shows the character a produced by each of the different fonts.

The available typeface and fontindex values are available as list components of the variable Hershey. The allowed pairs for (typeface, fontindex) are:

| serif       | plain       |
and the indices of these are available as \texttt{Hershey\$allowed}.

**Escape sequences:** The string to be drawn can include escape sequences, which all begin with a \\ (backslash). When \texttt{R} encounters a \, rather than drawing the \, it treats the subsequent character(s) as a coded description of what to draw.

One useful escape sequence (in the current context) is of the form: \texttt{\123}. The three digits following the \, specify an octal code for a character. For example, the octal code for \texttt{p} is 160 so the strings "p" and "\160" are equivalent. This is useful for producing characters when there is not an appropriate key on your keyboard.

The other useful escape sequences all begin with \texttt{\}. These are described below. Remember that backslashes have to be doubled in \texttt{R} character strings, so they need to be entered with four backslashes.

**Symbols:** an entire string of Greek symbols can be produced by selecting the Serif Symbol or Sans Serif Symbol typeface. To allow Greek symbols to be embedded in a string which uses a non-symbol typeface, there are a set of symbol escape sequences of the form \texttt{\ab}. For example, the escape sequence \texttt{\*a} produces a Greek alpha. The second table in \texttt{demo(Hershey)} shows all of the symbol escape sequences and the symbols that they produce.

**ISO Latin-1:** further escape sequences of the form \texttt{\ab} are provided for producing ISO Latin-1 characters. Another option is to use the appropriate octal code. The (non-ASCII) ISO Latin-1 characters are in the range 241...377. For example, \texttt{\366} produces the character o with an umlaut. The third table in \texttt{demo(Hershey)} shows all of the ISO Latin-1 escape sequences. These characters can be used directly in a Latin-1 or UTF-8 locale. (In the latter, non-Latin-1 characters are replaced by a dot.)

**Special Characters:** a set of characters are provided which do not fall into any standard font. These can only be accessed by escape sequence. For example, \texttt{\LI} produces the zodiac sign for Libra, and \texttt{\JU} produces the astronomical sign for Jupiter. The fourth table in \texttt{demo(Hershey)} shows all of the special character escape sequences.
Cyrillic Characters: cyrillic characters are implemented according to the K018-R encoding, and can be used directly in such a locale using the Serif typeface and Cyrillic (or Oblique Cyrillic) fontindex. Alternatively they can be specified via an octal code in the range 300 to 337 for lower case characters or 340 to 377 for upper case characters. The fifth table in demo(Hershey) shows the octal codes for the available cyrillic characters.

Cyrillic has to be selected via a ("serif", fontindex) pair rather than via a font family.

Japanese Characters: 83 Hiragana, 86 Katakana, and 603 Kanji characters are implemented according to the EUC-JP (Extended Unix Code) encoding. Each character is identified by a unique hexadecimal code. The Hiragana characters are in the range 0x2421 to 0x2473, Katakana are in the range 0x2521 to 0x2576, and Kanji are (scattered about) in the range 0x3021 to 0x6d55.

When using the Serif typeface and EUC fontindex, these characters can be produced by a pair of octal codes. Given the hexadecimal code (e.g., 0x2421), take the first two digits and add 0x80 and do the same to the second two digits (e.g., 0x21 and 0x24 become 0xa4 and 0xa1), then convert both to octal (e.g., 0xa4 and 0xa1 become 244 and 241). For example, the first Hiragana character is produced by \244\241.

It is also possible to use the hexadecimal code directly. This works for all non-EUC fonts by specifying an escape sequence of the form \#J1234. For example, the first Hiragana character is produced by \#J2421.

The Kanji characters may be specified in a third way, using the so-called "Nelson Index", by specifying an escape sequence of the form \#N1234. For example, the Kanji for “one” is produced by \#N0001.

demo(Japanese) shows the available Japanese characters.

Raw Hershey Glyphs: all of the characters in the Hershey fonts are stored in a large array. Some characters are not accessible in any of the Hershey fonts. These characters can only be accessed via an escape sequence of the form \#H1234. For example, the fleur-de-lys is produced by \#H0746. The sixth and seventh tables of demo(Hershey) shows all of the available raw glyphs.

Examples

Hershey

## for tables of examples, see demo(Hershey)
**hsv**  

**HSV Color Specification**

**Description**
Create a vector of colors from vectors specifying hue, saturation and value.

**Usage**

```r
hsv(h = 1, s = 1, v = 1, gamma = 1, alpha)
```

**Arguments**

- `h, s, v` numeric vectors of values in the range $[0, 1]$ for “hue”, “saturation” and “value” to be combined to form a vector of colors. Values in shorter arguments are recycled.
- `gamma` a “gamma correction” exponent, $\gamma$
- `alpha` numeric vector of values in the range $[0, 1]$ for alpha transparency channel ($0$ means transparent and $1$ means opaque).

**Details**
Semi-transparent colors ($0 < \alpha < 1$) are supported only on a few devices: at the time of writing only on the **pdf** and (on MacOS X) **quartz** devices.

**Value**
This function creates a vector of “colors” corresponding to the given values in HSV space. The values returned by `hsv` can be used with a `col=` specification in graphics functions or in `par`.

**Gamma correction**
For each color, $(r, g, b)$ in RGB space (with all values in $[0, 1]$), the final color corresponds to $(r^\gamma, g^\gamma, b^\gamma)$.

**See Also**
- `hcl` for a perceptually based version of `hsv()`.
- `rgb` and `rgb2hsv` for RGB to HSV conversion; `rainbow`, `gray`.

**Examples**

```r
hsv(.5,.5,.5)
## Look at gamma effect:
# n <- 20; y <- -sin(3*pi*((1:n)-1/2)/n)
# op <- par(mfrow=c(3,2),mar=rep(1.5,4))
# for(gamma in c(.4, .6, .8, 1, 1.2, 1.5))
#   plot(y, axes = FALSE, frame.plot = TRUE,
#        xlab = "", ylab = ", pch = 21, cex = 30,
#        bg = rainbow(n, start=.85, end=.1, gamma = gamma),
#        main = paste("Red tones; gamma=",format(gamma)))
# par(op)
```
**Japanese characters in R**

**Description**

The implementation of Hershey vector fonts provides a large number of Japanese characters (Hiragana, Katakana, and Kanji).

**Details**

Without keyboard support for typing Japanese characters, the only way to produce these characters is to use special escape sequences: see Hershey.

For example, the Hiragana character for the sound "ka" is produced by `\#J242b` and the Katakana character for this sound is produced by `\#J252b`. The Kanji ideograph for "one" is produced by `\#J306c` or `\#N0001`.

The output from `demo(Japanese)` shows tables of the escape sequences for the available Japanese characters.

**References**

**See Also**

demo(Japanese), Hershey, text, contour

**Examples**

```r
plot(1:9, type="n", axes=FALSE, frame=TRUE, ylab="", main = "example(Japanese)", xlab= "using Hershey fonts")
par(cex=3)
Vf <- c("serif", "plain")
text(4, 2, "\\#J2438\#J2421\#J2451\#J2473", vfont = Vf)
text(4, 4, "\\#J2538\#J2521\#J2551\#J2573", vfont = Vf)
text(4, 6, "\\#J467c\#J4b5c", vfont = Vf)
text(4, 8, "Japan", vfont = Vf)
par(cex=1)
text(8, 2, "Hiragana")
text(8, 4, "Katakana")
text(8, 6, "Kanji")
text(8, 8, "English")
```

**Create colour spaces**

**Description**

These functions specify colour spaces for use in convertColor.
Usage

```r
make.rgb(red, green, blue, name = NULL, white = "D65", gamma = 2.2)
colorConverter(toXYZ, fromXYZ, name, white=NULL)
```

Arguments

- `red,green,blue` Chromaticity (xy or xyY) of RGB primaries
- `name` Name for the colour space
- `white` Character string specifying the reference white (see Details)
- `gamma` Display gamma (nonlinearity). A positive number or the string "sRGB"
- `fromXYZ` Function to convert from XYZ tristimulus coordinates to this space
- `toXYZ` Function to convert from this space to XYZ tristimulus coordinates.

Details

An RGB colour space is defined by the chromaticities of the red, green and blue primaries. These are given as vectors of length 2 or 3 in xyY coordinates (the Y component is not used and may be omitted). The chromaticities are defined relative to a reference white, which must be one of the CIE standard illuminants: "A", "B", "C", "D50", "D55", "D60", "E" (usually "D65").

The display gamma is most commonly 2.2, though 1.8 is used for Apple RGB. The sRGB standard specifies a more complicated function that is close to a gamma of 2.2; `gamma="sRGB"` uses this function.

Colour spaces other than RGB can be specified directly by giving conversions to and from XYZ tristimulus coordinates. The functions should take two arguments. The first is a vector giving the coordinates for one colour. The second argument is the reference white. If a specific reference white is included in the definition of the colour space (as for the RGB spaces) this second argument should be ignored and may be ...

Value

An object of class `colorConverter`

`convertColor`

Examples

```r
(pal <- make.rgb(red= c(0.6400,0.3300),
green=c(0.2900,0.6000),
blue= c(0.1500,0.0600),
name = "PAL/SECAM RGB"))

## converter for sRGB in #rrggbb format
hexcolor <- colorConverter(toXYZ = function(hex,...) {
  rgb <- t(col2rgb(hex))/255
  colorspace$sRGB$toXYZ(rgb,...) },
```

```r"
fromXYZ <- function(xyz,...) {
  rgb <- colorspaces$sRGB$fromXYZ(xyz,...)
  rgb <- round(rgb,5)
  if (min(rgb) < 0 || max(rgb) > 1)
    as.character(NA)
  else
    rgb(rgb[1],rgb[2],rgb[3])},

white = "D65", name = "#rrggbb")

(cols <- t(col2rgb(palette())))
(luv <- convertColor(cols,from="sRGB", to="Luv", scale.in=255))
(hex <- convertColor(luv, from="Luv", to=hexcolor, scale.out=NULL))

## must make hex a matrix before using it
(cc <- round(convertColor(as.matrix(hex), from= hexcolor, to= "sRGB", 
                        scale.in=NULL, scale.out=255)))
stopifnot(cc == cols)

---

**n2mfrow**

*Compute Default mfrow From Number of Plots*

**Description**

Easy setup for plotting multiple figures (in a rectangular layout) on one page. This computes a sensible default for `par(mfrow)`.

**Usage**

`n2mfrow(nr.plots)`

**Arguments**

- `nr.plots` integer; the number of plot figures you’ll want to draw.

**Value**

A length two integer vector `nr, nc` giving the number of rows and columns, fulfilling `nr >= nc` >= 1 and `nr * nc >= nr.plots`.

**Author(s)**

Martin Maechler

**See Also**

`par`, `layout`.
Examples

n2mfrow(8) # 3 x 3

n <- 5 ; x <- seq(-2,2, len=51)
## suppose now that 'n' is not known {inside function}
op <- par(mfrow = n2mfrow(n))
for (j in 1:n)
    plot(x, x^j, main = substitute(x^ exp, list(exp = j)), type = "l",
        col = "blue")
sapply(1:10, n2mfrow)

nclass

Compute the Number of Classes for a Histogram

Description

Compute the number of classes for a histogram.

Usage

nclass.Sturges(x)
nclass.scott(x)
nclass.FD(x)

Arguments

x

A data vector.

Details

nclass.Sturges uses Sturges’ formula, implicitly basing bin sizes on the range of the data.
nclass.scott uses Scott’s choice for a normal distribution based on the estimate of the standard error, unless that is zero where it returns 1.
nclass.FD uses the Freedman-Diaconis choice based on the inter-quartile range (IQR) unless that’s zero where it reverts to mad(x, constant=2) and when that is 0 as well, returns 1.

Value

The suggested number of classes.

References

See Also

hist and truehist (which use a different default).

Examples

set.seed(1)
x <- rnorm(1111)
nclass.Sturges(x)

## Compare them:
NC <- function(x)
c(Sturges = nclass.Sturges(x), Scott = nclass.scott(x), FD = nclass.FD(x))
NC(x)
onePt <- rep(1, 11)
NC(onePt)  # no longer gives NaN

----------

palette Set or View the Graphics Palette

Description

View or manipulate the color palette which is used when a col= has a numeric index.

Usage

palette(value)

Arguments

value an optional character vector.

Details

If value has length 1, it is taken to be the name of a built in color palette. If value has length greater than 1 it is assumed to contain a description of the colors which are to make up the new palette (either by name or by RGB levels).

If value is omitted or has length 0, no change is made the current palette.

Currently, the only built-in palette is "default".

Value

The palette which was in effect. This is invisible unless the argument is omitted.

See Also

colors for the vector of built-in “named” colors; hsv, gray, rainbow, terrain.colors,...to construct colors.
colorRamp to interpolate colors, making custom palettes; col2rgb for translating colors to RGB 3-vectors.
### Palettes

#### Examples

```r
palette()  # obtain the current palette
palette(rainbow(6))  # six color rainbow

(palette(gray(seq(0,.9,len=25))))  # gray scales; print old palette
matplot(outer(1:100,1:30), type='l', lty=1,lwd=2, col=1:30,
        main = "Gray Scales Palette",
        sub = "palette(gray(seq(0,.9,len=25)))")
palette("default")  # reset back to the default
```

### Description

Create a vector of \( n \) “contiguous” colors.

#### Usage

```r
rainbow(n, s = 1, v = 1, start = 0, end = max(1,n - 1)/n,
        gamma = 1, alpha = 1)
heat.colors(n, alpha = 1)
terrain.colors(n, alpha = 1)
topo.colors(n, alpha = 1)
cm.colors(n, alpha = 1)
```

#### Arguments

- \( n \) the number of colors (\( \geq 1 \)) to be in the palette.
- \( s, v \) the “saturation” and “value” to be used to complete the HSV color descriptions.
- \( \text{start} \) the (corrected) hue in \([0,1]\) at which the rainbow begins.
- \( \text{end} \) the (corrected) hue in \([0,1]\) at which the rainbow ends.
- \( \text{gamma} \) the gamma correction, see argument \text{gamma} in \text{hsv}.
- \( \text{alpha} \) the alpha transparency, a number in \([0,1]\), see argument \text{alpha} in \text{hsv}.

#### Details

Conceptually, all of these functions actually use (parts of) a line cut out of the 3-dimensional color space, parametrized by \text{hsv}(h, s, v, \text{gamma}), where \text{gamma} = 1 for the \text{foo.colors} function, and hence, equispaced hues in RGB space tend to cluster at the red, green and blue primaries.

Some applications such as contouring require a palette of colors which do not “wrap around” to give a final color close to the starting one.

With \text{rainbow}, the parameters \text{start} and \text{end} can be used to specify particular subranges of hues. The following values can be used when generating such a subrange: red=0, yellow=\( \frac{1}{6} \), green=\( \frac{2}{6} \), cyan=\( \frac{3}{6} \), blue=\( \frac{4}{6} \) and magenta=\( \frac{5}{6} \).

#### Value

A character vector, \text{cv}, of color names. This can be used either to create a user-defined color palette for subsequent graphics by \text{palette(cv)}, a \text{col=} specification in graphics functions or in \text{par}.

### pdf

**PDF Graphics Device**

**Description**

pdf starts the graphics device driver for producing PDF graphics.

**Usage**

```r
pdf(file = ifelse(onefile, "Rplots.pdf", "Rplot%03d.pdf"),
    width = 6, height = 6, onefile = TRUE, family = "Helvetica",
    title = "R Graphics Output", fonts = NULL, version = "1.1",
    paper = "special", encoding, bg, fg, pointsize, pagecentre)
```

**Arguments**

- `file`: a character string giving the name of the file. For use with `onelpdf=false` give a C integer format such as "Rplot%03d.pdf" (the default in that case). (See `postscript` for further details.)
- `width, height`: the width and height of the graphics region in inches.
- `onelpdf`, `logical`: if true (the default) allow multiple figures in one file. If false, generate a file name containing the page number.
family the font family to be used, see `postscript`.
title the title string to embed in the file.
fonts a character vector specifying \texttt{R} graphics font family names for fonts which will be included in the PDF file.
version a string describing the PDF version that will be required to view the output. This is a minimum, and will be increased (with a warning) if necessary.
paper the target paper size. The choices are "a4", "letter", "legal" (or "us") and "executive" (and these can be capitalized), or "a4r" and "USr" for rotated ('landscape'). The default is "special", which means that the width and height specify the paper size. A further choice is "default"; if this is selected, the papersize is taken from the option "papersize" if that is set and to "a4" if it is unset or empty.
encoding the name of an encoding file. See `postscript` for details.
bg the default background color to be used.
fg the default foreground color to be used.
points the default point size to be used. Strictly speaking, in bp, that is 1/72 of an inch, but approximately in points.
pagecentre logical: should the device region be centred on the page? – defaults to true, but is only relevant for paper \texttt{!="special"}.

Details

\texttt{pdf()} opens the file \texttt{file} and the PDF commands needed to plot any graphics requested are sent to that file.

The \texttt{file} argument is interpreted as a C integer format as used by \texttt{sprintf}, with integer argument the page number. The default gives files 'Rplot001.pdf', ..., 'Rplot999.pdf', 'Rplot1000.pdf', ....

The family argument can be used to specify a PDF-specific font family as the initial/default font for the device.

If a device-independent \texttt{R} graphics font family is specified (e.g., via \texttt{par(family=)} in the graphics package), the PDF device makes use of the PostScript font mappings to convert the \texttt{R} graphics font family to a PDF-specific font family description. (See the documentation for \texttt{pdfFonts}.)

\texttt{R} does \texttt{not} embed fonts in the PDF file though, so it is only possible straightforward to use mappings to the font families that are assumed to be available in any PDF viewer: "Times" (equivalently "serif"), "Helvetica" (equivalently "sans"), "Courier" (equivalently "mono") and "Symbol" (equivalently "symbol"). Other families may be specified, but it is the user’s responsibility to ensure that these fonts are available on the system and third-party software, e.g., ghostscript, may be required to embed the fonts so that the PDF can be included in other documents (e.g., LaTeX). The URW-based families described for `postscript` can be used with viewers such as GSView which are based on URW fonts.

See `postscript` for details of encodings, as the internal code is shared between the drivers. The native PDF encoding is given in file `PDFDoc.enc`.

\texttt{pdf} writes uncompressed PDF. It is primarily intended for producing PDF graphics for inclusion in other documents, and PDF-includers such as \texttt{pdftex} are usually able to handle compression.

At present the PDF is fairly simple, with each page being represented as a single stream. The \texttt{R} graphics model does not distinguish graphics objects at the level of the driver interface.

The version argument declares the version of PDF that gets produced. The version must be at least 1.4 for semitransparent output to be understood, and at least 1.3 if CID fonts are to be used:
if these features are used the version number will be increased (with a warning). Specifying a low version number (as the default) is useful if you want to produce PDF output that can be viewed on older or non-Adobe PDF viewers. (PDF 1.4 requires Acrobat 5 or later.)

Line widths as controlled by \texttt{par(lwd=)} are in multiples of 1/96 inch. Multiples less than 1 are allowed. \texttt{pch="."} with \texttt{cex = 1} corresponds to a square of side 1/72 inch, which is also the 'pixel' size assumed for graphics parameters such as \texttt{"cra"}.

\section*{Note}
Acrobat Reader does not use the fonts specified but rather emulates them from multiple-master fonts. This can be seen in imprecise centering of characters, for example the multiply and divide signs in Helvetica.

Acrobat Reader 5.x and later can be extended by support for Asian and (so-called) Central European fonts (the latter only for 7.x), and this will be needed for full use of encodings other than Latin-1. See \url{http://www.adobe.com/products/acrobat/acrrasianfontpack.html}.

\section*{Examples}
\begin{verbatim}
## Not run:
## Test function for encodings
TestChars <- function(encoding="ISOLatin1", ...) {
  pdf(encoding=encoding, ...) 
  par(pty="s")
  plot(c(-1,16), c(-1,16), type="n", xlab="", ylab="", xaxs="i", yaxs="i")
  title(paste("Centred chars in encoding", encoding))
  grid(17, 17, lty=1)
  for(i in c(32:255)) {
    x <- i %% 16
    y <- i %/% 16
    points(x, y, pch=i)
  }
  dev.off()
}
## there will be many warnings.
TestChars("ISOLatin2")
## this does not view properly in older viewers.
TestChars("ISOLatin2", family="URWHelvetica")
## works well for viewing in gs-based viewers, and often in xpdf.
## End(Not run)
\end{verbatim}
Usage

pictex(file = "Rplots.tex", width = 5, height = 4, debug = FALSE, bg = "white", fg = "black")

Arguments

- **file**: the file where output will appear.
- **width**: The width of the plot in inches.
- **height**: the height of the plot in inches.
- **debug**: should debugging information be printed.
- **bg**: the background color for the plot. Ignored.
- **fg**: the foreground color for the plot. Ignored.

Details

This driver does not have any font metric information, so the use of `plotmath` is not supported. Multiple plots will be placed as separate environments in the output file. Line widths are ignored except when setting the spacing of line textures. `pch="."` corresponds to a square of side 1pt.

This device does not support colour (nor does the PicTeX package), and all colour settings are ignored.

Author(s)

This driver was provided by Valerio Aimale ⟨valerio@svpop.com.dist.unige.it⟩ of the Department of Internal Medicine, University of Genoa, Italy.

Mathematical Annotation in R

Description

If the text argument to one of the text-drawing functions (text, mtext, axis, legend) in R is an expression, the argument is interpreted as a mathematical expression and the output will be formatted according to TeX-like rules. Expressions can also be used for titles, subtitles and x- and y-axis labels (but not for axis labels on persp plots).

In most cases other language objects (names and calls) are coerced to expressions and so can also be used.

Details

A mathematical expression must obey the normal rules of syntax for any R expression, but it is interpreted according to very different rules than for normal R expressions.

It is possible to produce many different mathematical symbols, generate sub- or superscripts, produce fractions, etc.

The output from demo(plotmath) includes several tables which show the available features. In these tables, the columns of grey text show sample R expressions, and the columns of black text show the resulting output.

The available features are also described in the tables below:

<table>
<thead>

</tbody>
</table>

Note to TeX users: TeX’s
Upsilon is Upsilon1, TeX’s
varepsilon is close to epsilon, and there is no equivalent of TeX’s
epsilon. TeX’s
varpi is close to omeg1. vartheta, varphi and varsigma are allowed as synonyms for
theta, phi and sigma.
sigma is also known as stigma, its Unicode name.
Control characters (e.g. \n) are not interpreted in character strings in plotmath, unlike normal
plotting.

Examples

```r
x <- seq(-4, 4, len = 101)
y <- cbind(sin(x), cos(x))
matplot(x, y, type = "l", xaxt = "n",
       main = expression(paste(plain(sin) * phi, " and ",
                             plain(cos) * phi)),
       ylab = expression("sin" * phi, "cos" * phi), # only list is taken
       xlab = expression(paste("Phase Angle ", phi)),
```
### How to combine "math" and numeric variables:

```r
plot(1:10, type="n", xlab="", ylab="", main = "plot math & numbers")
theta <- 1.23 ; mtext(bquote(hat(theta) == .(theta)))
for(i in 2:9)
  text(i,i+1, substitute(list(xi,eta) == group("","),
                  list(x=i, y=i+1)))
## note that both of these use calls rather than expressions.

plot(1:10, 1:10)
text(4, 9, expression(hat(beta) == (X^t * X)^{-1} * X^t * y))
text(4, 8.4, "expression(hat(beta) == (X^t * X)^{-1} * X^t * y)",
     cex = .8)
text(4, 7, expression(bar(x) == sum(frac(x[i], n), i==1, n}))
text(4, 6.4, "expression(bar(x) == sum(frac(x[i], n), i==1, n))",
     cex = .8)
text(8, 5, expression(paste(frac(1, sigma *sqrt(2*pi)), " ",
                           plain(e)^{frac(-(x-mu)^2, 2*sigma^2)})),
     cex = 1.2)
```

---

**png**

**JPEG and PNG graphics devices**

**Description**

A graphics device for JPEG or PNG format bitmap files.

**Usage**

```r
jpeg(filename = "Rplot%03d.jpeg", width = 480, height = 480,
     pointsize = 12, quality = 75, bg = "white", res = NA, ...)

png(filename = "Rplot%03d.png", width = 480, height = 480,
     pointsize = 12, bg = "white", res = NA, ...)
```

**Arguments**

- `filename` the name of the output file. The page number is substituted if a C integer format is included in the character string, as in the default. (The result must be less than `PATH_MAX` characters long, and may be truncated if not. See `postscript` for further details.) Tilde expansion is performed where supported by the platform.
- `width` the width of the device in pixels.
- `height` the height of the device in pixels.
- `pointsize` the default pointsize of plotted text, interpreted at 72 dpi, so one point is approximately one pixel.
- `quality` the ‘quality’ of the JPEG image, as a percentage. Smaller values will give more compression but also more degradation of the image.
- `bg` default background colour.
The nominal resolution in dpi which will be recorded in the bitmap file, if a positive integer.

... additional arguments to the underlying X11 device.

Details

Plots in PNG and JPEG format can easily be converted to many other bitmap formats, and both can be displayed in modern web browsers. The PNG format is lossless and is best for line diagrams and blocks of solid colour. The JPEG format is lossy, but may be useful for image plots, for example.

`png` supports transparent backgrounds: use `bg = "transparent"`. Not all PNG viewers render files with transparency correctly. When transparency is in use a very light grey is used as the background and so will appear as transparent if used in the plot. This allows opaque white to be used, as on the example.

R can be compiled without support for either or both of these devices: this will be reported if you attempt to use them on a system where they are not supported. They may not be usable unless the X11 display is available to the owner of the R process.

By default no resolution is recorded in the file. Readers will often assume a nominal resolution of 72dpi when none is recorded. As resolutions in PNG files are recorded in pixels/metre, the dpi value will be changed slightly.

For graphics parameters that make use of dimensions in inches, a resolution of 96dpi is assumed. `png` will use a palette if there are less than 256 colours on the page, and record a 24-bit RGB file otherwise.

Value

A plot device is opened: nothing is returned to the R interpreter.

Warnings

Note that the width and height are in pixels not inches. A warning will be issued if both are less than 20.

If you plot more than one page on one of these devices and do not include something like `%d` for the sequence number in file, the file will contain the last page plotted.

Note

These are based on the X11 device, so the additional arguments to that device work, but are rarely appropriate. The colour handling will be that of the X11 device in use.

See Also

`Devices`,`dev.print`
`capabilities` to see if these devices are supported by this build of R.
`bitmap` provides an alternative way to generate PNG and JPEG plots that does not depend on accessing the X11 display but does depend on having GhostScript installed. (Devices GDD in CRAN package GDD and CairoJPEG/CairoPNG in CRAN package Cairo are alternatives using several other additional pieces of software.)
Examples

```r
## these examples will work only if the devices are available
## and the X11 display is available.

## copy current plot to a (large) PNG file
## Not run: dev.print(png, file="myplot.png", width=1024, height=768)

generic(file="myplot.png", bg="transparent")
plot(1:10)
rect(1, 5, 3, 7, col="white")
dev.off()

jpeg(file="myplot.jpeg")
example(rect)
dev.off()
## End(Not run)
```

Description

`postscript` starts the graphics device driver for producing PostScript graphics.

Usage

```r
postscript(file = ifelse(onefile, "Rplots.ps", "Rplot%03d.ps"),
onefile = TRUE, family,
title = "R Graphics Output", fonts = NULL,
encoding, bg, fg,
width, height, horizontal, pointsize,
paper, pagecentre, print.it, command, colormodel)
```

Arguments

- **file**: a character string giving the name of the file. If it is ",", the output is piped to the command given by the argument `command`. If it is of the form "|cmd", the output is piped to the command given by `cmd`.
- **onefile**: logical: if true (the default) allow multiple figures in one file. If false, generate a file name containing the page number and use an EPSF header and no DocumentMedia comment.
- **family**: the initial font family to be used, normally as a character string. See the section ‘Families’. This defaults to "Helvetica".
- **title**: title string to embed in the file.
- **fonts**: a character vector specifying additional `R` graphics font family names for font families whose declarations will be included in the PostScript file and are available for use with the device. See Details.
encoding the name of an encoding file. Defaults to "ISO8859-1.enc" unless the locale is recognized as corresponding to a language using ISO 8859-5,7,13,15 or KOI8-R,U, in the ‘enc’ directory of package grDevices, which is used if the path does not contain a path separator. An extension " .enc" can be omitted.

bg the default background color to be used. If "transparent" (or an equivalent specification), no background is painted.

fg the default foreground color to be used.

width, height the width and height of the graphics region in inches. The default is to use the entire page less a 0.25 inch border on each side.

horizontal the orientation of the printed image, a logical. Defaults to true, that is landscape orientation on paper sizes with width less than height.

pointsize the default point size to be used. Strictly speaking, in bp, that is 1/72 of an inch, but approximately in points.

paper the size of paper in the printer. The choices are "a4", "letter" (or "us"), "legal" and "executive" (and these can be capitalized). Also, "special" can be used, when the width and height specify the paper size. A further choice is "default", which is the default. If this is selected, the papersize is taken from the option "papersize" if that is set and to "a4" if it is unset or empty.

pagecentre logical: should the device region be centred on the page? – defaults to true.

print.it logical: should the file be printed when the device is closed? (This only applies if file is a real file name.)

command the command to be used for “printing”. Defaults to option "printcmd": this can also be selected as "default". The length limit is 2*PATH_MAX, typically 8096 bytes.

colormodel a character string describing the color model: currently allowed values as "rgb" (the default and the only model prior to R 2.5.0), "rgb-nogray", "gray" and "cmyk".

Details

postscript opens the file file and the PostScript commands needed to plot any graphics requested are written to that file. This file can then be printed on a suitable device to obtain hard copy.

A postscript plot can be printed via postscript in two ways.

1. Setting print.it = TRUE causes the command given in argument command to be called with argument "file" when the device is closed. Note that the plot file is not deleted unless command arranges to delete it.

2. file="" or file="|cmd" can be used to print using a pipe on systems that support ‘popen’. Failure to open the command will probably be reported to the terminal but not to ‘popen’, in which case close the device by dev.off immediately.

The file argument is interpreted as a C integer format as used by sprintf, with integer argument the page number. The default gives files ‘Rplot001.ps’, . . . , ‘Rplot999.ps’, ‘Rplot1000.ps’, . . . .

The postscript produced for a single R plot is EPS (Encapsulated PostScript) compatible, and can be included into other documents, e.g., into LaTeX, using
includegraphics(<filename>). For use in this way you will probably want to set horizontal = FALSE, onefile = FALSE, paper = "special". Note that the bounding box is for the device region: if you find the white space around the plot region excessive, reduce the margins of the figure region via par(mar=).

Most of the PostScript prologue used is taken from the \texttt{R} character vector \texttt{.ps.prolog}. This is marked in the output, and can be changed by changing that vector. (This is only advisable for PostScript experts: the standard version is in \texttt{namespace:grDevices}.)

A PostScript device has a default family, which can be set by the user via \texttt{family}. If other font families are to be used when drawing to the PostScript device, these must be declared when the device is created via \texttt{fonts}; the font family names for this argument are \texttt{R} graphics font family names (see the documentation for \texttt{postscriptFonts}).

Line widths as controlled by \texttt{par(lwd=)} are in multiples of 1/96 inch: multiples less than 1 are allowed. \texttt{pch="."} with \texttt{cex = 1} corresponds to a square of side 1/72 inch, which is also the ‘pixel’ size assumed for graphics parameters such as "cra".

### Families

Font families are collections of fonts covering the five font faces, (conventionally plain, bold, italic, bold-italic and symbol) selected by the graphics parameter \texttt{par(font=)} or the grid parameter \texttt{gpar(fontface=)}. Font families can be specified either as an an initial/default font family for the device via the \texttt{family} argument or after the device is opened by the graphics parameter \texttt{par(family=)} or the grid parameter \texttt{gpar(fontfamily=)}. Families which will be used in addition to the initial family must be specified in the \texttt{fonts} argument when the device is opened.

Font families are declared via a call to \texttt{postscriptFonts}.

The argument \texttt{family} specifies the initial/default font family to be used. In normal use it is one of "AvantGarde", "Bookman", "Courier", "Helvetica", "Helvetica-Narrow", "NewCenturySchoolbook", "Palatino" or "Times", and refers to the standard Adobe PostScript fonts families of those names which are included (or cloned) in all common PostScript devices.

Many PostScript emulators (including those based on ghostscript) use the URW equivalents of these fonts, which are "URWGothic", "URWBookman", "NimbusMon", "NimbusSan", "NimbusSanCond", "CenturySch", "URWPalladio" and "NimbusRom" respectively. If your PostScript device is using URW fonts, you will obtain access to more characters and more appropriate metrics by using these names. To make these easier to remember, "URWHelvetica" == "NimbusSan" and "URWTimes" == "NimbusRom" are also supported.

Another type of family makes use of CID-keyed fonts for East Asian languages – see \texttt{postscriptFonts}.

The \texttt{family} argument is normally a character string naming a font family, but family objects generated by \texttt{TypelFont} and \texttt{CIDFont} are also accepted. For compatibility with earlier versions of \texttt{R}, the initial family can also be specified as a vector of four or five \texttt{afm} files.

### Encodings

Encodings describe which glyphs are used to display the character codes (in the range 0–255). Most commonly \texttt{R} uses ISOLatin1 encoding, and the examples for \texttt{text} are in that encoding. However, the encoding used on machines running \texttt{R} may well be different, and by using the \texttt{encoding} argument the glyphs can be matched to encoding in use. This suffices for European and Cyrillic languages, but not for CJK languages. For the latter, composite CID fonts are used. These fonts are useful for other languages: for example they may contain Greek glyphs. (The rest of this section applies only when CID fonts are not used.)
None of this will matter if only ASCII characters (codes 32–126) are used as all the encodings (except "TeXtext") agree over that range. Some encodings are supersets of ISOLatin1, too. However, if accented and special characters do not come out as you expect, you may need to change the encoding. Some other encodings are supplied with R: "WinAnsi.enc" and "MacRoman.enc" correspond to the encodings normally used on Windows and Classic MacOS (at least by Adobe), and "PDFDoc.enc" is the first 256 characters of the Unicode encoding, the standard for PDF. There are also encodings "ISOLatin2.enc", "CP1250.enc", "ISOLatin7.enc" (ISO 8859-13), "CP1257.enc", and "ISOLatin9.enc" (ISO 8859-15), "Cyrillic.enc" (ISO 8859-5), "KOI8-R.enc", "KOI8-U.enc", "CP1251.enc", "Greek.enc" (ISO 8859-7) and "CP1253.enc". Note that many glyphs in these encodings are not in the fonts corresponding to the standard families. (The Adobe ones for all but Courier, Helvetica and Times cover little more than Latin-1, whereas the URW ones also cover Latin-2, Latin-7, Latin-9 and Cyrillic but no Greek. The Adobe exceptions cover the Latin character sets, but not the Euro.)

If you specify the encoding, it is your responsibility to ensure that the PostScript font contains the glyphs used. One issue here is the Euro symbol which is in the WinAnsi and MacRoman encodings but may well not be in the PostScript fonts. (It is in the URW variants; it is not in the supplied Adobe Font Metric files.)

There is an exception. Character 45 ("-" is always set as minus (its value in Adobe ISOLatin1) even though it is hyphen in the other encodings. Hyphen is available as character 173 (octal 0255) in all the Latin encodings, Cyrillic and Greek. There are some discrepancies in accounts of glyphs 39 and 96: the supplied encodings (except CP1250 and CP1251) treat these as ‘quoteright’ and ‘quoteleft’ (rather than ‘quotesingle’/‘acute’ and ‘grave’ respectively), as they are in the Adobe documentation.

TeX fonts

TeX has traditionally made use of fonts such as Computer Modern which are encoded rather differently, in a 7-bit encoding. This encoding can be specified by encoding = "TeXtext.enc", taking care that the ASCII characters < > \ _ { } are not available in those fonts.

There are supplied families "ComputerModern" and "ComputerModernItalic" which use this encoding, and which are only supported for postscript (and not pdf). They are intended to use with the Type 1 versions of the TeX CM fonts. It will normally be possible to include such output in TeX or LaTeX provided it is processed with dvips -Ppfb -j0 or the equivalent on your system. (-j0 turns off font subsetting.) When family = "ComputerModern" is used, the italic/bold-italic fonts used are slanted fonts (cmss10 and cmbxss10). To use text italic fonts instead, set family = "ComputerModernItalic".

These families use the TeX math italic and symbol fonts for a comprehensive but incomplete coverage of the glyphs covered by the Adobe symbol font in other families. This is achieved by special-casing the postscript code generated from the supplied ‘CM_symbol_10.afm’.

Color models

The default color model is RGB, with pure gray colors expressed as greyscales. Color model "rgb-nogray" uses only RGB, model "cmyk" only CMYK, and model "gray" only greyscales (and selecting any other colour is an error). Nothing in R specifies the interpretation of the RGB or CMYK color spaces, and the simplest possible conversion to CMYK is used (http://en.wikipedia.org/wiki/CMYK_color_model#Mapping_RGB_to_CMYK).

```
PostScript and PDF Font Families

Description

These functions handle the translation of a \texttt{R} graphics font family name to a PostScript or PDF font description, used by the \texttt{postscript} or \texttt{pdf} graphics devices.

Usage

\begin{verbatim}
postscriptFonts(...)
pdfFonts(...)
\end{verbatim}

Arguments

\begin{verbatim}
...
\end{verbatim}
either character strings naming mappings to display, or named arguments specifying mappings to add or change.

Details

If these functions are called with no argument they list all the existing mappings, whereas if they are called with named arguments they add (or change) mappings.

A PostScript or PDF device is created with a default font family (see the documentation for \texttt{postscript}), but it is also possible to specify a font family when drawing to the device (for example, see the documentation for "family" in \texttt{par} and for "fontfamily" in \texttt{gpar} in the \texttt{grid} package).

The font family sent to the device is a simple string name, which must be mapped to a set of PostScript fonts. Separate lists of mappings for \texttt{postscript} and \texttt{pdf} devices are maintained for the current \texttt{R} session and can be added to by the user.

The \texttt{postscriptFonts} and \texttt{pdfFonts} functions can be used to list existing mappings and to define new mappings. The \texttt{Type1Font} and \texttt{CIDFont} functions can be used to create new mappings, when the \texttt{xxxFonts} function is used to add them to the database. See the examples.

Default mappings are provided for four device-independent family names: "sans" for a sans-serif font, "serif" for a serif font, "mono" for a monospaced font, and "symbol" for a symbol font.

Mappings for a number of standard Adobe fonts (and URW equivalents) are also provided: "AvantGarde", "Bookman", "Courier", "Helvextica", "Helvextica-Narrow", "NewCenturySchoolbook", "Palatino" and "Times", "URWGothic", "URWBookman", "NimbusMon", "NimbusSan" (synonym "URWHelvetica"), "NimbusSanCond", "CenturySch", "URWPalladio" and "NimbusRom" (synonym "URWTimes").

There are also mappings for "ComputerModern" and "ComputerModernItallic".

Finally, there are some default mappings for East Asian locales described in a separate section.

The specification of font metrics and encodings is described in the help for the \texttt{postscript} function.

The fonts are not embedded in the resulting PostScript or PDF file, so software including the PostScript or PDF plot file should either embed the font outlines (usually from '.pfb' or '.pfa' files) or use DSC comments to instruct the print spooler or including application to do so (see also \texttt{embedFonts}).
A font family has both an R-level name, the argument name used when `postscriptFonts` was called, and an internal name, the family component. These two names are the same for all the pre-defined font families.

Once a font family is in use it cannot be changed. ‘In use’ means that it has been specified via a family or fonts argument to an invocation of the same graphics device already in the R session. (For these purposes `xfig` counts the same as `postscript` but only uses some of the predefined mappings.)

**Value**

A list of one or more font mappings.

**East Asian fonts**

There are some default mappings for East Asian locales: "Japan1", "Japan1HeiMin", "Japan1GothicBBB", and "Japan1Ryumin" for Japanese; "Korea1" and "Korea1deb" for Korean; "GB1" (Simplified Chinese) for mainland China and Singapore; "CNS1" (Traditional Chinese) for Hong Kong and Taiwan.

These refer to the following fonts

- **Japan1 (PS)**: HeiseiKakuGo-W5
  - Linotype Japanese printer font
- **Japan1 (PDF)**: KozMinPro-Regular-Acro from Adobe Reader 7.0 Japanese Font Pack
- **Japan1HeiMin (PS)**: HeiseiMin-W3
  - Linotype Japanese printer font
- **Japan1HeiMin (PDF)**: HeiseiMin-W3-Acro from Adobe Reader 7.0 Japanese Font Pack
- **Japan1GothicBBB**: GothicBBB-Medium
  - Japanese-market PostScript printer font
- **Japan1Ryumin**: Ryumin-Light
  - Japanese-market PostScript printer font
- **Korea1 (PS)**: Baekmuk-Batang
  - TrueType font found on some Linux systems
- **Korea1 (PDF)**: HYSMyeongJoStd-Medium-Acro from Adobe Reader 7.0 Korean Font Pack
- **Korea1deb (PS)**: Batang-Regular
  - another name for Baekmuk-Batang
- **Korea1deb (PDF)**: HYGothic-Medium-Acro
  - from Adobe Reader 4.0 Korean Font Pack
- **GB1 (PS)**: BousungEG-Light-GB
  - TrueType font found on some Linux systems
- **GB1 (PDF)**: STSong-Light-Acro from Adobe Reader 7.0 Simplified Chinese Font Pack
- **CNS1 (PS)**: MOESung-Regular
  - Ken Lunde’s CJKV resources
- **CNS1 (PDF)**: MSungStd-Light-Acro from Adobe Reader 7.0 Traditional Chinese Font Pack

com/pub/examples/nutshell/cjkv/adobe/samples/. These will need to be installed or otherwise made available to the postscript/PDF interpreter such as ghostscript (and not all interpreters can handle TrueType fonts).

You may well find that your postscript/PDF interpreters has been set up to provide aliases for many of these fonts. For example, ghostscript on Windows can optionally be installed to map common CJK fonts names to Windows TrueType fonts. (You may want to add the -Acro versions as well.)

Adding a mapping for a CID-keyed font is for gurus only.

ps.options

Auxiliary Function to Set/View Argument of postscript

Description

The auxiliary function ps.options can be used to set and view (if called without arguments) default values for the arguments to postscript.

ps.options needs to be called before calling postscript, and the default values it sets can be overridden by supplying arguments to postscript.

Usage

ps.options(..., reset = FALSE, override.check = FALSE)
quartz

Arguments

... arguments paper, horizontal, width, height, family, encoding, pointsize, bg, fg, onefile, print.it, colormodel and append (ignored) can be supplied.
reset, override.check
logical arguments passed to check.options. See the Examples.

Value

A named list of arguments.

See Also

postscript

Examples

ps.options(bg = "pink")
utils::str(ps.options(reset = TRUE))

### ---- error checking of arguments: ----
ps.options(width=0:12, onefile=0, bg=pi)
# override the check for 'onefile', but not the others:
utils::str(ps.options(width=0:12, onefile=1, bg=pi,
override.check = c(FALSE,TRUE,FALSE)))

quartz

MacOS X Quartz device

Description

quartz starts a graphics device driver for the MacOS X System. This can only be done on machines that run MacOS X.

Usage

quartz(display = "", width = 5, height = 5, pointsize = 12,
family = "Helvetica", antialias = TRUE, autorefresh = TRUE)

Arguments

display the display on which the graphics window will appear. The default is to use the value in the user’s environment variable DISPLAY.
width the width of the plotting window in inches.
height the height of the plotting window in inches.
pointsize the default pointsize to be used.
family this is the family name of the Postscript font that will be used by the device.
antialias whether to use antialiasing. It is never the case to set it FALSE
autorefresh logical specifying if realtime refreshing should be done. If FALSE, the system is charged to refresh the context of the device window.
Details

Quartz is the graphic engine based on the PDF format. It is used by the graphic interface of MacOS X to render high quality graphics. As PDF it is device independent and can be rescaled without loss of definition.

If a device-independent R graphics font family is specified (e.g., via `par(family=)` in the graphics package), the Quartz device makes use of the Quartz font database (see `quartzFonts`) to convert the R graphics font family to a Quartz-specific font family description.

Calling `quartz()` sets `.Device` to "quartz".

Line widths as controlled by `par(lwd=)` are in multiples of the 1/72 inch, and multiples < 1 are silently converted to 1.

See Also

`quartzFonts`, `Devices`.

---

`quartzFonts`  
`quartz Fonts`

Description

These functions handle the translation of a device-independent R graphics font family name to a quartz font description.

Usage

`quartzFont(family)`

`quartzFonts(...)`

Arguments

family  
a character vector containing the four PostScript font names for plain, bold, italic, and bolditalic versions of a font family.

...  
either character strings naming mappings to display, or new (named) mappings to define.

Details

A quartz device is created with a default font (see the documentation for `quartz`), but it is also possible to specify a font family when drawing to the device (for example, see the documentation for `gpar` in the grid package).

The font family sent to the device is a simple string name, which must be mapped to something more specific to quartz fonts. A list of mappings is maintained and can be modified by the user.

The `quartzFonts` function can be used to list existing mappings and to define new mappings. The `quartzFont` function can be used to create a new mapping.

Default mappings are provided for four device-independent font family names: "sans" for a sans-serif font, "serif" for a serif font, "mono" for a monospaced font, and "symbol" for a symbol font.
**recordGraphics**

**See Also**

*quartz*

**Examples**

```r
quartzFonts()
quartzFonts("mono")
```

---

**recordGraphics**  
Record graphics operations

**Description**

Records arbitrary code on the graphics engine display list. Useful for encapsulating calculations with graphical output that depends on the calculations. Intended *only* for expert use.

**Usage**

```r
recordGraphics(expr, list, env)
```

**Arguments**

- `expr`  
  object of mode `expression` or call or an “unevaluated expression”.
- `list`  
  a list defining the environment in which `expr` is to be evaluated.
- `env`  
  An environment specifying where R looks for objects not found in `envir`.

**Details**

The code in `expr` is evaluated in an environment constructed from `list`, with `env` as the parent of that environment.

All three arguments are saved on the graphics engine display list so that on a device resize or copying between devices, the original evaluation environment can be recreated and the code can be re-evaluated to reproduce the graphical output.

**Value**

The value from evaluating `expr`.

**Warning**

This function is not intended for general use. Incorrect or improper use of this function could lead to unintended and/or undesirable results.

An example of acceptable use is querying the current state of a graphics device or graphics system setting and then calling a graphics function.

An example of improper use would be calling the `assign` function to performing assignments in the global environment.

**See Also**

*eval*
Examples

plot(1:10)
# This rectangle remains 1 inch wide when the device is resized
recordGraphics(
    |
    rect(4, 2, 4 + diff(par("usr")[1:2]) / par("pin")[1], 3)
), list(), getNamespace("graphics"))
rgb  

**Description**

This function creates "colors" corresponding to the given intensities (between 0 and \( \text{max} \)) of the red, green and blue primaries.

An alpha transparency value can also be specified (0 means fully transparent and \( \text{max} \) means opaque). If \( \text{alpha} \) is not specified, an opaque colour is generated.

The names argument may be used to provide names for the colors.

The values returned by these functions can be used with a \( \text{col=} \) specification in graphics functions or in `par`.

**Usage**

```r
rgb(red, green, blue, alpha, names = NULL, maxColorValue = 1)
```

**Arguments**

- `red, blue, green, alpha`
  - numeric vectors with values in \([0, M]\) where \( M = \text{maxColorValue} \). When this is 255, the \( \text{red, blue, green, and alpha} \) values are coerced to integers in \( 0:255 \) and the result is computed most efficiently.

- `names` character. The names for the resulting vector.

- `maxColorValue` number giving the maximum of the color values range, see above.

**Details**

The colors may be specified by passing a matrix or dataframe as argument `red`, and leaving `blue` and `green` missing. In this case the first three columns of `red` are taken to be the `red, green` and `blue` values.

Semi-transparent colors \((0 < \text{alpha} < 1)\) are supported only on a few devices: at the time of writing only on the `pdf` and (on MacOS X) `quartz` devices.

**Value**

A character vector with elements of 7 or 9 characters, "#" followed by the red, blue, green and optionally alpha values in hexadecimal (after rescaling to \( 0 \ldots 255 \)).

**See Also**

`col2rgb` the "inverse" for translating \( \text{R} \) colors to RGB vectors; `rainbow, hsv, hcl, gray`. 
Examples

```r
rgb(0, 1, 0)
(u01 <- seq(0,1, length=11))
stopifnot(rgb(u01,u01,u01) == gray(u01))
reds <- rgb((0:15)/15, g=0, b=0, names=paste("red",0:15,sep="."))
reds
rgb(0, 0:12, 0, max = 255)# integer input
ramp <- colorRamp(c("red", "white"))
rgb( ramp(seq(0, 1, length = 5)), max = 255)
```

---

**rgb2hsv**  
**RGB to HSV Conversion**

**Description**

`rgb2hsv` transforms colors from RGB space (red/green/blue) into HSV space (hue/saturation/value).

**Usage**

```r
rgb2hsv(r, g = NULL, b = NULL, gamma = 1, maxColorValue = 255)
```

**Arguments**

- `r` vector of “red” values in \([0, M]\), \(M =\maxColorValue\) or 3-row rgb matrix.
- `g` vector of “green” values, or `NULL` when `r` is a matrix.
- `b` vector of “blue” values, or `NULL` when `r` is a matrix.
- `gamma` a “gamma correction” (supposedly applied to the `r,g,b` values previously), see `hsv(..., gamma)`.
- `maxColorValue` number giving the maximum of the RGB color values range. The default 255 corresponds to the typical \(0:255\) RGB coding as in `col2rgb()`.

**Details**

Value (brightness) gives the amount of light in the color.
Hue describes the dominant wavelength.
Saturation is the amount of Hue mixed into the color.

**Value**

A matrix with a column for each color. The three rows of the matrix indicate hue, saturation and value and are named "h", "s", and "v" accordingly.

**Author(s)**

R interface by Wolfram Fischer (wolfram@fischer-zim.ch); C code mainly by Nicholas Lewin-Koh (nikko@hailmail.net).

### Examples

```r
## These (saturated, bright ones) only differ by hue
(rc <- col2rgb(c("red", "yellow", "green", "cyan", "blue", "magenta")))
(hc <- rgb2hsv(rc))
6 * hc["h",] # the hues are equispaced
```

```r
(rgb3 <- floor(256 * matrix(runif(3*12), 3,12)))
(hsv3 <- rgb2hsv(rgb3))
## Consistency:
stopifnot(rgb3 == col2rgb(hsv(h=hsv3[1,], s=hsv3[2,], v=hsv3[3,])),
          all.equal(hsv3, rgb2hsv(rgb3/255, maxC = 1)))
```

```r
## A (simplified) pure R version -- originally by Wolfram Fischer --
## showing the exact algorithm:
rgb2hsvR <- function(rgb, gamma = 1, maxColorValue = 255) {
  if(!is.numeric(rgb)) stop("rgb matrix must be numeric")
  d <- dim(rgb)
  if(d[1] != 3) stop("rgb matrix must have 3 rows")
  n <- d[2]
  if(n == 0) return(cbind(h=1,s=1,v=1)[,0])
  rgb <- rgb/maxColorValue
  if(gamma != 1) rgb <- rgb ^ (1/gamma)

  ## get the max and min
  v <- apply( rgb, 2, max)
  s <- apply( rgb, 2, min)
  D <- v - s # range

  ## set hue to zero for undefined values (gray has no hue)
  h <- numeric(n)
  notgray <- ( s != v )

  ## blue hue
  idx <- (v == rgb[3,] & notgray )
  if (any (idx))
    h[idx] <- 2/3 + 1/6 * (rgb[1,idx] - rgb[2,idx]) / D[idx]

  ## green hue
  idx <- (v == rgb[2,] & notgray )
  if (any (idx))
    h[idx] <- 1/3 + 1/6 * (rgb[3,idx] - rgb[1,idx]) / D[idx]

  ## red hue
  idx <- (v == rgb[1,] & notgray )
  if (any (idx))

  ## correct for negative red
  idx <- (h < 0)
  h[idx] <- 1+h[idx]

  ## set the saturation
```
trans3d

3D to 2D Transformation for Perspective Plots

Description

Projection of 3-dimensional to 2-dimensional points using a 4x4 viewing transformation matrix. Mainly for adding to perspective plots such as `persp`.

Usage

```r
trans3d(x, y, z, pmat)
```

Arguments

- `x, y, z` numeric vectors of equal length, specifying points in 3D space.
- `pmat` a 4 x 4 viewing transformation matrix, suitable for projecting the 3D coordinates `(x, y, z)` into the 2D plane using homogeneous 4D coordinates `(x, y, z, t)`; such matrices are returned by `persp()`.

Value

a list with two components

- `x, y` the projected 2d coordinates of the 3d input `(x, y, z)`.

See Also

`persp`

Examples

```r
## confirm the equivalence:
all.equal(rgb2hsv (rgb3),
    rgb2hsvR(rgb3), tol=1e-14) # TRUE
```

## See help(persp) {after attaching the 'graphics' package}
```
Type1Font

Type 1 and CID Fonts

Description

These functions are used to define the translation of a R graphics font family name to a Type 1 or CID font descriptions, used by both the postscript and pdf graphics devices.

Usage

Type1Font(family, metrics, encoding = "default")

CIDFont(family, cmap, cmapEncoding, pdfresource = "")

Arguments

family a character string giving the name to be used internally for a Type 1 or CID-keyed font family. This needs to uniquely identify each family, so if you modify a family which is in use (see postscriptFonts) you need to change the family name.

metrics a character vector of four or five strings giving paths to the afm (Adobe Font Metric) files for the font.

cmap the name of a CMap file for a CID-keyed font.

encoding for Type1Font, the name of an encoding file. Defaults to "default", which maps on this platform to "ISOLatin1.enc". Otherwise, a file name in the 'enc' directory of the grDevices package, which is used if the path does not contain a path separator. An extension ".enc" can be omitted.

cmapEncoding The name of a charset encoding to be used with the named CMap file: strings will be translated to this encoding when written to the file.

pdfresource A chunk of PDF code; only required for using a CID-keyed font on pdf; users should not be expected to provide this.

Details

For Type1Fonts, if four .afm files are supplied the fifth is taken to be "Symbol.afm". Relative paths are taken relative to the directory R_HOME/library/grDevices/afm. The fifth (symbol) font must be in AdobeSym encoding. However, the glyphs in the first four fonts are referenced by name and any encoding given within the .afm files is not used.

Glyphs in CID-keyed fonts are accessed by ID (number) and not by name. The CMap file maps encoded strings (usually in a MBCS) to IDs, so cmap and cmapEncoding specifications must match. There are no real bold or italic versions of CID fonts (bold/italic were very rarely used in traditional CJK topography), and for the pdf device all four font faces will be identical. However, for the postscript device, bold and italic (and bold italic) are emulated.

CID-keyed fonts are intended only for use for the glyphs of CJK languages, which are all monospaced and are all treated as filling the same bounding box. (Thus plotmath will work with such characters, but the spacing will be less carefully controlled than with Western glyphs.) The CID-keyed fonts do contain other characters, including a Latin alphabet: non-CJK glyphs are regarded as monospaced with half the width of CJK glyphs. This is often the case, but sometimes Latin glyphs designed for proportional spacing are used (and may look odd). We strongly recommend that CID-keyed fonts are only used for CJK glyphs.
Value

A list of class "Type1Font" or "CIDFont".

See Also

`postscript.pdf`, `postscriptFonts` and `pdfFonts`.

Examples

```r
## This duplicates "ComputerModernItalic".
CMitalic <- Type1Font("ComputerModern2",
c("CM_regular_10.afm", "CM_boldx_10.afm",
   "cmti10.afm", "cmbxti10.afm",
   "CM_symbol_10.afm"),
   encoding = "TeXtext.enc")

## Not run:
## This could be used by
postscript(family = CMitalic)
## or
postscriptFonts(CMitalic = CMitalic) # once in a session
postscript(family = "CMitalic", encoding = "TeXtext.enc")
## End(Not run)
```

---

**x11**

*X Window System Graphics*

Description

`x11` starts a graphics device driver for the X Window System (version 11). This can only be done on machines that run X. `x11` is recognized as a synonym for `x11`.

Usage

```r
x11(display = "", width = 7, height = 7, pointsize = 12,
   gamma =getOption("gamma"), colortype =getOption("X11colortype"),
   maxcubesize = 256, bg = "transparent", canvas = "white",
   fonts =getOption("X11fonts"), xpos = NA, ypos = NA)
```

Arguments

- **display**: the display on which the graphics window will appear. The default is to use the value in the user's environment variable `DISPLAY`.
- **width, height**: the width and height of the plotting window, in inches. See also Resources.
- **pointsize**: the default pointsize to be used.
- **gamma**: the gamma correction factor. This value is used to ensure that the colors perceived are linearly related to RGB values (see `hsv`). By default this is taken from `getOption("gamma")`, or is 1 (no correction) if that is unset (which is the usual case).
colortype: the kind of color model to be used. The possibilities are "mono", "gray", "pseudo", "pseudo.cube" and "true". Ignored if an X11 device is already open.

maxcubesize: can be used to limit the size of color cube allocated for pseudocolor devices.

bg: color. The default background color.

canvas: color. The color of the canvas, which is visible only when the background color is transparent.

fonts: X11 font description strings into which weight, slant and size will be substituted. There are two, the first for fonts 1 to 4 and the second for font 5, the symbol font. See section Fonts.

xpos, ypos: initial position of the top left corner of the window, in pixels. Negative values are from the opposite corner, e.g. xpos=-100 says the top right corner should be 100 pixels from the right edge of the screen. If NA, successive devices are cascaded in 20 pixel steps from the top left. See also Resources.

Details

By default, an X11 device will use the best color rendering strategy that it can. The choice can be overridden with the colortype parameter. A value of "mono" results in black and white graphics, "gray" in grayscale and "true" in truecolor graphics (if this is possible). The values "pseudo" and "pseudo.cube" provide color strategies for pseudocolor displays. The first strategy provides on-demand color allocation which produces exact colors until the color resources of the display are exhausted. The second causes a standard color cube to be set up, and requested colors are approximated by the closest value in the cube. The default strategy for pseudocolor displays is "pseudo".

Note: All X11 devices share a colortype which is set by the first device to be opened. To change the colortype you need to close all open X11 devices then open one with the desired colortype.

With colortype equal to "pseudo.cube" or "gray" successively smaller palettes are tried until one is completely allocated. If allocation of the smallest attempt fails the device will revert to "mono".

Line widths as controlled by par(lwd=) are in multiples of the pixel size, and multiples < 1 are silently converted to 1.

pch="." with cex = 1 corresponds to a rectangle of sides the larger of one pixel and 0.01 inch.

The initial size and position are only hints, and may not be acted on by the window manager.

Fonts

An initial/default font family for the device can be specified via the fonts argument, but if a device-independent R graphics font family is specified (e.g. via par(family=) in the graphics package), the X11 device makes use of the X11 font database (see X11Fonts) to convert the R graphics font family to an X11-specific font family description.

X11 chooses fonts by matching to a pattern, and it is quite possible that it will choose a font in the wrong encoding or which does not contain glyphs for your language (particularly common in iso10646-1 fonts.

The fonts argument is a two-element character vector, and the first element will be crucial in successfully using non-Western-European fonts. Settings that have proved useful include

"*-mincho-%s-%s-***-%d-***********" for CJK languages and "-cronyx-helvetica-%s-%s-***-%d-***********" for Russian.
For UTF-8 locales, the XLC_LOCALE databases provide mappings between character encodings, and you may need to add an entry for your locale (e.g. Fedora Core 3 lacks one for ru_RU.utf8).

Resources

The standard X11 resource geometry can be use to specify the window position and/or size, but will be overridden by values specified as arguments. The class looked for is R_x11. Note that the resource specifies the width and height in pixels and not in inches.

---

### X11Fonts

**X11 Fonts**

Description

These functions handle the translation of a device-independent R graphics font family name to an X11 font description.

Usage

```r
X11Font(font)
X11Fonts(...)
```

Arguments

- `font` a character string containing an X11 font description.
- `...` either character strings naming mappings to display, or new (named) mappings to define.

Details

An X11 device is created with a default font (see the documentation for X11), but it is also possible to specify a font family when drawing to the device (for example, see the documentation for gpar in the grid package).

The font family sent to the device is a simple string name, which must be mapped to something more specific to X11 fonts. A list of mappings is maintained and can be modified by the user.

The `X11Fonts` function can be used to list existing mappings and to define new mappings. The `X11Font` function can be used to create a new mapping.

Default mappings are provided for four device-independent font family names: "sans" for a sans-serif font, "serif" for a serif font, "mono" for a monospaced font, and "symbol" for a symbol font.

X11Fonts(utopia=utopia)

---

**xfig**

**XFig Graphics Device**

---

**Description**

*xfig* starts the graphics device driver for producing XFig (version 3.2) graphics.

The auxiliary function *ps.options* can be used to set and view (if called without arguments) default values for the arguments to *xfig* and *postscript*.

**Usage**

```r
xfig(file = ifelse(onefile, "Rplots.fig", "Rplot%03d.fig"),
     onefile = FALSE, encoding = "none", ...)
```

**Arguments**

- **file**: a character string giving the name of the file. For use with *onefile = FALSE* give a C integer format such as "Rplot%03d.fig" (the default in that case). (See *postscript* for further details.)
- **onefile**: logical: if true allow multiple figures in one file. If false, assume only one page per file and generate a file number containing the page number.
- **encoding**: The encoding in which to write text strings. The default is not to re-encode. This can be any encoding recognized by *iconv*; in a Western UTF-8 locale you probably want to select an 8-bit encoding such as *latin1*, and in an East Asian locale an *EUC* encoding. If re-encoding fails, the text strings will be written in the current encoding with a warning.
- **...**: further arguments to *ps.options* accepted by *xfig*():
  - **paper**: the size of paper in the printer. The choices are "A4", "Letter" and "Legal" (and these can be lowercase). A further choice is "default", which is the default. If this is selected, the papersize is taken from the option "papersize" if that is set and to "A4" if it is unset or empty.
  - **horizontal**: the orientation of the printed image, a logical. Defaults to true, that is landscape orientation.
  - **width, height**: the width and height of the graphics region in inches. The default is to use the entire page less a 0.25 inch border.
  - **family**: the font family to be used. This must be one of "AvantGarde", "Bookman", "Courier", "Helvetica", "Helvetica-Narrow", "NewCenturySchoolbook", "Palatino" or "Times". Any other value is replaced by "Helvetica" with a warning.
  - **pointsize**: the default point size to be used.
  - **bg**: the default background color to be used.
  - **fg**: the default foreground color to be used.
  - **pagecentre**: logical: should the device region be centred on the page: defaults to TRUE.
Details

Although xfig can produce multiple plots in one file, the XFig format does not say how to separate or view them. So onefile = FALSE is the default.

The file argument is interpreted as a C integer format as used by sprintf, with integer argument the page number. The default gives files 'Rplot001.fig', ..., 'Rplot999.fig', 'Rplot1000.fig', ....

Line widths as controlled by par(lwd=) are in multiples of 5/6*1/72 inch. Multiples less than 1 are allowed. pch="." with cex = 1 corresponds to a square of side 1/72 inch.

Windows users can make use of WinFIG (http://www.schmidt-web-berlin.de/WinFIG.htm).

Note

Only some line textures (0 <= lty < 4) are used. Eventually this will be partially remedied, but the XFig file format does not allow as general line textures as the R model. Unimplemented line textures are displayed as dash-double-dotted.

There is a limit of 512 colours (plus white and black) per file.

---

xy.coords Extracting Plotting Structures

Description

xy.coords is used by many functions to obtain x and y coordinates for plotting. The use of this common mechanism across all relevant R functions produces a measure of consistency.

Usage

xy.coords(x, y = NULL, xlab = NULL, ylab = NULL, log = NULL, recycle = FALSE)

Arguments

x, y the x and y coordinates of a set of points. Alternatively, a single argument x can be provided.

xlab, ylab names for the x and y variables to be extracted.

log character. "x", "y" or both, as for plot. Sets negative values to NA and gives a warning.

recycle logical; if TRUE, recycle (rep) the shorter of x or y if their lengths differ.
xy.coords

Details

An attempt is made to interpret the arguments \( x \) and \( y \) in a way suitable for bivariate plotting (or other bivariate procedures).

If \( y \) is \texttt{NULL} and \( x \) is a

**formula:** of the form \( yvar \sim xvar \) \( xvar \) and \( yvar \) are used as \( x \) and \( y \) variables.

**list:** containing components \( x \) and \( y \), these are used to define plotting coordinates.

**time series:** the \( x \) values are taken to be \( \text{time}(x) \) and the \( y \) values to be the time series.

**matrix or data.frame with two or more columns:** the first is assumed to contain the \( x \) values and the second the \( y \) values. \textit{Note} that is also true if \( x \) has columns named "\texttt{x}" and "\texttt{y}"; these names will be irrelevant here.

In any other case, the \( x \) argument is coerced to a vector and returned as \( y \) component where the resulting \( x \) is just the index vector \( 1:n \). In this case, the resulting \( xlab \) component is set to "Index".

If \( x \) (after transformation as above) inherits from class "\texttt{POSIXt}" it is coerced to class "\texttt{POSIXct}".

Value

A list with the components

\[
\begin{align*}
 \text{x} & \quad \text{numeric (i.e., "double") vector of abscissa values.} \\
 \text{y} & \quad \text{numeric vector of the same length as} \ x. \\
 \text{xlab} & \quad \text{character(1) or} \ \text{NULL}, \ \text{the 'label' of} \ x. \\
 \text{ylab} & \quad \text{character(1) or} \ \text{NULL}, \ \text{the 'label' of} \ y.
\end{align*}
\]

See Also

\texttt{plot.default}, \texttt{lines}, \texttt{points} and \texttt{lowess} are examples of functions which use this mechanism.

Examples

\begin{verbatim}
xy.coords(stats::fft(c(1:10)), NULL)
with(cars, xy.coords(dist ~ speed, NULL)$xlab) # = "speed"
xy.coords(1:3, 1:2, recycle=TRUE)
xy.coords(-2:10,NULL, log="y")
##> warning: 3 y values <=0 omitted ..
\end{verbatim}
xyz.coords  Extracting Plotting Structures

Description

Utility for obtaining consistent x, y and z coordinates and labels for three dimensional (3D) plots.

Usage

```r
xyz.coords(x, y = NULL, z = NULL, xlab = NULL, ylab = NULL, zlab = NULL,
           log = NULL, recycle = FALSE)
```

Arguments

- `x`, `y`, `z` the x, y and z coordinates of a set of points. Both y and z can be left at `NULL`. In this case, an attempt is made to interpret x in a way suitable for plotting.

  If the argument is a formula `zvar ~ xvar + yvar`, `xvar`, `yvar`, `zvar` are used as x, y and z variables; if the argument is a list containing components `x`, `y` and `z`, these are assumed to define plotting coordinates; if the argument is a matrix or `data.frame` with three or more columns, the first is assumed to contain the x values, the 2nd the y ones, and the 3rd the z ones – independently of any column names that x may have.

  Alternatively two arguments `x` and `y` can be provided (leaving `z = NULL`). One may be real, the other complex; in any other case, the arguments are coerced to vectors and the values plotted against their indices.

- `xlab`, `ylab`, `zlab` names for the x, y and z variables to be extracted.

- `log` character, "x", "y", "z" or combinations. Sets negative values to `NA` and gives a warning.

- `recycle` logical; if TRUE, recycle (`rep`) the shorter ones of `x`, `y` or `z` if their lengths differ.

Value

A list with the components

- `x` numeric (i.e., `double`) vector of abscissa values.
- `y` numeric vector of the same length as `x`.
- `z` numeric vector of the same length as `x`.
- `xlab` character(1) or `NULL`, the axis label of `x`.
- `ylab` character(1) or `NULL`, the axis label of `y`.
- `zlab` character(1) or `NULL`, the axis label of `z`.

abline

Add Straight Lines to a Plot

Description
This function adds one or more straight lines through the current plot.

Usage
`abline(a = NULL, b = NULL, h = NULL, v = NULL, reg = NULL, coef = NULL, untf = FALSE, ...)"
Arguments

- **a, b**
  the intercept and slope, single values.
- **untf**
  logical asking whether to *untransform*. See Details.
- **h**
  the y-value(s) for horizontal line(s).
- **v**
  the x-value(s) for vertical line(s).
- **coef**
  a vector of length two giving the intercept and slope.
- **reg**
  an object with a `coef` method. See Details.
- **...**
  graphical parameters such as `col`, `lty` and `lwd` (possibly as vectors: see Details) and the line characteristics `lend`, `ljoin` and `lmitre`.

Details

Typical usages are

- `abline(a, b, untf = FALSE, ...)`
- `abline(h=, untf = FALSE, ...)`
- `abline(v=, untf = FALSE, ...)`
- `abline(coef=, untf = FALSE, ...)`
- `abline(reg=, untf = FALSE, ...)`

The first form specifies the line in intercept/slope form (alternatively a can be specified on its own and is taken to contain the slope and intercept in vector form).

The h= and v= forms draw horizontal and vertical lines at the specified coordinates.

The coef form specifies the line by a vector containing the slope and intercept.

reg is a regression object with a `coef` method. If this returns a vector of length 1 then the value is taken to be the slope of a line through the origin, otherwise, the first 2 values are taken to be the intercept and slope.

If `untf` is true, and one or both axes are log-transformed, then a curve is drawn corresponding to a line in original coordinates, otherwise a line is drawn in the transformed coordinate system. The h and v parameters always refer to original coordinates.

The graphical parameters `col`, `lty` and `lwd` can be specified; see `par` for details. For the h= and v= usages they can be vectors of length greater than one, recycled as necessary.

References

See Also

- `lines` and `segments` for connected and arbitrary lines given by their endpoints.
- `par`.

Examples

```r
## Setup up coordinate system (with x==y aspect ratio):
plot(c(-2,3), c(-1,5), type = "n", xlab="x", ylab="y", asp = 1)
## the x- and y-axis, and an integer grid
abline(h=0, v=0, col = "gray60")
text(1,0, "abline( h = 0 )", col = "gray60", adj = c(0, -.1))
```
arrows

### Simple Regression Lines:

```
sale5 <- c(6, 4, 9, 7, 6, 12, 8, 10, 9, 13)
plot(sale5)
abline(lsfit(1:10,sale5))
abline(lsfit(1:10,sale5, intercept = FALSE), col= 4) # less fitting
```

```
z <- lm(dist ~ speed, data = cars)
plot(cars)
abline(z) # equivalent to abline(reg = z) or
           abline(coef = coef(z))
```

```
## trivial intercept model
abline(mC <- lm(dist ~ 1, data = cars)) ## the same as
abline(a = coef(mC), b = 0, col = "blue")
```

---

**arrows**

*Add Arrows to a Plot*

**Description**

Draw arrows between pairs of points.

**Usage**

```r
arrows(x0, y0, x1, y1, length = 0.25, angle = 30, code = 2, col = par("fg"), lty = par("lty"), lwd = par("lwd"), ...)
```

**Arguments**

- `x0, y0`: coordinates of points from which to draw.
- `x1, y1`: coordinates of points to which to draw.
- `length`: length of the edges of the arrow head (in inches).
- `angle`: angle from the shaft of the arrow to the edge of the arrow head.
- `code`: integer code, determining kind of arrows to be drawn.
- `col, lty, lwd`: graphical parameters, possible vectors. NA values in `col` cause the arrow to be omitted.
- `...`: graphical parameters such as `xpd` and the line characteristics `lend`, `ljoin` and `lmitre`: see `par`.
Details

For each $i$, an arrow is drawn between the point $(x0[i], y0[i])$ and the point $(x1[i], y1[i])$.

If `code=1` an arrowhead is drawn at $(x0[i], y0[i])$ and if `code=2` an arrowhead is drawn at $(x1[i], y1[i])$. If `code=3` a head is drawn at both ends of the arrow. Unless `length = 0`, when no head is drawn.

The graphical parameters `col`, `lty` and `lwd` can be vectors of length greater than one and will be recycled if necessary.

The direction of a zero-length arrow is indeterminate, and hence so is the direction of the arrowheads. To allow for rounding error, arrowheads are omitted (with a warning) on any arrow of length less than $1/1000$ inch.

Note

The first four arguments in the comparable S function are named `x1, y1, x2, y2`.

References

See Also

`segments` to draw segments.

Examples

```r
x <- runif(12); y <- rnorm(12)
i <- order(x, y); x <- x[i]; y <- y[i]
plot(x, y, main="arrows(.) and segments(.)")
## draw arrows from point to point :
s <- seq(length(x)-1)# one shorter than data
arrows(x[s], y[s], x[s+1], y[s+1], col= 1:3)
s <- s[-length(s)]
segments(x[s], y[s], x[s+2], y[s+2], col= 'pink')
```

assocplot

**Association Plots**

**Description**

Produce a Cohen-Friendly association plot indicating deviations from independence of rows and columns in a 2-dimensional contingency table.

**Usage**

```r
assocplot(x, col = c("black", "red"), space = 0.3,
         main = NULL, xlab = NULL, ylab = NULL)
```
assocplot

Arguments

- `x` a two-dimensional contingency table in matrix form.
- `col` a character vector of length two giving the colors used for drawing positive and negative Pearson residuals, respectively.
- `space` the amount of space (as a fraction of the average rectangle width and height) left between each rectangle.
- `main` overall title for the plot.
- `xlab` a label for the x axis. Defaults to the name (if any) of the row dimension in `x`.
- `ylab` a label for the y axis. Defaults to the name (if any) of the column dimension in `x`.

Details

For a two-way contingency table, the signed contribution to Pearson’s $\chi^2$ for cell $i,j$ is $d_{ij} = (f_{ij} - e_{ij})/\sqrt{e_{ij}}$, where $f_{ij}$ and $e_{ij}$ are the observed and expected counts corresponding to the cell. In the Cohen-Friendly association plot, each cell is represented by a rectangle that has (signed) height proportional to $d_{ij}$ and width proportional to $\sqrt{e_{ij}}$, so that the area of the box is proportional to the difference in observed and expected frequencies. The rectangles in each row are positioned relative to a baseline indicating independence ($d_{ij} = 0$). If the observed frequency of a cell is greater than the expected one, the box rises above the baseline and is shaded in the color specified by the first element of `col`, which defaults to black; otherwise, the box falls below the baseline and is shaded in the color specified by the second element of `col`, which defaults to red.

A more flexible and extensible implementation of association plots written in the grid graphics system is provided in the function `assoc` in the contributed package `vcd` (Meyer, Zeileis and Hornik, 2005).

## Aggregate over sex:
x <- margin.table(HairEyeColor, c(1, 2))
x
assocplot(x, main = "Relation between hair and eye color")
```
Description

Generic function to add a suitable axis to the current plot.

Usage

Axis(x = NULL, at = NULL, ..., side, labels = NULL)

Arguments

x an object which indicates the range over which an axis should be drawn
at the points at which tick-marks are to be drawn.
side an integer specifying which side of the plot the axis is to be drawn on. The axis is placed as follows: 1=below, 2=left, 3=above and 4=right.
labels this can either be a logical value specifying whether (numerical) annotations are to be made at the tickmarks, or a character or expression vector of labels to be placed at the tickpoints. If this is specified as a character or expression vector, at should be supplied and they should be the same length.

... Arguments to be passed to methods and perhaps then to axis.

Details

This is a generic function. It works in a slightly non-standard way: if x is supplied and non-NULL it dispatches on x, otherwise if at is supplied and non-NULL it dispatches on at, and the default action is to call axis, omitting argument x.

The idea is that for plots for which either or both of the axes are numerical but with a special interpretation, the standard plotting functions (including boxplot, contour, coplot, filled.contour, pairs, plot.default, rug and stripchart) will set up user coordinates and Axis will be called to label them appropriately.

There are "Date", "POSIXct" and "POSIXlt" methods which can pass an argument format onto the appropriate axis method.

Value

The numeric locations on the axis scale at which tick marks were drawn when the plot was first drawn (see Details).

This function is usually invoked for its side effect, which is to add an axis to an already existing plot.

See Also

axis.
Description

Adds an axis to the current plot, allowing the specification of the side, position, labels, and other options.

Usage

```r
axis(side, at = NULL, labels = TRUE, tick = TRUE, line = NA,
     pos = NA, outer = FALSE, font = NA,
     lty = "solid", lwd = 1, col = NULL, hadj = NA, padj = NA,
     ...)```

Arguments

- `side`: an integer specifying which side of the plot the axis is to be drawn on. The axis is placed as follows: 1=below, 2=left, 3=above and 4=right.
- `at`: the points at which tick-marks are to be drawn. Non-finite (infinite, NaN or NA) values are omitted. By default, when NULL, tickmark locations are computed, see Details below.
- `labels`: this can either be a logical value specifying whether (numerical) annotations are to be made at the tickmarks, or a character or expression vector of labels to be placed at the tickpoints. (Other objects are coerced by `as.graphicsAnnot`.)
  If this is not logical, `at` should also be supplied and of the same length. If `labels` is of length zero after coercion, it has the same effect as supplying TRUE.
- `tick`: a logical value specifying whether tickmarks and an axis line should be drawn.
- `line`: the number of lines into the margin which the axis will be drawn. If not NA this overrides the value of the graphical parameter `mgp[3]`. The relative placing of tickmarks and tick labels is unchanged.
- `pos`: the coordinate at which the axis line is to be drawn: if not NA this overrides the values of both `line` and `mgp[3].`
- `outer`: a logical value indicating whether the axis should be drawn in the outer plot margin, rather than the standard plot margin.
- `font`: font for text. Defaults to `par("font").`
- `lty, lwd`: line type, width for the axis line and the tick marks.
- `col`: color for the axis line and the tick marks. Here NULL means to use `par("fg")`, possibly specified inline.
- `hadj`: adjustment (see `par("adj").`) for all labels parallel (`"horizontal"`) to the reading direction. If this is not a finite value, the default is used (centering for strings parallel to the axis, justification of the end nearest the axis otherwise).
- `padj`: adjustment for each tick label perpendicular to the reading direction. For labels parallel to the axes, `padj=0` means right or top alignment, and `padj=1` means left or bottom alignment. This can be a vector given a value for each string, and will be recycled as necessary.
If `padj` is not a finite value (the default), the value of `par("las")` determines the adjustment. For strings plotted perpendicular to the axis the default is to centre the string.

... other graphical parameters may also be passed as arguments to this function, particularly, `cex.axis`, `col.axis` and `font.axis` for axis annotation, `mgp` and `xaxp` or `yaxp` for positioning, `tck` or `tcl` for tick mark length and direction, `las` for vertical/horizontal label orientation, or `fg` instead of `col`, see `par` on these.

Parameters `xaxt` (sides 1 and 3) and `yaxt` (sides 2 and 4) control if the axis is plotted at all.

Note that `xpd` is not accepted as clipping is always to the device region, and that `lab` will partial match to argument `labels` unless the latter is also supplied. (Since the default axes has already been set up by `plot.window`, `lab` will not be acted on by `axis`.)

Details

The axis line is drawn from the lowest to the highest value of `at`, but will be clipped at the plot region. Only ticks which are drawn from points within the plot region (up to a tolerance for rounding error) are plotted, but the ticks and their labels may well extend outside the plot region.

When `at = NULL`, pretty tick mark locations are computed internally (the same way `axTicks(side)` would) from `par("xaxp")` or `"yaxp"` and `par("xlog")` (or `"ylog"`). Note that these locations may change if an on-screen plot is resized (for example, if the `plot` argument `asp` (see `plot.window`) is set.)

If `labels` is not specified, the numeric values supplied or calculated for `at` are converted to character strings as if they were a numeric vector printed by `print.default` (`digits=7`).

The code tries hard not to draw overlapping tick labels, and so will omit labels where they would abut or overlap previously drawn labels. This can result in, for example, every other tick being labelled. (The ticks are drawn left to right or bottom to top, and space at least the size of an ‘m’ is left between labels.)

Several of the graphics parameters affect the way axes are drawn. The vertical (for sides 1 and 3) positions of the axis and the tick labels are controlled by `mgp`, the size and direction of the ticks is controlled by `tck` and `tcl` and the appearance of the tick labels by `cex.axis`, `col.axis` and `font.axis` with orientation controlled by `las` (but not `srt`, unlike S which uses `srt` if `at` is supplied and `las` if it is not). Note that `adj` is not supported. See `par` for details.

Value

The numeric locations on the axis scale at which tick marks were drawn when the plot was first drawn (see Details).

This function is usually invoked for its side effect, which is to add an axis to an already existing plot.

References

See Also

Axis for a generic interface.

axTicks returns the axis tick locations corresponding to at=NULL; pretty is more flexible for computing pretty tick coordinates and does not depend on (nor adapt to) the coordinate system in use.

Several graphics parameters affecting the appearance are documented in par.

Examples

```r
plot(1:4, rnorm(4), axes = FALSE)
axis(1, 1:4, LETTERS[1:4])
axis(2)
box() # to make it look "as usual"

plot(1:7, rnorm(7), main = "axis() examples",
    type = "s", xaxt = "n", frame = FALSE, col = "red")
axis(1, 1:7, LETTERS[1:7], col.axis = "blue")
# unusual options:
axis(4, col = "violet", col.axis="dark violet", lwd = 2)
axis(3, col = "gold", lty = 2, lwd = 0.5)

# one way to have a custom x axis
plot(1:10, xaxt = "n")
axis(1, xaxp=c(2, 9, 7))
```

Date and Date-time Plotting Functions

Description

Functions to plot objects of classes "POSIXlt", "POSIXct" and "Date" representing calendar dates and times.

Usage

```r
axis.POSIXct(side, x, at, format, labels = TRUE, ...)
axis.Date(side, x, at, format, labels = TRUE, ...)
```

Arguments

- `x, at` A date-time or date object.
- `y` numeric values to be plotted against `x`.
- `xlab` a character string giving the label for the x axis.
- `side` See `axis`.
format

See `strptime`.

labels

Either a logical value specifying whether annotations are to be made at the tickmarks, or a vector of character strings to be placed at the tickpoints.

Further arguments to be passed from or to other methods, typically graphical parameters or arguments of `plot.default`. For the plot methods, also `format`.

Details

The functions plot against an x-axis of date-times. `axis.POSIXct` and `axis.Date` work quite hard to choose suitable time units (years, months, days, hours, minutes or seconds) and a sensible output format, but this can be overridden by supplying a `format` specification.

If `at` is supplied it specifies the locations of the ticks and labels whereas if `x` is specified a suitable grid of labels is chosen. Printing of tick labels can be suppressed by using `labels = FALSE`.

Value

The locations on the axis scale at which tick marks were drawn.

See Also

`DateTimeClasses`, `Dates` for details of the classes.

Examples

```r
with(beaver1, {
  time <- strptime(paste(1990, day, time %/% 100, time %% 100),
                   "%Y %j %H %M")
  plot(time, temp, type="l") # axis at 4-hour intervals.
  # now label every hour on the time axis
  plot(time, temp, type="l", xaxt="n")
  r <- as.POSIXct(round(range(time), "hours"))
  axis.POSIXct(1, at=seq(r[1], r[2], by="hour"), format="%H")
})

plot(.leap.seconds, 1:23, type="n", yaxt="n",
     xlab="leap seconds", ylab="", bty="n")
  rug(.leap.seconds)
  ## or as dates
  lps <- as.Date(.leap.seconds)
  plot(lps, 1:23, type="n", yaxt="n", xlab="leap seconds", ylab="", bty="n")
  rug(lps)

  ## 100 random dates in a 10-week period
  random.dates <- as.Date("2001/1/1") + 70*sort(runif(100))
  plot(random.dates, 1:100)
  # or for a better axis labelling
  plot(random.dates, 1:100, xaxt="n")
  axis.Date(1, at=seq(as.Date("2001/1/1"), max(random.dates)+6, "weeks"))
  axis.Date(1, at=seq(as.Date("2001/1/1"), max(random.dates)+6, "days"),
            labels = FALSE, tcl = -0.2)
```
axTicks

Compute Axis Tickmark Locations

Description

Compute pretty tickmark locations, the same way as R does internally. This is only non-trivial when log coordinates are active. By default, gives the at values which axis(side) would use.

Usage

axTicks(side, axp = NULL, usr = NULL, log = NULL)

Arguments

side  integer in 1:4, as for axis.
axp   numeric vector of length three, defaulting to par("Zaxp") where “Z” is “x” or “y” depending on the side argument.
usr   numeric vector of length four, defaulting to par("usr") giving horizontal (’x’) and vertical (’y’) user coordinate limits.
log   logical indicating if log coordinates are active; defaults to par("Zlog") where ‘Z’ is as for the axp argument above.

Details

The axp, usr, and log arguments must be consistent as their default values (the par(.) results) are. If you specify all three (as non-NULL), the graphics environment is not used at all. Note that the meaning of axp alters very much when log is TRUE, see the documentation on par(xaxp=.).

axTicks() can be regarded as an R implementation of the C function CreateAtVector() in ‘.../src/main/plot.c’ which is called by axis(side, *) when no argument at is specified.

Value

numeric vector of coordinate values at which axis tickmarks can be drawn. By default, when only the first argument is specified, these values should be identical to those that axis(side) would use or has used.

See Also

axis, par. pretty uses the same algorithm (but independently of the graphics environment) and has more options. However it is not available for log = TRUE.

Examples

plot(1:7, 10*21:27)
axTicks(1)
axTicks(2)
stopifnot(identical(axTicks(1), axTicks(3)),
          identical(axTicks(2), axTicks(4)))

## Show how axTicks() and axis() correspond:

```r
```
Bar Plots

Description

Creates a bar plot with vertical or horizontal bars.

Usage

barplot(height, ...)

## Default S3 method:
barplot(height, width = 1, space = NULL,
        names.arg = NULL, legend.text = NULL, beside = FALSE,
        horiz = FALSE, density = NULL, angle = 45,
        col = NULL, border = par("fg"),
        main = NULL, sub = NULL, xlab = NULL, ylab = NULL,
        xlim = NULL, ylim = NULL, xpd = TRUE, log = "",
        axes = TRUE, axisnames = TRUE,
        cex.axis = par("cex.axis"), cex.names = par("cex.axis"),
        inside = TRUE, plot = TRUE, axis.lty = 0, offset = 0,
        add = FALSE, ...)

Arguments

height either a vector or matrix of values describing the bars which make up the plot. If height is a vector, the plot consists of a sequence of rectangular bars with heights given by the values in the vector. If height is a matrix and beside is FALSE then each bar of the plot corresponds to a column of height, with the values in the column giving the heights of stacked “sub-bars” making up the bar. If height is a matrix and beside is TRUE, then the values in each column are juxtaposed rather than stacked.

width optional vector of bar widths. Re-cycled to length the number of bars drawn. Specifying a single value will no visible effect unless xlim is specified.

space the amount of space (as a fraction of the average bar width) left before each bar. May be given as a single number or one number per bar. If height is a matrix and beside is TRUE, space may be specified by two numbers, where the first is the space between bars in the same group, and the second the space between the groups. If not given explicitly, it defaults to c(0,1) if height is a matrix and beside is TRUE, and to 0.2 otherwise.

names.arg a vector of names to be plotted below each bar or group of bars. If this argument is omitted, then the names are taken from the names attribute of height if this is a vector, or the column names if it is a matrix.
legend.text  a vector of text used to construct a legend for the plot, or a logical indicating whether a legend should be included. This is only useful when height is a matrix. In that case given legend labels should correspond to the rows of height; if legend.text is true, the row names of height will be used as labels if they are non-null.

beside  a logical value. If FALSE, the columns of height are portrayed as stacked bars, and if TRUE the columns are portrayed as juxtaposed bars.

horiz  a logical value. If FALSE, the bars are drawn vertically with the first bar to the left. If TRUE, the bars are drawn horizontally with the first at the bottom.

density  a vector giving the density of shading lines, in lines per inch, for the bars or bar components. The default value of NULL means that no shading lines are drawn. Non-positive values of density also inhibit the drawing of shading lines.

angle  the slope of shading lines, given as an angle in degrees (counter-clockwise), for the bars or bar components.

col  a vector of colors for the bars or bar components. By default, grey is used if height is a vector, and a gamma-corrected grey palette if height is a matrix.

border  the color to be used for the border of the bars. Use border = NA to omit borders. If there are shading lines, border = TRUE means use the same colour for the border as for the shading lines.

main, sub  overall and sub title for the plot.

xlab  a label for the x axis.

ylab  a label for the y axis.

xlim  limits for the x axis.

ylim  limits for the y axis.

xpd  logical. Should bars be allowed to go outside region?

log  string specifying if axis scales should be logarithmic; see plot.default.

axes  logical. If TRUE, a vertical (or horizontal, if horiz is true) axis is drawn.

axisnames  logical. If TRUE, and if there are names.arg (see above), the other axis is drawn (with lty=0) and labeled.

cex.axis  expansion factor for numeric axis labels.

cex.names  expansion factor for axis names (bar labels).

inside  logical. If TRUE, the lines which divide adjacent (non-stacked!) bars will be drawn. Only applies when space = 0 (which it partly is when beside = TRUE).

plot  logical. If FALSE, nothing is plotted.

axis.lty  the graphics parameter lty applied to the axis and tick marks of the categorical (default horizontal) axis. Note that by default the axis is suppressed.

offset  a vector indicating how much the bars should be shifted relative to the x axis.

add  logical specifying if bars should be added to an already existing plot; defaults to FALSE.

...  arguments to be passed to/from other methods. For the default method these can include further arguments (such as axes, asp and main) and graphical parameters (see par) which are passed to plot.window(), title() and axis.
Details

This is a generic function, it currently only has a default method. A formula interface may be added eventually.

Value

A numeric vector (or matrix, when \texttt{beside = TRUE}), say \texttt{mp}, giving the coordinates of all the bar midpoints drawn, useful for adding to the graph.

If \texttt{beside} is true, use \texttt{colMeans(mp)} for the midpoints of each group of bars, see example.

Examples

\begin{verbatim}
tN <- table(Ni <- rpois(100, lambda=5))
r <- barplot(tN, col=rainbow(20))
#- type = "h" plotting *is* 'bar'plot
lines(r, tN, type='h', col='red', lwd=2)

barplot(tN, space = 1.5, axisnames=FALSE,
       sub = "barplot(..., space= 1.5, axisnames = FALSE)"
)

barplot(VADeaths, plot = FALSE)
barplot(VADeaths, plot = FALSE, beside = TRUE)

mp <- barplot(VADeaths) # default
tot <- colMeans(VADeaths)
text(mp, tot + 3, format(tot), xpd = TRUE, col = "blue")
barplot(VADeaths, beside = TRUE,
         col = c("lightblue", "mistyrose", "lightcyan",
                "lavender", "cornsilk"),
         legend = rownames(VADeaths), ylim = c(0, 100))
title(main = "Death Rates in Virginia", font.main = 4)

hh <- t(VADeaths)[, 5:1]
mybarcol <- "gray20"
mp <- barplot(hh, beside = TRUE,
              col = c("lightblue", "mistyrose",
                     "lightcyan", "lavender"),
              legend = colnames(VADeaths), ylim= c(0,100),
              main = "Death Rates in Virginia", font.main = 4,
              sub = "Faked upper 2*sigma error bars", col.sub = mybarcol,
              cex.names = 1.5)
segments(mp, hh, mp, hh + 2*sqrt(1000*hh/100), col = mybarcol, lwd = 1.5)
stopifnot(dim(mp) == dim(hh))# corresponding matrices
mtext(side = 1, at = colMeans(mp), line = -2,
       text = paste("Mean", formatC(colMeans(hh))), col = "red")
\end{verbatim}
# Bar shading example

```r
code
barplot(VADeaths, angle = 15+10*1:5, density = 20, col = "black",
        legend = rownames(VADeaths))
title(main = list("Death Rates in Virginia", font = 4))
```

# border:

```r
code
barplot(VADeaths, border = "dark blue")
```

# log scales (not much sense here):

```r
code
barplot(tN, col=heat.colors(12), log = "y")
barplot(tN, col=gray.colors(20), log = "xy")
```

---

**box**  
*Draw a Box around a Plot*

**Description**

This function draws a box around the current plot in the given color and linetype. The `bty` parameter determines the type of box drawn. See `par` for details.

**Usage**

```r
code
box(which = "plot", lty = "solid", ...)
```

**Arguments**

- `which` character, one of "plot", "figure", "inner" and "outer".
- `lty` line type of the box.
- `...` further graphical parameters, such as `bty`, `col`, or `lwd`, see `par`. Note that `xpd` is not accepted as clipping is always to the device region.

**Details**

The choice of colour is complicated. If `col` was supplied and is not `NA`, it is used. Otherwise, if `fg` was supplied and is not `NA`, it is used. The final default is `par("col")`.

**References**

**See Also**

`rect` for drawing of arbitrary rectangles.

**Examples**

```r
code
plot(1:7, abs(rnorm(7)), type = 'h', axes = FALSE)
axis(1, at = 1:7, labels = letters[1:7])
box(lty = '1373', col = 'red')
```
**Description**

Produce box-and-whisker plot(s) of the given (grouped) values.

**Usage**

```r
boxplot(x, 
## S3 method for class 'formula':
boxplot(formula, data = NULL, ..., subset, na.action = NULL)
## Default S3 method:
boxplot(x, ..., range = 1.5, width = NULL, varwidth = FALSE, 
notch = FALSE, outline = TRUE, names, plot = TRUE, 
border = par("fg"), col = NULL, log = ",", 
pars = list(boxwex = 0.8, staplewex = 0.5, outwex = 0.5), 
horizontal = FALSE, add = FALSE, at = NULL)
```

**Arguments**

- `formula` a formula, such as `y ~ grp`, where `y` is a numeric vector of data values to be split into groups according to the grouping variable `grp` (usually a factor).
- `data` a data.frame (or list) from which the variables in `formula` should be taken.
- `subset` an optional vector specifying a subset of observations to be used for plotting.
- `na.action` a function which indicates what should happen when the data contain NAs. The default is to ignore missing values in either the response or the group.
- `x` for specifying data from which the boxplots are to be produced. Either a numeric vector, or a single list containing such vectors. Additional unnamed arguments specify further data as separate vectors (each corresponding to a component boxplot). NAs are allowed in the data.
- `...` For the `formula` method, named arguments to be passed to the default method. For the default method, unnamed arguments are additional data vectors (unless `x` is a list when they are ignored), and named arguments are arguments and graphical parameters to be passed to `bxp` in addition to the ones given by argument `pars` (and override those in `pars`).
- `range` this determines how far the plot whiskers extend out from the box. If `range` is positive, the whiskers extend to the most extreme data point which is no more than `range` times the interquartile range from the box. A value of zero causes the whiskers to extend to the data extremes.
- `width` a vector giving the relative widths of the boxes making up the plot.
- `varwidth` if `varwidth` is TRUE, the boxes are drawn with widths proportional to the square-roots of the number of observations in the groups.
- `notch` if `notch` is TRUE, a notch is drawn in each side of the boxes. If the notches of two plots do not overlap this is ‘strong evidence’ that the two medians differ (Chambers et al., 1983, p. 62). See `boxplot.stats` for the calculations used.
The generic function `boxplot` currently has a default method (`boxplot.default`) and a formula interface (`boxplot.formula`).

If multiple groups are supplied either as multiple arguments or via a formula, parallel boxplots will be plotted, in the order of the arguments or the order of the levels of the factor (see `factor`).

Missing values are ignored when forming boxplots.

**Details**

The generic function `boxplot` currently has a default method (`boxplot.default`) and a formula interface (`boxplot.formula`).

If multiple groups are supplied either as multiple arguments or via a formula, parallel boxplots will be plotted, in the order of the arguments or the order of the levels of the factor (see `factor`).

Missing values are ignored when forming boxplots.

**Value**

List with the following components:

- `stats` a matrix, each column contains the extreme of the lower whisker, the lower hinge, the median, the upper hinge and the extreme of the upper whisker for one group/plot. If all the inputs have the same class attribute, so will this component.
- `n` a vector with the number of observations in each group.
- `conf` a matrix where each column contains the lower and upper extremes of the notch.
- `out` the values of any data points which lie beyond the extremes of the whiskers.
- `group` a vector of the same length as `out` whose elements indicate to which group the outlier belongs.
- `names` a vector of names for the groups.
References

See also `boxplot.stats`.

See Also

`boxplot.stats` which does the computation, `bxp` for the plotting and more examples; and `stripchart` for an alternative (with small data sets).

Examples

```r
## boxplot on a formula:
boxplot(count ~ spray, data = InsectSprays, col = "lightgray")

# *add* notches (somewhat funny here):
boxplot(count ~ spray, data = InsectSprays,
notch = TRUE, add = TRUE, col = "blue")

boxplot(decrease ~ treatment, data = OrchardSprays,
log = "y", col = "bisque")

rb <- boxplot(decrease ~ treatment, data = OrchardSprays,
col = "bisque")
title("Comparing boxplot()s and non-robust mean +/- SD")

mn.t <- tapply(OrchardSprays$decrease, OrchardSprays$treatment, mean)
sd.t <- tapply(OrchardSprays$decrease, OrchardSprays$treatment, sd)
xi <- 0.3 + seq(rb$n)
points(xi, mn.t, col = "orange", pch = 18)
arrows(xi, mn.t - sd.t, xi, mn.t + sd.t,
code = 3, col = "pink", angle = 75, length = .1)

## boxplot on a matrix:
mat <- cbind(Uni05 = (1:100)/21, Norm = rnorm(100),
T5 = rt(100, df = 5), Gam2 = rgamma(100, shape = 2))
boxplot(data.frame(mat), main = "boxplot(data.frame(mat), main = ...)"
par(las=1)# all axis labels horizontal
boxplot(data.frame(mat), main = "boxplot(*, horizontal = TRUE)",
horizontal = TRUE)

## Using 'at = ' and adding boxplots -- example idea by Roger Bivand:
boxplot(len ~ dose, data = ToothGrowth,
boxwex = 0.25, at = 1:3 - 0.2,
subset = supp == "VC", col = "yellow",
main = "Guinea Pigs' Tooth Growth",
xlab = "Vitamin C dose mg",
ylab = "tooth length", ylim = c(0, 35), yaxs = "i")
boxplot(len ~ dose, data = ToothGrowth, add = TRUE,
boxwex = 0.25, at = 1:3 + 0.2,
subset = supp == "OJ", col = "orange")
legend(2, 9, c("Ascorbic acid", "Orange juice"),
fill = c("yellow", "orange"))
```
## more examples in help(bxp)

### bxp

**Draw Box Plots from Summaries**

**Description**

`bxp` draws box plots based on the given summaries in `z`. It is usually called from within `boxplot`, but can be invoked directly.

**Usage**

```r
bxp(z, notch = FALSE, width = NULL, varwidth = FALSE,
    outline = TRUE, notch.frac = 0.5, log = "", border = par("fg"),
    pars = NULL, frame.plot = axes, horizontal = FALSE, add = FALSE,
    at = NULL, show.names = NULL, 
    ...)
```

**Arguments**

- `z` a list containing data summaries to be used in constructing the plots. These are usually the result of a call to `boxplot`, but can be generated in any fashion.
- `notch` if `notch` is `TRUE`, a notch is drawn in each side of the boxes. If the notches of two plots do not overlap then the medians are significantly different at the 5 percent level.
- `width` a vector giving the relative widths of the boxes making up the plot.
- `varwidth` if `varwidth` is `TRUE`, the boxes are drawn with widths proportional to the square-roots of the number of observations in the groups.
- `outline` if `outline` is not `true`, the outliers are not drawn.
- `notch.frac` numeric in (0,1). When `notch=TRUE`, the fraction of the box width that the notches should use.
- `border` character or numeric (vector), the color of the box borders. Is recycled for multiple boxes. Is used as default for the `boxcol`, `medcol`, `whiskcol`, `staplecol`, and `outcol` options (see below).
- `log` character, indicating if any axis should be drawn in logarithmic scale, as in `plot.default`.
- `frame.plot` logical, indicating if a "frame" (box) should be drawn; defaults to `TRUE`, unless `axes = FALSE` is specified.
- `horizontal` logical indicating if the boxplots should be horizontal; default `FALSE` means vertical boxes.
- `add` logical, if true `add` boxplot to current plot.
- `at` numeric vector giving the locations where the boxplots should be drawn, particularly when `add = TRUE`; defaults to `1:n` where `n` is the number of boxes.
- `show.names` Set to `TRUE` or `FALSE` to override the defaults on whether an x-axis label is printed for each group.
graphical parameters (etc) can be passed as arguments to this function, either as a list (pars) or normally(...), see the following. (Those in ... take precedence over those in pars.)

Currently, yaxs and ylim are used 'along the boxplot', i.e., vertically, when horizontal is false. xaxt, yaxt, las, cex.axis, and col.axis are passed to axis, and main, cex.main, col.main, sub, cex.sub, col.sub, xlab, ylab, cex.lab, and col.lab are passed to title.

In addition, axes is accepted (see plot.window), with default TRUE.

The following arguments (or pars components) allow further customization of the boxplot graphics. Their defaults are typically determined from the non-prefixed version (e.g., boxlty from lty), either from the specified argument or pars component or the corresponding par one.

boxwex: a scale factor to be applied to all boxes. When there are only a few groups, the appearance of the plot can be improved by making the boxes narrower.

staplewex, outwex: staple and outlier line width expansion, proportional to box width.

boxlty, boxlwd, boxcol, boxfill: box outline type, width, color, and fill color (which currently defaults to col and will in future default to par("bg")).

medlty, medlwd, medpch, medcex, medcol, medbg: median line type, line width, point character, point size expansion, color, and background color. The default medpch=NA suppresses the point, and medlty="blank" does so for the line. Note that medlwd defaults to 3× the "default" lwd.

whisklty, whisklwd, whiskcol: whisker line type, width, and color.

stapletlty, staplelwd, staplecol: staple (= end of whisker) line type, width, and color.

outlty, outlwd, outpch, outcex, outcol, outbg: outlier line type, line width, point character, point size expansion, color, and background color. The default outlty= "blank" suppresses the lines and outpch=NA suppresses points.

Value

An invisible vector, actually identical to the at argument, with the coordinates ("x" if horizontal is false, "y" otherwise) of box centers, useful for adding to the plot.

Author(s)

The R Core development team and Arni Magnusson (arnima@u.washington.edu) who has provided most changes for the box*, med*, whisk*, staple*, and out* arguments.

**cdplot**

### Conditional Density Plots

**Description**

Computes and plots conditional densities describing how the conditional distribution of a categorical variable y changes over a numerical variable x.

**Usage**

```r
cdplot(x, ...)```

## Default S3 method:
```
cdplot(x, y, 
```
cdplot

plot = TRUE, tol.ylab = 0.05,
bw = "nrd0", n = 512, from = NULL, to = NULL,
col = NULL, border = 1, main = "", xlab = NULL, ylab = NULL,
yaxlabels = NULL, xlim = NULL, ylim = c(0, 1), ...)

## S3 method for class 'formula':
cdplot(formula, data = list(),
plot = TRUE, tol.ylab = 0.05,
bw = "nrd0", n = 512, from = NULL, to = NULL,
col = NULL, border = 1, main = "", xlab = NULL, ylab = NULL,
yaxlabels = NULL, xlim = NULL, ylim = c(0, 1), ..., 
subset = NULL)

Arguments

x

an object, the default method expects either a single numerical variable.

y

a "factor" interpreted to be the dependent variable

formula

a "formula" of type y ~ x with a single dependent "factor" and a single
numerical explanatory variable.

data

an optional data frame.

plot

logical. Should the computed conditional densities be plotted?

tol.ylab

convenience tolerance parameter for y-axis annotation. If the distance between
two labels drops under this threshold, they are plotted equidistantly.

bw, n, from, to, ...

arguments passed to density

col

a vector of fill colors of the same length as levels(y). The default is to call
gray.colors.

border

border color of shaded polygons.

main, xlab, ylab

character strings for annotation

yaxlabels

character vector for annotation of y axis, defaults to levels(y).

xlim, ylim

the range of x and y values with sensible defaults.

subset

an optional vector specifying a subset of observations to be used for plotting.

Details
cdplot computes the conditional densities of x given the levels of y weighted by the marginal
distribution of y. The densities are derived cumulatively over the levels of y.

This visualization technique is similar to spinograms (see spineplot) and plots P(y|x) against
x. The conditional probabilities are not derived by discretization (as in the spinogram), but using a
smoothing approach via density.

Note, that the estimates of the conditional densities are more reliable for high-density regions of x.
Conversely, the are less reliable in regions with only few x observations.

Value

The conditional density functions (cumulative over the levels of y) are returned invisibly.

contour

Display Contours

Description

Create a contour plot, or add contour lines to an existing plot.

Usage

contour(x, ...)

## Default S3 method:
contour(x = seq(0, 1, len = nrow(z)),
y = seq(0, 1, len = ncol(z)),
z,
levels = 10, levels = pretty(zlim, nlevels), labels = NULL,
xlim = range(x, finite = TRUE),
ylim = range(y, finite = TRUE),
zlim = range(z, finite = TRUE),
\texttt{labcex = 0.6, drawlabels = TRUE, method = "flattest", vfont = c("sans serif", "plain"), axes = TRUE, frame.plot = axes, col = par("fg"), lty = par("lty"), lwd = par("lwd"), add = FALSE, ...}

\textbf{Arguments}

\begin{itemize}
  \item \texttt{x, y} locations of grid lines at which the values in \texttt{z} are measured. These must be in ascending order. By default, equally spaced values from 0 to 1 are used. If \texttt{x} is a list, its components \texttt{x$x} and \texttt{x$y} are used for \texttt{x} and \texttt{y}, respectively. If the list has component \texttt{z} this is used for \texttt{z}.
  \item \texttt{z} a matrix containing the values to be plotted (\texttt{NAs} are allowed). Note that \texttt{x} can be used instead of \texttt{z} for convenience.
  \item \texttt{nlevels} number of contour levels desired if \texttt{levels} is not supplied.
  \item \texttt{levels} numeric vector of levels at which to draw contour lines.
  \item \texttt{labels} a vector giving the labels for the contour lines. If \texttt{NULL} then the levels are used as labels, otherwise this is coerced by \texttt{as.character}.
  \item \texttt{labcex} \texttt{cex} for contour labelling. This is an absolute size, not a multiple of \texttt{par("cex")}.
  \item \texttt{drawlabels} logical. Contours are labelled if \texttt{TRUE}.
  \item \texttt{method} character string specifying where the labels will be located. Possible values are "simple", "edge" and "flattest" (the default). See the \textbf{Details} section.
  \item \texttt{vfont} if a character vector of length 2 is specified, then Hershey vector fonts are used for the contour labels. The first element of the vector selects a typeface and the second element selects a fontindex (see \texttt{text} for more information).
  \item \texttt{xlim, ylim, zlim} \texttt{x}, \texttt{y} and \texttt{z}-limits for the plot.
  \item \texttt{axes, frame.plot} logical indicating whether axes or a box should be drawn, see \texttt{plot.default}.
  \item \texttt{col} color for the lines drawn.
  \item \texttt{lty} line type for the lines drawn.
  \item \texttt{lwd} line width for the lines drawn.
  \item \texttt{add} logical. If \texttt{TRUE}, add to a current plot.
\end{itemize}

\textbf{Details}

\texttt{contour} is a generic function with only a default method in base \texttt{R}.

The methods for positioning the labels on contours are "simple" (draw at the edge of the plot, overlaying the contour line), "edge" (draw at the edge of the plot, embedded in the contour line, with no labels overlapping) and "flattest" (draw on the flattest section of the contour, embedded in the contour line, with no labels overlapping). The second and third may not draw a label on every contour line.

For information about vector fonts, see the help for \texttt{text} and \texttt{Hershey}.
Notice that `contour` interprets the z matrix as a table of \( f(x[i], y[j]) \) values, so that the x axis corresponds to row number and the y axis to column number, with column 1 at the bottom, i.e. a 90 degree clockwise rotation of the conventional textual layout.

Alternatively, use `contourplot` from the `lattice` package where the `formula` notation allows to use vectors \( x, y, z \) of the same length.

There is limited control over the axes and frame as arguments `col`, `lwd` and `lty` refer to the contour lines (rather than being general graphical parameters). For more control, add contours to a plot, or add axes and frame to a contour plot.

**References**

**See Also**

`options`("max.countour.segments") for the maximal complexity of a single contour line.

`contourLines`, `filled.contour` for “color-filled” contours, `contourplot` (and `levelplot`) from package `lattice`. Further, `image` and the graphics demo which can be invoked as `demo(graphics)`.

**Examples**

```r
x <- -6:16
op <- par(mfrow = c(2, 2))
contour(outer(x, x), method = "edge", vfont = c("sans serif", "plain"))
z <- outer(x, sqrt(abs(x)), FUN = "/")
image(x, x, z)
contour(x, x, z, col = "pink", add = TRUE, method = "edge",
        vfont = c("sans serif", "plain"))
contour(x, x, z, ylim = c(1, 6), method = "simple", labcex = 1)
contour(x, x, z, ylim = c(-6, 6), nlev = 20, lty = 2, method = "simple")
par(op)

## Persian Rug Art:
x <- y <- seq(-4*pi, 4*pi, len = 27)
r <- sqrt(outer(x^2, y^2, "+"))
opar <- par(mfrow = c(2, 2), mar = rep(0, 4))
for(f in pi^(0:3))
  contour(cos(r^2)*exp(-r/f),
          drawlabels = FALSE, axes = FALSE, frame = TRUE)
rx <- range(x <- 10*1:nrow(volcano))
ry <- range(y <- 10*1:ncol(volcano))
ry <- ry + c(-1,1) * (diff(rx) - diff(ry))/2
tcol <- terrain.colors(12)
par(opar); opar <- par(pty = "s", bg = "lightcyan")
plot(x = 0, y = 0, type = "n", xlim = rx, ylim = ry, xlab = "", ylab = "")
u <- par("usr")
rect(u[1], u[3], u[2], u[4], col = tcol[8], border = "red")
contour(x, y, volcano, col = tcol[2], lty = "solid", add = TRUE,
        vfont = c("sans serif", "plain"))
title("A Topographic Map of Maunga Whau", font = 4)
abline(h = 200*0:4, v = 200*0:4, col = "lightgray", lty = 2, lwd = 0.1)
```
## contourLines produces the same contour lines as contour

```r
coplot
line.list <- contourLines(x, y, volcano)
plot(x = 0, y = 0, type = "n", xlim = rx, ylim = ry, xlab = "", ylab = "")
u <- par("usr")
rect(u[1], u[3], u[2], u[4], col = tcol[8], border = "red")
contour(x, y, volcano, col = tcol[2], lty = "solid", add = TRUE,
vfont = c("sans serif", "plain"))
templines <- function(clines) {
  lines(clines[[2]], clines[[3]])
}
invisible(lapply(line.list, templines))
par(opar)
```

---

**coplot**

*Conditioning Plots*

### Description

This function produces two variants of the conditioning plots discussed in the reference below.

### Usage

```r
coplot(formula, data, given.values, panel = points, rows, columns, show.given = TRUE, col = par("fg"), pch = par("pch"), bar.bg = c(num = gray(0.8), fac = gray(0.95)), xlab = c(x.name, paste("Given ":, a.name)), ylab = c(y.name, paste("Given ":, b.name)), subscripts = FALSE, axlabels = function(f) abbreviate(levels(f)), number = 6, overlap = 0.5, xlim, ylim, ...)
```

### Arguments

- **formula**: a formula describing the form of conditioning plot. A formula of the form `y ~ x | a` indicates that plots of `y` versus `x` should be produced conditional on the variable `a`. A formula of the form `y ~ x | a * b` indicates that plots of `y` versus `x` should be produced conditional on the two variables `a` and `b`. All three or four variables may be either numeric or factors. When `x` or `y` are factors, the result is almost as if `as.numeric()` was applied, whereas for factor `a` or `b`, the conditioning (and its graphics if `show.given` is true) are adapted.
- **data**: a data frame containing values for any variables in the formula. By default the environment where `coplot` was called from is used.
- **given.values**: a value or list of two values which determine how the conditioning on `a` and `b` is to take place. When there is no `b` (i.e., conditioning only on `a`), usually this is a matrix with two columns each row of which gives an interval, to be conditioned on, but it can also be a single vector of numbers or a set of factor levels if the variable being conditioned on is a factor. In this case (no `b`), the result of `co.intervals` can be used directly as `given.values` argument.
- **panel**: a function to be used to draw each panel. By default, this is `plot()` with the `pch` and `col` options set to the current values of `par()`. `panel` is applied to the `panelArgs` argument.
- **rows**: the number of rows to use in displaying the conditioning plots. This may be set to `NULL` which leads to the use of an automatic layout.
- **columns**: the number of columns to use in displaying the conditioning plots. This may be set to `NULL` which leads to the use of an automatic layout.
- **show.given**: a logical value indicating whether or not to show the conditioning variables in the graph (if not `FALSE`).
- **col**: the color to use for plots. By default, this is the color in `par("fg")`.
- **pch**: the symbol to use for plots. By default, this is the symbol in `par("pch")`.
- **bar.bg**: a vector giving the color to use for the bars of the bar chart. The first color is used for the bars, the second for the background.
- **xlab**: a label for the x-axis.
- **ylab**: a label for the y-axis.
- **axlabels**: a function to be applied to each axis label to modify the labels.
- **number**: the number of classes to be used when a factor is conditioned on.
- **overlap**: the amount by which the bars overlap when conditioned on a factor.
- **xlim**, **ylim**: limits for the x and y axes.
- **...**: further arguments to be passed to `coplot`.

### Examples

```r
## Example usage

# Conditioning on a single factor
library(graphics)
co.intervals(x, number = 6, overlap = 0.5)
```
panel a function(x, y, col, pch, ...) which gives the action to be carried out in each panel of the display. The default is points.

rows the panels of the plot are laid out in a rows by columns array. rows gives the number of rows in the array.
columns the number of columns in the panel layout array.
show.given logical (possibly of length 2 for 2 conditioning variables): should conditioning plots be shown for the corresponding conditioning variables (default TRUE)
col a vector of colors to be used to plot the points. If too short, the values are recycled.
pch a vector of plotting symbols or characters. If too short, the values are recycled.
bar.bg a named vector with components "num" and "fac" giving the background colors for the (shingle) bars, for numeric and factor conditioning variables respectively.
xlab character; labels to use for the x axis and the first conditioning variable. If only one label is given, it is used for the x axis and the default label is used for the conditioning variable.
ylab character; labels to use for the y axis and any second conditioning variable.
subscripts logical: if true the panel function is given an additional (third) argument subscripts giving the subscripts of the data passed to that panel.
axlabels function for creating axis (tick) labels when x or y are factors.
number integer; the number of conditioning intervals, for a and b, possibly of length 2. It is only used if the corresponding conditioning variable is not a factor.
overlap numeric < 1; the fraction of overlap of the conditioning variables, possibly of length 2 for x and y direction. When overlap < 0, there will be gaps between the data slices.
xlim the range for the x axis.
ylim the range for the y axis.
... additional arguments to the panel function.
x a numeric vector.

Details

In the case of a single conditioning variable a, when both rows and columns are unspecified, a “close to square” layout is chosen with columns >= rows.

In the case of multiple rows, the order of the panel plots is from the bottom and from the left (corresponding to increasing a, typically).

A panel function should not attempt to start a new plot, but just plot within a given coordinate system: thus plot and boxplot are not panel functions.

The rendering of arguments xlab and ylab is not controlled by par arguments cex.lab and font.lab even though they are plotted by mtext rather than title.

Value

co.intervals(., number, .) returns a (number x 2) matrix, say ci, where ci[k,] is the range of x values for the k-th interval.
References

pairs, panel.smooth, points.

Examples

## Tonga Trench Earthquakes

```r
coplot(lat ~ long | depth, data = quakes)
given.dept <- co.intervals(quakes$depth, number=4, overlap=.1)
coplot(lat ~ long | depth, data = quakes, given.v=given.dept, rows=1)
```

## Conditioning on 2 variables:

```r
ll.dm <- lat ~ long | depth * mag
coplot(ll.dm, data = quakes)
coplot(ll.dm, data = quakes, number=c(4,7), show.given=c(TRUE,FALSE))
coplot(ll.dm, data = quakes, number=c(3,7),
       overlap=c(-.5,.1)) # negative overlap DROPS values
```

## given two factors

```r
Index <- seq(length=nrow(warpbreaks)) # to get nicer default labels
coplot(breaks ~ Index | wool * tension, data = warpbreaks, show.given = 0:1)
coplot(breaks ~ Index | wool * tension, data = warpbreaks,
       col = "red", bg = "pink", pch = 21, bar.bg = c(fac = "light blue"))
```

## Example with empty panels:

```r
with(data.frame(state.x77), {
coplot(Life.Exp ~ Income | Illiteracy * state.region, number = 3,
       panel = function(x, y, ...) panel.smooth(x, y, span = .8, ...))
```

```r
## y ~ factor -- not really sensical, but 'show off':
coplot(Life.Exp ~ state.region | Income * state.division,
       panel = panel.smooth)
```

```
```}
```

curve

Draw Function Plots

Description

Draws a curve corresponding to the given function or expression (in x) over the interval [from, to].

Usage

```r
curve(expr, from, to, n = 101, add = FALSE, type = "l",
      ylab = NULL, log = NULL, xlim = NULL, ...)
```

```r
## S3 method for class 'function':
plot(x, from = 0, to = 1, xlim = NULL, ...)
```
Arguments

- **expr**: an expression written as a function of \( x \), or alternatively the name of a function which will be plotted.
- **x**: a ‘vectorizing’ numeric \( \mathbb{R} \) function.
- **from, to**: the range over which the function will be plotted.
- **n**: integer; the number of \( x \) values at which to evaluate.
- **add**: logical; if TRUE add to already existing plot.
- **xlim**: numeric of length 2; if specified, it serves as default for \( \text{c(from, to)} \).
- **type**: plot type; see \( \text{plot.default} \).
- **ylab, log, ...**: labels and graphical parameters can also be specified as arguments. \( \text{plot.function} \) passes all these to \( \text{curve} \).

Details

The evaluation of \( \text{expr} \) is at \( n \) points equally spaced over the range \([\text{from, to}]\), possibly adapted to log scale. The points determined in this way are then joined with straight lines. \( x(t) \) or \( \text{expr}(\text{with } x \text{ inside}) \) must return a numeric of the same length as the argument \( t \) or \( x \).

If \( \text{add} = \text{TRUE} \), \( \text{c(from, to)} \) default to \( \text{xlim} \) which defaults to the current x-limits. Further, \( \log \) is taken from the current plot when \( \text{add} \) is true.

This used to be a quick hack which now seems to serve a useful purpose, but can give bad results for functions which are not smooth.

For “expensive” \( \text{expr} \)essions, you should use smarter tools.

See Also

- \( \text{splinefun} \) for spline interpolation, \( \text{lines} \).

Examples

```r
op <- \text{par(mfrow=c(2,2))}
\text{curve}(x^3-3*x, \text{-2, 2})
\text{curve}(x^2-2, \text{add = TRUE, col = "violet"})
\text{plot(cos, xlim = c(-\text{pi},3*\text{pi}), n = 1001, col = "blue")}
\text{chippy} <- \text{function(x) sin(cos(x)*exp(-x/2))}
\text{curve(chippy, \text{-8, 7, n=2001})}
\text{curve(chippy, \text{-8, -5})}
\text{for(ll in c("","x","y","xy"))}
  \text{curve(log(1+x), 1,100, log=ll, sub=paste("log= ",ll,"",sep=""))}
\text{par(op)}
```
dotchart

Cleveland Dot Plots

Description

Draw a Cleveland dot plot.

Usage

dotchart(x, labels = NULL, groups = NULL, gdata = NULL,
cex = par("cex"), pch = 21, gpch = 21, bg = par("bg"),
color = par("fg"), gcolor = par("fg"), lcolor = "gray",
xlim = range(x[is.finite(x)]),
main = NULL, xlab = NULL, ylab = NULL, ...)

Arguments

x either a vector or matrix of numeric values (NAs are allowed). If x is a matrix
the overall plot consists of juxtaposed dotplots for each row.

labels a vector of labels for each point. For vectors the default is to use names(x)
and for matrices the row labels dimnames(x)[[1]].

groups an optional factor indicating how the elements of x are grouped. If x is a matrix,
groups will default to the columns of x.

gdata data values for the groups. This is typically a summary such as the median or
mean of each group.

cex the character size to be used. Setting cex to a value smaller than one can be
a useful way of avoiding label overlap. Unlike many other graphics functions,
this sets the actual size, not a multiple of par("cex").

pch the plotting character or symbol to be used.

gpch the plotting character or symbol to be used for group values.

bg the background color of plotting characters or symbols to be used; use
par(bg= *) to set the background color of the whole plot.

color the color(s) to be used for points and labels.

gcolor the single color to be used for group labels and values.

lcolor the color(s) to be used for the horizontal lines.

xlim horizontal range for the plot, see plot.window, e.g.

main overall title for the plot, see title.

xlab, ylab axis annotations as in title.

... graphical parameters can also be specified as arguments.

Value

This function is invoked for its side effect, which is to produce two variants of dotplots as described
in Cleveland (1985).

Dot plots are a reasonable substitute for bar plots.
References

Examples

dotchart(VADeaths, main = "Death Rates in Virginia - 1940")

```r
op <- par(xaxs="i") # 0 -- 100%
dotchart(t(VADeaths), xlim = c(0,100),
         main = "Death Rates in Virginia - 1940")
par(op)
```

---

**filled.contour**  
*Level (Contour) Plots*

**Description**

This function produces a contour plot with the areas between the contours filled in solid color (Cleveland calls this a level plot). A key showing how the colors map to \( z \) values is shown to the right of the plot.

**Usage**

```r
filled.contour(x = seq(0, 1, len = nrow(z)),
y = seq(0, 1, len = ncol(z)),
          z,  
xlim = range(x, finite=TRUE),
       ylim = range(y, finite=TRUE),
      zlim = range(z, finite=TRUE),
     levels = pretty(zlim, nlevels), nlevels = 20,
    color.palette = cm.colors,
   col = color.palette(length(levels) - 1),
 plot.title, plot.axes, key.title, key.axes,
 asp = NA, xaxs = "i", yaxs = "i", las = 1,
    axes = TRUE, frame.plot = axes, ...)  
```

**Arguments**

- **x, y**  
  locations of grid lines at which the values in \( z \) are measured. These must be in ascending order. By default, equally spaced values from 0 to 1 are used. If \( x \) is a list, its components \( x$x \) and \( x$y \) are used for \( x \) and \( y \), respectively. If the list has component \( z \) this is used for \( z \).

- **z**  
  a matrix containing the values to be plotted (\( \text{NAs} \) are allowed). Note that \( x \) can be used instead of \( z \) for convenience.

- **xlim**  
  \( x \) limits for the plot.

- **ylim**  
  \( y \) limits for the plot.

- **zlim**  
  \( z \) limits for the plot.
levels

A set of levels which are used to partition the range of \( z \). Must be strictly increasing (and finite). Areas with \( z \) values between consecutive levels are painted with the same color.

nlevels

If \( \text{levels} \) is not specified, the range of \( z \), values is divided into approximately this many levels.

color.palette

A color palette function to be used to assign colors in the plot.

col

An explicit set of colors to be used in the plot. This argument overrides any palette function specification.

plot.title

Statements which add titles to the main plot.

plot.axes

Statements which draw axes (and a box) on the main plot. This overrides the default axes.

key.title

Statements which add titles for the plot key.

key.axes

Statements which draw axes on the plot key. This overrides the default axis.

asp

The \( y/x \) aspect ratio, see \text{plot.window}.

xaxs

The \( x \) axis style. The default is to use internal labeling.

yaxs

The \( y \) axis style. The default is to use internal labeling.

las

The style of labeling to be used. The default is to use horizontal labeling.

axes, frame.plot

Logicals indicating if axes and a box should be drawn, as in \text{plot.default}.

... additional graphical parameters, currently only passed to \text{title}().

Note

This function currently uses the \text{layout} function and so is restricted to a full page display. As an alternative consider the \text{levelplot} and \text{contourplot} functions from the \text{lattice} package which work in multipanel displays.

The output produced by \text{filled.contour} is actually a combination of two plots; one is the filled contour and one is the legend. Two separate coordinate systems are set up for these two plots, but they are only used internally - once the function has returned these coordinate systems are lost. If you want to annotate the main contour plot, for example to add points, you can specify graphics commands in the \text{plot.axes} argument. An example is given below.

# Annotating a filled contour plot
a <- expand.grid(1:20, 1:20)
b <- matrix(a[,1] + a[,2], 20)
filled.contour(x = 1:20, y = 1:20, z = b,
    plot.axes={( axis(1); axis(2); points(10,10) )})

## Persian Rug Art:
x <- y <- seq(-4*pi, 4*pi, len = 27)
r <- sqrt(outer(x^2, y^2, "+"))
filled.contour(cos(r^2)*exp(-r/(2*pi)), axes = FALSE)
## rather, the key *should* be labeled:
filled.contour(cos(r^2)*exp(-r/(2*pi)), frame.plot = FALSE, plot.axes = {])
```

Description

Creates a fourfold display of a 2 by 2 by \(k\) contingency table on the current graphics device, allowing for the visual inspection of the association between two dichotomous variables in one or several populations (strata).

Usage

```r
fourfoldplot(x, color = c("#99CCFF", "#6699CC"), conf.level = 0.95,
    std = c("margins", "ind.max", "all.max"),
    margin = c(1, 2), space = 0.2, main = NULL,
    mfrow = NULL, mfcol = NULL)
```

Arguments

- **x**: a 2 by 2 by \(k\) contingency table in array form, or as a 2 by 2 matrix if \(k\) is 1.
- **color**: a vector of length 2 specifying the colors to use for the smaller and larger diagonals of each 2 by 2 table.
- **conf.level**: confidence level used for the confidence rings on the odds ratios. Must be a single nonnegative number less than 1; if set to 0, confidence rings are suppressed.
std  a character string specifying how to standardize the table. Must be one of "margins", "ind.max", or "all.max", and can be abbreviated by the initial letter. If set to "margins", each 2 by 2 table is standardized to equate the margins specified by margin while preserving the odds ratio. If "ind.max" or "all.max", the tables are either individually or simultaneously standardized to a maximal cell frequency of 1.

margin  a numeric vector with the margins to equate. Must be one of 1, 2, or c(1, 2) (the default), which corresponds to standardizing the row, column, or both margins in each 2 by 2 table. Only used if std equals "margins".

space  the amount of space (as a fraction of the maximal radius of the quarter circles) used for the row and column labels.

main  character string for the fourfold title.

mfrow  a numeric vector of the form c(nr, nc), indicating that the displays for the 2 by 2 tables should be arranged in an nr by nc layout, filled by rows.

mfcol  a numeric vector of the form c(nr, nc), indicating that the displays for the 2 by 2 tables should be arranged in an nr by nc layout, filled by columns.

Details

The fourfold display is designed for the display of 2 by 2 by k tables. Following suitable standardization, the cell frequencies $f_{ij}$ of each 2 by 2 table are shown as a quarter circle whose radius is proportional to $\sqrt{f_{ij}}$ so that its area is proportional to the cell frequency. An association (odds ratio different from 1) between the binary row and column variables is indicated by the tendency of diagonally opposite cells in one direction to differ in size from those in the other direction; color is used to show this direction. Confidence rings for the odds ratio allow a visual test of the null of no association; the rings for adjacent quadrants overlap if and only if the observed counts are consistent with the null hypothesis.

Typically, the number k corresponds to the number of levels of a stratifying variable, and it is of interest to see whether the association is homogeneous across strata. The fourfold display visualizes the pattern of association. Note that the confidence rings for the individual odds ratios are not adjusted for multiple testing.

fourfoldplot(x, margin = 2)

---

### Frame

Create / Start a New Plot Frame

#### Description

This function (frame is an alias for plot.new) causes the completion of plotting in the current plot (if there is one) and an advance to a new graphics frame. This is used in all high-level plotting functions and also useful for skipping plots when a multi-figure region is in use.

#### Usage

```r
plot.new()
frame()
```

#### Details

There is a hook called "plot.new" (see setHook) called immediately after advancing the frame, which is used in the testing code to annotate the new page. The hook function(s) are called with no argument. (If the value is a character string, get is called on it from within the graphics namespace.)

grid

Add Grid to a Plot

Description
grid adds an nx by ny rectangular grid to an existing plot.

Usage
grid(nx = NULL, ny = nx, col = "lightgray", lty = "dotted",
     lwd = par("lwd"), equilogs = TRUE)

Arguments
- nx, ny: number of cells of the grid in x and y direction. When NULL, as per default, the grid aligns with the tick marks on the corresponding default axis (i.e., tick-marks as computed by axTicks). When NA, no grid lines are drawn in the corresponding direction.
- col: character or (integer) numeric; color of the grid lines.
- lty: character or (integer) numeric; line type of the grid lines.
- lwd: non-negative numeric giving line width of the grid lines.
- equilogs: logical, only used when log coordinates and alignment with the axis tick marks are active. Setting equilogs = FALSE in that case gives non equidistant tick aligned grid lines.

Note
If more fine tuning is required, use abline(h = ., v = .) directly.

References

See Also
plot, abline, lines, points.

Examples
plot(1:3)
grid(NA, 5, lwd = 2) # grid only in y-direction

## maybe change the desired number of tick marks: par(lab=c(mx,my,7))
op <- par(mfcol = 1:2)
with(iris,
  {
    plot(Sepal.Length, Sepal.Width, col = as.integer(Species),
         xlim = c(4, 8), ylim = c(2, 4.5), panel.first = grid(),
         main = "with(iris, plot(..., panel.first = grid(), .. ) )")
    plot(Sepal.Length, Sepal.Width, col = as.integer(Species),
         panel.first = grid(3, lty=1,lwd=2),
         main = ". . . panel.first = grid(3, lty=1,lwd=2), ..")
  )
The generic function `hist` computes a histogram of the given data values. If `plot=TRUE`, the resulting object of class "histogram" is plotted by `plot.histogram`, before it is returned.

### Usage

```r
hist(x, ...)  
## Default S3 method:  
hist(x, breaks = "Sturges", freq = NULL, probability = !freq,  
   include.lowest = TRUE, right = TRUE,  
   density = NULL, angle = 45, col = NULL, border = NULL,  
   main = paste("Histogram of" , xname),  
   xlim = range(breaks), ylim = NULL,  
   xlab = xname, ylab,  
   axes = TRUE, plot = TRUE, labels = FALSE,  
   nclass = NULL, ...)  
```

### Arguments

- **x**: a vector of values for which the histogram is desired.
- **breaks**: one of:
  - a vector giving the breakpoints between histogram cells,
  - a single number giving the number of cells for the histogram,
  - a character string naming an algorithm to compute the number of cells (see Details),
  - a function to compute the number of cells.

In the last three cases the number is a suggestion only.

- **freq**: logical; if `TRUE`, the histogram graphic is a representation of frequencies, the counts component of the result; if `FALSE`, probability densities, component density, are plotted (so that the histogram has a total area of one). Defaults to `TRUE if and only if breaks` are equidistant (and `probability` is not specified).

- **probability**: an alias for `!freq`, for S compatibility.
- **include.lowest**: logical; if `TRUE`, an `x[i]` equal to the `breaks` value will be included in the first (or last, for `right = FALSE`) bar. This will be ignored (with a warning) unless `breaks` is a vector.
- **right**: logical; if `TRUE`, the histograms cells are right-closed (left open) intervals.
density the density of shading lines, in lines per inch. The default value of NULL means that no shading lines are drawn. Non-positive values of density also inhibit the drawing of shading lines.

angle the slope of shading lines, given as an angle in degrees (counter-clockwise).

col a colour to be used to fill the bars. The default of NULL yields unfilled bars.

border the color of the border around the bars. The default is to use the standard foreground color.

main, xlab, ylab these arguments to title have useful defaults here.

xlim, ylim the range of x and y values with sensible defaults. Note that xlim is not used to define the histogram (breaks), but only for plotting (when plot = TRUE).

axes logical. If TRUE (default), axes are draw if the plot is drawn.

plot logical. If TRUE (default), a histogram is plotted, otherwise a list of breaks and counts is returned. In the latter case, a warning is used if (typically graphical) arguments are specified that only apply to the plot = TRUE case.

labels logical or character. Additionally draw labels on top of bars, if not FALSE; see plot.histogram.

nclass numeric (integer). For S(-PLUS) compatibility only, nclass is equivalent to breaks for a scalar or character argument.

... further graphical parameters passed to plot.histogram and their to title and axis (if plot=TRUE).

Details

The definition of “histogram” differs by source (with country-specific biases). R’s default with equi-spaced breaks (also the default) is to plot the counts in the cells defined by breaks. Thus the height of a rectangle is proportional to the number of points falling into the cell, as is the area provided the breaks are equally-spaced.

The default with non-equi-spaced breaks is to give a plot of area one, in which the area of the rectangles is the fraction of the data points falling in the cells.

If right = TRUE (default), the histogram cells are intervals of the form (a, b], i.e., they include their right-hand endpoint, but not their left one, with the exception of the first cell when include.lowest is TRUE.

For right = FALSE, the intervals are of the form [a, b), and include.lowest really has the meaning of "include highest".

A numerical tolerance of $10^{-7}$ times the median bin size is applied when counting entries on the edges of bins.

The default for breaks is "Sturges": see nclass.Sturges. Other names for which algorithms are supplied are "Scott" and "FD" / "Freedman-Diaconis" (with corresponding functions nclass.scott and nclass.FD). Case is ignored and partial matching is used. Alternatively, a function can be supplied which will compute the intended number of breaks as a function of x.

Value

an object of class "histogram" which is a list with components:

breaks the $n + 1$ cell boundaries (= breaks if that was a vector).

counts $n$ integers; for each cell, the number of $x[ ]$ inside.
density values $\hat{f}(x_i)$, as estimated density values. If all(diff(breaks) == 1), they are the relative frequencies $\frac{\text{counts}}{n}$ and in general satisfy $\sum_i \hat{f}(x_i)(b_{i+1} - b_i) = 1$, where $b_i = \text{breaks}[i]$.

intensities same as density. Deprecated, but retained for compatibility.

mids the $n$ cell midpoints.

xname a character string with the actual x argument name.

equidist logical, indicating if the distances between breaks are all the same.

Note

The resulting value does not depend on the values of the arguments freq (or probability) or plot. This is intentionally different from S.

Prior to R 1.7.0, the element breaks of the result was adjusted for numerical tolerances. The nominal values are now returned even though tolerances are still used when counting.

nclass.Sturges, stem, density, truehist in package MASS.

Typical plots with vertical bars are not histograms. Consider barplot or plot(*, type = "h") for such bar plots.

Examples

```r
op <- par(mfrow=c(2, 2))
hist(islands)
utils::str(hist(islands, col="gray", labels = TRUE))

hist(sqrt(islands), br = 12, col="lightblue", border="pink")
###-- For non-equidistant breaks, counts should NOT be graphed unscaled:
r <- hist(sqrt(islands), br = c(4*0:5, 10*3:5, 70, 100, 140), col="blue1")
text(r$mids, r$density, r$counts, adj=c(.5, -.5), col='blue3')
sapply(r[2:3], sum)
lines(r, lty = 3, border = "purple") # -> lines.histogram(*)
par(op)

utils::str(hist(islands, br=12, plot= FALSE)) #=> 10 (== 12) breaks
utils::str(hist(islands, br=c(12,20,36,80,200,1000,17000), plot = FALSE))

hist(islands, br=c(12,20,36,80,200,1000,17000), freq = TRUE, 
     main = "WRONG histogram") # and warning

set.seed(14)
x <- rchisq(100, df = 4)

## Comparing data with a model distribution should be done with qqplot()!
$qqplot(x, qchisq(ppoints(x), df = 4)); abline(0,1, col = 2, lty = 2)
```
## if you really insist on using hist() ... :
```r
hist(x, freq = FALSE, ylim = c(0, 0.2))
curve(dchisq(x, df = 4), col = 2, lty = 2, lwd = 2, add = TRUE)
```

### hist.POSIXt

**Histogram of a Date or Date-Time Object**

**Description**

Method for `hist` applied to date or date-time objects.

**Usage**

```r
## S3 method for class 'POSIXt':
hist(x, breaks, ..., 
    xlab = deparse(substitute(x)),
    plot = TRUE, freq = FALSE,
    start.on.monday = TRUE, format)
```  
```r
## S3 method for class 'Date':
hist(x, breaks, ..., 
    xlab = deparse(substitute(x)),
    plot = TRUE, freq = FALSE,
    start.on.monday = TRUE, format)
```

**Arguments**

- **x**: an object inheriting from class "POSIXt" or "Date".
- **breaks**: a vector of cut points or number giving the number of intervals which `x` is to be cut into or an interval specification, one of "days", "weeks", "months" or "years", plus "secs", "mins", "hours" for date-time objects.
- **...**: graphical parameters, or arguments to `hist.default` such as `include.lowest`, `right` and `labels`.
- **xlab**: a character string giving the label for the x axis, if plotted.
- **plot**: logical. If `TRUE` (default), a histogram is plotted, otherwise a list of breaks and counts is returned.
- **freq**: logical; if `TRUE`, the histogram graphic is a representation of frequencies, i.e., the `counts` component of the result; if `FALSE`, relative frequencies ("probabilities") are plotted.
- **start.on.monday**: logical. If `breaks = "weeks"`, should the week start on Mondays or Sundays?
- **format**: for the x-axis labels. See `strptime`.

**Value**

An object of class "histogram": see `hist`. 

---

## if you really insist on using hist() ... : 
hist(x, freq = FALSE, ylim = c(0, 0.2))
curve(dchisq(x, df = 4), col = 2, lty = 2, lwd = 2, add = TRUE)
identify

See Also

seq.POSIXt, axis.POSIXct, hist

Examples

hist(.leap.seconds, "years", freq = TRUE)
hist(.leap.seconds,
       seq(ISOdate(1970, 1, 1), ISOdate(2010, 1, 1), "5 years"))

## 100 random dates in a 10-week period
random.dates <- as.Date("2001/1/1") + 70*runif(100)
hist(random.dates, "weeks", format = "%d %b")

identify

Identify Points in a Scatter Plot

Description

identify reads the position of the graphics pointer when the (first) mouse button is pressed. It then searches the coordinates given in x and y for the point closest to the pointer. If this point is close enough to the pointer, its index will be returned as part of the value of the call.

Usage

identify(x, ...)

## Default S3 method:
identify(x, y = NULL, labels = seq(along = x), pos = FALSE,
       n = length(x), plot = TRUE, atpen = FALSE, offset = 0.5,
       tolerance = 0.25, ...)

Arguments

x,y coordinates of points in a scatter plot. Alternatively, any object which defines coordinates (a plotting structure, time series etc: see xy.coords) can be given as x, and y left undefined.

labels an optional character vector, the same length as x and y, giving labels for the points. Will be coerced using as.character.

pos if pos is TRUE, a component is added to the return value which indicates where text was plotted relative to each identified point: see Value.

n the maximum number of points to be identified.

plot logical: if plot is TRUE, the labels are printed at the points and if FALSE they are omitted.

atpen logical: if TRUE and plot = TRUE, the lower-left corners of the labels are plotted at the points clicked rather than relative to the points.

offset the distance (in character widths) which separates the label from identified points. Ignored if atpen = TRUE or pos = 0.

tolerance the maximal distance (in inches) for the pointer to be ‘close enough’ to a point.

... further arguments passed to par such as cex, col and font.
Details

identify is only supported on screen devices such as X11, windows and quartz. On other devices the call will do nothing.

If plot is TRUE, the point is labelled with the corresponding element of text. The labels are placed below, to the left, above or to the right of the identified point, depending on where the cursor was relative to the point.

For the usual X11 device the identification process is terminated by pressing any mouse button other than the first. For the quartz device the process is terminated by pressing the ESC key.

On most devices which support identify, successful selection of a point is indicated by a bell sound unless options(locatorBell = FALSE) has been set.

If the window is resized or hidden and then exposed before the identification process has terminated, any labels drawn by identify will disappear. These will reappear once the identification process has terminated and the window is resized or hidden and exposed again. This is because the labels drawn by identify are not recorded in the device’s display list until the identification process has terminated.

Value

If pos is FALSE, an integer vector containing the indexes of the identified points.

If pos is TRUE, a list containing a component ind, indicating which points were identified and a component pos, indicating where the labels were placed relative to the identified points (1=below, 2=left, 3=above, 4=right and 0=no offset, used if atpen = TRUE).

locator

image

Display a Color Image

Description

Creates a grid of colored or gray-scale rectangles with colors corresponding to the values in z. This can be used to display three-dimensional or spatial data aka “images”. This is a generic function.

The functions heat.colors, terrain.colors and topo.colors create heat-spectrum (red to white) and topographical color schemes suitable for displaying ordered data, with n giving the number of colors desired.

Usage

image(x, ...

## Default S3 method:
image(x, y, z, zlim, xlim, ylim, col = heat.colors(12),
       add = FALSE, xaxs = "i", yaxs = "i", xlab, ylab,
       breaks, oldstyle = FALSE, ...)
Arguments

\textbf{x, y} \quad \text{locations of grid lines at which the values in z are measured. These must be finite, non-missing and in (strictly) ascending order. By default, equally spaced values from 0 to 1 are used. If x is a list, its components x$x and x$y are used for x and y, respectively. If the list has component z this is used for z.}

\textbf{z} \quad \text{a matrix containing the values to be plotted (NAs are allowed). Note that x can be used instead of z for convenience.}

\textbf{zlim} \quad \text{the minimum and maximum z values for which colors should be plotted, defaulting to the range of the finite values of z. Each of the given colors will be used to color an equispaced interval of this range. The midpoints of the intervals cover the range, so that values just outside the range will be plotted.}

\textbf{xlim, ylim} \quad \text{ranges for the plotted x and y values, defaulting to the ranges of x and y.}

\textbf{col} \quad \text{a list of colors such as that generated by rainbow, heat.colors, topo.colors, terrain.colors or similar functions.}

\textbf{add} \quad \text{logical; if TRUE, add to current plot (and disregard the following arguments). This is rarely useful because image “paints” over existing graphics.}

\textbf{xaxs, yaxs} \quad \text{style of x and y axis. The default "i" is appropriate for images. See par.}

\textbf{xlab, ylab} \quad \text{each a character string giving the labels for the x and y axis. Default to the ‘call names’ of x or y, or to "" if these were unspecified.}

\textbf{breaks} \quad \text{a set of breakpoints for the colours: must give one more breakpoint than colour.}

\textbf{oldstyle} \quad \text{logical. If true the midpoints of the colour intervals are equally spaced, and zlim[1] and zlim[2] were taken to be midpoints. The default is to have colour intervals of equal lengths between the limits.}

\textbf{...} \quad \text{graphical parameters for plot may also be passed as arguments to this function, as can the plot aspect ratio asp and axes (see plot.window).}

Details

The length of \textbf{x} should be equal to the \texttt{nrow(z)+1} or \texttt{nrow(z)}. In the first case \textbf{x} specifies the boundaries between the cells: in the second case \textbf{x} specifies the midpoints of the cells. Similar reasoning applies to \textbf{y}. It probably only makes sense to specify the midpoints of an equally-spaced grid. If you specify just one row or column and a length-one \textbf{x} or \textbf{y}, the whole user area in the corresponding direction is filled.

Rectangles corresponding to missing values are not plotted (and so are transparent and (unless add=TRUE) the default background painted in \texttt{par("bg")} will show though and if that is transparent, the canvas colour will be seen).

If \textbf{breaks} is specified then \textbf{zlim} is unused and the algorithm used follows \texttt{cut}, so intervals are closed on the right and open on the left except for the lowest interval.

Notice that \textbf{image} interprets the \textbf{z} matrix as a table of \(f(x[i], y[j])\) values, so that the \textbf{x} axis corresponds to row number and the \textbf{y} axis to column number, with column 1 at the bottom, i.e. a 90 degree counter-clockwise rotation of the conventional printed layout of a matrix.

Note

Based on a function by Thomas Lumley (tlumley@u.washington.edu).

```

---

**layout**

**Specifying Complex Plot Arrangements**

**Description**

layout divides the device up into as many rows and columns as there are in matrix mat, with the column-widths and the row-heights specified in the respective arguments.

**Usage**

```r
layout(mat, widths = rep(1, ncol(mat)),
       heights = rep(1, nrow(mat)), respect = FALSE)

layout.show(n = 1)
lcm(x)
```

**Arguments**

- `mat` a matrix object specifying the location of the next \( N \) figures on the output device. Each value in the matrix must be 0 or a positive integer. If \( N \) is the largest positive integer in the matrix, then the integers \( \{1, \ldots, N-1\} \) must also appear at least once in the matrix.
widths  a vector of values for the widths of columns on the device. Relative widths are specified with numeric values. Absolute widths (in centimetres) are specified with the `lcm()` function (see examples).

heights  a vector of values for the heights of rows on the device. Relative and absolute heights can be specified, see `widths` above.

respect  either a logical value or a matrix object. If the latter, then it must have the same dimensions as `mat` and each value in the matrix must be either 0 or 1.

n  number of figures to plot.

x  a dimension to be interpreted as a number of centimetres.

Details

Figure `i` is allocated a region composed from a subset of these rows and columns, based on the rows and columns in which `i` occurs in `mat`.

The `respect` argument controls whether a unit column-width is the same physical measurement on the device as a unit row-height.

There is a limit (currently 50) for the numbers of rows and columns in the layout, and also for the total number of cells (500).

`layout.show(n)` plots (part of) the current layout, namely the outlines of the next `n` figures.

`lcm` is a trivial function, to be used as the interface for specifying absolute dimensions for the `widths` and `heights` arguments of `layout()`.

Value

`layout` returns the number of figures, `N`, see above.

Warnings

These functions are totally incompatible with the other mechanisms for arranging plots on a device: `par(mfrow), par(mfcol)` and `split.screen`.

Add Legends to Plots

Description

This function can be used to add legends to plots. Note that a call to the function locator(1) can be used in place of the x and y arguments.

Usage

legend(x, y = NULL, legend, fill = NULL, col = par("col"),
   lty, lwd, pch,
   angle = 45, density = NULL, bty = "o", bg = par("bg"),
   ...
box.lwd = par("lwd"), box.lty = par("lty"),
pt.bg = NA, cex = 1, pt.cex = cex, pt.lwd = lwd,
xjust = 0, yjust = 1, x.intersp = 1, y.intersp = 1,
adj = c(0, 0.5), text.width = NULL, text.col = par("col"),
merge = do.lines & has.pch, trace = FALSE,
plot = TRUE, ncol = 1, horiz = FALSE, title = NULL,
inset = 0)

Arguments

x, y the x and y co-ordinates to be used to position the legend. They can be specified by keyword or in any way which is accepted by `xy.coords`; See Details.

legend a character or `expression` vector. of length ≥ 1 to appear in the legend. Other objects will be coerced by `as.graphicsAnnot`.

fill if specified, this argument will cause boxes filled with the specified colors (or shaded in the specified colors) to appear beside the legend text.

col the color of points or lines appearing in the legend.
lty, lwd the line types and widths for lines appearing in the legend. One of these two must be specified for line drawing.
pch the plotting symbols appearing in the legend, either as vector of 1-character strings, or one (multi character) string. Must be specified for symbol drawing.

angle angle of shading lines.
density the density of shading lines, if numeric and positive. If NULL or negative or NA color filling is assumed.
bty the type of box to be drawn around the legend. The allowed values are "o" (the default) and "n".

type the background color for the legend box. (Note that this is only used if `bty` != "n".)

box.lty, box.lwd the line type and width for the legend box.

pt.bg the background color for the points, corresponding to its argument bg.
cex character expansion factor relative to current par("cex").

pt.cex expansion factor(s) for the points.

pt.lwd line width for the points, defaults to the one for lines, or if that is not set, to par("lwd").

xjust how the legend is to be justified relative to the legend x location. A value of 0 means left justified, 0.5 means centered and 1 means right justified.

yjust the same as `xjust` for the legend y location.

x.intersp character interspacing factor for horizontal (x) spacing.

y.intersp the same for vertical (y) line distances.

adj numeric of length 1 or 2; the string adjustment for legend text. Useful for y-adjustment when labels are `plotmath` expressions.

text.width the width of the legend text in x ("user") coordinates. (Should be positive even for a reversed x axis.) Defaults to the proper value computed by `strwidth(legend)`.

text.col the color used for the legend text.
merge
logical; if TRUE, “merge” points and lines but not filled boxes. Defaults to TRUE if there are points and lines.

trace
logical; if TRUE, shows how legend does all its magical computations.

plot
logical. If FALSE, nothing is plotted but the sizes are returned.

ncol
the number of columns in which to set the legend items (default is 1, a vertical legend).

horiz
logical; if TRUE, set the legend horizontally rather than vertically (specifying horiz overrides the ncol specification).

title
a character string or length-one expression giving a title to be placed at the top of the legend. Other objects will be coerced by as.graphicsAnnot.

inset
inset distance(s) from the margins as a fraction of the plot region when legend is placed by keyword.

Details
Arguments x, y, legend are interpreted in a non-standard way to allow the coordinates to be specified via one or two arguments. If legend is missing and y is not numeric, it is assumed that the second argument is intended to be legend and that the first argument specifies the coordinates. The coordinates can be specified in any way which is accepted by xy.coords. If this gives the coordinates of one point, it is used as the top-left coordinate of the rectangle containing the legend. If it gives the coordinates of two points, these specify opposite corners of the rectangle (either pair of corners, in any order).

The location may also be specified by setting x to a single keyword from the list "bottomright", "bottom", "bottomleft", "left", "topleft", "top", "topright", "right" and "center". This places the legend on the inside of the plot frame at the given location. Partial argument matching is used. The optional inset argument specifies how far the legend is inset from the plot margins. If a single value is given, it is used for both margins; if two values are given, the first is used for x-distance, the second for y-distance.

“Attribute” arguments such as col, pch, lty, etc, are recycled if necessary. merge is not.

Points are drawn after lines in order that they can cover the line with their background color pt.bg, if applicable.

See the examples for how to right-justify labels.

Value
A list with list components

rect a list with components

w, h positive numbers giving width and height of the legend’s box.

left, top x and y coordinates of upper left corner of the box.

text a list with components

x, y numeric vectors of length length(legend), giving the x and y coordinates of the legend’s text(s).

returned invisibly.

legend("top", "(x,y)", pch=1, title="top")
legend("topright", "(x,y)", pch=1, title="topright, inset = .02", inset = .02)
legend("right", "(x,y)", pch=1, title="right")
legend("center", "(x,y)", pch=1, title="center")
Add Connected Line Segments to a Plot

Description

A generic function taking coordinates given in various ways and joining the corresponding points with line segments.

Usage

lines(x, ...)

## Default S3 method:
lines(x, y = NULL, type = "l", ...)

Arguments

x, y  
coordinate vectors of points to join.

type  
character indicating the type of plotting; actually any of the types as in plot.default.

...  
Further graphical parameters (see par) may also be supplied as arguments, particularly, line type, lty, line width, lwd, color, col and for type = "b", pch. Also the line characteristics lend, ljoin and lmitre.

Details

The coordinates can be passed to lines in a plotting structure (a list with x and y components), a time series, etc. See xy.coords.

The coordinates can contain NA values. If a point contains NA in either its x or y value, it is omitted from the plot, and lines are not drawn to or from such points. Thus missing values can be used to achieve breaks in lines.

For type = "h", col can be a vector and will be recycled as needed.

lwd can be a vector: its first element will apply to lines but the whole vector to symbols (recycled as necessary).

References

See Also

points, particularly for type %in% c("p","b","o"). plot, and the workhorse function plot.xy.

abline for drawing (single) straight lines.

par for how to specify colors.
Examples

# draw a smooth line through a scatter plot
plot(cars, main="Stopping Distance versus Speed")
lines(lowess(cars))

locator

Graphical Input

Description

Reads the position of the graphics cursor when the (first) mouse button is pressed.

Usage

locator(n = 512, type = "n", ...)

Arguments

n
the maximum number of points to locate. Valid values start at 1.

type
One of "n", "p", "l" or "o". If "p" or "o" the points are plotted; if "l" or "o" they are joined by lines.

... additional graphics parameters used if type != "n" for plotting the locations.

Details

locator is only supported on screen devices such as X11, windows and quartz. On other devices the call will do nothing.

Unless the process is terminated prematurely by the user (see below) at most n positions are determined.

For the usual X11 device the identification process is terminated by pressing any mouse button other than the first. For the quartz device the process is terminated by pressing the ESC key.

The current graphics parameters apply just as if plot.default has been called with the same value of type. The plotting of the points and lines is subject to clipping, but locations outside the current clipping rectangle will be returned.

On most devices which support locator, successful selection of a point is indicated by a bell sound unless options(locatorBell=FALSE) has been set.

If the window is resized or hidden and then exposed before the input process has terminated, any lines or points drawn by locator will disappear. These will reappear once the input process has terminated and the window is resized or hidden and exposed again. This is because the points and lines drawn by locator are not recorded in the device’s display list until the input process has terminated.

Value

A list containing x and y components which are the coordinates of the identified points in the user coordinate system, i.e., the one specified by par("usr").

**matplot**

*Plot Columns of Matrices*

**Description**

Plot the columns of one matrix against the columns of another.

**Usage**

```r
matplot(x, y, type = "p", lty = 1:5, lwd = 1, pch = NULL,
        col = 1:6, cex = NULL, bg = NA,
        xlab = NULL, ylab = NULL, xlim = NULL, ylim = NULL,
        ..., add = FALSE, verbose = getOption("verbose"))
```

```r
matpoints(x, y, type = "p", lty = 1:5, lwd = 1, pch = NULL,
          col = 1:6, ...)
```

```r
matlines (x, y, type = "l", lty = 1:5, lwd = 1, pch = NULL,
          col = 1:6, ...)
```

**Arguments**

- **x, y**
  - vectors or matrices of data for plotting. The number of rows should match. If one of them are missing, the other is taken as `y` and an `x` vector of `1:n` is used. Missing values (NAs) are allowed.

- **type**
  - character string (length 1 vector) or vector of 1-character strings indicating the type of plot for each column of `y`, see `plot` for all possible types. The first character of `type` defines the first plot, the second character the second, etc. Characters in `type` are cycled through; e.g., "pl" alternately plots points and lines.

- **lty, lwd**
  - vector of line types and widths. The first element is for the first column, the second element for the second column, etc., even if lines are not plotted for all columns. Line types will be used cyclically until all plots are drawn.

- **pch**
  - character string or vector of 1-characters or integers for plotting characters, see `points`. The first character is the plotting-character for the first plot, the second for the second, etc. The default is the digits (1 through 9, 0) then the letters.

- **col**
  - vector of colors. Colors are used cyclically.

- **cex**
  - vector of character expansion sizes, used cyclically. This works as a multiple of `par("cex")`. `NULL` is equivalent to 1.0.

- **bg**
  - vector of (“fill”) colors for the open plot symbols given by `pch=21:25` as in `points`. The default NA corresponds to the one of the underlying function `plot.xy`. 
xlab, ylab titles for x and y axes, as in plot.
xlim, ylim ranges of x and y axes, as in plot.
... Graphical parameters (see par) and any further arguments of plot, typically plot.default, may also be supplied as arguments to this function. Hence, the high-level graphics control arguments described under par and the arguments to title may be supplied to this function.

add logical. If TRUE, plots are added to current one, using points and lines.
verbose logical. If TRUE, write one line of what is done.

Details
Points involving missing values are not plotted.
The first column of x is plotted against the first column of y, the second column of x against the second column of y, etc. If one matrix has fewer columns, plotting will cycle back through the columns again. (In particular, either x or y may be a vector, against which all columns of the other argument will be plotted.)
The first element of col, cex, lty, lwd is used to plot the axes as well as the first line.
Because plotting symbols are drawn with lines and because these functions may be changing the line style, you should probably specify lty=1 when using plotting symbols.

Side Effects
Function matplot generates a new plot; matpoints and matlines add to the current one.

 "Versicolor Petals", "Versicolor Sepals"),
 pch = "sSvV", col = rep(c(2,4), 2))

nam.var <- colnames(iris)[-5]
nam.spec <- as.character(iris[1+50*0:2, "Species"])
for(i in 1:3) iris.S[,i] <- data.matrix(iris[1:50+50*(i-1), -5])

col = rainbow(3, start = .8, end = .1),
sub = paste(c("S", "C", "V"), dimnames(iris.S)[[3]],
sep = "=", collapse= "", ),
main = "Fisher's Iris Data")
par(op)

mosaicplot

Mosaic Plots

Description

Plots a mosaic on the current graphics device.

Usage

mosaicplot(x, ...)

## Default S3 method:
mosaicplot(x, main = deparse(substitute(x)),
sub = NULL, xlab = NULL, ylab = NULL,
sort = NULL, off = NULL, dir = NULL,
color = NULL, shade = FALSE, margin = NULL,
cex.axis = 0.66, las = par("las"),
type = c("pearson", "deviance", "FT"), ...)

## S3 method for class 'formula':
mosaicplot(formula, data = NULL, ..., main = deparse(substitute(data)), subset,
na.action = stats::na.omit)

Arguments

x

a contingency table in array form, with optional category labels specified in the
dimnames(x) attribute. The table is best created by the table() command.

main

character string for the mosaic title.

sub

character string for the mosaic sub-title (at bottom).

xlab, ylab

x- and y-axis labels used for the plot; by default, the first and second element of
names(dimnames(X)) (i.e., the name of the first and second variable in X).
sort vector ordering of the variables, containing a permutation of the integers 1:length(dim(x)) (the default).

off vector of offsets to determine percentage spacing at each level of the mosaic (appropriate values are between 0 and 20, and the default is 20 times the number of splits for 2-dimensional tables, and 10 otherwise. Rescaled to maximally 50, and recycled if necessary.

dir vector of split directions ("v" for vertical and "h" for horizontal) for each level of the mosaic, one direction for each dimension of the contingency table. The default consists of alternating directions, beginning with a vertical split.

color logical or (recycling) vector of colors for color shading, used only when shade is FALSE, or NULL (default). By default, grey boxes are drawn. color=TRUE uses a gamma-corrected grey palette. color=FALSE gives empty boxes with no shading.

shade a logical indicating whether to produce extended mosaic plots, or a numeric vector of at most 5 distinct positive numbers giving the absolute values of the cut points for the residuals. By default, shade is FALSE, and simple mosaics are created. Using shade = TRUE cuts absolute values at 2 and 4.

margin a list of vectors with the marginal totals to be fit in the log-linear model. By default, an independence model is fitted. See loglin for further information.

cex.axis The magnification to be used for axis annotation, as a multiple of par("cex").

las numeric; the style of axis labels, see par.

type a character string indicating the type of residual to be represented. Must be one of "pearson" (giving components of Pearson’s χ²), "deviance" (giving components of the likelihood ratio χ²), or "FT" for the Freeman-Tukey residuals. The value of this argument can be abbreviated.

formula a formula, such as y ~ x.

data a data frame (or list), or a contingency table from which the variables in formula should be taken.

... further arguments to be passed to or from methods.

subset an optional vector specifying a subset of observations in the data frame to be used for plotting.

na.action a function which indicates what should happen when the data contains variables to be cross-tabulated, and these variables contain NAs. The default is to omit cases which have an NA in any variable. Since the tabulation will omit all cases containing missing values, this will only be useful if the na.action function replaces missing values.

Details

This is a generic function. It currently has a default method (mosaicplot.default) and a formula interface (mosaicplot.formula).

Extended mosaic displays visualize standardized residuals of a loglinear model for the table by color and outline of the mosaic’s tiles. (Standardized residuals are often referred to a standard normal distribution.) Negative residuals are drawn in shaded of red and with broken outlines; positive ones are drawn in blue with solid outlines.

For the formula method, if data is an object inheriting from classes "table" or "ftable", or an array with more than 2 dimensions, it is taken as a contingency table, and hence all entries should
be nonnegative. In this case, the left-hand side of `formula` should be empty, and the variables on
the right-hand side should be taken from the names of the dimnames attribute of the contingency
table. A marginal table of these variables is computed, and a mosaic of this table is produced.
Otherwise, `data` should be a data frame or matrix, list or environment containing the variables
to be cross-tabulated. In this case, after possibly selecting a subset of the data as specified by the
`subset` argument, a contingency table is computed from the variables given in `formula`, and a
mosaic is produced from this.

See Emerson (1998) for more information and a case study with television viewer data from Nielsen
Media Research.

Missing values are not supported except via an `na.action` function when `data` contains vari-
able to be cross-tabulated.

A more flexible and extensible implementation of mosaic plots written in the grid graphics system
is provided in the function `mosaic` in the contributed package `vcd` (Meyer, Zeileis and Hornik,
2005).

```r
mosaicplot(Titanic, main = "Survival on the Titanic", color = TRUE)
## Formula interface for tabulated data:
mosaicplot(~ Sex + Age + Survived, data = Titanic, color = TRUE)
mosaicplot(HairEyeColor, shade = TRUE)
## Independence model of hair and eye color and sex. Indicates that
## there are more blue eyed blonde females than expected in the case
## of independence and too few brown eyed blonde females.
## The corresponding model is:
fm <- loglin(HairEyeColor, list(1, 2, 3))
```
pchisq(fm$pearson, fm$df, lower.tail = FALSE)

mosaicplot(HairEyeColor, shade = TRUE, margin = list(1:2, 3))
## Model of joint independence of sex from hair and eye color. Males
## are underrepresented among people with brown hair and eyes, and are
## overrepresented among people with brown hair and blue eyes.
## The corresponding model is:
fm <- loglin(HairEyeColor, list(1:2, 3))
pchisq(fm$pearson, fm$df, lower.tail = FALSE)
## Formula interface for raw data: visualize cross-tabulation of numbers
## of gears and carburettors in Motor Trend car data.
mosaicplot(~ gear + carb, data = mtcars, color = TRUE, las = 1)
# color recycling
mosaicplot(~ gear + carb, data = mtcars, color = 2:3, las = 1)

---

### mtext

**Write Text into the Margins of a Plot**

**Description**

Text is written in one of the four margins of the current figure region or one of the outer margins of the device region.

**Usage**

```r
mtext(text, side = 3, line = 0, outer = FALSE, at = NA,
       adj = NA, padj = NA, cex = NA, col = NA, font = NA, ...)
```

**Arguments**

- `text`: a character or `expression` vector specifying the text to be written. Other objects are coerced by `as.graphicsAnnot`.
- `side`: on which side of the plot (1=bottom, 2=left, 3=top, 4=right).
- `line`: on which MARgin line, starting at 0 counting outwards.
- `outer`: use outer margins if available.
- `at`: give location in user-coordinates. If `length(at)==0` (the default), the location will be determined by `adj`.
- `adj`: adjustment for each string in reading direction. For strings parallel to the axes, `adj = 0` means left or bottom alignment, and `adj = 1` means right or top alignment.
  
  If `adj` is not a finite value (the default), the value of `par("las")` determines the adjustment. For strings plotted parallel to the axis the default is to centre the string.

- `padj`: adjustment for each string perpendicular to the reading direction (which is controlled by `adj`). For strings parallel to the axes, `padj = 0` means right or top alignment, and `padj = 1` means left or bottom alignment.
  
  If `padj` is not a finite value (the default), the value of `par("las")` determines the adjustment. For strings plotted perpendicular to the axis the default is to centre the string.
**mtext**

- **cex**: character expansion factor. NULL and NA are equivalent to 1.0. This is an absolute measure, not scaled by `par("cex")` or by setting `par("mfrow")` or `par("mfcol")`. Can be a vector.
- **col**: color to use. Can be a vector. NA values (the default) mean use `par("col")`. For strings plotted perpendicular to the axis the default justification is to place the end of the string nearest the axis on the specified line. (Note that this differs from S, which uses `srt` if `at` is supplied and `las` if it is not.)
- **font**: font for text. Can be a vector. NA values (the default) mean use `par("font")`.
- **...**: Further graphical parameters (see `par`), including `family`, `las` and `xpd`. (This defaults to the figure region unless `outer = TRUE`, otherwise the device region. It can only be increased.)

**Details**

The “user coordinates” in the outer margins always range from zero to one, and are not affected by the user coordinates in the figure region(s) — R is differing here from other implementations of S.

All of the named arguments can be vectors, and recycling will take place to plot as many strings as the longest of the vector arguments.

Note that a vector `adj` has a different meaning from `text.adj = 0.5` will centre the string, but for `outer=TRUE` on the device region rather than the plot region.

Parameter `las` will determine the orientation of the string(s). For strings plotted perpendicular to the axis the default justification is to place the end of the string nearest the axis on the specified line. Note that this differs from S, which uses `srt` if `at` is supplied and `las` if it is not.)

Note that if the text is to be plotted perpendicular to the axis, `adj` determines the justification of the string and the position along the axis unless `at` is specified.

**Side Effects**

The given text is written onto the current plot.

**References**

**See Also**

`title, text, plot, par; plotmath` for details on mathematical annotation.

**Examples**

```r
plot(1:10, (-4:5)^2, main="Parabola Points", xlab="xlab")
mtext("10 of them")
for(s in 1:4)
  mtext(paste("mtext(..., line= -", s,
             ", col=s, font=s, cex= (1+s)/2)
for(s in 1:4) mtext(paste("mtext(..., side=", s, ", line= -", s, ", adj=0)"), line = -2, adj =0)
```

```r
##--- log axis :
plot(1:10, exp(1:10), log='y', main="log'y'", xlab="xlab")
for(s in 1:4) mtext(paste("mtext(...,side="",s,"" ), side=s)
```
pairs

### Scatterplot Matrices

**Description**

A matrix of scatterplots is produced.

**Usage**

```r
pairs(x, ...)
```

```r
## S3 method for class 'formula':
pairs(formula, data = NULL, subset, na.action = stats::na.pass)
```

```r
## Default S3 method:
pairs(x, labels, panel = points, ..., lower.panel = panel, upper.panel = panel, diag.panel = NULL, text.panel = textPanel, label.pos = 0.5 + has.diag/3, cex.labels = NULL, font.labels = 1, row1attop = TRUE, gap = 1)
```

**Arguments**

- **x**: the coordinates of points given as numeric columns of a matrix or dataframe. Logical and factor columns are converted to numeric in the same way that `data.matrix` does.
- **formula**: a formula, such as `~ x + y + z`. Each term will give a separate variable in the pairs plot, so terms should be numeric vectors. (A response will be interpreted as another variable, but not treated specially, so it is confusing to use one.)
- **data**: a data.frame (or list) from which the variables in `formula` should be taken.
- **subset**: an optional vector specifying a subset of observations to be used for plotting.
- **na.action**: a function which indicates what should happen when the data contain NA values. The default is to pass missing values on to the panel functions, but `na.action = na.omit` will cause cases with missing values in any of the variables to be omitted entirely.
- **labels**: the names of the variables.
- **panel**: `function(x, y, ...)` which is used to plot the contents of each panel of the display.
- **...**: arguments to be passed to or from methods.
- Also, graphical parameters can be given as can arguments to `plot` such as `main`, `par("oma")` will be set appropriately unless specified.
- **lower.panel**, **upper.panel**: separate panel functions to be used below and above the diagonal respectively.
- **diag.panel**: optional `function(x, ...)` to be applied on the diagonals.
text.panel  optional function(x, y, labels, cex, font, ...) to be applied on the diagonals.

label.pos  y position of labels in the text panel.

cex.labels, font.labels  graphics parameters for the text panel.

rowlattop  logical. Should the layout be matrix-like with row 1 at the top, or graph-like with row 1 at the bottom?

gap  Distance between subplots, in margin lines.

Details

The i/jth scatterplot contains x[,i] plotted against x[,j]. The “scatterplot” can be customised by setting panel functions to appear as something completely different. The off-diagonal panel functions are passed the appropriate columns of x as x and y: the diagonal panel function (if any) is passed a single column, and the text.panel function is passed a single (x, y) location and the column name.

The graphical parameters pch and col can be used to specify a vector of plotting symbols and colors to be used in the plots.

The graphical parameter oma will be set by pairs.default unless supplied as an argument.

A panel function should not attempt to start a new plot, but just plot within a given coordinate system: thus plot and boxplot are not panel functions.

By default, missing values are passed to the panel functions and will often be ignored within a panel. However, for the formula method and na.action = na.omit, all cases which contain a missing values for any of the variables are omitted completely (including when the scales are selected).

panel.smooth  

Simple Panel Plot

Description

An example of a simple useful panel function to be used as argument in e.g., `coplot` or `pairs`.

Usage

panel.smooth(x, y, col = par("col"), bg = NA, pch = par("pch"),
cex = 1, col.smooth = "red", span = 2/3, iter = 3, ...

Arguments

- **x, y** numeric vectors of the same length
- **col, bg, pch, cex** numeric or character codes for the color(s), point type and size of points; see also `par`.
- **col.smooth** color to be used by `lines` for drawing the smooths.
- **span** smoothing parameter \( f \) for `lowess`, see there.
- **iter** number of robustness iterations for `lowess`.
- **...** further arguments to `lines`.

See Also

coplot and pairs where `panel.smooth` is typically used; lowess which does the smoothing.
**Examples**

```r
pairs(swiss, panel = panel.smooth, pch = ".") # emphasize the smooths
pairs(swiss, panel = panel.smooth, lwd = 2, cex= 1.5, col="blue") # hmm...
```

---

**par**

*Set or Query Graphical Parameters*

**Description**

`par` can be used to set or query graphical parameters. Parameters can be set by specifying them as arguments to `par` in `tag = value` form, or by passing them as a list of tagged values.

**Usage**

```r
par(..., no.readonly = FALSE)
<highlevel plot> (...,
<tag> = <value>)
```

**Arguments**

- `...` arguments in `tag = value` form, or a list of tagged values. The tags must come from the graphical parameters described below.
- `no.readonly` logical; if `TRUE` and there are no other arguments, only parameters are returned which can be set by a subsequent `par()` call.

**Details**

Parameters are queried by giving one or more character vectors to `par`.

`par()` (no arguments) or `par(no.readonly=TRUE)` is used to get all the graphical parameters (as a named list). Their names are currently taken from the unexported variable `.Pars`.

**R.O.** indicates read-only arguments: These may only be used in queries and cannot be set. ("cin", "cra", "csi", "cxy" and "din" are always read-only, and "gamma" is on most devices.)

There are several parameters can only be set by a call to `par()`:

- "ask",
- "fig", "fin",
- "lheight",
- "mai", "mar", "mex", "mfcol", "mfrow", "mfg",
- "new",
- "oma", "omd", "omi",
- "pin", "plt", "ps", "pty",
- "usr",
- "xlog", "ylog"
The remaining parameters can also be set as arguments (often via \ldots) to high-level plot functions such as \texttt{plot.default}, \texttt{plot.window}, \texttt{points}, \texttt{lines}, \texttt{abline}, \texttt{axis}, \texttt{title}, \texttt{text}, \texttt{mtext}, \texttt{segments}, \texttt{symbols}, \texttt{arrows}, \texttt{polygon}, \texttt{rect}, \texttt{box}, \texttt{contour}, \texttt{filled.contour} and \texttt{image}. Such settings will be active during the execution of the function, only. However, see the comments on \texttt{bg} and \texttt{cex}, which may be taken as arguments to certain plot functions rather than as graphical parameters.

The meaning of ‘character size’ is not well-defined: this is set up for the device taking \texttt{pointsize} into account but often not the actual font family in use. It can be considered to be an estimate of the size of character M in a proportionally-spaced font.

\textbf{Value}

When parameters are set, their former values are returned in an invisible named list. Such a list can be passed as an argument to \texttt{par} to restore the parameter values. Use \texttt{par(no.readonly = TRUE)} for the full list of parameters that can be restored.

When just one parameter is queried, the value of that parameter is returned as (atomic) vector. When two or more parameters are queried, their values are returned in a list, with the list names giving the parameters.

Note the inconsistency: setting one parameter returns a list, but querying one parameter returns a vector.

\textbf{Graphical Parameters}

\texttt{adj} The value of \texttt{adj} determines the way in which text strings are justified. A value of 0 produces left-justified text, 0.5 centered text and 1 right-justified text. (Any value in [0, 1] is allowed, and on most devices values outside that interval will also work.) Note that the \texttt{adj} argument of \texttt{text} also allows \texttt{adj = c(x, y)} for different adjustment in x- and y- direction.

\texttt{ann} If set to \texttt{FALSE}, high-level plotting functions calling \texttt{plot.default} do not annotate the plots they produce with axis titles and overall titles. The default is to do annotation.

\texttt{ask} logical. If \texttt{TRUE} (and the R session is interactive) the user is asked for input, before a new figure is drawn. As this applies to the device, it also affects output by packages \texttt{grid} and \texttt{lattice}. It can be set even on non-screen devices.

\texttt{bg} The color to be used for the background of plots. When called from \texttt{par()} it also sets \texttt{new=FALSE}. A description of how colors are specified is given below. Note that some graphics functions such as \texttt{plot.default} and \texttt{points} have an \texttt{argument} of this name with a different meaning.

\texttt{bty} A character string which determined the type of \texttt{box} which is drawn about plots. If \texttt{bty} is one of "o", "l", "?", "c", "u", or "j" the resulting box resembles the corresponding upper case letter. A value of "n" suppresses the box.

\texttt{cex} A numerical value giving the amount by which plotting text and symbols should be scaled relative to the default. Note that some graphics functions such as \texttt{plot.default} have an \texttt{argument} of this name which multiplies this graphical parameter.

\texttt{cex.axis} The magnification to be used for axis annotation relative to the current setting of \texttt{cex}. (Some functions such as \texttt{points} accept a vector of values which are recycled. Other uses will take just the first value if a vector of length greater than one is supplied.)

\texttt{cex.lab} The magnification to be used for x and y labels relative to the current setting of \texttt{cex}.

\texttt{cex.main} The magnification to be used for main titles relative to the current setting of \texttt{cex}.

\texttt{cex.sub} The magnification to be used for sub-titles relative to the current setting of \texttt{cex}.

\texttt{cin} \textit{R.O.}; character size \texttt{(width, height)} in inches.
par

**col**  A specification for the default plotting color. A description of how colors are specified is given below. (Some functions such as `lines` accept a vector of values which are recycled. Other uses will take just the first value if a vector of length greater than one is supplied.)

**col.axis**  The color to be used for axis annotation.

**col.lab**  The color to be used for x and y labels.

**col.main**  The color to be used for plot main titles.

**col.sub**  The color to be used for plot sub-titles.

**cra**  `R.O.;` size of default character `(width, height)` in “rasters” (pixels). Some devices have no concept of pixels and so assume an arbitrary pixel size, usually 1/72 inch.

**crt**  A numerical value specifying (in degrees) how single characters should be rotated. It is unwise to expect values other than multiples of 90 to work. Compare with `srt` which does string rotation.

**csi**  `R.O.;` height of (default sized) characters in inches.

**cxy**  `R.O.;` size of default character `(width, height)` in user coordinate units. `par("cxy")` is `par("cin")/par("pin")` scaled to user coordinates. Note that `c(strwidth(ch), strwidth(ch))` for a given string `ch` is usually much more precise.

**din**  `R.O.;` the device dimensions, `(width, height)`, in inches.

**err**  *(Unimplemented; `R` is silent when points outside the plot region are not plotted.)* The degree of error reporting desired.

**family**  The name of a font family for drawing text. The maximum allowed length is 200 bytes. This name gets mapped by each graphics device to device-specific font descriptions. The default value is "" which means that the default device fonts will be used. Standard values are "serif", "sans", "mono", and "symbol" and the Hershey font families are also available. (Different devices may define others, and some devices will ignore this setting completely.) This can be specified inline for `text`.

**fg**  The color to be used for the foreground of plots. This is the default color used for things like axes and boxes around plots. When called from `par()` this also sets parameter `col` to the same value.

A description of how colors are specified is given below.

**fig**  A numerical vector of the form `c(x1, x2, y1, y2)` which gives the (NDC) coordinates of the figure region in the display region of the device. If you set this, unlike S, you start a new plot, so to add to an existing plot use `new=TRUE` as well.

**fin**  The figure region dimensions, `(width, height)`, in inches. If you set this, unlike S, you start a new plot.

**font**  An integer which specifies which font to use for text. If possible, device drivers arrange so that 1 corresponds to plain text, 2 to bold face, 3 to italic and 4 to bold italic. Also, font 5 is expected to be the symbol font, in Adobe symbol encoding. On some devices font families can be selected by `family` to choose different sets of 5 fonts.

**font.axis**  The font to be used for axis annotation.

**font.lab**  The font to be used for x and y labels.

**font.main**  The font to be used for plot main titles.

**font.sub**  The font to be used for plot sub-titles.

**gamma**  the gamma correction, see argument `gamma` to `hsv`. This is only accepted if the current device has support for changing the gamma correction: currently only `windows` and `quartz` do. (`X11` has support for setting the gamma correction when opening the device, but not for changing it.)
lab A numerical vector of the form \( c(x, y, \text{len}) \) which modifies the default way that axes are annotated. The values of \( x \) and \( y \) give the (approximate) number of tickmarks on the x and y axes and \( \text{len} \) specifies the label length. The default is \( c(5, 5, 7) \). Note that this only affects the way the parameters \( \text{xaxp} \) and \( \text{yaxp} \) are set when the user coordinate system is set up, and is not consulted when axes are drawn. \( \text{len} \) is unimplemented in R.

\( \text{las} \) numeric in \( \{0, 1, 2, 3\} \); the style of axis labels.
- 0: always parallel to the axis [default],
- 1: always horizontal,
- 2: always perpendicular to the axis,
- 3: always vertical.

Note that other string/character rotation (via argument \text{srt} to \text{par}) does not affect the axis labels.

\( \text{lend} \) The line end style. This can be specified as an integer or string:
- 0 and "round" mean rounded line caps [default];
- 1 and "butt" mean butt line caps;
- 2 and "square" mean square line caps.

\( \text{lheight} \) The line height multiplier. The height of a line of text (used to vertically space multiline text) is found by multiplying the current font size both by the current character expansion and by the line height multiplier. Default value is 1.

\( \text{ljoin} \) The line join style. This can be specified as an integer or string:
- 0 and "round" mean rounded line joins [default];
- 1 and "mitre" mean mitred line joins;
- 2 and "bevel" mean bevelled line joins.

\( \text{lmitre} \) The line mitre limit. This controls when mitred line joins are automatically converted into bevelled line joins. The value must be larger than 1 and the default is 10. Not all devices will honour this setting.

\( \text{lty} \) The line type. Line types can either be specified as an integer (0=blank, 1=solid, 2=dashed, 3=dotted, 4=dotdash, 5=longdash, 6=twodash) or as one of the character strings "blank", "solid", "dashed", "dotted", "dotdash", "longdash", or "twodash", where "blank" uses "invisible lines" (i.e., does not draw them).

Alternatively, a string of up to 8 characters (from \( c(1:9, \text{"A"}:\text{"F"}) \)) may be given, giving the length of line segments which are alternatively drawn and skipped. See section ‘Line Type Specification’ below.

Some functions such as \text{lines} accept a vector of values which are recycled. Other uses will take just the first value if a vector of length greater than one is supplied.

\( \text{lwd} \) The line width, a \textit{positive} number, defaulting to 1. The interpretation is device-specific, and some devices do not implement line widths less than one. (See the help on the device for details of the interpretation.) Some functions such as \text{lines} accept a vector of values which are recycled. Other uses will take just the first value if a vector of length greater than one is supplied.

\( \text{mai} \) A numerical vector of the form \( c(\text{bottom}, \text{left}, \text{top}, \text{right}) \) which gives the margin size specified in inches.

\( \text{mar} \) A numerical vector of the form \( c(\text{bottom}, \text{left}, \text{top}, \text{right}) \) which gives the number of lines of margin to be specified on the four sides of the plot. The default is \( c(5, 4, 4, 2) + 0.1 \).

\( \text{mex} \) \( \text{mex} \) is a character size expansion factor which is used to describe coordinates in the margins of plots. Note that this does not change the font size, rather specifies the size of font used to convert between \text{mar} and \text{mai}, and between \text{oma} and \text{omi}.
**mfcol, mfrow** A vector of the form \(c(nr, nc)\). Subsequent figures will be drawn in an \(nr\)-by-\(nc\) array on the device by **columns** (mfcol), or **rows** (mfrow), respectively. In a layout with exactly two rows and columns the base value of "cex" is reduced by a factor of 0.83: if there are three or more of either rows or columns, the reduction factor is 0.66.

Consider the alternatives, **layout** and **split.screen**.

**mfg** A numerical vector of the form \(c(i, j)\) where \(i\) and \(j\) indicate which figure in an array of figures is to be drawn next (if setting) or is being drawn (if enquiring). The array must already have been set by mfcol or mfrow.

For compatibility with S, the form \(c(i, j, nr, nc)\) is also accepted, when \(nr\) and \(nc\) should be the current number of rows and number of columns. Mismatches will be ignored, with a warning.

**mgp** The margin line (in \(\text{mex}\) units) for the axis title, axis labels and axis line. The default is \(c(3, 1, 0)\).

**mkh** The height in inches of symbols to be drawn when the value of pch is an integer. Completely ignored currently.

**new** logical, defaulting to FALSE. If set to TRUE, the next high-level plotting command (actually **plot.new**) should *not clean* the frame before drawing "as if it was on a new device".

**oma** A vector of the form \(c(\text{bottom}, \text{left}, \text{top}, \text{right})\) giving the size of the outer margins in lines of text.

**omd** A vector of the form \(c(x1, x2, y1, y2)\) giving the outer margin region in NDC (= normalized device coordinates), i.e., as fraction (in \([0, 1]\)) of the device region.

**omi** A vector of the form \(c(\text{bottom}, \text{left}, \text{top}, \text{right})\) giving the size of the outer margins in inches.

**pch** Either an integer specifying a symbol or a single character to be used as the default in plotting points. See **points** for possible values and their interpretation.

**pin** The current plot dimensions, \((\text{width, height})\), in inches.

**plt** A vector of the form \(c(x1, x2, y1, y2)\) giving the coordinates of the plot region as fractions of the current figure region.

**ps** integer; the pointsize of text (but not symbols). Unlike the **pointsize** argument of most devices, this does not change the relationship between **mar** and **mai** (nor **oma** and **omi**), but it does scale **cin** and **csi**.

What is meant by ‘pointsize’ is device-specific, but most devices mean a multiple of 1bp, that is 1/72 of an inch.

**pty** A character specifying the type of plot region to be used; "s" generates a square plotting region and "m" generates the maximal plotting region.

**smo** (*Unimplemented*) a value which indicates how smooth circles and circular arcs should be.

**srt** The string rotation in degrees. See the comment about **crt**.

**tck** The length of tick marks as a fraction of the smaller of the width or height of the plotting region. If \(tck >= 0.5\) it is interpreted as a fraction of the relevant side, so if \(tck = 1\) grid lines are drawn. The default setting (\(tck = \text{NA}\)) is to use \(tcl = -0.5\) (see below).

**tcl** The length of tick marks as a fraction of the height of a line of text. The default value is \(-0.5\); setting \(tcl = \text{NA}\) sets \(tck = -0.01\) which is S’ default.

**usr** A vector of the form \(c(x1, x2, y1, y2)\) giving the extremes of the user coordinates of the plotting region. When a logarithmic scale is in use (i.e., **par("xlog")** is true, see below), then the x-limits will be \(10 ^ \text{par("usr")}[1:2]\). Similarly for the y-axis.
xaxp A vector of the form c(x1, x2, n) giving the coordinates of the extreme tick marks and the number of intervals between tick-marks when par("xlog") is false. Otherwise, when log coordinates are active, the three values have a different meaning: For a small range, n is negative, and the ticks are as in the linear case, otherwise, n is in 1:3, specifying a case number, and x1 and x2 are the lowest and highest power of 10 inside the user coordinates, \(10^{\text{par("usr")}[1:2]}\). (The "usr" coordinates are log10-transformed here!)

n=1 will produce tick marks at \(10^j\) for integer j,
n=2 gives marks \(k10^j\) with \(k \in \{1,5\}\),
n=3 gives marks \(k10^j\) with \(k \in \{1,2,5\}\).

See axTicks() for a pure R implementation of this.

This parameter is reset when a user coordinate system is set up, for example by starting a new page or by calling plot.window or setting par("usr"): n is taken from par("lab"). It affects the default behaviour of subsequent calls to axis for sides 1 or 3.

xaxs The style of axis interval calculation to be used for the x-axis. Possible values are "r", "i", "s", "e", "d". The styles are generally controlled by the range of data or xlim, if given. Style "r" (regular) first extends the data range by 4 percent and then finds an axis with pretty labels that fits within the range. Style "i" (internal) just finds an axis with pretty labels that fits within the original data range. Style "s" (standard) finds an axis with pretty labels within which the original data range fits. Style "e" (extended) is like style "s", except that it also ensures that there is room for plotting symbols within the bounding box. Style "d" (direct) specifies that the current axis should be used on subsequent plots. (Only "r" and "i" styles are currently implemented)

xaxt A character which specifies the x axis type. Specifying "n" suppresses plotting of the axis. The standard value is "s": for compatibility with S values "l" and "t" are accepted but are equivalent to "s": any value other than "n" implies plotting.

xlog A logical value (see log in plot.default). If TRUE, a logarithmic scale is in use (e.g., after plot(*, log = "x")). For a new device, it defaults to FALSE, i.e., linear scale.

xpd A logical value or NA. If FALSE, all plotting is clipped to the plot region, if TRUE, all plotting is clipped to the figure region, and if NA, all plotting is clipped to the device region.

yaxp A vector of the form c(y1, y2, n) giving the coordinates of the extreme tick marks and the number of intervals between tick-marks unless for log coordinates, see xaxp above.

yaxs The style of axis interval calculation to be used for the y-axis. See xaxs above.

yaxt A character which specifies the y axis type. Specifying "n" suppresses plotting.

ylog A logical value; see xlog above.

Color Specification

Colors can be specified in several different ways. The simplest way is with a character string giving the color name (e.g., "red"). A list of the possible colors can be obtained with the function colors. Alternatively, colors can be specified directly in terms of their RGB components with a string of the form "#RRGGBB" where each of the pairs RR, GG, BB consist of two hexadecimal digits giving a value in the range 00 to FF. Colors can also be specified by giving an index into a small table of colors, the palette. This provides compatibility with S. Index 0 corresponds to the background color.

Additionally, "transparent" or (integer)NA is transparent, useful for filled areas (such as the background!), and just invisible for things like lines or text. Semi-transparent colors are available for use on devices that support them.

The functions rgb, hsv, hcl, gray and rainbow provide additional ways of generating colors.
Line Type Specification

Line types can either be specified by giving an index into a small built-in table of line types (1 = solid, 2 = dashed, etc; see lty above) or directly as the lengths of on/off stretches of line. This is done with a string of an even number (up to eight) of characters, namely non-zero (hexadecimal) digits which give the lengths in consecutive positions in the string. For example, the string "33" specifies three units on followed by three off and "3313" specifies three units on followed by three off followed by one on and finally three off. The 'units' here are (on most devices) proportional to lwd, and with lwd = 1 are in pixels or points or 1/96 inch.

The five standard dash-dot line types (lty = 2:6) correspond to c("44", "13", "1343", "73", "2262").

Note that NA is not a valid value for lty.

Prior to R 2.4.0, zero hex digits were accepted and handled in a device-dependent way, e.g. X11() mapped them to one, pdf() regarded zero as terminating the string and windows() gave a zero-length stretch.

Note

The effect of restoring all the (settable) graphics parameters as in the examples is hard to predict if the device has been resized. Several of them are attempting to set the same things in different ways, and those last in the alphabet will win. In particular, the settings of mai, mar, pin, plt and pty interact, as do the outer margin settings, the figure layout and figure region size.

plot.default for some high-level plotting parameters; colors; options for other setup parameters; graphic devices x11, postscript and setting up device regions by layout and split.screen.

Examples

```r
op <- par(mfrow = c(2, 2), # 2 x 2 pictures on one plot
pty = "s") # square plotting region,
            # independent of device size

## At end of plotting, reset to previous settings:
par(op)

## Alternatively,
op <- par(no.readonly = TRUE) # the whole list of settable par's.
## do lots of plotting and par(.) calls, then reset:
par(op)

par("ylog") # FALSE
plot(1:12, log = "y")
par("ylog") # TRUE

plot(1:2, xaxs = "i") # 'inner axis' w/o extra space
```
par(c("usr", "xaxp"))

.nr.prof <-
c(prof.pilots=16,lawyers=11,farmers=10,salesmen=9,physicians=9,
 mechanics=6,policemen=6,managers=6,engineers=5,teachers=4,
 housewives=3,students=3,armed.forces=1))
par(las = 3)
barplot(rbind(nr.prof)) # R 0.63.2: shows alignment problem
par(las = 0)# reset to default

## 'fg' use:
plot(1:12, type = "b", main="'fg' : axes, ticks and box in gray",
 fg = gray(0.7), bty="7" , sub=R.version.string)

ex <- function() {
  old.par <- par(no.readonly = TRUE) # all par settings which
  # could be changed.
  on.exit(par(old.par))
  ## ...
  ## ... do lots of par() settings and plots
  ## ...
  invisible() #-- now, par(old.par) will be executed
}
ex()

persp

Perspective Plots

Description

This function draws perspective plots of surfaces over the x–y plane. persp is a generic function.

Usage

persp(x, ...)

## Default S3 method:
persp(x = seq(0, 1, len = nrow(z)), y = seq(0, 1, len = ncol(z)),
 z, xlim = range(x), ylim = range(y),
 zlim = range(z, na.rm = TRUE),
xlab = NULL, ylab = NULL, zlab = NULL, main = NULL, sub = NULL,
 theta = 0, phi = 15, r = sqrt(3), d = 1, scale = TRUE, expand = 1,
 col = "white", border = NULL, ltheta = -135, lphi = 0, shade = NA,
 box = TRUE, axes = TRUE, nticks = 5, ticktype = "simple", ...)

Arguments

x, y

locations of grid lines at which the values in z are measured. These must be in ascending order. By default, equally spaced values from 0 to 1 are used. If x is a list, its components x$x and x$y are used for x and y, respectively.

z

a matrix containing the values to be plotted (NAs are allowed). Note that x can be used instead of z for convenience.
xlim, ylim, zlim

x-, y- and z-limits. The plot is produced so that the rectangular volume defined by these limits is visible.

xlab, ylab, zlab

titles for the axes. N.B. These must be character strings; expressions are not accepted. Numbers will be coerced to character strings.

main, sub

main and sub title, as for title.

theta, phi

angles defining the viewing direction. theta gives the azimuthal direction and phi the colatitude.

r

the distance of the eyepoint from the centre of the plotting box.

d

a value which can be used to vary the strength of the perspective transformation. Values of d greater than 1 will lessen the perspective effect and values less and 1 will exaggerate it.

scale

before viewing the x, y and z coordinates of the points defining the surface are transformed to the interval [0,1]. If scale is TRUE the x, y and z coordinates are transformed separately. If scale is FALSE the coordinates are scaled so that aspect ratios are retained. This is useful for rendering things like DEM information.

expand

a expansion factor applied to the z coordinates. Often used with 0 < expand < 1 to shrink the plotting box in the z direction.

col

the color(s) of the surface facets. Transparent colours are ignored. This is recycled to the \((nx-1)(ny-1)\) facets.

border

the color of the line drawn around the surface facets. The default, NULL, corresponds to par("fg"). A value of NA will disable the drawing of borders: this is sometimes useful when the surface is shaded.

ltheta, lphi

if finite values are specified for ltheta and lphi, the surface is shaded as though it was being illuminated from the direction specified by azimuth ltheta and colatitude lphi.

shade

the shade at a surface facet is computed as \(((1+d)/2)^{\text{shade}}\), where d is the dot product of a unit vector normal to the facet and a unit vector in the direction of a light source. Values of shade close to one yield shading similar to a point light source model and values close to zero produce no shading. Values in the range 0.5 to 0.75 provide an approximation to daylight illumination.

box

should the bounding box for the surface be displayed. The default is TRUE.

axes

should ticks and labels be added to the box. The default is TRUE. If box is FALSE then no ticks or labels are drawn.

ticktype

character: "simple" draws just an arrow parallel to the axis to indicate direction of increase; "detailed" draws normal ticks as per 2D plots.

nticks

the (approximate) number of tick marks to draw on the axes. Has no effect if ticktype is "simple".

... additional graphical parameters (see par).

**Details**

The plots are produced by first transforming the coordinates to the interval \([0,1]\). The surface is then viewed by looking at the origin from a direction defined by theta and phi. If theta and phi are both zero the viewing direction is directly down the negative y axis. Changing theta will vary the azimuth and changing phi the colatitude.
There is a hook called "persp" (see `setHook`) called after the plot is completed, which is used in the testing code to annotate the plot page. The hook function(s) are called with no argument.

Notice that `persp` interprets the `z` matrix as a table of \( f(x[i], y[j]) \) values, so that the `x` axis corresponds to row number and the `y` axis to column number, with column 1 at the bottom, so that with the standard rotation angles, the top left corner of the matrix is displayed at the left hand side, closest to the user.

The sizes and fonts of the axis labels and the annotations for `ticktype="detailed"` are controlled by graphics parameters "cex.lab"/"font.lab" and "cex.axis"/"font.axis" respectively. (This changed in R 2.5.0.)

**Value**

`persp()` returns the viewing transformation matrix, say \( VT \), a \( 4 \times 4 \) matrix suitable for projecting 3D coordinates \((x,y,z)\) into the 2D plane using homogeneous 4D coordinates \((x,y,z,t)\). It can be used to superimpose additional graphical elements on the 3D plot, by `lines()` or `points()`, using the simple function `trans3d()`.

x <- 10 * (1:nrow(z))  # 10 meter spacing (S to N)
y <- 10 * (1:ncol(z))  # 10 meter spacing (E to W)
## Don't draw the grid lines : border = NA
par(bg = "slategray")
persp(x, y, z, theta = 135, phi = 30, col = "green3", scale = FALSE,
    ltheta = -120, shade = 0.75, border = NA, box = FALSE)
par(op)

---

**pie**  

**Pie Charts**

**Description**

Draw a pie chart.

**Usage**

```r
pie(x, labels = names(x), edges = 200, radius = 0.8,
    clockwise = FALSE, init.angle = if(clockwise) 90 else 0,
    density = NULL, angle = 45, col = NULL, border = NULL,
    lty = NULL, main = NULL, ...)
```

**Arguments**

- **x**: a vector of non-negative numerical quantities. The values in x are displayed as the areas of pie slices.
- **labels**: one or more expressions or character strings giving names for the slices. Other objects are coerced by `as.graphicsAnnot`. For empty or NA (after coercion to character) labels, no label nor pointing line is drawn.
- **edges**: the circular outline of the pie is approximated by a polygon with this many edges.
- **radius**: the pie is drawn centered in a square box whose sides range from −1 to 1. If the character strings labeling the slices are long it may be necessary to use a smaller radius.
- **clockwise**: logical indicating if slices are drawn clockwise or counter clockwise (i.e., mathematically positive direction), the latter is default.
- **init.angle**: number specifying the starting angle (in degrees) for the slices. Defaults to 0 (i.e., ‘3 o’clock’) unless clockwise is true where init.angle defaults to 90 (degrees), (i.e., ‘12 o’clock’).
- **density**: the density of shading lines, in lines per inch. The default value of NULL means that no shading lines are drawn. Non-positive values of density also inhibit the drawing of shading lines.
angle the slope of shading lines, given as an angle in degrees (counter-clockwise).

col a vector of colors to be used in filling or shading the slices. If missing a set of 6 pastel colours is used, unless density is specified when par("fg") is used.

border, lty (possibly vectors) arguments passed to polygon which draws each slice.

main an overall title for the plot.

... graphical parameters can be given as arguments to pie. They will affect the main title and labels only.

Note

Pie charts are a very bad way of displaying information. The eye is good at judging linear measures and bad at judging relative areas. A bar chart or dot chart is a preferable way of displaying this type of data.

Cleveland (1985), page 264: “Data that can be shown by pie charts always can be shown by a dot chart. This means that judgements of position along a common scale can be made instead of the less accurate angle judgements.” This statement is based on the empirical investigations of Cleveland and McGill as well as investigations by perceptual psychologists.

dotchart.

Examples

pie(rep(1, 24), col = rainbow(24), radius = 0.9)

pie.sales <- c(0.12, 0.3, 0.26, 0.16, 0.04, 0.12)
names(pie.sales) <- c("Blueberry", "Cherry", "Apple", "Boston Cream", "Other", "Vanilla Cream")
pie(pie.sales) # default colours
pie(pie.sales, col = c("purple", "violetred1", "green3", "cornsilk", "cyan", "white"))
pie(pie.sales, col = gray(seq(0.4,1.0,length=6)))
pie(pie.sales, density = 10, angle = 15 + 10 * 1:6)
pie(pie.sales, clockwise=TRUE, main="pie(*, clockwise=TRUE)")
segments(0,0, 0,1, col= "red", lwd = 2)
text(0,1, "init.angle = 90", col= "red")

n <- 200
pie(rep(1,n), labels="", col=rainbow(n), border=NA,
    main = "pie(*, labels="\"", col=rainbow(n), border=NA,..")
Generic X-Y Plotting

Description

Generic function for plotting of R objects. For more details about the graphical parameter arguments, see `par`.

Usage

`plot(x, y, ...)`

Arguments

- **x**: the coordinates of points in the plot. Alternatively, a single plotting structure, function or any R object with a plot method can be provided.
- **y**: the y coordinates of points in the plot, optional if `x` is an appropriate structure.
- **...**: Arguments to be passed to methods, such as graphical parameters (see `par`). Many methods will accept the following arguments:
  - **type**: what type of plot should be drawn. Possible types are
    - "p" for points,
    - "l" for lines,
    - "b" for both,
    - "c" for the lines part alone of "b",
    - "o" for both "overplotted",
    - "h" for “histogram” like (or “high-density”) vertical lines,
    - "s" for stair steps,
    - "S" for other steps, see Details below,
    - "n" for no plotting.
  All other types give a warning or an error; using, e.g., `type = "punkte"` being equivalent to `type = "p"` for S compatibility.
- **main**: an overall title for the plot: see `title`.
- **sub**: a sub title for the plot: see `title`.
- **xlab**: a title for the x axis: see `title`.
- **ylab**: a title for the y axis: see `title`.
- **asp**: the y/x aspect ratio, see `plot.window`.

Details

For simple scatter plots, `plot.default` will be used. However, there are plot methods for many R objects, including functions, data.frames, density objects, etc. Use methods(`plot`) and the documentation for these.

The two step types differ in their x-y preference: Going from `(x1, y1)` to `(x2, y2)` with `x1 < x2`, `type = "s"` moves first horizontal, then vertical, whereas `type = "S"` moves the other way around.
plot.data.frame

Plot Method for Data Frames

Description

plot.data.frame, a method for the plot generic. It is designed for a quick look at numeric data frames.

Usage

### S3 method for class 'data.frame':
plot(x, ...)

Arguments

x object of class data.frame.

... further arguments to stripchart.plot.default or pairs.

Details

This is intended for data frames with numeric columns. For more than two columns it first calls data.matrix to convert the data frame to a numeric matrix and then calls pairs to produce a scatterplot matrix). This can fail and may well be inappropriate: for example numerical conversion of dates will lose their special meaning and a warning will be given.

For a two-column data frame it plots the second column against the first by the most appropriate method for the first column.

For a single numeric column it uses stripchart, and for other single-column data frames tries to find a plot method for the single column.

data.frame
Examples

```r
plot(OrchardSprays[1], method="jitter")
plot(OrchardSprays[4:1])
plot(OrchardSprays)
plot(iris)
plot(iris[5:4])
plot(women)
```

---

**plot.default**  
*The Default Scatterplot Function*

**Description**

Draw a scatter plot with “decorations” such as axes and titles in the active graphics window.

**Usage**

```r
## Default S3 method:
plot(x, y = NULL, type = "p", xlim = NULL, ylim = NULL,
     log = "", main = NULL, sub = NULL, xlab = NULL, ylab = NULL,
     ann = par("ann"), axes = TRUE, frame.plot = axes,
     panel.first = NULL, panel.last = NULL, asp = NA, ...)
```

**Arguments**

- `x, y`  
The x and y arguments provide the x and y coordinates for the plot. Any reasonable way of defining the coordinates is acceptable. See the function `xy.coords` for details.
- `type`  
A 1-character string giving the type of plot desired. The following values are possible, for details, see `plot`:
  - "p" for points,
  - "l" for lines,
  - "o" for overplotted points and lines,
  - "b" or "c" for (empty if "c") points joined by lines,
  - "s" and "S" for stair steps and "h" for histogram-like vertical lines. Finally, "n" does not produce any points or lines.
- `xlim`  
The x limits (x1, x2) of the plot. Note that x1 > x2 is allowed and leads to a "reversed axis".
- `ylim`  
The y limits of the plot.
- `log`  
A character string which contains "x" if the x axis is to be logarithmic, "y" if the y axis is to be logarithmic and "xy" or "yx" if both axes are to be logarithmic.
- `main`  
A main title for the plot, see also `title`.
- `sub`  
A sub title for the plot.
- `xlab`  
A label for the x axis, defaults to a description of x.
- `ylab`  
A label for the y axis, defaults to a description of y.
- `ann`  
A logical value indicating whether the default annotation (title and x and y axis labels) should appear on the plot.
- `axes`  
A logical value indicating whether both axes should be drawn on the plot. Use graphical parameter "xaxt" or "yaxt" to suppress just one of the axes.
frame.plot  a logical indicating whether a box should be drawn around the plot.
panel.first an expression to be evaluated after the plot axes are set up but before any plotting
  takes place. This can be useful for drawing background grids or scatterplot
  smooths.
panel.last  an expression to be evaluated after plotting has taken place.
asp  the y/x aspect ratio, see plot.window.
...  other graphical parameters (see par and section ‘Details’ below).

Details

Commonly used graphical parameters are:

**col**  The colors for lines and points. Multiple colors can be specified so that each point can be
  given its own color. If there are fewer colors than points they are recycled in the standard
  fashion. Lines will all be plotted in the first colour specified.

**bg**  a vector of background colors for open plot symbols, see points. Note: this is not the same
  setting as par("bg").

**pch**  a vector of plotting characters or symbols: see points.

**cex**  a numerical vector giving the amount by which plotting text and symbols should be scaled
  relative to the default. This works as a multiple of par("cex"). NULL and NA are equivalent
  to 1.0.

**lty**  the line type, see par.

**cex.main, col.lab, font.sub, etc** settings for main- and sub-title and axis annotation,
  see title and par.

**lwd**  the line width, see par.

```
for (tp in c("p","l","b", "c","o","h", "s","S","n")) {
  plot(y ~ x, type = tp,
       main = paste("plot( *, type = ",tp," )",sep=""))
  if(tp == "S") {
    lines(x,y, type = "s", col = "red", lty = 2)
    mtext("lines( *, type = "s", ...)", col = "red", cex=.8)
  }
}
par(op)

##--- Log-Log Plot with custom axes
lx <- seq(1,5, length=41)
yl <- expression(e^{-frac(1,2) * {log[10](x)}^2})
y <- exp(-.5 *lx^2)
op <- par(mfrow=c(2,1), mar=par("mar")c(0,1,0,0))
plot(10^lx, y, log="xy", type="l", col="purple",
     main="Log-Log plot", ylab=yl, xlab="x")
plot(10^lx, y, log="xy", type="o", pch='.', col="forestgreen",
     main="Log-Log plot with custom axes", ylab=yl, xlab="x",
     axes = FALSE, frame.plot = TRUE)
my.at <- 10^(1:5)
axis(1, at = my.at, labels = formatC(my.at, format="fg"))
at.y <- 10^(-5:-1)
axis(2, at = at.y, labels = formatC(at.y, format="fg"), col.axis="red")
par(op)

plot.design  

Plot Univariate Effects of a ‘Design’ or Model

Description

Plot univariate effects of one or more factors, typically for a designed experiment as analyzed by aov(). Further, in S this a method of the plot generic function for design objects.

Usage

plot.design(x, y = NULL, fun = mean, data = NULL, ...,
            ylim = NULL, xlab = "Factors", ylab = NULL,
            main = NULL, ask = NULL, xaxt = par("xaxt"),
            axes = TRUE, xtick = FALSE)

Arguments

x  
either a data frame containing the design factors and optionally the response, or a formula or terms object.

y  
the response, if not given in x.

fun  
a function (or name of one) to be applied to each subset. It must return one number for a numeric (vector) input.

data  
data frame containing the variables referenced by x when that is formula like.

...  
graphical arguments such as col, see par.

ylim  
range of y values, as in plot.default.
xlab  x axis label, see title.
ylab  y axis label with a “smart” default.
main  main title, see title.
ask   logical indicating if the user should be asked before a new page is started — in the case of multiple y’s.
xaxt  character giving the type of x axis.
axes  logical indicating if axes should be drawn.
xtick logical indicating if “ticks” (one per factor) should be drawn on the x axis.

Details

The supplied function will be called once for each level of each factor in the design and the plot will show these summary values. The levels of a particular factor are shown along a vertical line, and the overall value of \( \text{fun()} \) for the response is drawn as a horizontal line.

This is a new R implementation which will not be completely compatible to the earlier S implementations. This is not a bug but might still change.

Note

A big effort was taken to make this closely compatible to the S version. However, col (and fg) specification has different effects.

Author(s)

Roberto Frisullo and Martin Maechler

interaction.plot for a “standard graphic” of designed experiments.

Examples

```r
plot.design(warpbreaks)# automatic for data frame with one numeric var.

Form <- breaks ~ wool + tension
summary(fml <- aov(Form, data = warpbreaks))
plot.design( Form, data = warpbreaks, col = 2)# same as above

## More than one y :
utils::str(esoph)
plot.design(esoph) ## two plots; if interactive you are "ask"ed

## or rather, compare mean and median:
op <- par(mfcol = 1:2)
plot.design(ncases/ncontrols ~ ., data = esoph, ylim = c(0, 0.8))
```
plot.factor

Plotting Factor Variables

Description

This function implements a “scatterplot” method for factor arguments of the generic plot function. Actually, boxplot is used when y is numeric and a spineplot when y is a factor. For a single factor x (i.e., with y missing) a simple barplot is produced.

Usage

## S3 method for class 'factor':
plot(x, y, legend.text = NULL, ...)

Arguments

x, y numeric or factor. y may be missing.

legend.text character vector for annotation of y axis, defaults to levels(y). Can be used instead of yaxlabels (for backward compatibility).

... Further arguments to plot, see also par.

See Also

plot.default, plot.formula, barplot, boxplot, spineplot.

Examples

plot(PlantGrowth) # -> plot.data.frame
plot(weight ~ group, data = PlantGrowth) # numeric vector ~ factor
plot(cut(weight, 2) ~ group, data = PlantGrowth) # factor ~ factor
## passing "..." to spineplot() eventually:
plot(cut(weight, 3) ~ group, data = PlantGrowth,
col = hcl(c(0, 120, 240), 50, 70))

plot(PlantGrowth$group, axes=FALSE, main="no axes") # extremely silly
plot.formula  

Formula Notation for Scatterplots

Description

Specify a scatterplot or add points or lines via a formula.

Usage

```r
## S3 method for class 'formula':
plot(formula, data = parent.frame(), ..., subset,
     ylab = varnames[response], ask = TRUE)

## S3 method for class 'formula':
points(formula, data = parent.frame(), ..., subset)

## S3 method for class 'formula':
lines(formula, data = parent.frame(), ..., subset)
```

Arguments

- `formula`: a formula, such as `y ~ x`.
- `data`: a data.frame (or list) from which the variables in `formula` should be taken.
- `...`: Arguments to be passed to or from other methods. `horizontal = TRUE` is also accepted.
- `subset`: an optional vector specifying a subset of observations to be used in the fitting process.
- `ylab`: the y label of the plot(s).
- `ask`: logical, see `par`.

Details

Both the terms in the formula and the `...` arguments are evaluated in `data` enclosed in `parent.frame()` if `data` is a list or a data frame. The terms of the formula and those arguments in `...` that are of the same length as `data` are subjected to the subsetting specified in `subset`. If the formula in `plot.formula` contains more than one non-response term, a series of plots of `y` against each term is given. A plot against the running index can be specified as `plot(y ~ 1)`.

Missing values are not considered in these methods, and in particular cases with missing values are not removed.

If `y` is an object (i.e. has a `class` attribute) then `plot.formula` looks for a plot method for that class first. Otherwise, the class of `x` will determine the type of the plot. For factors this will be a parallel boxplot, and argument `horizontal = TRUE` can be used (see `boxplot`).

Value

These functions are invoked for their side effect of drawing in the active graphics device.
plot.histogram

See Also

plot.default, points, lines, plot.factor.

Examples

```r
op <- par(mfrow=c(2,1))
plot(Ozone ~ Wind, data = airquality, pch=as.character(Month))
plot(Ozone ~ Wind, data = airquality, pch=as.character(Month),
     subset = Month != 7)
par(op)
```

Description

These are methods for objects of class "histogram", typically produced by `hist`.

Usage

```r
## S3 method for class 'histogram':
plot(x, freq = equidist, density = NULL, angle = 45,
     col = NULL, border = par("fg"), lty = NULL,
     main = paste("Histogram of",
                  paste(x$xname, collapse="\n")),
     sub = NULL, xlab = x$xname, ylab,
     xlim = range(x$breaks), ylim = NULL,
     axes = TRUE, labels = FALSE, add = FALSE, ...)

## S3 method for class 'histogram':
lines(x, ...)
```

Arguments

- **x**: a histogram object, or a list with components density, mid, etc, see `hist` for information about the components of `x`.
- **freq**: logical; if `TRUE`, the histogram graphic is to present a representation of frequencies, i.e, `x$counts`; if `FALSE`, relative frequencies ("probabilities"), i.e., `x$density`, are plotted. The default is true for equidistant breaks and false otherwise.
- **col**: a colour to be used to fill the bars. The default of `NULL` yields unfilled bars.
- **border**: the color of the border around the bars.
- **angle, density**: select shading of bars by lines: see `rect`.
- **lty**: the line type used for the bars, see also `lines`.
- **main, sub, xlab, ylab**: these arguments to `title` have useful defaults here.
- **xlim, ylim**: the range of x and y values with sensible defaults.
- **axes**: logical, indicating if axes should be drawn.
labels logical or character. Additionally draw labels on top of bars, if not FALSE; if TRUE, draw the counts or rounded densities; if labels is a character, draw itself.

add logical. If TRUE, only the bars are added to the current plot. This is what `lines.histogram(*)` does.

... further graphical parameters to `title` and `axis`.

Details

`lines.histogram(*)` is the same as `plot.histogram(*, add = TRUE)`.

See Also

`hist`, `stem`, `density`.

Examples

```r
(wwt <- hist(women$weight, nc= 7, plot = FALSE))
plot(wwt, labels = TRUE) # default main & xlab using wwt$xname
plot(wwt, border = "dark blue", col = "light blue",
     main = "Histogram of 15 women's weights", xlab = "weight [pounds]")

## Fake "lines" example, using non-default labels:
w2 <- wwt; w2$counts <- w2$counts - 1
lines(w2, col = "Midnight Blue", labels = ifelse(w2$counts, "> 1", "1"))
```

plot.table

Plot Methods for 'table' Objects

Description

This is a method of the generic `plot` function for (contingency) `table` objects. Whereas for two- and more dimensional tables, a `mosaicplot` is drawn, one-dimensional ones are plotted “bar like”.

Usage

```r
## S3 method for class 'table':
plot(x, type = "h", ylim = c(0, max(x)), lwd = 2,
     xlab = NULL, ylab = NULL, frame.plot = is.num, ...)
```

Arguments

- `x` a `table` (like) object.
- `type` plotting type.
- `ylim` range of y-axis.
- `lwd` line width for bars when `type = "h"` is used in the 1D case.
- `xlab`, `ylab` x- and y-axis labels.
- `frame.plot` logical indicating if a frame (box) should be drawn in the 1D case. Defaults to true when `x` has `dimnames` coerce-able to numbers.
- ... further graphical arguments, see `plot.default`.
Details

The current implementation (R 1.2) is somewhat experimental and will be improved and extended.

See Also

plot.factor, the plot method for factors.

Examples

## 1-d tables
(Poiss.tab <- table(N = rpois(200, lam= 5)))
plot(Poiss.tab, main = "plot(table(rpois(200, lam=5)))")

plot(table(state.division))

## 4-D :
plot(Titanic, main ="plot(Titanic, main= *)")

plot.window

Set up World Coordinates for Graphics Window

Description

This function sets up the world coordinate system for a graphics window. It is called by higher level functions such as plot.default (after plot.new).

Usage

plot.window(xlim, ylim, log = "", asp = NA, ...)

Arguments

xlim, ylim numeric vectors of length 2, giving the x and y coordinates ranges.
log character; indicating which axes should be in log scale.
asp numeric, giving the aspect ratio y/x.
... further graphical parameters as in par. The relevant ones are xaxs, yaxs and lab.

Details

Note that if asp is a finite positive value then the window is set up so that one data unit in the x direction is equal in length to asp \times one data unit in the y direction.

The special case asp == 1 produces plots where distances between points are represented accurately on screen. Values with asp > 1 can be used to produce more accurate maps when using latitude and longitude.

To reverse an axis, use xlim or ylim of the form c(hi, lo).

The function attempts to produce a plausible set of scales if one or both of xlim and ylim is of length one or the two values given are identical, but it is better to avoid that case.
Usually, one should rather use the higher level functions such as `plot`, `hist`, `image`, ..., instead and refer to their help pages for explanation of the arguments.

A side-effect of the call is to set up the `usr`, `xaxp` and `yaxp` graphical parameters. (It is for the latter two that `lab` is used.)

`xy.coords`, `plot.xy`, `plot.default`.

Examples

```r
##--- An example for the use of 'asp' :
require(stats) # normally loaded
loc <- cmdscale(eurodist)
rx <- range(x <- loc[,1])
ry <- range(y <- -loc[,2])
plot(x, y, type="n", asp=1, xlab="", ylab="")
abline(h = pretty(rx, 10), v = pretty(ry, 10), col = "lightgray")
text(x, y, labels(eurodist), cex=0.8)
```

---

**plot.xy**

*Basic Internal Plot Function*

Description

This is *the* internal function that does the basic plotting of points and lines. Usually, one should rather use the higher level functions instead and refer to their help pages for explanation of the arguments.

Usage

```r
plot.xy(xy, type, pch = par("pch"), lty = par("lty"),
       col = par("col"), bg = NA,
       cex = 1, lwd = par("lwd"), ...)
```

Arguments

- `xy`  
  A four-element list as results from `xy.coords`.

- `type`  
  1 character code: see `plot.default`. NULL is accepted as a synonym for "p".

- `pch`  
  character or integer code for kind of points, see `points.default`.

- `lty`  
  line type code, see `lines`.

- `col`  
  color code or name, see `colors, palette`. Here NULL means colour 0.

- `bg`  
  background ("fill") color for the open plot symbols 21:25: see `points.default`.

- `cex`  
  character expansion.

- `lwd`  
  line width, also used for (non-filled) plot symbols, see `lines` and `points`.

- `...`  
  further graphical parameters such as `xpd, lend, ljoin` and `lmitre`. 
points

Details

The arguments \texttt{pch}, \texttt{col}, \texttt{bg}, \texttt{cex}, \texttt{lwd} may be vectors and may be recycled, depending on \texttt{type}: see \texttt{points} and \texttt{lines} for specifics. In particular note that \texttt{lwd} is treated as a vector for points and as a single (first) value for lines.

See Also

\texttt{plot, plot.default, points, lines}.

Examples

\begin{verbatim}
points.default # to see how it calls "plot.xy(xy.coords(x, y), ...)"
\end{verbatim}

Description

\texttt{points} is a generic function to draw a sequence of points at the specified coordinates. The specified character(s) are plotted, centered at the coordinates.

Usage

\begin{verbatim}
points(x, ...)
## Default S3 method:
points(x, y = NULL, type = "p", ...)
\end{verbatim}

Arguments

\begin{itemize}
  \item \texttt{x, y} coordinate vectors of points to plot.
  \item \texttt{type} character indicating the type of plotting: actually any of the \texttt{types} as in \texttt{plot.default}.
  \item \ldots Further graphical parameters may also be supplied as arguments. See Details.
\end{itemize}

Details

The coordinates can be passed in a plotting structure (a list with \texttt{x} and \texttt{y} components), a two-column matrix, a time series, …. See \texttt{xy.coords}.

Graphical parameters commonly used are

\begin{itemize}
  \item \texttt{pch} plotting “character”, i.e., symbol to use. This can either be a single character or an integer code for one of a set of graphics symbols. The full set of S symbols is available with \texttt{pch=0:18}, see the last picture from \texttt{example(points)}, i.e., the examples below.
  \texttt{In addition, there is a special set of \texttt{R} plotting symbols which can be obtained with \texttt{pch=19:25} and \texttt{21:25} can be colored and filled with different colors:}
    \begin{itemize}
      \item \texttt{pch=19}: solid circle,
      \item \texttt{pch=20}: bullet (smaller circle),
      \item \texttt{pch=21}: circle,
      \item \texttt{pch=22}: square,
    \end{itemize}
\end{itemize}
• pch=23: diamond,
• pch=24: triangle point-up,
• pch=25: triangle point down.

Values pch=26:32 are currently unused, and pch=32:255 give the text symbol in a single-byte locale. In a multi-byte locale such as UTF-8, numeric values of pch greater than or equal to 32 specify a Unicode code point (except for the symbol font as selected by \texttt{par(font = 5)}).

If pch is an integer or character \texttt{NA} or an empty character string, the point is omitted from the plot.

Value pch="." is handled specially. It is a rectangle of side 0.01 inch (scaled by \texttt{cex}). In addition, if \texttt{cex} = 1 (the default), each side is at least one pixel (1/72 inch on the pdf, postscript and xfig devices).

\texttt{col} color code or name, see \texttt{par}.

\texttt{bg} background ("fill") color for the open plot symbols given by pch=21:25.

\texttt{cex} character (or symbol) expansion: a numerical vector. This works as a multiple of \texttt{par("cex")}.

\texttt{lwd} line width for drawing symbols see \texttt{par}.

Others less commonly used are \texttt{lty} and \texttt{lwd} for types such as "b" and "l".

Graphical parameters pch, col, bg, cex and lwd can be vectors (which will be recycled as needed) giving a value for each point plotted. If lines are to be plotted (e.g. for \texttt{type = "b"} the first element of \texttt{lwd} is used.

Points whose \texttt{x}, \texttt{y}, \texttt{pch}, \texttt{col} or \texttt{cex} value is \texttt{NA} are omitted from the plot.

\textbf{Note}

What is meant by ‘a single character’ is locale-dependent.

The encoding may not have symbols for some or all of the characters in pch=128:255

\textbf{References}

\textbf{See Also}

\texttt{plot}, \texttt{lines}, and the underlying workhorse function \texttt{plot.xy}.

\textbf{Examples}

\begin{verbatim}
plot(-4:4, -4:4, type = "n")# setting up coord. system
points(rnorm(200), rnorm(200), col = "red")
points(rnorm(100)/2, rnorm(100)/2, col = "blue", cex = 1.5)
op <- par(bg = "light blue")
x <- seq(0,2*pi, len=51)
## something "between type='b' and type='o'":
plot(x, sin(x), type="o", pch=21, bg=par("bg"), col = "blue", cex=.6, main='plot(..., type="o", pch=21, bg=par("bg"))')
par(op)

##------- Showing all the extra & some char graphics symbols ---------
\end{verbatim}
Pex <- 3 ## good for both .Device="postscript" and "x11"
ipch <- 0:35; np <- length(ipch); k <- floor(sqrt(np)); dd <- c(-1,1)/2
rx <- dd + range(ix <- ipch %/% k)
ry <- dd + range(iy <- 3 + (k-1)- ipch %% k)
pch <- as.list(ipch)
pch[26+ 1:10] <- as.list(c(" *"," .", "o"," O"," 0"," +"," -"," |"," %"," #"))
plot(rx, ry, type="n", axes = FALSE, xlab = "", ylab = ""
          main = paste("plot symbols : points (... pch = *, cex =", Pex,")"))
abline(v = ix, h = iy, col = "lightgray", lty = "dotted")
for(i in 1:np) {
  pc <- pch[[i]]
  points(ix[i], iy[i], pch = pc, col = "red", bg = "yellow", cex = Pex)
  ## red symbols with a yellow interior (where available)
  text(ix[i] - .3, iy[i], pc, col = "brown", cex = 1.2)
}
Details

The coordinates can be passed in a plotting structure (a list with x and y components), a two-column matrix, .... See xy.coords.

It is assumed that the polygon is to be closed by joining the last point to the first point.

The coordinates can contain missing values. The behaviour is similar to that of lines, except that instead of breaking a line into several lines, NA values break the polygon into several complete polygons (including closing the last point to the first point). See the examples below.

When multiple polygons are produced, the values of density, angle, col, border, and lty are recycled in the usual manner.

Bugs

The present shading algorithm can produce incorrect results for self-intersecting polygons.

Author(s)

The code implementing polygon shading was donated by Kevin Buhr (buhr@stat.wisc.edu).

segments for even more flexibility, lines, rect, box, abline.

par for how to specify colors.

Examples

```r
x <- c(1:9,8:1)
y <- c(1,2*(5:3),2,-1,17,9,8,2:9)
op <- par(mfcol=c(3,1))
for(xpd in c(FALSE,TRUE,NA)) {
  plot(1:10, main = paste("xpd =", xpd))
  box("figure", col = "pink", lwd=3)
  polygon(x,y, xpd=xpd, col="orange", lty=2, lwd=2, border="red")
}
par(op)
```

```r
n <- 100
xx <- c(0:n, n:0)
yy <- c(c(0,cumsum(rnorm(n))), rev(c(0,cumsum(rnorm(n)))))
plot (xx, yy, type="n", xlab="Time", ylab="Distance")
polygon(xx, yy, col="gray", border = "red")
title("Distance Between Brownian Motions")
```

```r
# Multiple polygons from NA values
# and recycling of col, border, and lty
op <- par(mfrow=c(2,1))
plot(c(1,9), 1:2, type="n")
polygon(1:9, c(2,1,2,1,1,2,1,2,1),
```
rect

**Draw One or More Rectangles**

Description

**rect** draws a rectangle (or sequence of rectangles) with the given coordinates, fill and border colors.

Usage

```r
rect(xleft, ybottom, xright, ytop, density = NULL, angle = 45,
    col = NA, border = NULL, lty = par("lty"), lwd = par("lwd"),
    ...)  
```

Arguments

- **xleft** a vector (or scalar) of left x positions.
- **ybottom** a vector (or scalar) of bottom y positions.
- **xright** a vector (or scalar) of right x positions.
- **ytop** a vector (or scalar) of top y positions.
- **density** the density of shading lines, in lines per inch. The default value of **NULL** means that no shading lines are drawn. A zero value of **density** means no shading lines whereas negative values (and **NA**) suppress shading (and so allow color filling).
- **angle** angle (in degrees) of the shading lines.
- **col** color(s) to fill or shade the rectangle(s) with. The default **NA** (or also **NULL**) means do not fill, i.e., draw transparent rectangles, unless **density** is specified.
- **border** color for rectangle border(s). The default means **par("fg")**. Use **border = NA** to omit borders. If there are shading lines, **border = TRUE** means use the same colour for the border as for the shading lines.
- **lty** line type for borders and shading; defaults to "solid".
- **lwd** line width for borders and shading.
- **...** graphical parameters such as **xpd**, **lend**, **ljoin** and **lmitre** can be given as arguments.
Details

The positions supplied, i.e., xleft, ..., are relative to the current plotting region. If the x-axis goes from 100 to 200 then xleft must be larger than 100 and xright must be less than 200.

It is a primitive function used in `hist`, `barplot`, `legend`, etc.

See Also

`box` for the “standard” box around the plot; `polygon` and `segments` for flexible line drawing. `par` for how to specify colors.

Examples

```r
## set up the plot region:
op <- par(bg = "thistle")
plot(c(100, 250), c(300, 450), type = "n", xlab="", ylab="",
     main = "2 x 11 rectangles; 'rect(100+i,300+i, 150+i,380+i)'")
i <- 4*(0:10)
## draw rectangles with bottom left (100, 300)+i
## and top right (150, 380)+i
rect(100+i, 300+i, 150+i, 380+i, col=rainbow(11, start=.7,end=.1))
rect(240-i, 320+i, 250-i, 410+i, col=heat.colors(11), lwd=i/5)
## Background alternating ( transparent / "bg" ) :
j <- 10*(0:5)
rect(125+j, 360+j, 141+j, 405+j/2, col = c(NA,0),
     border = "gold", lwd = 2)
rect(125+j, 296+j/2, 141+j, 331+j/5, col = c(NA,"midnightblue"))
mtext("+ 2 x 6 rect(*, col = c(NA,0)) and col = c(NA,\"m..blue\")")
## an example showing colouring and shading
plot(c(100, 200), c(300, 450), type= "n", xlab="", ylab="")
rect(100, 300, 125, 350) # transparent
rect(100, 400, 125, 450, col="green", border="blue") # coloured
rect(115, 375, 150, 425, col=par("bg"), border="transparent")
rect(150, 300, 175, 350, density=10, border="red")
rect(150, 400, 175, 450, density=30, col="blue",
     angle=-30, border="transparent")
legend(180, 450, legend=1:4, fill=c(NA, "green", par("fg"), "blue"),
       density=c(NA, NA, 10, 30), angle=c(NA, NA, 30, -30))
par(op)
```

rug

Add a Rug to a Plot

Description

Adds a rug representation (1-d plot) of the data to the plot.

Usage

```r
rug(x, ticksize = 0.03, side = 1, lwd = 0.5, col = par("fg"),
     quiet = getOption("warn") < 0, ...)
```
Arguments

- **x**: A numeric vector
- **ticksize**: The length of the ticks making up the ‘rug’. Positive lengths give inwards ticks.
- **side**: On which side of the plot box the rug will be plotted. Normally 1 (bottom) or 3 (top).
- **lwd**: The line width of the ticks.
- **col**: The colour the ticks are plotted in.
- **quiet**: logical indicating if there should be a warning about clipped values.
- **...**: further arguments, passed to `axis`, such as `line` or `pos` for specifying the location of the rug.

Details

Because of the way `rug` is implemented, only values of `x` that fall within the plot region are included. There will be a warning if any finite values are omitted, but non-finite values are omitted silently.

Because of the way colours are done the axis itself is redrawn in the same colour, `lty` and `lwd` as the ticks. You can replot the box if you don’t like this feature.

References

See Also

- `jitter` which you may want for ties in `x`.

Examples

```r
require(stats)# both 'density' and its default method
with(faithful, {
  plot(density(eruptions, bw = 0.15))
  rug(eruptions)
  rug(jitter(eruptions, amount = 0.01), side = 3, col = "light blue")
})
```

---

**screen**

Creating and Controlling Multiple Screens on a Single Device

Description

`split.screen` defines a number of regions within the current device which can, to some extent, be treated as separate graphics devices. It is useful for generating multiple plots on a single device. Screens can themselves be split, allowing for quite complex arrangements of plots.

`screen` is used to select which screen to draw in.

`erase.screen` is used to clear a single screen, which it does by filling with the background colour.

`close.screen` removes the specified screen definition(s).
Usage

split.screen(figs, screen, erase = TRUE)
screen(n = , new = TRUE)
erase.screen(n = )
close.screen(n, all.screens = FALSE)

Arguments

figs
A two-element vector describing the number of rows and the number of columns
in a screen matrix or a matrix with 4 columns. If a matrix, then each row de-
scribes a screen with values for the left, right, bottom, and top of the screen (in
that order) in NDC units, that is 0 at the lower left corner of the device surface,
and 1 at the upper right corner.

screen
A number giving the screen to be split. It defaults to the current screen if there
is one, otherwise the whole device region.

erase
logical: should be selected screen be cleared?

n
A number indicating which screen to prepare for drawing (screen), erase
(erase.screen), or close (close.screen). (close.screen will ac-
cept a vector of screen numbers.)

new
A logical value indicating whether the screen should be erased as part of the
preparation for drawing in the screen.

all.screens
A logical value indicating whether all of the screens should be closed.

Details

The first call to split.screen places R into split-screen mode. The other split-screen functions
only work within this mode. While in this mode, certain other commands should be avoided (see
the Warnings section below). Split-screen mode is exited by the command close.screen(all
= TRUE).

If the current screen is closed, close.screen sets the current screen to be the next larger screen
number if there is one, otherwise to the first available screen.

Value

split.screen returns a vector of screen numbers for the newly-created screens. With no argu-
ments, split.screen returns a vector of valid screen numbers.
screen invisibly returns the number of the selected screen. With no arguments, screen returns
the number of the current screen.
close.screen returns a vector of valid screen numbers.
screen, erase.screen, and close.screen all return FALSE if R is not in split-screen
mode.

Warnings

The recommended way to use these functions is to completely draw a plot and all additions (i.e.
points and lines) to the base plot, prior to selecting and plotting on another screen. The behavior
associated with returning to a screen to add to an existing plot is unpredictable and may result in
problems that are not readily visible.

These functions are totally incompatible with the other mechanisms for arranging plots on a device:
par(mfrow), par(mfcol) and layout().
The functions are also incompatible with some plotting functions, such as `coplot`, which make use of these other mechanisms.

`erase.screen` will appear not to work if the background colour is transparent (as it is by default on most devices).

**References**

**See Also**

`par`, `layout`, `Devices`, `dev.*`

**Examples**

```r
if (interactive()) {
  par(bg = "white") # default is likely to be transparent
  split.screen(c(2,1)) # split display into two screens
  split.screen(c(1,3), screen = 2) # now split the bottom half into 3
  screen(1) # prepare screen 1 for output
  plot(10:1)
  screen(4) # prepare screen 4 for output
  plot(10:1)
  close.screen(all = TRUE) # exit split-screen mode

  split.screen(c(2,1)) # split display into two screens
  split.screen(c(1,2),2) # split bottom half in two
  plot(1:10) # screen 3 is active, draw plot
  erase.screen() # forgot label, erase and redraw
  plot(1:10, ylab = "ylab 3")
  screen(1) # prepare screen 1 for output
  plot(1:10)
  screen(4) # prepare screen 4 for output
  plot(1:10, ylab="ylab 4")
  screen(1, FALSE) # return to screen 1, but do not clear
  plot(10:1, axes=FALSE, lty=2, ylab="") # overlay second plot
  axis(4) # add tic marks to right-hand axis
  title("Plot 1")
  close.screen(all = TRUE) # exit split-screen mode
}
```

---

**segments**

*Add Line Segments to a Plot*

**Description**

Draw line segments between pairs of points.

**Usage**

```r
segments(x0, y0, x1, y1,
  col = par("fg"), lty = par("lty"), lwd = par("lwd"), ...
)```

Arguments

- **x0, y0**: coordinates of points from which to draw.
- **x1, y1**: coordinates of points to which to draw.
- **col, lty, lwd**: usual graphical parameters as in `par`, possibly vectors. NA values in `col` cause the segment to be omitted.
- **...**: further graphical parameters (from `par`), such as `xpd` and the line characteristics `lend`, `ljoin` and `lmitre`.

Details

For each i, a line segment is drawn between the point \((x0[i], y0[i])\) and the point \((x1[i], y1[i])\).

The graphical parameters `col`, `lty` and `lwd` can be vectors of length greater than one and will be recycled if necessary.

References

See Also

- `arrows`, `polygon` for slightly easier and less flexible line drawing, and `lines` for the usual polygons.

Examples

```r
x <- runif(12); y <- rnorm(12)
i <- order(x,y); x <- x[i]; y <- y[i]
plot(x, y, main="arrows(.) and segments(.)")
#### draw arrows from point to point :
s <- seq(length(x)-1)# one shorter than data
arrows(x[s], y[s], x[s+1], y[s+1], col= 1:3)
s <- s[-length(s)]
segments(x[s], y[s], x[s+2], y[s+2], col= 'pink')
```

Description

Spine plots are a special cases of mosaic plots, and can be seen as a generalization of stacked (or highlighted) bar plots. Analogously, spinograms are an extension of histograms.
Usage

spineplot(x, ...)

## Default S3 method:
spineplot(x, y = NULL,
  breaks = NULL, tol.ylab = 0.05, off = NULL,
  col = NULL, main = "", xlab = NULL, ylab = NULL,
  xaxlabels = NULL, yaxlabels = NULL,
  xlim = NULL, ylim = c(0, 1), ...)

## S3 method for class 'formula':
spineplot(formula, data = list(),
  breaks = NULL, tol.ylab = 0.05, off = NULL,
  col = NULL, main = "", xlab = NULL, ylab = NULL,
  xaxlabels = NULL, yaxlabels = NULL,
  xlim = NULL, ylim = c(0, 1), ...,
  subset = NULL)

Arguments

x
  an object, the default method expects either a single variable (interpreted to be
  the explanatory variable) or a 2-way table. See details.

y
  a "factor" interpreted to be the dependent variable

formula
  a "formula" of type y ~ x with a single dependent "factor" and a single
  explanatory variable.

data
  an optional data frame.

breaks
  if the explanatory variable is numeric, this controls how it is discretized.
  breaks is passed to hist and can be a list of arguments.

tol.ylab
  convenience tolerance parameter for y-axis annotation. If the distance between
  two labels drops under this threshold, they are plotted equidistantly.

off
  vertical offset between the bars (in per cent). It is fixed to 0 for spinograms and
  defaults to 2 for spine plots.

col
  a vector of fill colors of the same length as levels(y). The default is to call
  gray.colors.

main, xlab, ylab
  character strings for annotation

xaxlabels, yaxlabels
  character vectors for annotation of x and y axis. Default to levels(y) and
  levels(x), respectively for the spine plot. For xaxlabels in the spinogram,
  the breaks are used.

xlim, ylim
  the range of x and y values with sensible defaults.

... additional arguments passed to rect.

subset
  an optional vector specifying a subset of observations to be used for plotting.

Details

spineplot creates either a spinogram or a spine plot. It can be called via spineplot(x, y) or spineplot(y ~ x) where y is interpreted to be the dependent variable (and has to be categorical) and x the explanatory variable. x can be either categorical (then a spine plot is created)
or numerical (then a spinogram is plotted). Additionally, spineplot can also be called with only a single argument which then has to be a 2-way table, interpreted to correspond to $\text{table}(x, y)$.

Both, spine plots and spinograms, are essentially mosaic plots with special formatting of spacing and shading. Conceptually, they plot $P(y|x)$ against $P(x)$. For the spine plot (where both $x$ and $y$ are categorical), both quantities are approximated by the corresponding empirical relative frequencies. For the spinogram (where $x$ is numerical), $x$ is first discretized (by calling \texttt{hist} with \texttt{breaks} argument) and then empirical relative frequencies are taken.

Thus, spine plots can also be seen as a generalization of stacked bar plots where not the heights but the widths of the bars corresponds to the relative frequencies of $x$. The heights of the bars then correspond to the conditional relative frequencies of $y$ in every $x$ group. Analogously, spinograms extend stacked histograms.

### Value

The table visualized is returned invisibly.

           main = "Admissions at UCB"))
```
## NASA space shuttle o-ring failures

```r
fail <- factor(c(2, 2, 2, 2, 1, 1, 1, 1, 2, 1, 2, 1, 1, 1, 1, 2, 1, 1, 2, 1, 2, 1, 1, 1, 2, 1, 1, 1, 1, 1),
    levels = c(1, 2), labels = c("no", "yes"))
temperature <- c(53, 57, 58, 63, 66, 67, 67, 67, 68, 69, 70, 70,
    70, 72, 73, 75, 75, 76, 76, 78, 79, 81)
```

## (dependence on a numerical variable)

```r
(spineplot(fail ~ temperature))
(spineplot(fail ~ temperature, breaks = 3))
(spineplot(fail ~ temperature, breaks = quantile(temperature)))
```

---

### stars

**Star (Spider/Radar) Plots and Segment Diagrams**

**Description**

Draw star plots or segment diagrams of a multivariate data set. With one single location, also draws “spider” (or "radar") plots.

**Usage**

```r
stars(x, full = TRUE, scale = TRUE, radius = TRUE,
    labels = dimnames(x)[[1]], locations = NULL,
    nrow = NULL, ncol = NULL, len = 1,
    key.loc = NULL, key.labels = dimnames(x)[[2]], key.xpd = TRUE,
    xlim = NULL, ylim = NULL, flip.labels = NULL,
    draw.segments = FALSE, col.segments = 1:n.seg, col.stars = NA,
    axes = FALSE, frame.plot = axes,
    main = NULL, sub = NULL, xlab = "", ylab = "",
    cex = 0.8, lwd = 0.25, lty = par("lty"), xpd = FALSE,
    mar = pmin(par("mar"),
        1.1 + c(2*axes+ (xlab != ""),
        2*axes+ (ylab != ""), 1,0)),
    add = FALSE, plot = TRUE, ...)
```

**Arguments**

- **x**: matrix or data frame of data. One star or segment plot will be produced for each row of x. Missing values (NA) are allowed, but they are treated as if they were 0 (after scaling, if relevant).
- **full**: logical flag: if TRUE, the segment plots will occupy a full circle. Otherwise, they occupy the (upper) semicircle only.
- **scale**: logical flag: if TRUE, the columns of the data matrix are scaled independently so that the maximum value in each column is 1 and the minimum is 0. If FALSE, the presumption is that the data have been scaled by some other algorithm to the range [0, 1].
- **radius**: logical flag: in TRUE, the radii corresponding to each variable in the data will be drawn.
- **labels**: vector of character strings for labeling the plots. Unlike the S function stars, no attempt is made to construct labels if labels = NULL.
locations  Either two column matrix with the x and y coordinates used to place each of the
segment plots; or numeric of length 2 when all plots should be superimposed
(for a “spider plot”). By default, locations = NULL, the segment plots will
be placed in a rectangular grid.

nrow, ncol  integers giving the number of rows and columns to use when locations is
NULL. By default, nrow == ncol, a square layout will be used.

len  scale factor for the length of radii or segments.

key.loc  vector with x and y coordinates of the unit key.

key.labels  vector of character strings for labeling the segments of the unit key. If omitted,
the second component of dimnames(x) is used, if available.

key.xpd  clipping switch for the unit key (drawing and labeling), see par("xpd").

xlim  vector with the range of x coordinates to plot.

ylim  vector with the range of y coordinates to plot.

flip.labels  logical indicating if the label locations should flip up and down from diagram to
diagram. Defaults to a somewhat smart heuristic.

draw.segments  logical. If TRUE draw a segment diagram.

col.segments  color vector (integer or character, see par), each specifying a color for one of
the segments (variables). Ignored if draw.segments = FALSE.

col.stars  color vector (integer or character, see par), each specifying a color for one of
the stars (cases). Ignored if draw.segments = TRUE.

axes  logical flag: if TRUE axes are added to the plot.

frame.plot  logical flag: if TRUE, the plot region is framed.

main  a main title for the plot.

sub  a sub title for the plot.

xlab  a label for the x axis.

ylab  a label for the y axis.

cex  character expansion factor for the labels.

lwd  line width used for drawing.

lty  line type used for drawing.

xpd  logical or NA indicating if clipping should be done, see par(xpd = .).

mar  argument to par(mar = *), typically choosing smaller margins than by de-
fault.

...  further arguments, passed to the first call of plot(), see plot.default and
to box() if frame.plot is true.

add  logical, if TRUE add stars to current plot.

plot  logical, if FALSE, nothing is plotted.

Details

Missing values are treated as 0.

Each star plot or segment diagram represents one row of the input x. Variables (columns) start on
the right and wind counterclockwise around the circle. The size of the (scaled) column is shown by
the distance from the center to the point on the star or the radius of the segment representing the
variable.

Only one page of output is produced.
Note

This code started life as spatial star plots by David A. Andrews. See http://www.udallas.edu:8080/~andrews/software/software.html.

Prior to 1.4.1, scaling only shifted the maximum to 1, although documented as here.

```
stem

Stem-and-Leaf Plots

Description

stem produces a stem-and-leaf plot of the values in x. The parameter scale can be used to expand the scale of the plot. A value of scale=2 will cause the plot to be roughly twice as long as the default.

Usage

stem(x, scale = 1, width = 80, atom = 1e-08)

Arguments

x a numeric vector.

scale This controls the plot length.

width The desired width of plot.

atom a tolerance.

References

Examples

stem(islands)
stem(log10(islands))

stripchart

1-D Scatter Plots

Description

stripchart produces one dimensional scatter plots (or dot plots) of the given data. These plots are a good alternative to boxplots when sample sizes are small.

Usage

stripchart(x, method = "overplot", jitter = 0.1, offset = 1/3,
vertical = FALSE, group.names, add = FALSE,
at = NULL, xlim = NULL, ylim = NULL,
main = ",", ylab = ",", xlab = ",",
log = ",", pch = 0, col = par("fg"), cex = par("cex"))
stripchart

Arguments

x
the data from which the plots are to be produced. The data can be specified as a single numeric vector, or as list of numeric vectors, each corresponding to a component plot. Alternatively a symbolic specification of the form x ~ g can be given, indicating the observations in the vector x are to be grouped according to the levels of the factor g. NAs are allowed in the data.

method
the method to be used to separate coincident points. The default method "overplot" causes such points to be overplotted, but it is also possible to specify "jitter" to jitter the points, or "stack" have coincident points stacked. The last method only makes sense for very granular data.

jitter
when method="jitter" is used, jitter gives the amount of jittering applied.

offset
when stacking is used, points are stacked this many line-heights (symbol widths) apart.

vertical
when vertical is TRUE the plots are drawn vertically rather than the default horizontal.

group.names
group labels which will be printed alongside (or underneath) each plot.

add
logical, if true add the chart to the current plot.

at
numeric vector giving the locations where the charts should be drawn, particularly when add = TRUE; defaults to 1:n where n is the number of boxes.

main, ylab, xlab
labels: see title.

xlim, ylim
plot limits: see plot.window.

log, pch, col, cex
Graphical parameters: see par.

Details

Extensive examples of the use of this kind of plot can be found in Box, Hunter and Hunter or Seber and Wild.

Examples

x <- rnorm(50)
xr <- round(x, 1)
stripchart(x) ; m <- mean(par("usr")[1:2])
text(m, 1.04, "stripchart(x, "overplot")")

stripchart(xr, method = "stack", add = TRUE, at = 1.2)
text(m, 1.35, "stripchart(round(x,1), "stack")")

stripchart(xr, method = "jitter", add = TRUE, at = 0.7)
text(m, 0.85, "stripchart(round(x,1), "jitter")")

with(OrchardSprays,
    stripchart(decrease ~ treatment,
                main = "stripchart(Orchardsprays)", ylab = "decrease",
                vertical = TRUE, log = "y")
)

with(OrchardSprays,
    stripchart(decrease ~ treatment, at = c(1:8)^2,
                main = "stripchart(Orchardsprays)", ylab = "decrease",
                vertical = TRUE, log = "y")
)
strwidth

Plotting Dimensions of Character Strings and Math Expressions

Description

These functions compute the width or height, respectively, of the given strings or mathematical expressions \( s[i] \) on the current plotting device in user coordinates, inches or as fraction of the figure width \( \text{par("fin")} \).

Usage

\[
\text{strwidth}(s, \text{units = "user"}, \text{cex = NULL}) \\
\text{strheight}(s, \text{units = "user"}, \text{cex = NULL})
\]

Arguments

\( s \)
a character or expression vector whose dimensions are to be determined. Other objects are coerced by \( \text{as.graphicsAnnot} \).

\( \text{units} \)
character indicating in which units \( s \) is measured; should be one of "user", "inches", "figure"; partial matching is performed.

\( \text{cex} \)
numeric character expansion factor; multiplied by \( \text{par("cex")} \) yields the final character size; the default NULL is equivalent to 1.

Value

Numeric vector with the same length as \( s \), giving the width or height for each \( s[i] \). NA strings are given width and height 0 (as they are not plotted).

Examples

\[
\text{str.ex} \leftarrow \text{c("W","w","I",".","WwI."\)} \\
\text{op} \leftarrow \text{par(pty='s')}; \text{plot}(1:100,1:100, \text{type="n"}) \\
\text{sw} \leftarrow \text{strwidth(str.ex)}; \text{sw} \\
\text{all.equal(sum(sw[1:4]), sw[5])}\# since the last string contains the others \\
\text{sw.i} \leftarrow \text{strwidth(str.ex, "inches")}; 25.4 * sw.i \# width in [mm] \\
\text{unique(sw / sw.i)} \\
\text{# constant factor: 1 value} \\
\text{mean(sw.i / strwidth(str.ex, "fig")) / par('fin')[1]} \# = 1: are the same \\
\]

## See how letters fall in classes -- depending on graphics device and font!
\text{all.lett} \leftarrow \text{c(letters, LETTERS)} \\
\text{shL} \leftarrow \text{strheight(all.lett, units = "inches") * 72} \# 'big points' \\
\text{table(shL)} \# all have same heights ... \\
\text{mean(shL)/par("cin")[2]} \# around 0.6 \\
\text{(swL} \leftarrow \text{strwidth(all.lett, units="inches") * 72}) \# 'big points' \\
\text{split(all.lett, factor(round(swL, 2)))}
sunflowerplot <- expression(sum(x[i], i=1,n), e^(i * pi) == -1)
strwidth(sumex)
strheight(sumex)
par(op)#- reset to previous setting

sunflowerplot  Produce a Sunflower Scatter Plot

Description

Multiple points are plotted as “sunflowers” with multiple leaves (“petals”) such that overplotting is visualized instead of accidental and invisible.

Usage

sunflowerplot(x, y = NULL, number, log = "", digits = 6,
  xlab = NULL, ylab = NULL, xlim = NULL, ylim = NULL,
  add = FALSE, rotate = FALSE,
  pch = 16, cex = 0.8, cex.fact = 1.5,
  col = par("col"), bg = NA, size = 1/8, seg.col = 2,
  seg.lwd = 1.5, ...)

Arguments

x  numeric vector of x-coordinates of length n, say, or another valid plotting structure, as for plot.default, see also xy.coords.
y  numeric vector of y-coordinates of length n.
number  integer vector of length n. number[i] = number of replicates for (x[i],y[i]), may be 0. Default: compute the exact multiplicity of the points x[],y[].
log  character indicating log coordinate scale, see plot.default.
digits  when number is computed (i.e., not specified), x and y are rounded to digits significant digits before multiplicities are computed.
xlab,ylab  character label for x-, or y-axis, respectively.
xlim,ylim  numeric(2) limiting the extents of the x-, or y-axis.
add  logical; should the plot be added on a previous one? Default is FALSE.
rotate  logical; if TRUE, randomly rotate the sunflowers (preventing artefacts).
pch  plotting character to be used for points (number[i]==1) and center of sunflowers.
cex  numeric; character size expansion of center points (s. pch).
cex.fact  numeric shrinking factor to be used for the center points when there are flower leaves, i.e., cex / cex.fact is used for these.
col, bg  colors for the plot symbols, passed to plot.default.
size  of sunflower leaves in inches, 1[in] := 2.54[cm]. Default: 1/8; approximately 3.2mm.
sunflowerplot

seg.col  color to be used for the segments which make the sunflowers' leaves, see `par(col=); col = "gold"` reminds of real sunflowers.
seg.lwd  numeric; the line width for the leaves' segments.
...

Details

For `number[i] == 1`, a (slightly enlarged) usual plotting symbol (`pch`) is drawn. For `number[i] > 1`, a small plotting symbol is drawn and `number[i]` equi-angular “rays” emanate from it.

If `rotate=TRUE` and `number[i] >= 2`, a random direction is chosen (instead of the y-axis) for the first ray. The goal is to jitter the orientations of the sunflowers in order to prevent artefactual visual impressions.

Value

A list with three components of same length,

`x`  x coordinates
`y`  y coordinates
`number`  number

Side Effects

A scatter plot is drawn with “sunflowers” as symbols.

Examples

```r
## 'number' is computed automatically:
sunflowerplot(iris[, 3:4])
## Imitating Chambers et al., p.109, closely:
sunflowerplot(iris[, 3:4], cex=.2, cex.f=1, size=.035, seg.lwd=.8)

sunflowerplot(x=sort(2*round(rnorm(100))), y= round(rnorm(100),0),
         main = "Sunflower Plot of Rounded N(0,1)"
)```

```
symbols

## A 'point process' (explicit 'number' argument):
sunflowerplot(rnorm(100), rnorm(100), number=rpois(n=100, lambda=2),
rotate=TRUE, main="Sunflower plot", col = "blue4")

symbols

Draw Symbols (Circles, Squares, Stars, Thermometers, Boxplots) on a Plot

Description

This function draws symbols on a plot. One of six symbols: circles, squares, rectangles, stars, thermometers, and boxplots, can be plotted at a specified set of x and y coordinates. Specific aspects of the symbols, such as relative size, can be customized by additional parameters.

Usage

symbols(x, y = NULL, circles, squares, rectangles, stars,
thermometers, boxplots, inches = TRUE, add = FALSE,
fg = par("col"), bg = NA, xlab = NULL, ylab = NULL, main = NULL,
xlim = NULL, ylim = NULL, ...)  

Arguments

x, y  
the x and y co-ordinates for the centres of the symbols. They can be specified in any way which is accepted by xy.coords.

circles  
a vector giving the radii of the circles.
squares  
a vector giving the length of the sides of the squares.
rectangles  
a matrix with two columns. The first column gives widths and the second the heights of rectangles.
stars  
a matrix with three or more columns giving the lengths of the rays from the center of the stars. NA values are replaced by zeroes.
thermometers  
a matrix with three or four columns. The first two columns give the width and height of the thermometer symbols. If there are three columns, the third is taken as a proportion: the thermometers are filled (using colour fg) from their base to this proportion of their height. If there are four columns, the third and fourth columns are taken as proportions and the thermometers are filled between these two proportions of their heights. The part of the box not filled in fg will be filled in the background colour (default transparent) given by bg.
boxplots  
a matrix with five columns. The first two columns give the width and height of the boxes, the next two columns give the lengths of the lower and upper whiskers and the fifth the proportion (with a warning if not in [0,1]) of the way up the box that the median line is drawn.
inches  
TRUE, FALSE or a positive number. See Details.
add  
if add is TRUE, the symbols are added to an existing plot, otherwise a new plot is created.
fg  
colour(s) the symbols are to be drawn in.
bg  
if specified, the symbols are filled with colour(s), the vector bg being recycled to the number of symbols. The default is to leave the symbols unfilled.
symbols

- **xlab**
  - the x label of the plot if `add` is not true. Defaults to the `deparse`d expression used for x.

- **ylab**
  - the y label of the plot. Unused if `add = TRUE`.

- **main**
  - a main title for the plot. Unused if `add = TRUE`.

- **xlim**
  - numeric vector of length 2 giving the x limits for the plot. Unused if `add = TRUE`.

- **ylim**
  - numeric vector of length 2 giving the y limits for the plot. Unused if `add = TRUE`.

- **...**
  - graphics parameters can also be passed to this function, as can the plot aspect ratio `asp` (see `plot.window`).

**Details**

Observations which have missing coordinates or missing size parameters are not plotted. The exception to this is `stars`. In that case, the length of any ray which is `NA` is reset to zero.

Argument `inches` controls the sizes of the symbols. If `TRUE` (the default), the symbols are scaled so that the largest dimension of any symbol is one inch. If a positive number is given the symbols are scaled to make largest dimension this size in inches (so `TRUE` and `1` are equivalent). If `inches` is `FALSE`, the units are taken to be those of the appropriate axes. (For circles, squares and stars the units of the x axis are used. For boxplots, the lengths of the whiskers are regarded as dimensions alongside width and height when scaling by `inches`, and are otherwise interpreted in the units of the y axis.)

Circles of radius zero are plotted at radius one pixel (which is device-dependent).

**References**

**See Also**

- `stars` for drawing `stars` with a bit more flexibility. If are about doing “bubble plots” by `symbols(*,circles=*)`, you should really consider using `sunflowerplot` instead.

**Examples**

```r
x <- 1:10
y <- sort(10*runif(10))
z <- runif(10)
z3 <- cbind(z, 2*runif(10), runif(10))
symbols(x, y, thermometers=cbind(.5, 1, z), inches=.5, fg = 1:10)
symbols(x, y, thermometers = z3, inches=FALSE)
text(x,y, apply(format(round(z3, dig=2)), 1, paste, collapse = ","),
     adj = c(-.2,0), cex = .75, col = "purple", xpd=NA)
```

```r
## Note that example(trees) shows more sensible plots!
N <- nrow(trees)
with(trees, {
  ## Girth is diameter in inches
  symbols(Height, Volume, circles=Girth/24, inches=FALSE,
```
text

main="Trees' Girth")# xlab and ylab automatically
## Colours too:
palette(rainbow(N, end = 0.9))
symbols(Height, Volume, circles=Girth/16, inches=FALSE, bg = 1:N,
  fg="gray30", main="symbols(*, circles=Girth/16, bg = 1:N")
palette("default")
}

Description

`text` draws the strings given in the vector `labels` at the coordinates given by `x` and `y`. `y` may be missing since `xy.coords(x,y)` is used for construction of the coordinates.

Usage

```r
text(x, ...)```

## Default S3 method:
text(x, y = NULL, labels = seq(along = x), adj = NULL,
pos = NULL, offset = 0.5, vfont = NULL,
cex = 1, col = NULL, font = NULL, ...)
```

Arguments

- `x, y` numeric vectors of coordinates where the text `labels` should be written. If the length of `x` and `y` differs, the shorter one is recycled.
- `labels` a character vector or expression specifying the text to be written. An attempt is made to coerce other language objects (names and calls) to expressions, and vectors and other classed objects to character vectors by `as.character`. If `labels` is longer than `x` and `y`, the coordinates are recycled to the length of `labels`.
- `adj` one or two values in [0, 1] which specify the x (and optionally y) adjustment of the labels. On most devices values outside that interval will also work.
- `pos` a position specifier for the text. If specified this overrides any `adj` value given. Values of 1, 2, 3 and 4, respectively indicate positions below, to the left of, above and to the right of the specified coordinates.
- `offset` when `pos` is specified, this value gives the offset of the label from the specified coordinate in fractions of a character width.
- `vfont` if a character vector of length 2 is specified, then Hershey vector fonts are used. The first element of the vector selects a typeface and the second element selects a style.
- `cex` numeric character expansion factor; multiplied by `par("cex")` yields the final character size. `NULL` and `NA` are equivalent to 1.0.
- `col, font` the color and font to be used, possibly vectors. These default to the values of the global graphical parameters in `par()`.
- `...` further graphical parameters (from `par`), such as `family` and `xpd`.
Details

labels must be of type character or expression (or be coercible to such a type). In the latter case, quite a bit of mathematical notation is available such as sub- and superscripts, greek letters, fractions, etc.

adj allows adjustment of the text with respect to \((x, y)\). Values of 0, 0.5, and 1 specify left/bottom, middle and right/top, respectively. The default is for centered text, i.e., \(\text{adj} = c(0.5, 0.5)\). Accurate vertical centering needs character metric information on individual characters, which is only available on some devices.

The pos and offset arguments can be used in conjunction with values returned by identify to recreate an interactively labelled plot.

Text can be rotated by using graphical parameters srt (see par); this rotates about the centre set by adj.

Graphical parameters col, cex and font can be vectors and will then be applied cyclically to the labels (and extra values will be ignored). NA values of font are replaced by \(\text{par("font")}\). Labels whose \(x, y, \text{labels}, \text{cex or col} \) value is NA are omitted from the plot.

Euro symbol

The Euro symbol was introduced relatively recently, and may not be available in older fonts. In recent versions of Adobe symbol fonts it is character 160, so \texttt{text(x, y, "\text{\u00A0}", font = 5)} will work. People using Western European locales on Unix-alikes can probably select ISO-8895-15 (Latin-9) which has the Euro as character 165: this can also be used for postscript and pdf.

The Euro should be rendered correctly by \texttt{X11} in UTF-8 locales, but the corresponding single-byte encoding in postscript and pdf will be to be selected as ISOLatin9.enc.

Examples

\begin{verbatim}
plot(-1:1,-1:1, type = "n", xlab = "Re", ylab = "Im")
K <- 16; text(exp(1i * 2 * pi * (1:K) / K), col = 2)

## The following two examples use latin1 characters: these may not
## appear correctly (or be omitted entirely).
plot(1:10, 1:10, main = "text(...) examples\n~~~~~~~~~~~",
sub = "R is GNU ©, but not ® ...")
mtext("Latin-1 accented chars": éè øØ å<Å æ<Æ", side=3)
points(c(6,2), c(2,1), pch = 3, cex = 4, col = "red")
text(6, 2, "the text is CENTERED around \(x,y\) = (6,2) by default",
  cex = .8)
text(2, 1, "or Left/Bottom - JUSTIFIED at (2,1) by 'adj = c(0,0)'",
  adj = c(0,0))
\end{verbatim}
### Plot Annotation

This function can be used to add labels to a plot. Its first four principal arguments can also be used as arguments in most high-level plotting functions. They must be of type `character` or `expression`. In the latter case, quite a bit of mathematical notation is available such as sub- and superscripts, greek letters, fractions, etc: see `plotmath`

#### Arguments

- `main`: The main title (on top) using font and size (character expansion) `par("font.main")` and color `par("col.main")`.
- `sub`: Sub-title (at bottom) using font and size `par("font.sub")` and color `par("col.sub")`.
- `xlab`: X axis label using font and character expansion `par("font.lab")` and color `par("col.lab")`.
- `ylab`: Y axis label, same font attributes as `xlab`.
- `line`: Specifying a value for `line` overrides the default placement of labels, and places them this many lines outwards from the plot edge.
- `outer`: A logical value. If `TRUE`, the titles are placed in the outer margins of the plot.
- `...`: Further graphical parameters from `par`. Use e.g., `col.main` or `cex.sub` instead of just `col` or `cex`. `xpd` can be used to set the clipping region: this defaults to the figure region unless `outer = TRUE`, otherwise the device region and can only be increased. `mgp` controls the default placing of the axis titles.

#### Details

The labels passed to `title` can be a character strings or language objects (names, calls or expressions), or a list containing the string to be plotted, and a selection of the optional modifying graphical parameters `cex=`, `col=` and `font=`. Other objects will be coerced by `as.graphicsAnnot`.

Examples

plot(cars, main = "") # here, could use main directly
title(main = "Stopping Distance versus Speed")

plot(cars, main = "")
title(main = list("Stopping Distance versus Speed", cex=1.5,
                   col="red", font=3))

## Specifying "...":
plot(1, col.axis = "sky blue", col.lab = "thistle")
title("Main Title", sub = "sub title",
      cex.main = 2, font.main= 4, col.main= "blue",
      cex.sub = 0.75, font.sub = 3, col.sub = "red")

x <- seq(-4, 4, len = 101)
y <- cbind(sin(x), cos(x))
matplot(x, y, type = "l", xaxt = "n",
       main = expression(paste(plain(sin) * phi, " and ",
                            plain(cos) * phi)),
       ylab = expression("sin" * phi, "cos" * phi), # only 1st is taken
       xlab = expression(paste("Phase Angle ", phi)),
       col.main = "blue")
axis(1, at = c(-pi, -pi/2, 0, pi/2, pi),
     labels = expression(-pi, -pi/2, 0, pi/2, pi))
abline(h = 0, v = pi/2 * c(-1,1), lty = 2, lwd = .1, col = "gray70")

Description

xinch and yinch convert the specified number of inches given as their arguments into the correct units for plotting with graphics functions. Usually, this only makes sense when normal coordinates are used, i.e., no log scale (see the log argument to par).

xyinch does the same for a pair of numbers xy, simultaneously.

Usage

xinch(x = 1, warn.log = TRUE)
yinch(y = 1, warn.log = TRUE)
xyinch(xy = 1, warn.log = TRUE)

Arguments

x, y numeric vector
xy numeric of length 1 or 2.
warn.log logical; if TRUE, a warning is printed in case of active log scale.
Examples

all(c(xinch(),yinch()) == xyinch()) # TRUE
xyinch()
xyinch #<-- to see that is really delta("usr") / "pin"

## plot labels offset 0.12 inches to the right
## of plotted symbols in a plot
with(mtcars, {
  plot(mpg, disp, pch=19, main= "Motor Trend Cars")
  text(mpg + xinch(0.12), disp, row.names(mtcars),
       adj = 0, cex = .7, col = 'blue')
})
Chapter 5

The grid package

grid-package  The Grid Graphics Package

Description

A rewrite of the graphics layout capabilities, plus some support for interaction.

Details

This package contains a graphics system which supplements old-style S graphics. Further information is available in the following vignettes:

- displaylist: Display Lists in grid (source, pdf)
- frame: Frames and packing grobs (source, pdf)
- grid: Introduction to grid (source, pdf)
- grobs: Working with grid grobs (source, pdf)
- interactive: Editing grid Graphics (source, pdf)
- locndimn: Locations versus Dimensions (source, pdf)
- moveline: Demonstrating move-to and line-to (source, pdf)
- nonfinite: Non-finite values (source, pdf)
- plotexample: Writing grid Code (source, pdf)
- rotated: Rotated Viewports (source, pdf)
- saveload: Persistent representations (source, pdf)
- sharing: Modifying multiple grobs simultaneously (source, pdf)
- viewports: Working with viewports (source, pdf)

For a complete list of functions with individual help pages, use `library(help="grid")`.

Author(s)

Paul Murrell (paul@stat.auckland.ac.nz)
Maintainer: R Core Team (R-core@r-project.org)

References

absolute.size  

*Absolute Size of a Grob*

**Description**

This function converts a unit object into absolute units. Absolute units are unaffected, but non-absolute units are converted into "null" units.

**Usage**

```r
absolute.size(unit)
```

**Arguments**

- `unit` An object of class "unit".

**Details**

Absolute units are things like "inches", "cm", and "lines". Non-absolute units are "npc" and "native".

This function is designed to be used in `widthDetails` and `heightDetails` methods.

**Value**

An object of class "unit".

**Author(s)**

Paul Murrell

**See Also**

`widthDetails` and `heightDetails` methods.

---

**arrow**

*Describe arrows to add to a line.*

**Description**

Produces a description of what arrows to add to a line. The result can be passed to a function that draws a line, e.g., `grid.lines`.

**Usage**

```r
arrow(angle = 30, length = unit(0.25, "inches"),
       ends = "last", type = "open")
```
**Arguments**

- **angle**: The angle of the arrow head in degrees (smaller numbers produce narrower, pointier arrows). Essentially describes the width of the arrow head.
- **length**: A unit specifying the length of the arrow head (from tip to base).
- **ends**: One of "last", "first", or "both", indicating which ends of the line to draw arrow heads.
- **type**: One of "open" or "closed" indicating whether the arrow head should be a closed triangle.

**Examples**

```r
arrow()
```

---

**convertNative**: Convert a Unit Object to Native units

**Description**

This function is deprecated in grid version 0.8 and will be made defunct in grid version 1.9. You should use the `convertUnit()` function or one of its close allies instead.

This function returns a numeric vector containing the specified x or y locations or dimensions, converted to "user" or "data" units, relative to the current viewport.

**Usage**

```r
convertNative(unit, dimension="x", type="location")
```

**Arguments**

- **unit**: A unit object.
- **dimension**: Either "x" or "y".
- **type**: Either "location" or "dimension".

**Value**

A numeric vector.

**WARNING**

If you draw objects based on output from these conversion functions, then resize your device, the objects will be drawn incorrectly – the base R display list will not recalculate these conversions. This means that you can only rely on the results of these calculations if the size of your device is fixed.

grid.convert, unit

Examples

grid.newpage()
pushViewport(viewport(width=unit(.5, "npc"),
          height=unit(.5, "npc")))
grid.rect()
w <- convertNative(unit(1, "inches"))
h <- convertNative(unit(1, "inches"), "y")
# This rectangle starts off life as 1in square, but if you
# resize the device it will no longer be 1in square
grid.rect(width=unit(w, "native"), height=unit(h, "native"),
          gp=gpar(col="red"))
popViewport(1)

# How to use grid.convert(), etc instead
convertNative(unit(1, "inches")) ==
  convertX(unit(1, "inches"), "native", valueOnly=TRUE)
convertNative(unit(1, "inches"), "y", "dimension") ==
  convertHeight(unit(1, "inches"), "native", valueOnly=TRUE)

dataViewport

Create a Viewport with Scales based on Data

Description

This is a convenience function for producing a viewport with x- and/or y-scales based on numeric values passed to the function.

Usage

dataViewport(xData = NULL, yData = NULL, xscale = NULL,
              yscale = NULL, extension = 0.05, ...)

Arguments

xData A numeric vector of data.
yData A numeric vector of data.
xscale A numeric vector (length 2).
yscale A numeric vector (length 2).
extension A numeric. If length greater than 1, then first value is used to extend the xscale and second value is used to extend the yscale.
... All other arguments will be passed to a call to the viewport() function.

Details

If xscale is not specified then the values in x are used to generate an x-scale based on the range of x, extended by the proportion specified in extension. Similarly for the y-scale.
**Value**

A grid viewport object.

**Author(s)**

Paul Murrell

**Customising grid Drawing**

**Description**

These generic hook functions are called whenever a grid grob is drawn. They provide an opportunity for customising the drawing of a new class derived from grob (or gTree).

**Usage**

```r
drawDetails(x, recording)
draw.details(x, recording)
preDrawDetails(x)
postDrawDetails(x)
```

**Arguments**

- `x` A grid grob.
- `recording` A logical value indicating whether a grob is being added to the display list or redrawn from the display list.

**Details**

These functions are called by the `grid.draw` methods for grobs and gTrees.

`preDrawDetails` is called first during the drawing of a grob. This is where any additional viewports should be pushed (see, for example, `grid::preDrawDetails.frame`). Note that the default behaviour for grobs is to push any viewports in the `vp` slot, and for gTrees is to also push and up any viewports in the `childrenvp` slot so there is typically nothing to do here.

`drawDetails` is called next and is where any additional calculations and graphical output should occur (see, for example, `grid::drawDetails.xaxis`). Note that the default behaviour for gTrees is to draw all grobs in the `children` slot so there is typically nothing to do here.

`postDrawDetails` is called last and should reverse anything done in `preDrawDetails` (i.e., pop or up any viewports that were pushed; again, see, for example, `grid::postDrawDetails.frame`). Note that the default behaviour for grobs is to pop any viewports that were pushed so there is typically nothing to do here.

Note that `preDrawDetails` and `postDrawDetails` are also called in the calculation of "grobwidth" and "grobheight" units.
Value

None of these functions are expected to return a value.

Author(s)

Paul Murrell

See Also

grid.draw

description

This generic hook function is called whenever a grid grob is edited via grid.edit or editGrob. This provides an opportunity for customising the editing of a new class derived from grob (or gTree).

Usage

editDetails(x, specs)

Arguments

x A grid grob.
specs A list of named elements. The names indicate the grob slots to modify and the values are the new values for the slots.

details

This function is called by grid.edit and editGrob. A method should be written for classes derived from grob or gTree if a change in a slot has an effect on other slots in the grob or children of a gTree (e.g., see grid:::editDetails.xaxis).

Note that the slot already has the new value.

Value

The function MUST return the modified grob.

Author(s)

Paul Murrell

See Also

grid.edit
**gEdit**  
*Create and Apply Edit Objects*

**Description**

The functions `gEdit` and `gEditList` create objects representing an edit operation (essentially a list of arguments to `editGrob`).

The functions `applyEdit` and `applyEdits` apply one or more edit operations to a graphical object.

These functions are most useful for developers creating new graphical functions and objects.

**Usage**

```r
gEdit(...)  
gEditList(...)  
applyEdit(x, edit)  
applyEdits(x, edits)
```

**Arguments**

```
...                 one or more arguments to the editGrob function (for gEdit) or one or more "gEdit" objects (for gEditList).

x                   a grob (grid graphical object).

edit                a "gEdit" object.

edits               either a "gEdit" object or a "gEditList" object.
```

**Value**

- `gEdit` returns an object of class "gEdit".
- `gEditList` returns an object of class "gEditList".
- `applyEdit` and `applyEditList` return the modified grob.

**Author(s)**

Paul Murrell

**See Also**

- `grob`  
- `editGrob`

**Examples**

```r
grid.rect(gp=gpar(col="red"))
# same thing, but more verbose
grid.draw(applyEdit(rectGrob(), gEdit(gp=gpar(col="red"))))
```
getNames

List the names of grobs on the display list

Description
Returns a character vector containing the names of all top-level grobs on the display list.

Usage
getNames()

Value
A character vector.

Author(s)
Paul Murrell

Examples
grid.grill()
getNames()

---

gpar

Handling Grid Graphical Parameters

Description
gpar() should be used to create a set of graphical parameter settings. It returns an object of class "gpar". This is basically a list of name-value pairs.
get.gpar() can be used to query the current graphical parameter settings.

Usage
gpar(...)  
get.gpar(names = NULL)

Arguments
... Any number of named arguments.
names A character vector of valid graphical parameter names.
Details

All grid viewports and (predefined) graphical objects have a slot called \texttt{gp}, which contains a "\texttt{gpar}" object. When a viewport is pushed onto the viewport stack and when a graphical object is drawn, the settings in the "\texttt{gpar}" object are enforced. In this way, the graphical output is modified by the \texttt{gp} settings until the graphical object has finished drawing, or until the viewport is popped off the viewport stack, or until some other viewport or graphical object is pushed or begins drawing.

Valid parameter names are:
The alpha setting is combined with the alpha channel for individual colours by multiplying (with both alpha settings normalised to the range 0 to 1).

The size of text is fontsize*cex. The size of a line is fontsize*cex*lineheight.

The cex setting is cumulative; if a viewport is pushed with a cex of 0.5 then another viewport is pushed with a cex of 0.5, the effective cex is 0.25.

The alpha and lex settings are also cumulative.

Changes to the fontfamily may be ignored by some devices, but is supported by PostScript, PDF, X11, Windows, and Quartz. The fontfamily may be used to specify one of the Hershey Font families (e.g., HersheySerif) and this specification will be honoured on all devices.

The specification of fontface can be an integer or a string. If an integer, then it follows the R base graphics standard: 1 = plain, 2 = bold, 3 = italic, 4 = bold italic. If a string, then valid values are: "plain", "bold", "italic", "oblique", and "bold.italic". For the special case of the HersheySerif font family, "cyrillic", "cyrillic.oblique", and "EUC" are also available.

Specifying the value NULL for a parameter is the same as not specifying any value for that parameter, except for col and fill, where NULL indicates not to draw a border or not to fill an area (respectively).

All parameter values can be vectors of multiple values. (This will not always make sense – for example, viewports will only take notice of the first parameter value.)

The gamma parameter is deprecated.

get.gpar() returns all current graphical parameter settings.

Value

An object of class "gpar".

Author(s)

Paul Murrell

See Also

Hershey.
Examples

```r
gp <- get.gpar()
utils::str(gp)
## These *do* nothing but produce a "gpar" object:
gpar(col = "red")
gpar(col = "blue", lty = "solid", lwd = 3, fontsize = 16)
get.gpar(c("col", "lty"))
grid.newpage()
vp <- viewport(w = .8, h = .8, gp = gpar(col="blue"))
grid.draw(gTree(children=gList(rectGrob(gp = gpar(col="red")),
                   textGrob(paste("The rect is its own colour (red)",
                                 "but this text is the colour",
                                 "set by the gTree (green)",
                                 sep = "\n")))),
           gp = gpar(col="green"), vp = vp)
grid.text("This text is the colour set by the viewport (blue)",
y = 1, just = c("center", "bottom"),
       gp = gpar(fontsize=20), vp = vp)
grid.newpage()
## example with multiple values for a parameter
pushViewport(viewport())
grids.points(1:10/11, 1:10/11, gp = gpar(col=1:10))
popViewport()
```

gPath

**Concatenate Grob Names**

**Description**

This function can be used to generate a grob path for use in `grid.edit` and friends.

A grob path is a list of nested grob names.

**Usage**

```r
gPath(...)
```

**Arguments**

```r
...
```

Character values which are grob names.

**Details**

Grob names must only be unique amongst grobs which share the same parent in a `gTree`.

This function can be used to generate a specification for a grob that includes the grob’s parent’s name (and the name of its parent and so on).

For interactive use, it is possible to directly specify a path, but it is strongly recommended that this function is used otherwise in case the path separator is changed in future versions of grid.

**Value**

A `gPath` object.
Examples

```r
gPath("g1", "g2")
```

### Description

General information about the grid graphics package.

### Details

Grid graphics provides an alternative to the standard R graphics. The user is able to define arbitrary rectangular regions (called viewports) on the graphics device and define a number of coordinate systems for each region. Drawing can be specified to occur in any viewport using any of the available coordinate systems.

Grid graphics and standard R graphics do not mix!

Type `library(help = grid)` to see a list of (public) Grid graphics functions.

### Author(s)

Paul Murrell

### See Also

`viewport`, `grid.layout`, and `unit`.

### Examples

```r
## Diagram of a simple layout
grid.show.layout(grid.layout(4,2,
  heights=unit(rep(1, 4),
    c("lines", "lines", "lines", "null")),
  widths=unit(c(1, 1), "inches")))
## Diagram of a sample viewport
grid.show.viewport(viewport(x=0.6, y=0.6,
   w=unit(1, "inches"), h=unit(1, "inches")))
## A flash plotting example
grid.multipanel(vp=viewport(0.5, 0.5, 0.8, 0.8))
```
Grid Viewports

Create a Grid Viewport

Description
These functions create viewports, which describe rectangular regions on a graphics device and define a number of coordinate systems within those regions.

Usage
viewport(x = unit(0.5, "npc"), y = unit(0.5, "npc"),
       width = unit(1, "npc"), height = unit(1, "npc"),
       default.units = "npc", just = "centre",
       gp = gpar(), clip = "inherit",
       xscale = c(0, 1), yscale = c(0, 1),
       angle = 0,
       layout = NULL,
       layout.pos.row = NULL, layout.pos.col = NULL,
       name = NULL)
_vpList(...)
_vpStack(...)
_vpTree(parent, children)

Arguments
x
A numeric vector or unit object specifying x-location.
y
A numeric vector or unit object specifying y-location.
width
A numeric vector or unit object specifying width.
height
A numeric vector or unit object specifying height.
default.units
A string indicating the default units to use if x, y, width, or height are only given as numeric vectors.
just
A string or numeric vector specifying the justification of the viewport relative to its (x, y) location. If there are two values, the first value specifies horizontal justification and the second value specifies vertical justification. Possible string values are: "left", "right", "centre", "center", "bottom", and "top". For numeric values, 0 means left alignment and 1 means right alignment.
gp
An object of class gpar, typically the output from a call to the function gpar. This is basically a list of graphical parameter settings.
clip
One of "on", "inherit", or "off", indicating whether to clip to the extent of this viewport, inherit the clipping region from the parent viewport, or turn clipping off altogether. For back-compatibility, a logical value of TRUE corresponds to "on" and FALSE corresponds to "inherit".
xscale
A numeric vector of length two indicating the minimum and maximum on the x-scale.
yscale
A numeric vector of length two indicating the minimum and maximum on the y-scale.
angle  A numeric value indicating the angle of rotation of the viewport. Positive values indicate the amount of rotation, in degrees, anticlockwise from the positive x-axis.

layout  A Grid layout object which splits the viewport into subregions.

layout.pos.row  A numeric vector giving the rows occupied by this viewport in its parent’s layout.

layout.pos.col  A numeric vector giving the columns occupied by this viewport in its parent’s layout.

name  A character value to uniquely identify the viewport once it has been pushed onto the viewport tree.

...  Any number of grid viewport objects.

parent  A grid viewport object.

children  A vpList object.

Details

The location and size of a viewport are relative to the coordinate systems defined by the viewport’s parent (either a graphical device or another viewport). The location and size can be specified in a very flexible way by specifying them with unit objects. When specifying the location of a viewport, specifying both layout.pos.row and layout.pos.col as NULL indicates that the viewport ignores its parent’s layout and specifies its own location and size (via its locn). If only one of layout.pos.row and layout.pos.col is NULL, this means occupy ALL of the appropriate row(s)/column(s). For example, layout.pos.row = 1 and layout.pos.col = NULL means occupy all of row 1. Specifying non-NULL values for both layout.pos.row and layout.pos.col means occupy the intersection of the appropriate rows and columns. If a vector of length two is specified for layout.pos.row or layout.pos.col, this indicates a range of rows or columns to occupy. For example, layout.pos.row = c(1, 3) and layout.pos.col = c(2, 4) means occupy cells in the intersection of rows 1, 2, and 3, and columns, 2, 3, and 4.

Clipping obeys only the most recent viewport clip setting. For example, if you clip to viewport1, then clip to viewport2, the clipping region is determined wholly by viewport2, the size and shape of viewport1 is irrelevant (until viewport2 is popped of course).

If a viewport is rotated (because of its own angle setting or because it is within another viewport which is rotated) then the clip flag is ignored.

Viewport names need not be unique. When pushed, viewports sharing the same parent must have unique names, which means that if you push a viewport with the same name as an existing viewport, the existing viewport will be replaced in the viewport tree. A viewport name can be any string, but grid uses the reserved name "ROOT" for the top-level viewport. Also, when specifying a viewport name in downViewport and seekViewport, it is possible to provide a viewport path, which consists of several names concatenated using the separator (currently ::). Consequently, it is not advisable to use this separator in viewport names.

The viewports in a vpList are pushed in parallel. The viewports in a vpStack are pushed in series. When a vpTree is pushed, the parent is pushed first, then the children are pushed in parallel.

Value

An R object of class viewport.
Grid Viewports

Author(s)
Paul Murrell

Examples

```r
# Diagram of a sample viewport
grid.show.viewport(viewport(x=0.6, y=0.6,
    w=unit(1, "inches"), h=unit(1, "inches")))

# Demonstrate viewport clipping
clip.demo <- function(i, j, clip1, clip2) {
  pushViewport(viewport(layout.pos.col=i,
    layout.pos.row=j))
  pushViewport(viewport(width=0.6, height=0.6, clip=clip1))
  grid.rect(gp=gpar(fill="white"))
  grid.circle(r=0.55, gp=gpar(col="red", fill="pink"))
  popViewport()
  pushViewport(viewport(width=0.6, height=0.6, clip=clip2))
  grid.polygon(x=c(0.5, 1.1, 0.6, 1.1, 0.5, -0.1, 0.4, -0.1),
    y=c(0.6, 1.1, 0.5, -0.1, 0.4, -0.1, 0.5, 1.1),
    gp=gpar(col="blue", fill="light blue"))
  popViewport(2)
}

grid.newpage()
grid.rect(gp=gpar(fill="grey"))
pushViewport(viewport(layout=grid.layout(2, 2)))
clip.demo(1, 1, FALSE, FALSE)
clip.demo(1, 2, TRUE, FALSE)
clip.demo(2, 1, FALSE, TRUE)
clip.demo(2, 2, TRUE, TRUE)
popViewport()

# Demonstrate turning clipping off
grid.newpage()
pushViewport(viewport(w=.5, h=.5, clip="on"))
grid.rect()
grid.circle(r=.6, gp=gpar(lwd=10))
pushViewport(viewport(clip="inherit"))
grid.circle(r=.6, gp=gpar(lwd=5, col="grey"))
pushViewport(viewport(clip="off"))
grid.circle(r=.6)
popViewport(3)

# Demonstrate vpList, vpStack, and vpTree
grid.newpage()
tree <- vpTree(viewport(w=0.8, h=0.8, name="A"),
  vpList(vpStack(viewport(x=0.1, y=0.1, w=0.5, h=0.5,
    just=c("left", "bottom"), name="B"),
    viewport(x=0.1, y=0.1, w=0.5, h=0.5,
    just=c("left", "bottom"), name="C"),
    viewport(x=0.1, y=0.1, w=0.5, h=0.5,
    just=c("left", "bottom"), name="D")),
    viewport(x=0.5, w=0.4, h=0.9),
  )
```
grid.add

Add a Grid Graphical Object

Description

Add a grob to a gTree or a descendant of a gTree.

Usage

grid.add(gPath, child, strict = FALSE, grep = FALSE, global = FALSE, allDevices = FALSE, redraw = TRUE)

addGrob(gTree, child, gPath = NULL, strict = FALSE, grep = FALSE, global = FALSE)

setChildren(x, children)

Arguments

gTree, x A gTree object.
gPath A gPath object. For grid.add this specifies a gTree on the display list. For addGrob this specifies a descendant of the specified gTree.
child A grob object.
children A gList object.
strict A boolean indicating whether the gPath must be matched exactly.
grep A boolean indicating whether the gPath should be treated as a regular expression. Values are recycled across elements of the gPath (e.g., c(TRUE, FALSE)) means that every odd element of the gPath will be treated as a regular expression).
global A boolean indicating whether the function should affect just the first match of the gPath, or whether all matches should be affected.
allDevices A boolean indicating whether all open devices should be searched for matches, or just the current device. NOT YET IMPLEMENTED.
redraw A logical value to indicate whether to redraw the grob.
Details

addGrob copies the specified grob and returns a modified grob. grid.add destructively modifies a grob on the display list. If redraw is TRUE it then redraws everything to reflect the change. setChildren is a basic function for setting all children of a gTree at once (instead of repeated calls to addGrob).

Value

addGrob returns a grob object; grid.add returns NULL.

Author(s)

Paul Murrell

See Also

grob, getGrob, addGrob, removeGrob.

grid.arrows  
**Draw Arrows**

Description

Functions to create and draw arrows at either end of a line, or at either end of a line.to, lines, or segments grob.

These functions have been deprecated in favour of arrow arguments to the line-related primitives.

Usage

```r
grid.arrows(x = c(0.25, 0.75), y = 0.5, default.units = "npc",
grob = NULL,
angle = 30, length = unit(0.25, "inches"),
ends = "last", type = "open", name = NULL,
gp = gpar(), draw = TRUE, vp = NULL)
```

```r
arrowsGrob(x = c(0.25, 0.75), y = 0.5, default.units = "npc",
grob = NULL,
angle = 30, length = unit(0.25, "inches"),
ends = "last", type = "open", name = NULL,
gp = gpar(), vp = NULL)
```

Arguments

x  
A numeric vector or unit object specifying x-values.

y  
A numeric vector or unit object specifying y-values.

default.units

A string indicating the default units to use if x or y are only given as numeric vectors.

grob  
A grob to add arrows to; currently can only be a line.to, lines, or segments grob.
grid.arrows

angle
A numeric specifying (half) the width of the arrow head (in degrees).

length
A unit object specifying the length of the arrow head.

ends
One of "first", "last", or "both", indicating which end of the line to add arrow heads.

type
Either "open" or "closed" to indicate the type of arrow head.

name
A character identifier.

gp
An object of class gpar, typically the output from a call to the function gpar. This is basically a list of graphical parameter settings.

draw
A logical value indicating whether graphics output should be produced.

vp
A Grid viewport object (or NULL).

Details

Both functions create an arrows grob (a graphical object describing arrows), but only grid.arrows() draws the arrows (and then only if draw is TRUE).

If the grob argument is specified, this overrides any x and/or y arguments.

Value

An arrows grob. grid.arrows() returns the value invisibly.

grid.circle  Draw a Circle

Description

Functions to create and draw a circle.
Usage

```r
grid.circle(x=0.5, y=0.5, r=0.5, default.units="npc", name=NULL, 
gp=gpar(), draw=TRUE, vp=NULL)
circleGrob(x=0.5, y=0.5, r=0.5, default.units="npc", name=NULL, 
gp=gpar(), vp=NULL)
```

Arguments

- `x` A numeric vector or unit object specifying x-locations.
- `y` A numeric vector or unit object specifying y-locations.
- `r` A numeric vector or unit object specifying radii.
- `default.units` A string indicating the default units to use if `x`, `y`, `width`, or `height` are only given as numeric vectors.
- `name` A character identifier.
- `gp` An object of class `gpar`, typically the output from a call to the function `gpar`. This is basically a list of graphical parameter settings.
- `draw` A logical value indicating whether graphics output should be produced.
- `vp` A Grid viewport object (or NULL).

Details

Both functions create a circle grob (a graphical object describing a circle), but only `grid.circle()` draws the circle (and then only if `draw` is `TRUE`).

The radius may be given in any units; if the units are relative (e.g., "npc" or "native") then the radius will be different depending on whether it is interpreted as a width or as a height. In such cases, the smaller of these two values will be the result. To see the effect, type `grid.circle()` and adjust the size of the window.

Value

A circle grob. `grid.circle()` returns the value invisibly.

Warning

Negative values for the radius are silently converted to their absolute value.

`Grid`, `viewport`
grid.clip

Set the Clipping Region

Description

These functions set the clipping region within the current viewport without altering the current coordinate system.

Usage

grid.clip(...)  
clipGrob(x = unit(0.5, "npc"), y = unit(0.5, "npc"),  
width = unit(1, "npc"), height = unit(1, "npc"),  
just = "centre", hjust = NULL, vjust = NULL,  
default.units = "npc", name = NULL, vp = NULL)

Arguments

x  
A numeric vector or unit object specifying x-location.

y  
A numeric vector or unit object specifying y-location.

width  
A numeric vector or unit object specifying width.

height  
A numeric vector or unit object specifying height.

just  
The justification of the clip rectangle relative to its (x, y) location. If there are two values, the first value specifies horizontal justification and the second value specifies vertical justification. Possible string values are: "left", "right", "centre", "center", "bottom", and "top". For numeric values, 0 means left alignment and 1 means right alignment.

hjust  
A numeric vector specifying horizontal justification. If specified, overrides the just setting.

vjust  
A numeric vector specifying vertical justification. If specified, overrides the just setting.

default.units  
A string indicating the default units to use if x, y, width, or height are only given as numeric vectors.

name  
A character identifier.

vp  
A Grid viewport object (or NULL).

...  
Arguments passed to clipGrob.

Details

Both functions create a clip rectangle (a graphical object describing a clip rectangle), but only grid.clip enforces the clipping.

Pushing or popping a viewport always overrides the clip region set by a clip grob, regardless of whether that viewport explicitly enforces a clipping region.

Value

clipGrob returns a clip grob.
grid.collection

Create a Coherent Group of Grid Graphical Objects

Description

This function is deprecated; please use gTree.

This function creates a graphical object which contains several other graphical objects. When it is
drawn, it draws all of its children.

It may be convenient to name the elements of the collection.

Usage

grid.collection(..., gp=gpar(), draw=TRUE, vp=NULL)

Arguments

... Zero or more objects of class "grob".

gp An object of class gpar, typically the output from a call to the function gpar.
This is basically a list of graphical parameter settings.

draw A logical value to indicate whether to produce graphical output.

vp A Grid viewport object (or NULL).

Value

A collection grob.
grid.convert

**Convert Between Different grid Coordinate Systems**

**Description**

These functions take a unit object and convert it to an equivalent unit object in a different coordinate system.

**Usage**

```r
convertX(x, unitTo, valueOnly = FALSE)
convertY(x, unitTo, valueOnly = FALSE)
convertWidth(x, unitTo, valueOnly = FALSE)
convertHeight(x, unitTo, valueOnly = FALSE)
convertUnit(x, unitTo,
  axisFrom = "x", typeFrom = "location",
  axisTo = axisFrom, typeTo = typeFrom,
  valueOnly = FALSE)
grid.convertX(x, unitTo, valueOnly = FALSE)
grid.convertY(x, unitTo, valueOnly = FALSE)
grid.convertWidth(x, unitTo, valueOnly = FALSE)
grid.convertHeight(x, unitTo, valueOnly = FALSE)
grid.convert(x, unitTo,
  axisFrom = "x", typeFrom = "location",
  axisTo = axisFrom, typeTo = typeFrom,
  valueOnly = FALSE)
```

**Arguments**

- **x** A unit object.
- **unitTo** The coordinate system to convert the unit to. See the `unit` function for valid coordinate systems.
- **axisFrom** Either "x" or "y" to indicate whether the unit object represents a value in the x- or y-direction.
- **typeFrom** Either "location" or "dimension" to indicate whether the unit object represents a location or a length.
- **axisTo** Same as `axisFrom`, but applies to the unit object that is to be created.
- **typeTo** Same as `typeFrom`, but applies to the unit object that is to be created.
- **valueOnly** A logical indicating. If TRUE then the function does not return a unit object, but rather only the converted numeric values.
Details

The `convertUnit` function allows for general-purpose conversions. The other four functions are just more convenient front-ends to it for the most common conversions.

The conversions occur within the current viewport.

It is not currently possible to convert to all valid coordinate systems (e.g., "strwidth" or "grob-width"). I’m not sure if all of these are impossible, they just seem implausible at this stage.

In normal usage of grid, these functions should not be necessary. If you want to express a location or dimension in inches rather than user coordinates then you should simply do something like `unit(1, "inches")` rather than something like `unit(0.134, "native")`.

In some cases, however, it is necessary for the user to perform calculations on a unit value and this function becomes necessary. In such cases, please take note of the warning below.

The `grid.*` versions are just previous incarnations which have been deprecated.

Value

A unit object in the specified coordinate system (unless `valueOnly` is `TRUE` in which case the returned value is a numeric).

Warning

The conversion is only valid for the current device size. If the device is resized then at least some conversions will become invalid. For example, suppose that I create a unit object as follows: `oneinch <- convertUnit(unit(1, "inches"), "native")`. Now if I resize the device, the unit object in `oneinch` no longer corresponds to a physical length of 1 inch.

`unit`

Examples

```r
## A tautology
convertX(unit(1, "inches"), "inches")
## The physical units
convertX(unit(2.54, "cm"), "inches")
convertX(unit(25.4, "mm"), "inches")
convertX(unit(72.27, "points"), "inches")
convertX(unit(1/12*72.27, "picas"), "inches")
convertX(unit(72, "bigpts"), "inches")
convertX(unit(1157/1238*72.27, "dida"), "inches")
convertX(unit(1/12+1157/1238*72.27, "cicero"), "inches")
convertX(unit(65536*72.27, "scaledpts"), "inches")
convertX(unit(1/2.54, "inches"), "cm")
convertX(unit(1/25.4, "inches"), "mm")
convertX(unit(1/72, "inches"), "points")
convertX(unit(1/(1/12*72.27), "inches"), "picas")
convertX(unit(1/72, "inches"), "bigpts")
convertX(unit(1/(1157/1238*72.27), "inches"), "dida")
convertX(unit(1/(1/12+1157/1238*72.27), "inches"), "cicero")
```
### grid.copy

Make a Copy of a Grid Graphical Object

#### Description

This function is redundant and will disappear in future versions.

#### Usage

```r
grid.copy(grob)
```

#### Arguments

- `grob`: A grob object.

#### Value

A copy of the grob object.

#### Author(s)

Paul Murrell

#### See Also

- `grid.grob`
grid.curve  

Draw a Curve Between Locations

Description

These functions create and draw a curve from one location to another.

Usage

grid.curve(...)  
curveGrob(x1, y1, x2, y2, default.units = "npc",  
curvature = 1, angle = 90, ncp = 1, shape = 0.5,  
square = TRUE, squareShape = 1,  
inflect = FALSE, arrow = NULL, open = TRUE,  
debug = FALSE,  
name = NULL, gp = gpar(), vp = NULL)  
arccurvature(theta)

Arguments

x1  
A numeric vector or unit object specifying the x-location of the start point.
y1  
A numeric vector or unit object specifying the y-location of the start point.
x2  
A numeric vector or unit object specifying the x-location of the end point.
y2  
A numeric vector or unit object specifying the y-location of the end point.
default.units  
A string indicating the default units to use if x1, y1, x2 or y2 are only given as numeric values.
curvature  
A numeric value giving the amount of curvature. Negative values produce left-hand curves, positive values produce right-hand curves, and zero produces a straight line.
angle  
A numeric value between 0 and 180, giving an amount to skew the control points of the curve. Values less than 90 skew the curve towards the start point and values greater than 90 skew the curve towards the end point.
ncp  
The number of control points used to draw the curve. More control points creates a smoother curve.
shape  
A numeric vector of values between -1 and 1, which control the shape of the curve relative to its control points. See grid.xspline for more details.
square  
A logical value that controls whether control points for the curve are created city-block fashion or obliquely. When ncp is 1 and angle is 90, this is typically TRUE, otherwise this should probably be set to FALSE (see Examples below).
squareShape  
A shape value to control the behaviour of the curve relative to any additional control point that is inserted if square is TRUE.
infect  
A logical value specifying whether the curve should be cut in half and inverted (see Examples below).
arrow  
A list describing arrow heads to place at either end of the curve, as produced by the arrow function.
grid.curve

open A logical value indicating whether to close the curve (connect the start and end points).

ddebug A logical value indicating whether debugging information should be drawn.

name A character identifier.

gp An object of class gpar, typically the output from a call to the function gpar. This is basically a list of graphical parameter settings.

vp A Grid viewport object (or NULL).

... Arguments to be passed to curveGrob.

theta An angle (in degrees).

Details

Both functions create a curve grob (a graphical object describing an curve), but only grid.curve draws the curve.

The arcCurvature function can be used to calculate a curvature such that control points are generated on an arc corresponding to angle theta. This is typically used in conjunction with a large ncp to produce a curve corresponding to the desired arc.

Value

A grob object.

See Also

Grid, viewport, grid.xspline, arrow

Examples

curveTest <- function(i, j, ...) {
  pushViewport(viewport(layout.pos.col=j, layout.pos.row=i))
  do.call("grid.curve", c(list(x1=.25, y1=.25, x2=.75, y2=.75),
    if (is.null(...)) NULL else list(...)))
  grid.text(sub("list", ",", deparse(substitute(list(...)))),
    y=unit(1, "npc"))
  popViewport()
}
# grid.newpage()
pushViewport(plotViewport(c(0, 0, 1, 0),
    layout=grid.layout(2, 1, heights=c(2, 1))))
pushViewport(viewport(layout.pos.row=1,
    layout=grid.layout(3, 3, respect=TRUE)))
curveTest(1, 1, NULL)
curveTest(1, 2, inflect=TRUE)
curveTest(1, 3, angle=135)
curveTest(2, 1, arrow=arrow())
curveTest(2, 2, ncp=8)
curveTest(2, 3, shape=0)
curveTest(3, 1, curvature=-1)
curveTest(3, 2, square=FALSE)
curveTest(3, 3, debug=TRUE)
popViewport()
pushViewport(viewport(layout.pos.row=2,
    layout=grid.layout(3, 3)))
grid.display.list

Control the Grid Display List

Description

Turn the Grid display list on or off.

Usage

grid.display.list(on=TRUE)
engine.display.list(on=TRUE)

Arguments

on A logical value to indicate whether the display list should be on or off.

Details

All drawing and viewport-setting operations are (by default) recorded in the Grid display list. This allows redrawing to occur following an editing operation.
This display list could get very large so it may be useful to turn it off in some cases; this will of course disable redrawing.
All graphics output is also recorded on the main display list of the R graphics engine (by default). This supports redrawing following a device resize and allows copying between devices.
Turning off this display list means that grid will redraw from its own display list for device resizes and copies. This will be slower than using the graphics engine display list.

Value

None.

WARNING

Turning the display list on causes the display list to be erased!
Turning off both the grid display list and the graphics engine display list will result in no redrawing whatsoever.

Author(s)

Paul Murrell
grid.draw  

**Draw a grid grob**

**Description**

Produces graphical output from a graphical object.

**Usage**

```r
grid.draw(x, recording=TRUE)
```

**Arguments**

- `x`  
  An object of class "grob" or NULL.

- `recording`  
  A logical value to indicate whether the drawing operation should be recorded on the Grid display list.

**Details**

This is a generic function with methods for grob and gTree objects.

The grob and gTree methods automatically push any viewports in a `vp` slot and automatically apply any `gpar` settings in a `gp` slot. In addition, the gTree method pushes and ups any viewports in a `childrenvp` slot and automatically calls `grid.draw` for any grobs in a `children` slot.

The methods for grob and gTree call the generic hook functions `preDrawDetails`, `drawDetails`, and `postDrawDetails` to allow classes derived from grob or gTree to perform additional viewport pushing/popping and produce additional output beyond the default behaviour for grobs and gTrees.

**Value**

None.

**Author(s)**

Paul Murrell

**See Also**

`grob`.

**Examples**

```r
grid.newpage()
## Create a graphical object, but don't draw it
l <- linesGrob()
## Draw it
grid.draw(l)
```
grid.edit

Edit the Description of a Grid Graphical Object

Description
Changes the value of one of the slots of a grob and redraws the grob.

Usage
grid.edit(gPath, ..., strict = FALSE, grep = FALSE, global = FALSE, allDevices = FALSE, redraw = TRUE)
editGrob(grob, gPath = NULL, ..., strict = FALSE, grep = FALSE, global = FALSE)

Arguments
grob
A grob object.

...  Zero or more named arguments specifying new slot values.
gPath
A gPath object. For grid.edit this specifies a grob on the display list. For editGrob this specifies a descendant of the specified grob.
strict
A boolean indicating whether the gPath must be matched exactly.
grep
A boolean indicating whether the gPath should be treated as a regular expression. Values are recycled across elements of the gPath (e.g., c(TRUE, FALSE) means that every odd element of the gPath will be treated as a regular expression).
global
A boolean indicating whether the function should affect just the first match of the gPath, or whether all matches should be affected.
allDevices
A boolean indicating whether all open devices should be searched for matches, or just the current device. NOT YET IMPLEMENTED.
redraw
A logical value to indicate whether to redraw the grob.

Details
editGrob copies the specified grob and returns a modified grob.
grid.edit destructively modifies a grob on the display list. If redraw is TRUE it then redraws everything to reflect the change.
Both functions call editDetails to allow a grob to perform custom actions and validDetails to check that the modified grob is still coherent.

Value
editGrob returns a grob object; grid.edit returns NULL.

Author(s)
Paul Murrell

See Also
grob, getGrob, addGrob, removeGrob.
**Examples**

```r
grid.newpage()
grid.xaxis(name = "xa", vp = viewport(width=.5, height=.5))
grid.edit("xa", gp = gpar(col="red"))
# won't work because no ticks (at is NULL)
try(grid.edit(gPath("xa", "ticks"), gp = gpar(col="green")))
grid.edit("xa", at = 1:4/5)
# Now it should work
try(grid.edit(gPath("xa", "ticks"), gp = gpar(col="green")))
```

---

**grid.frame**  
Create a Frame for Packing Objects

**Description**

These functions, together with `grid.pack`, `grid.place`, `packGrob`, and `placeGrob` are part of a GUI-builder-like interface to constructing graphical images. The idea is that you create a frame with this function then use `grid.pack` or whatever to pack/place objects into the frame.

**Usage**

```r
grid.frame(layout=NULL, name=NULL, gp=gpar(), vp=NULL, draw=TRUE)
frameGrob(layout=NULL, name=NULL, gp=gpar(), vp=NULL)
```

**Arguments**

- `layout`  
  A Grid layout, or NULL. This can be used to initialise the frame with a number of rows and columns, with initial widths and heights, etc.

- `name`  
  A character identifier.

- `vp`  
  An object of class `viewport`, or NULL.

- `gp`  
  An object of class `gpar`; typically the output from a call to the function `gpar`.

- `draw`  
  Should the frame be drawn.

**Details**

Both functions create a frame grob (a graphical object describing a frame), but only `grid.frame()` draws the frame (and then only if `draw` is `TRUE`). Nothing will actually be drawn, but it will put the frame on the display list, which means that the output will be dynamically updated as objects are packed into the frame. Possibly useful for debugging.

**Value**

A frame grob. `grid.frame()` returns the value invisibly.

**Author(s)**

Paul Murrell

**See Also**

- `grid.pack`
Examples

```r
grid.newpage()
grid.frame(name="gf", draw=TRUE)
grid.pack("gf", rectGrob(gp=gpar(fill="grey")), width=unit(1, "null"))
grid.pack("gf", textGrob("hi there"), side="right")
```

---

grid.get  
Get a Grid Graphical Object

Description

Retrieve a grob or a descendant of a grob.

Usage

```r
grid.get(gPath, strict = FALSE, grep = FALSE, global = FALSE,
allDevices = FALSE)
```

```r
getGrob(gTree, gPath, strict = FALSE, grep = FALSE, global = FALSE)
```

Arguments

- `gTree`: A gTree object.
- `gPath`: A gPath object. For `grid.get` this specifies a grob on the display list. For `getGrob` this specifies a descendant of the specified gTree.
- `strict`: A boolean indicating whether the gPath must be matched exactly.
- `grep`: A boolean indicating whether the gPath should be treated as a regular expression. Values are recycled across elements of the gPath (e.g., `c(TRUE, FALSE)` means that every odd element of the gPath will be treated as a regular expression).
- `global`: A boolean indicating whether the function should affect just the first match of the gPath, or whether all matches should be affected.
- `allDevices`: A boolean indicating whether all open devices should be searched for matches, or just the current device. NOT YET IMPLEMENTED.

Value

A grob object.

Author(s)

Paul Murrell

See Also

`grob`, `getGrob`, `addGrob`, `removeGrob`. 
Examples

grid.xaxis(name="xa")
grid.get("xa")
grid.get(gPath("xa", "ticks"))

grid.draw(gTree(name="gt", children=gList(xaxisGrob(name="axis"))))
grid.get(gPath("gt", "axis", "ticks"))

grid.grab  

Grab the current grid output

Description

Creates a gTree object from the current grid display list or from a scene generated by user-specified code.

Usage

grid.grab(warn = 2, wrap = FALSE, ...)
grid.grabExpr(expr, warn = 2, wrap = FALSE, ...)

Arguments

expr  
An expression to be evaluated. Typically, some calls to grid drawing functions.

warn  
An integer specifying the amount of warnings to emit. 0 means no warnings, 1 means warn when it is certain that the grab will not faithfully represent the original scene. 2 means warn if there’s any possibility that the grab will not faithfully represent the original scene.

wrap  
A logical indicating how the output should be captured. If TRUE, each non-grob element on the display list is captured by wrapping it in a grob.

...  
arguments passed to gTree, for example, a name and/or class for the gTree that is created.

Details

There are four ways to capture grid output as a gTree.

There are two functions for capturing output: use grid.grab to capture an existing drawing and grid.grabExpr to capture the output from an expression (without drawing anything).

For each of these functions, the output can be captured in two ways. One way tries to be clever and make a gTree with a childrenvp slot containing all viewports on the display list (including those that are popped) and every grob on the display list as a child of the new gTree; each child has a vpPath in the vp slot so that it is drawn in the appropriate viewport. In other words, the gTree contains all elements on the display list, but in a slightly altered form.

The other way, wrap=TRUE, is to create a grob for every element on the display list (and make all of those grobs children of the gTree).

The first approach creates a more compact and elegant gTree, which is more flexible to work with, but is not guaranteed to faithfully replicate all possible grid output. The second approach is more brute force, and harder to work with, but should always faithfully replicate the original output.
grid.grill

Draw a Grill

Description

This function draws a grill within a Grid viewport.

Usage

```r
grid.grill(h = unit(seq(0.25, 0.75, 0.25), "npc"),
          v = unit(seq(0.25, 0.75, 0.25), "npc"),
          default.units = "npc", gp = gpar(col = "grey"), vp = NULL)
```

Arguments

- `h`: A numeric vector or unit object indicating the horizontal location of the vertical grill lines.
- `v`: A numeric vector or unit object indicating the vertical location of the horizontal grill lines.
- `default.units`: A string indicating the default units to use if `h` or `v` are only given as numeric vectors.
- `gp`: An object of class `gpar`, typically the output from a call to the function `gpar`. This is basically a list of graphical parameter settings.
- `vp`: A Grid viewport object.

Value

None.

Author(s)

Paul Murrell
grid.grob

Create a Grid Graphical Object

Description

These functions create grid graphical objects.

Usage

grid.grob(list.struct, cl = NULL, draw = TRUE)
grob(..., name = NULL, gp = NULL, vp = NULL, cl = NULL)
gTree(..., name = NULL, gp = NULL, vp = NULL, children = NULL,
      childrenvp = NULL, cl = NULL)
childNames(gTree)
gList(...)

Arguments

... 
list.struct 
name 
children 
childrenvp 
gp 
vp 
cl 
draw 
gTree

For grob and gTree, the named slots describing important features of the graphical object. For gList, a series of grob objects.

A list (preferably with each element named).

A character identifier for the grob. Used to find the grob on the display list and/or as a child of another grob.

A gList object.

A viewport object (or NULL).

A gpar object, typically the output from a call to the function gpar. This is basically a list of graphical parameter settings.

A viewport object (or NULL).

A string giving the class attribute for the list.struct

A logical value to indicate whether to produce graphical output.

A gTree object.

Details

These functions can be used to create a basic grob, gTree, or gList object, or a new class derived from one of these.

A grid graphical object (grob) is a description of a graphical item. These basic classes provide default behaviour for validating, drawing, and modifying graphical objects. Both call the function validDetails to check that the object returned is coherent.

A gTree can have other grobs as children; when a gTree is drawn, it draws all of its children. Before drawing its children, a gTree pushes its childrenvp slot and then navigates back up (calls upViewport) so that the children can specify their location within the childrenvp via a vpPath.

Grob names need not be unique in general, but all children of a gTree must have different names.

A grob name can be any string, though it is not advisable to use the gPath separator (currently ::) in grob names.

See Also

Grid, viewport.
The function `childNames` returns the names of the grobs which are children of a gTree.

All grid primitives (`grid.lines`, `grid.rect`, ...) and some higher-level grid components (e.g., `grid.xaxis` and `grid.yaxis`) are derived from these classes.

`grid.grob` is deprecated.

Value

A grob object.

`grid.draw`, `grid.edit`, `grid.get`.

Examples

---

grid.layout

Create a Grid Layout

Description

This function returns a Grid layout, which describes a subdivision of a rectangular region.

Usage

```r
grid.layout(nrow = 1, ncol = 1,
            widths = unit(rep(1, ncol), "null"),
            heights = unit(rep(1, nrow), "null"),
            default.units = "null", respect = FALSE,
            just="centre")
```

Arguments

- `nrow`: An integer describing the number of rows in the layout.
- `ncol`: An integer describing the number of columns in the layout.
- `widths`: A numeric vector or unit object describing the widths of the columns in the layout.
- `heights`: A numeric vector or unit object describing the heights of the rows in the layout.
- `default.units`: A string indicating the default units to use if `widths` or `heights` are only given as numeric vectors.
- `respect`: A logical value or a numeric matrix. If a logical, this indicates whether row heights and column widths should respect each other. If a matrix, non-zero values indicate that the corresponding row and column should be respected (see examples below).
grid.layout

just A string vector indicating how the layout should be justified if it is not the same size as its parent viewport. If there are two values, the first value specifies horizontal justification and the second value specifies vertical justification. Possible values are: "left", "right", "centre", "center", "bottom", and "top". NOTE that in this context, "left", for example, means align the left edge of the left-most layout column with the left edge of the parent viewport.

Details

The unit objects given for the widths and heights of a layout may use a special units that only has meaning for layouts. This is the "null" unit, which indicates what relative fraction of the available width/height the column/row occupies. See the reference for a better description of relative widths and heights in layouts.

Value

A Grid layout object.

WARNING

This function must NOT be confused with the base R graphics function layout. In particular, do not use layout in combination with Grid graphics. The documentation for layout may provide some useful information and this function should behave identically in comparable situations. The grid.layout function has added the ability to specify a broader range of units for row heights and column widths, and allows for nested layouts (see viewport).

Examples

## A variety of layouts (some a bit mid-bending ...)
layout.torture()
## Demonstration of layout justification
grid.newpage()
testlay <- function(just="centre") {
  pushViewport(viewport(layout=grid.layout(1, 1, widths=unit(1, "inches"), height=unit(0.25, "npc"), just=just))
  pushViewport(viewport(layout.pos.col=1, layout.pos.row=1))
  grid.rect()
  grid.text(paste(just, collapse="--"))
  popViewport(2)
}
testlay()
grid.lines

Draw Lines in a Grid Viewport

Description

These functions create and draw a series of lines.

Usage

grid.lines(x = unit(c(0, 1), "npc"),
    y = unit(c(0, 1), "npc"),
    default.units = "npc",
    arrow = NULL, name = NULL,
    gp=gpar(), draw = TRUE, vp = NULL)

linesGrob(x = unit(c(0, 1), "npc"),
    y = unit(c(0, 1), "npc"),
    default.units = "npc",
    arrow = NULL, name = NULL,
    gp=gpar(), vp = NULL)

grid.polyline(...)

polylineGrob(x = unit(c(0, 1), "npc"),
    y = unit(c(0, 1), "npc"),
    id=NULL, id.lengths=NULL,
    default.units = "npc",
    arrow = NULL, name = NULL,
    gp=gpar(), vp = NULL)

Arguments

x
    A numeric vector or unit object specifying x-values.

y
    A numeric vector or unit object specifying y-values.

default.units
    A string indicating the default units to use if x or y are only given as numeric vectors.

arrow
    A list describing arrow heads to place at either end of the line, as produced by the arrow function.

name
    A character identifier.

gp
    An object of class gpar, typically the output from a call to the function gpar. This is basically a list of graphical parameter settings.

draw
    A logical value indicating whether graphics output should be produced.

vp
    A Grid viewport object (or NULL).
grid.locator

Capture a Mouse Click

Description

Allows the user to click the mouse once within the current graphics device and returns the location of the mouse click within the current viewport, in the specified coordinate system.

Usage

grid.locator(unit = "native")
Arguments

unit  
The coordinate system in which to return the location of the mouse click. See the \texttt{unit} function for valid coordinate systems.

Details

This function is modal (like the graphics package function \texttt{locator}) so the command line and graphics drawing is blocked until the use has clicked the mouse in the current device.

Value

A unit object representing the location of the mouse click within the current viewport, in the specified coordinate system.

If the user did not click mouse button 1, the function (invisibly) returns NULL.

Author(s)

Paul Murrell

Examples

if (interactive()) {
  ## Need to write a more sophisticated unit as.character method
  unittrim <- function(unit) {
    sub("^([0-9]+|\[0-9\]+\.[0-9]+)\[0-9]*", "\1", as.character(unit))
  }
  do.click <- function(unit) {
    click.locn <- grid.locator(unit)
    grid.segments(unit.c(click.locn$x, unit(0, "npc")),
                   unit.c(unit(0, "npc"), click.locn$y),
                   click.locn$x, click.locn$y,
                   gp=gpar(lty="dashed", col="grey"))
    grid.points(click.locn$x, click.locn$y, pch=16, size=unit(1, "mm"))
    clickx <- unittrim(click.locn$x)
    clicky <- unittrim(click.locn$y)
    grid.text(paste("(", clickx, ",", clicky, ")", sep=""),
              click.locn$x + unit(2, "mm"), click.locn$y,
              just="left")
  }
  do.click("inches")
  pushViewport(viewport(width=0.5, height=0.5,
                        xscale=c(0, 100), yscale=c(0, 10)))
  grid.rect()
  grid.xaxis()
  grid.yaxis()
  do.click("native")
  popViewport()
}
grid.move.to  Move or Draw to a Specified Position

Description

Grid has the notion of a current location. These functions sets that location.

Usage

```r
grid.move.to(x = 0, y = 0, default.units = "npc", name = NULL,
            draw = TRUE, vp = NULL)
moveToGrob(x = 0, y = 0, default.units = "npc", name = NULL, vp = NULL)
grid.line.to(x = 1, y = 1, default.units = "npc",
              arrow = NULL, name = NULL,
              gp = gpar(), draw = TRUE, vp = NULL)
lineToGrob(x = 1, y = 1, default.units = "npc", arrow = NULL,
           name = NULL, gp = gpar(), vp = NULL)
```

Arguments

- `x`: A numeric value or a unit object specifying an x-value.
- `y`: A numeric value or a unit object specifying a y-value.
- `default.units`: A string indicating the default units to use if `x` or `y` are only given as numeric values.
- `arrow`: A list describing arrow heads to place at either end of the line, as produced by the `arrow` function.
- `name`: A character identifier.
- `draw`: A logical value indicating whether graphics output should be produced.
- `gp`: An object of class `gpar`, typically the output from a call to the function `gpar`. This is basically a list of graphical parameter settings.
- `vp`: A Grid viewport object (or NULL).

Details

Both functions create a move.to/line.to grob (a graphical object describing a move-to/line-to), but only `grid.move.to/line.to()` draws the move.to/line.to (and then only if `draw` is TRUE).

Value

A move.to/line.to grob. `grid.move.to/line.to()` returns the value invisibly.

Author(s)

Paul Murrell
grid.newpage

Move to a New Page on a Grid Device

Description
This function erases the current device or moves to a new page.

Usage
grid.newpage(recording = TRUE)

Arguments
recording A logical value to indicate whether the new-page operation should be saved onto the Grid display list.

Details
There is a hook called "grid.newpage" (see setHook) which is used in the testing code to annotate the new page. The hook function(s) are called with no argument. (If the value is a character string, get is called on it from within the grid name space.)

Value
None.

Grid
grid.pack

Pack an Object within a Frame

Description

This function, together with grid.frame and frameGrob, are part of a GUI-builder-like interface to constructing graphical images. The idea is that you create a frame with grid.frame or frameGrob then use this function to pack objects into the frame.

Usage

grid.pack(gPath, grob, redraw = TRUE, side = NULL,
row = NULL, row.before = NULL, row.after = NULL,
col = NULL, col.before = NULL, col.after = NULL,
width = NULL, height = NULL,
force.width = FALSE, force.height = FALSE, border = NULL,
dynamic = FALSE)

packGrob(frame, grob, side = NULL,
row = NULL, row.before = NULL, row.after = NULL,
col = NULL, col.before = NULL, col.after = NULL,
width = NULL, height = NULL,
force.width = FALSE, force.height = FALSE, border = NULL,
dynamic = FALSE)

Arguments

gPath A gPath object, which specifies a frame on the display list.
frame An object of class frame, typically the output from a call to grid.frame.
grob An object of class grob. The object to be packed.
redraw A boolean indicating whether the output should be updated.
side One of "left", "top", "right", "bottom" to indicate which side to pack the object on.
row Which row to add the object to. Must be between 1 and the number of rows currently in the frame + 1, or NULL in which case the object occupies all rows.
row.before Add the object to a new row just before this row.
row.after Add the object to a new row just after this row.
col Which col to add the object to. Must be between 1 and the number of cols currently in the frame + 1, or NULL in which case the object occupies all cols.
col.before Add the object to a new col just before this col.
col.after Add the object to a new col just after this col.
width Specifies the width of the column that the object is added to (rather than allowing the width to be taken from the object).
height Specifies the height of the row that the object is added to (rather than allowing the height to be taken from the object).
force.width A logical value indicating whether the width of the column that the grob is being packed into should be either the width specified in the call to grid.pack OR the maximum of that width and the pre-existing width.
force.height A logical value indicating whether the height of the column that the grob is being packed into should be EITHER the height specified in the call to grid.pack OR the maximum of that height and the pre-existing height.

border A unit object of length 4 indicating the borders around the object.

dynamic If the width/height is taken from the grob being packed, this boolean flag indicates whether the grobwidth/height unit refers directly to the grob, or uses a gPath to the grob. In the latter case, changes to the grob will trigger a recalculation of the width/height.

Details

packGrob modifies the given frame grob and returns the modified frame grob.

grid.pack destructively modifies a frame grob on the display list (and redraws the display list if redraw is TRUE).

These are (meant to be) very flexible functions. There are many different ways to specify where the new object is to be added relative to the objects already in the frame. The function checks that the specification is not self-contradictory.

NOTE that the width/height of the row/col that the object is added to is taken from the object itself unless the width/height is specified.

Value

packGrob returns a frame grob, but grid.pack returns NULL.

grid.frame, grid.place, grid.edit, and gPath.

---

grid.place Place an Object within a Frame

Description

These functions provide a simpler (and faster) alternative to the grid.pack() and packGrob functions. They can be used to place objects within the existing rows and columns of a frame layout. They do not provide the ability to add new rows and columns nor do they affect the heights and widths of the rows and columns.

Usage

grid.place(gPath, grob, row = 1, col = 1, redraw = TRUE)
placeGrob(frame, grob, row = NULL, col = NULL)
Arguments

- **gPath**: A gPath object, which specifies a frame on the display list.
- **frame**: An object of class `frame`, typically the output from a call to `grid.frame`.
- **grob**: An object of class `grob`. The object to be placed.
- **row**: Which row to add the object to. Must be between 1 and the-number-of-rows-currently-in-the-frame.
- **col**: Which col to add the object to. Must be between 1 and the-number-of-cols-currently-in-the-frame.
- **redraw**: A boolean indicating whether the output should be updated.

Details

- `placeGrob` modifies the given frame grob and returns the modified frame grob.
- `grid.place` destructively modifies a frame grob on the display list (and redraws the display list if `redraw` is TRUE).

Value

- `placeGrob` returns a frame grob, but `grid.place` returns `NULL`.

Author(s)

Paul Murrell

See Also

- `grid.frame`, `grid.pack`, `grid.edit`, and `gPath`.

Description

This function is just a wrapper for a simple demonstration of how a basic plot and legend can be drawn from scratch using grid.

Usage

```r
grid.plot.and.legend()
```

Author(s)

Paul Murrell

Examples

```r
grid.plot.and.legend()
```
grid.points  

Draw Data Symbols

Description

These functions create and draw data symbols.

Usage

```r
grid.points(x = stats::runif(10),
    y = stats::runif(10),
    pch = 1, size = unit(1, "char"),
    default.units = "native", name = NULL,
    gp=gpar(), draw = TRUE, vp = NULL)
pointsGrob(x = stats::runif(10),
    y = stats::runif(10),
    pch = 1, size = unit(1, "char"),
    default.units = "native", name = NULL,
    gp=gpar(), vp = NULL)
```

Arguments

- `x`: A numeric vector or unit object specifying x-values.
- `y`: A numeric vector or unit object specifying y-values.
- `pch`: A numeric or character vector indicating what sort of plotting symbol to use.
- `size`: A unit object specifying the size of the plotting symbols.
- `default.units`: A string indicating the default units to use if `x` or `y` are only given as numeric vectors.
- `name`: A character identifier.
- `gp`: An object of class `gpar`, typically the output from a call to the function `gpar`. This is basically a list of graphical parameter settings.
- `draw`: A logical value indicating whether graphics output should be produced.
- `vp`: A Grid viewport object (or NULL).

Details

Both functions create a points grob (a graphical object describing points), but only `grid.points` draws the points (and then only if `draw` is TRUE).

Value

A points grob. `grid.points` returns the value invisibly.

Author(s)

Paul Murrell

`Grid, viewport`
grid.polygon

**Draw a Polygon**

**Description**

These functions create and draw a polygon. The final point will automatically be connected to the initial point.

**Usage**

```r
grid.polygon(x=c(0, 0.5, 1, 0.5), y=c(0.5, 1, 0.5, 0),
             id=NULL, id.lengths=NULL,
             default.units="npc", name=NULL,
             gp=gpar(), draw=TRUE, vp=NULL)
polygonGrob(x=c(0, 0.5, 1, 0.5), y=c(0.5, 1, 0.5, 0),
            id=NULL, id.lengths=NULL,
            default.units="npc", name=NULL,
            gp=gpar(), vp=NULL)
```

**Arguments**

- `x` A numeric vector or unit object specifying x-locations.
- `y` A numeric vector or unit object specifying y-locations.
- `id` A numeric vector used to separate locations in `x` and `y` into multiple polygons. All locations with the same `id` belong to the same polygon.
- `id.lengths` A numeric vector used to separate locations in `x` and `y` into multiple polygons. Specifies consecutive blocks of locations which make up separate polygons.
- `default.units` A string indicating the default units to use if `x`, `y`, `width`, or `height` are only given as numeric vectors.
- `name` A character identifier.
- `gp` An object of class `gpar`, typically the output from a call to the function `gpar`. This is basically a list of graphical parameter settings.
- `draw` A logical value indicating whether graphics output should be produced.
- `vp` A Grid viewport object (or NULL).

**Details**

Both functions create a polygon grob (a graphical object describing a polygon), but only `grid.polygon` draws the polygon (and then only if `draw` is `TRUE`).

**Value**

A grob object.

**Author(s)**

Paul Murrell

Grid, viewport

Examples

grid.polygon()
# Using id (NOTE: locations are not in consecutive blocks)
grid.newpage()
grid.polygon(x = c((0:4)/10, rep(.5, 5), (10:6)/10, rep(.5, 5)),
            y = c(rep(.5, 5), (10:6)/10, rep(.5, 5), (0:4)/10),
            id = rep(1:5, 4),
            gp = gpar(fill = 1:5))
# Using id.lengths
grid.newpage()
grid.polygon(x = outer(c(0, .5, 1, .5), 5:1/5),
             y = outer(c(.5, 1, .5, 0), 5:1/5),
             id = rep(1:5, 4),
             gp = gpar(fill = 1:5))

grid.pretty Generate a Sensible Set of Breakpoints

Description

Produces a pretty set of breakpoints within the range given.

Usage

grid.pretty(range)

Arguments

range A numeric vector

Value

A numeric vector of breakpoints.

Author(s)

Paul Murrell
grid.prompt

Prompt before new page

Description

This function can be used to control whether the user is prompted before starting a new page of output.

Usage

grid.prompt(ask)

Arguments

ask

a logical value. If TRUE, the user is prompted before a new page of output is started.

Value

The current prompt setting before any new setting is applied.

Author(s)

Paul Murrell

grid.newpage

grid.record

Encapsulate calculations and drawing

Description

Evaluates an expression that includes both calculations and drawing that depends on the calculations so that both the calculations and the drawing will be rerun when the scene is redrawn (e.g., device resize or editing).

Intended only for expert use.

Usage

recordGrob(expr, list, name=NULL, gp=NULL, vp=NULL)
grid.record(expr, list, name=NULL, gp=NULL, vp=NULL)
grid.rect

Arguments

- expr: object of mode expression or call or an “unevaluated expression”.
- list: a list defining the environment in which expr is to be evaluated.
- name: A character identifier.
- gp: An object of class gpar, typically the output from a call to the function gpar. This is basically a list of graphical parameter settings.
- vp: A Grid viewport object (or NULL).

Details

A grob is created of special class "recordedGrob" (and drawn, in the case of grid.record). The drawDetails method for this class evaluates the expression with the list as the evaluation environment (and the grid Namespace as the parent of that environment).

Note

This function must be used instead of the function recordGraphics; all of the dire warnings about using recordGraphics responsibly also apply here.

Author(s)

Paul Murrell

See Also

recordGraphics

Examples

```r
grid.record(
  w <- convertWidth(unit(1, "inches"), "npc")
  grid.rect(width=w)
),
list())
```

grid.rect  

Draw rectangles

Description

These functions create and draw rectangles.

Usage

```r
grid.rect(x = unit(0.5, "npc"), y = unit(0.5, "npc"),
  width = unit(1, "npc"), height = unit(1, "npc"),
  just = "centre", hjust = NULL, vjust = NULL,
  default.units = "npc", name = NULL,
  gp=gpar(), draw = TRUE, vp = NULL)
rectGrob(x = unit(0.5, "npc"), y = unit(0.5, "npc"),
  width = unit(1, "npc"), height = unit(1, "npc"),
  ...)```
Arguments

- **x**: A numeric vector or unit object specifying x-location.
- **y**: A numeric vector or unit object specifying y-location.
- **width**: A numeric vector or unit object specifying width.
- **height**: A numeric vector or unit object specifying height.
- **just**: The justification of the rectangle relative to its (x, y) location. If there are two values, the first value specifies horizontal justification and the second value specifies vertical justification. Possible string values are: "left", "right", "centre", "center", "bottom", and "top". For numeric values, 0 means left alignment and 1 means right alignment.
- **hjust**: A numeric vector specifying horizontal justification. If specified, overrides the just setting.
- **vjust**: A numeric vector specifying vertical justification. If specified, overrides the just setting.
- **default.units**: A string indicating the default units to use if x, y, width, or height are only given as numeric vectors.
- **name**: A character identifier.
- **gp**: An object of class gpar, typically the output from a call to the function gpar. This is basically a list of graphical parameter settings.
- **draw**: A logical value indicating whether graphics output should be produced.
- **vp**: A Grid viewport object (or NULL).

Details

Both functions create a rect grob (a graphical object describing rectangles), but only grid.rect draws the rectangles (and then only if draw is TRUE).

Value

A rect grob. grid.rect returns the value invisibly.

Grid, viewport
grid.refresh  

*Refresh the current grid scene*

**Description**

Replays the current grid display list.

**Usage**

grid.refresh()

**Author(s)**

Paul Murrell

grid.remove  

*Remove a Grid Graphical Object*

**Description**

Remove a grob from a gTree or a descendant of a gTree.

**Usage**

grid.remove(gPath, warn = TRUE, strict = FALSE, grep = FALSE, global = FALSE, allDevices = FALSE, redraw = TRUE)

removeGrob(gTree, gPath, strict = FALSE, grep = FALSE, global = FALSE, warn = TRUE)

**Arguments**

- **gTree**
  A gTree object.

- **gPath**
  A gPath object. For grid.remove this specifies a gTree on the display list. For removeGrob this specifies a descendant of the specified gTree.

- **strict**
  A boolean indicating whether the gPath must be matched exactly.

- **grep**
  A boolean indicating whether the gPath should be treated as a regular expression. Values are recycled across elements of the gPath (e.g., c(TRUE, FALSE)) means that every odd element of the gPath will be treated as a regular expression.

- **global**
  A boolean indicating whether the function should affect just the first match of the gPath, or whether all matches should be affected.

- **allDevices**
  A boolean indicating whether all open devices should be searched for matches, or just the current device. NOT YET IMPLEMENTED.

- **warn**
  A logical to indicate whether failing to find the specified grob should trigger an error.

- **redraw**
  A logical value to indicate whether to redraw the grob.
Details

removeGrob copies the specified grob and returns a modified grob.
grid.remove destructively modifies a grob on the display list. If redraw is TRUE it then redraws everything to reflect the change.

Value

removeGrob returns a grob object; grid.remove returns NULL.

Author(s)

Paul Murrell

See Also

grob, getGrob, removeGrob, removeGrob.

grid.segments  Draw Line Segments

Description

These functions create and draw line segments.

Usage

grid.segments(x0 = unit(0, "npc"), y0 = unit(0, "npc"),
x1 = unit(1, "npc"), y1 = unit(1, "npc"),
default.units = "npc",
arrow = NULL,
name = NULL, gp = gpar(), draw = TRUE, vp = NULL)
segmentsGrob(x0 = unit(0, "npc"), y0 = unit(0, "npc"),
x1 = unit(1, "npc"), y1 = unit(1, "npc"),
default.units = "npc",
arrow = NULL, name = NULL, gp = gpar(), vp = NULL)

Arguments

x0  Numeric indicating the starting x-values of the line segments.
y0  Numeric indicating the starting y-values of the line segments.
x1  Numeric indicating the stopping x-values of the line segments.
y1  Numeric indicating the stopping y-values of the line segments.
default.units  A string.
arrow  A list describing arrow heads to place at either end of the line segments, as produced by the arrow function.
ame  A character identifier.
gp  An object of class gpar.
draw  A logical value indicating whether graphics output should be produced.
vp  A Grid viewport object (or NULL)
Details

Both functions create a segments grob (a graphical object describing segments), but only `grid.segments` draws the segments (and then only if `draw = TRUE`).

Value

A segments grob. `grid.segments` returns the value invisibly.

### grid.set

**Set a Grid Graphical Object**

#### Description

Replace a grob or a descendant of a grob.

#### Usage

```r
grid.set(gPath, newGrob, strict = FALSE, grep = FALSE, redraw = TRUE)
```

```r
setGrob(gTree, gPath, newGrob, strict = FALSE, grep = FALSE)
```

#### Arguments

- `gTree`: A gTree object.
- `gPath`: A gPath object. For `grid.set` this specifies a grob on the display list. For `setGrob` this specifies a descendant of the specified gTree.
- `newGrob`: A grob object.
- `strict`: A boolean indicating whether the `gPath` must be matched exactly.
- `grep`: A boolean indicating whether the `gPath` should be treated as a regular expression. Values are recycled across elements of the `gPath` (e.g., `c(TRUE, FALSE)`) means that every odd element of the `gPath` will be treated as a regular expression).
- `redraw`: A logical value to indicate whether to redraw the grob.

#### Details

`setGrob` copies the specified grob and returns a modified grob.

`grid.set` destructively replaces a grob on the display list. If `redraw = TRUE` it then redraws everything to reflect the change.

These functions should not normally be called by the user.
Value

setGrob returns a grob object; grid.set returns NULL.

grid.grob.

draw a Diagram of a Grid Layout

Description

This function uses Grid graphics to draw a diagram of a Grid layout.

Usage

grid.show.layout(l, newpage=TRUE, bg = "light grey",
cell.border = "blue", cell.fill = "light blue",
cell.label = TRUE, label.col = "blue",
unit.col = "red", vp = NULL)

Arguments

l A Grid layout object.
newpage A logical value indicating whether to move on to a new page before drawing the
diagram.
bg The colour used for the background.
cell.border The colour used to draw the borders of the cells in the layout.
cell.fill The colour used to fill the cells in the layout.
cell.label A logical indicating whether the layout cells should be labelled.
label.col The colour used for layout cell labels.
unit.col The colour used for labelling the widths/heights of columns/rows.
vp A Grid viewport object (or NULL).

Details

A viewport is created within vp to provide a margin for annotation, and the layout is drawn within
that new viewport. The margin is filled with light grey, the new viewport is filled with white and
framed with a black border, and the layout regions are filled with light blue and framed with a blue
border. The diagram is annotated with the widths and heights (including units) of the columns and
rows of the layout using red text. (All colours are defaults and may be customised via function
arguments.)

Value

None.
grid.show.viewport

Author(s)
Paul Murrell

See Also
Grid, viewport, grid.layout

Examples

```r
## Diagram of a simple layout
grid.show.layout(grid.layout(4,2,
  heights=unit(rep(1, 4),
    c("lines", "lines", "lines", "null")),
  widths=unit(c(1, 1), "inches")))
```

Description

This function uses Grid graphics to draw a diagram of a Grid viewport.

Usage

```r
grid.show.viewport(v, parent.layout = NULL, newpage = TRUE,
  border.fill="light grey",
  vp.col="blue", vp.fill="light blue",
  scale.col="red",
  vp = NULL)
```

Arguments

- `v` A Grid viewport object.
- `parent.layout` A grid layout object. If this is not NULL and the viewport given in `v` has its location specified relative to the layout, then the diagram shows the layout and which cells `v` occupies within the layout.
- `newpage` A logical value to indicate whether to move to a new page before drawing the diagram.
- `border.fill` Colour to fill the border margin.
- `vp.col` Colour for the border of the viewport region.
- `vp.fill` Colour to fill the viewport region.
- `scale.col` Colour to draw the viewport axes.
- `vp` A Grid viewport object (or NULL).
Details

A viewport is created within `vp` to provide a margin for annotation, and the diagram is drawn within that new viewport. By default, the margin is filled with light grey, the new viewport is filled with white and framed with a black border, and the viewport region is filled with light blue and framed with a blue border. The diagram is annotated with the width and height (including units) of the viewport, the \((x, y)\) location of the viewport, and the \(x\)- and \(y\)-scales of the viewport, using red lines and text.

Value

None.

Examples

```r
## Diagram of a sample viewport
grid.show.viewport(viewport(x=0.6, y=0.6,
                        w=unit(1, "inches"), h=unit(1, "inches")))
grid.show.viewport(viewport(layout.pos.row=2, layout.pos.col=2:3),
                   grid.layout(3, 4))
```

grid.text  Draw Text

Description

These functions create and draw text and `plotmath` expressions.

Usage

```r
grid.text(label, x = unit(0.5, "npc"), y = unit(0.5, "npc"),
           just = "centre", hjust = NULL, vjust = NULL, rot = 0,
           check.overlap = FALSE, default.units = "npc",
           name = NULL, gp = gpar(), draw = TRUE, vp = NULL)

textGrob(label, x = unit(0.5, "npc"), y = unit(0.5, "npc"),
         just = "centre", hjust = NULL, vjust = NULL, rot = 0,
         check.overlap = FALSE, default.units = "npc",
         name = NULL, gp = gpar(), vp = NULL)
```
Arguments

label
A character or expression vector. Other objects are coerced by as.graphicsAnnot.

x
A numeric vector or unit object specifying x-values.

y
A numeric vector or unit object specifying y-values.

just
The justification of the text relative to its (x, y) location. If there are two values, the first value specifies horizontal justification and the second value specifies vertical justification. Possible string values are: "left", "right", "centre", "center", "bottom", and "top". For numeric values, 0 means left alignment and 1 means right alignment.

hjust
A numeric vector specifying horizontal justification. If specified, overrides the just setting.

vjust
A numeric vector specifying vertical justification. If specified, overrides the just setting.

rot
The angle to rotate the text.

check.overlap
A logical value to indicate whether to check for and omit overlapping text.

default.units
A string indicating the default units to use if x or y are only given as numeric vectors.

name
A character identifier.

gp
An object of class gpar, typically the output from a call to the function gpar. This is basically a list of graphical parameter settings.

draw
A logical value indicating whether graphics output should be produced.

vp
A Grid viewport object (or NULL).

Details

Both functions create a text grob (a graphical object describing text), but only grid.text draws the text (and then only if draw is TRUE).

If the label argument is an expression, the output is formatted as a mathematical annotation, as for base graphics text.

Value

A text grob. grid.text returns the value invisibly.

x <- stats::runif(20)
y <- stats::runif(20)
rot <- stats::runif(20, 0, 360)
grid.text("SOMETHING NICE AND BIG", x=x, y=y, rot=rot,
gp=gpar(fontsize=20, col="grey"))
grid.text("SOMETHING NICE AND BIG", x=x, y=y, rot=rot,
gp=gpar(fontsize=20), check=TRUE)
grid.newpage()
draw.text <- function(just, i, j) {
grid.text("ABCD", x=x[j], y=y[i], just=just)
grid.text(deparse(substitute(just)), x=x[j], y=y[i] + unit(2, "lines"),
gp=gpar(col="grey", fontsize=8))
}
x <- unit(1:4/5, "npc")
y <- unit(1:4/5, "npc")
grid.grill(h=y, v=x, gp=gpar(col="grey"))
draw.text(c("bottom"), 1, 1)
draw.text(c("left", "bottom"), 2, 1)
draw.text(c("right", "bottom"), 3, 1)
draw.text(c("centre", "bottom"), 4, 1)
draw.text(c("centre"), 1, 2)
draw.text(c("left", "centre"), 2, 2)
draw.text(c("right", "centre"), 3, 2)
draw.text(c("centre", "centre"), 4, 2)
draw.text(c("top"), 1, 3)
draw.text(c("left", "top"), 2, 3)
draw.text(c("right", "top"), 3, 3)
draw.text(c("centre", "top"), 4, 3)
draw.text(c(), 1, 4)
draw.text(c("right"), 2, 4)
draw.text(c("centre"), 4, 4)
```
Arguments

at
A numeric vector of x-value locations for the tick marks.

label
A logical value indicating whether to draw the labels on the tick marks, or an expression or character vector which specify the labels to use. If not logical, must be the same length as the at argument.

main
A logical value indicating whether to draw the axis at the bottom (TRUE) or at the top (FALSE) of the viewport.

edits
A gEdit or gEditList containing edit operations to apply (to the children of the axis) when the axis is first created and during redrawing whenever at is NULL.

name
A character identifier.

gp
An object of class gpar, typically the output from a call to the function gpar. This is basically a list of graphical parameter settings.

draw
A logical value indicating whether graphics output should be produced.

vp
A Grid viewport object (or NULL).

Details

Both functions create an xaxis grob (a graphical object describing an xaxis), but only grid.xaxis draws the xaxis (and then only if draw is TRUE).

Value

An xaxis grob. grid.xaxis returns the value invisibly.

Children

If the at slot of an xaxis grob is not NULL then the xaxis will have the following children:

major representing the line at the base of the tick marks.

ticks representing the tick marks.

labels representing the tick labels.

If the at slot is NULL then there are no children and ticks are drawn based on the current viewport scale.

Grid, viewport, grid.yaxis
grid.xspline

**Description**

These functions create and draw an xspline, a curve drawn relative to control points.

**Usage**

```r
grid.xspline(...)
xsplineGrob(x = c(0, 0.5, 1, 0.5), y = c(0.5, 1, 0.5, 0),
    id = NULL, id.lengths = NULL,
    default.units = "npc",
    shape = 0, open = TRUE, arrow = NULL, repEnds = TRUE,
    name = NULL, gp = gpar(), vp = NULL)
```

**Arguments**

- `x` A numeric vector or unit object specifying x-locations of spline control points.
- `y` A numeric vector or unit object specifying y-locations of spline control points.
- `id` A numeric vector used to separate locations in `x` and `y` into multiple xsplines. All locations with the same `id` belong to the same xspline.
- `id.lengths` A numeric vector used to separate locations in `x` and `y` into multiple xspline. Specifies consecutive blocks of locations which make up separate xsplines.
- `default.units` A string indicating the default units to use if `x` or `y` are only given as numeric vectors.
- `shape` A numeric vector of values between -1 and 1, which control the shape of the spline relative to the control points.
- `open` A logical value indicating whether the spline is a line or a closed shape.
- `arrow` A list describing arrow heads to place at either end of the xspline, as produced by the `arrow` function.
- `repEnds` A logical value indicating whether the first and last control points should be replicated for drawing the curve (see Details below).
- `name` A character identifier.
- `gp` An object of class `gpar`, typically the output from a call to the function `gpar`. This is basically a list of graphical parameter settings.
- `vp` A Grid viewport object (or NULL).
- `...` Arguments to be passed to `xsplineGrob`.

**Details**

Both functions create an xspline grob (a graphical object describing an xspline), but only `grid.xspline` draws the xspline.

An xspline is a line drawn relative to control points. For each control point, the line may pass through (interpolate) the control point or it may only approach (approximate) the control point; the behaviour is determined by a shape parameter for each control point.
If the shape parameter is greater than zero, the spline approximates the control points (and is very similar to a cubic B-spline when the shape is 1). If the shape parameter is less than zero, the spline interpolates the control points (and is very similar to a Catmull-Rom spline when the shape is -1). If the shape parameter is 0, the spline forms a sharp corner at that control point.

For open xsplines, the start and end control points must have a shape of 0 (and non-zero values are silently converted to zero without warning).

For open xsplines, by default the start and end control points are actually replicated before the curve is drawn. A curve is drawn between (interpolating or approximating) the second and third of each set of four control points, so this default behaviour ensures that the resulting curve starts at the first control point you have specified and ends at the last control point. The default behaviour can be turned off via the `repEnds` argument, in which case the curve that is drawn starts (approximately) at the second control point and ends (approximately) at the first and second-to-last control point.

The `repEnds` argument is ignored for closed xsplines.

Missing values are not allowed for x and y (i.e., it is not valid for a control point to be missing).

For closed xsplines, a curve is automatically drawn between the final control point and the initial control point.

**Value**

A grob object.

---

draw a y-axis

description

These functions create and draw a y-axis.

usage

grid.yaxis(at = NULL, label = TRUE, main = TRUE,
edits = NULL, name = NULL,
gp = gpar(), draw = TRUE, vp = NULL)
yaxisGrob(at = NULL, label = TRUE, main = TRUE,
edits = NULL, name = NULL,
gp = gpar(), vp = NULL)

arguments

at          A numeric vector of y-value locations for the tick marks.
label       A logical value indicating whether to draw the labels on the tick marks, or an
            expression or character vector which specify the labels to use. If not logical,
            must be the same length as the at argument.
main        A logical value indicating whether to draw the axis at the left (TRUE) or at the
            right (FALSE) of the viewport.
edits       A gEdit or gEditList containing edit operations to apply (to the children of the
            axis) when the axis is first created and during redrawing whenever at is NULL.
name  A character identifier.
gp    An object of class gpar, typically the output from a call to the function gpar. This is basically a list of graphical parameter settings.
draw  A logical value indicating whether graphics output should be produced.
vp    A Grid viewport object (or NULL).

Details

Both functions create a yaxis grob (a graphical object describing a yaxis), but only grid.yaxis draws the yaxis (and then only if draw is TRUE).

Value

A yaxis grob. grid.yaxis returns the value invisibly.

Children

If the at slot of an xaxis grob is not NULL then the xaxis will have the following children:

- major representing the line at the base of the tick marks.
- ticks representing the tick marks.
- labels representing the tick labels.

If the at slot is NULL then there are no children and ticks are drawn based on the current viewport scale.

grobName  Generate a Name for a Grob

Description

This function generates a unique (within-session) name for a grob, based on the grob’s class.

Usage

grobName(grob = NULL, prefix = "GRID")

Arguments

grob  A grob object or NULL.
prefix The prefix part of the name.
grobWidth

Value
A character string of the form \texttt{prefix.class(grob).index}

Author(s)
Paul Murrell

---

\texttt{grobWidth} \hspace{1cm} \textit{Create a Unit Describing the Width of a Grob}

Description
These functions create a unit object describing the width or height of a grob. They are generic.

Usage
\begin{verbatim}
grobWidth(x)  
grobHeight(x)
\end{verbatim}

Arguments
\begin{itemize}
  \item \texttt{x} \hspace{1cm} A grob object.
\end{itemize}

Value
A unit object.

Author(s)
Paul Murrell

See Also
\texttt{unit} and \texttt{stringWidth}

---

\texttt{grobX} \hspace{1cm} \textit{Create a Unit Describing a Grob Boundary Location}

Description
These functions create a unit object describing a location somewhere on the boundary of a grob. They are generic.

Usage
\begin{verbatim}
grobX(x, theta)  
grobY(x, theta)
\end{verbatim}

**Arguments**

- x: A grob, or gList, or gTree, or gPath.
- theta: An angle indicating where the location is on the grob boundary. Can be one of "east", "north", "west", or "south", which correspond to angles 0, 90, 180, and 270, respectively.

**Details**

The angle is anti-clockwise with zero corresponding to a line with an origin centred between the extreme points of the shape, and pointing at 3 o’clock.

If the grob describes a single shape, the boundary value should correspond to the exact edge of the shape.

If the grob describes multiple shapes, in most cases, the boundary value will correspond to the edge of a bounding box around all of the shapes. The exception to this is a polygon grob describing multiple polygons; in that case, the edge corresponds to a convex hull around all points of all polygons described by the grob.

**Value**

A unit object.

**Author(s)**

Paul Murrell

**plotViewport**

Create a Viewport with a Standard Plot Layout

**Description**

This is a convenience function for producing a viewport with the common S-style plot layout – i.e., a central plot region surrounded by margins given in terms of a number of lines of text.

**Usage**

```r
plotViewport(margins=c(5.1, 4.1, 4.1, 2.1), ...)
```

**Arguments**

- margins: A numeric vector interpreted in the same way as `par(mar)` in base graphics.
- ...: All other arguments will be passed to a call to the `viewport()` function.

**Value**

A grid viewport object.
pop.viewport

Author(s)
Paul Murrell

See Also
viewport and dataViewport.

Description
Grid maintains a viewport stack — a list of nested drawing contexts.
This function makes the parent of the specified viewport the new default viewport.

Usage
pop.viewport(n=1, recording=TRUE)

Arguments
n An integer giving the number of viewports to pop. Defaults to 1.
recording A logical value to indicate whether the setviewport operation should be recorded on the Grid display list.

Value
None.

Warning
This function has been deprecated. Please use popViewport instead.

Author(s)
Paul Murrell

See Also
push.viewport.
push.viewport  

*Push a Viewport onto the Grid Viewport Stack*

**Description**

Grid maintains a viewport stack — a list of nested drawing contexts.

This function makes the specified viewport the default viewport and makes its parent the previous default viewport (i.e., nests the specified context within the previous default context).

**Usage**

```
push.viewport(..., recording=TRUE)
```

**Arguments**

- `...` One or more objects of class "viewport", or NULL.
- `recording` A logical value to indicate whether the set-viewport operation should be recorded on the Grid display list.

**Value**

None.

**Warning**

This function has been deprecated. Please use `pushViewport` instead.

---

**Querying the Viewport Tree**

*Get the Current Grid Viewport (Tree)*

**Description**

- `current.viewport()` returns the viewport that Grid is going to draw into.
- `current.vpTree` returns the entire Grid viewport tree.
- `current.vpPath` returns the viewport path to the current viewport.
- `current.transform` returns the transformation matrix for the current viewport.
Querying the Viewport Tree

Usage

```r
current.viewport(vp=NULL)
current.vpTree(all=TRUE)
current.vpPath()
current.transform()
```

Arguments

- **vp**  A Grid viewport object. Use of this argument has been deprecated.
- **all**  A logical value indicating whether the entire viewport tree should be returned.

Details

If `all` is `FALSE` then `current.vpTree` only returns the subtree below the current viewport.

Value

A Grid viewport object from `current.viewport` or `current.vpTree`. `current.transform` returns a 4x4 transformation matrix.

The viewport path returned by `current.vpPath` is `NULL` if the current viewport is the ROOT viewport.

current.vpPath()
current.vpTree()
current.viewport()
current.vpTree(all=FALSE)
popViewport(0)
```
**stringWidth**  
*Create a Unit Describing the Width of a String*

Description

These functions create a unit object describing the width or height of a string.

Usage

```r
stringWidth(string)
stringHeight(string)
```

Arguments

- `string`: A character vector.

Value

A unit object.

Author(s)

Paul Murrell

See Also

`unit` and `grobWidth`

---

**unit**  
*Function to Create a Unit Object*

Description

This function creates a unit object — a vector of unit values. A unit value is typically just a single numeric value with an associated unit.

Usage

```r
unit(x, units, data=NULL)
```

Arguments

- `x`: A numeric vector.
- `units`: A character vector specifying the units for the corresponding numeric values.
- `data`: This argument is used to supply extra information for special unit types.
Details

Unit objects allow the user to specify locations and dimensions in a large number of different coordinate systems. All drawing occurs relative to a viewport and the `units` specifies what coordinate system to use within that viewport.

Possible `units` (coordinate systems) are:

"npc" Normalised Parent Coordinates (the default). The origin of the viewport is (0, 0) and the viewport has a width and height of 1 unit. For example, (0.5, 0.5) is the centre of the viewport.

"cm" Centimetres.

"inches" Inches. 1 in = 2.54 cm.

"mm" Millimetres. 10 mm = 1 cm.

"points" Points. 72.27 pt = 1 in.

"picas" Picas. 1 pc = 12 pt.

"bigpts" Big Points. 72 bp = 1 in.

"dida" Dida. 1157 dd = 1238 pt.

"cicero" Cicero. 1 cc = 12 dd.

"scaledpts" Scaled Points. 65536 sp = 1 pt.

"lines" Lines of text. Locations and dimensions are in terms of multiples of the default text size of the viewport (as specified by the viewport’s `fontsize` and `lineheight`).

"char" Multiples of nominal font height of the viewport (as specified by the viewport’s `fontsize`).

"native" Locations and dimensions are relative to the viewport’s `xscale` and `yscale`.

"snpc" Square Normalised Parent Coordinates. Same as Normalised Parent Coordinates, except gives the same answer for horizontal and vertical locations/dimensions. It uses the lesser of_npc-width and npc-height_. This is useful for making things which are a proportion of the viewport, but have to be square (or have a fixed aspect ratio).

"strwidth" Multiples of the width of the string specified in the `data` argument. The font size is determined by the pointsize of the viewport.

"strheight" Multiples of the height of the string specified in the `data` argument. The font size is determined by the pointsize of the viewport.

"grobwidth" Multiples of the width of the grob specified in the `data` argument.

"grobheight" Multiples of the height of the grob specified in the `data` argument.

A special `units` value of "null" is also allowed, but only makes sense when used in specifying widths of columns or heights of rows in grid layouts (see `grid.layout`).

The `data` argument must be a list when the `unit.length()` is greater than 1. For example, `unit(rep(1, 3), c("npc", "strwidth", "inches"), data=list(NULL, "my string", NULL))`.

It is possible to subset unit objects in the normal way (e.g., `unit(1:5, "npc")[2:4]`), but a special function `unit.c` is provided for combining unit objects.

Certain arithmetic and summary operations are defined for unit objects. In particular, it is possible to add and subtract unit objects (e.g., `unit(1, "npc") - unit(1, "inches")`), and to specify the minimum or maximum of a list of unit objects (e.g., `min(unit(0.5, "npc"), unit(1, "inches"))`).
Value

An object of class "unit".

WARNING

There is a special function unit.c for concatenating several unit objects.
The c function will not give the right answer.
There used to be "mylines", "mychar", "mystrwidth", "mystrheight" units. These
will still be accepted, but work exactly the same as "lines", "char", "strwidth", "strheight".

Author(s)

Paul Murrell

unit.c

Examples

unit(1, "npc")
unit(1:3/4, "npc")
unit(1:3/4, "npc") + unit(1, "inches")
min(unit(0.5, "npc"), unit(1, "inches"))
unit.c(unit(0.5, "npc"), unit(2, "inches") + unit(1:3/4, "npc"),
      unit(1, "strwidth", "hi there"))
**unit.length**  
*Length of a Unit Object*

**Description**

The length of a unit object is defined as the number of unit values in the unit object.

This function has been deprecated in favour of a unit method for the generic `length` function.

**Usage**

```r
unit.length(unit)
```

**Arguments**

- **unit**  
  A unit object.

**Value**

An integer value.

**Author(s)**

Paul Murrell

**See Also**

- `unit`

**Examples**

```r
length(unit(1:3, "npc"))
length(unit(1:3, "npc") + unit(1, "inches"))
length(max(unit(1:3, "npc") + unit(1, "inches")))
length(max(unit(1:3, "npc") + unit(1, "strwidth", "a")×4))
length(unit(1:3, "npc") + unit(1, "strwidth", "a")×4)
```

---

**unit.pmin**  
*Parallel Unit Minima and Maxima*

**Description**

Returns a unit object whose i’th value is the minimum (or maximum) of the i’th values of the arguments.

**Usage**

```r
unit.pmin(...)
unit.pmax(...)
```
Arguments

... One or more unit objects.

Details

The length of the result is the maximum of the lengths of the arguments; shorter arguments are recycled in the usual manner.

Value

A unit object.

Author(s)

Paul Murrell

Examples

max(unit(1:3, "cm"), unit(0.5, "npc"))
unit.pmax(unit(1:3, "cm"), unit(0.5, "npc"))

Description

Replicates the units according to the values given in `times` and `length.out`.

This function has been deprecated in favour of a unit method for the generic `rep` function.

Usage

`unit.rep(x, ...)`

Arguments

`x` An object of class "unit".

... arguments to be passed to `rep` such as `times` and `length.out`.

Value

An object of class "unit".

Author(s)

Paul Murrell

See Also

`rep`
validDetails

Examples

```r
rep(unit(1:3, "npc"), 3)
rep(unit(1:3, "npc"), 1:3)
rep(unit(1:3, "npc") + unit(1, "inches"), 3)
rep(max(unit(1:3, "npc") + unit(1, "inches")), 3)
rep(max(unit(1:3, "npc") + unit(1, "strwidth", "a")) * 4, 3)
rep(unit(1:3, "npc") + unit(1, "strwidth", "a") * 4, 3)
```

validDetails  Customising grid grob Validation

Description

This generic hook function is called whenever a grid grob is created or edited via `grob`, `gTree`, `grid.edit` or `editGrob`. This provides an opportunity for customising the validation of a new class derived from grob (or gTree).

Usage

`validDetails(x)`

Arguments

`x`  A grid grob.

Details

This function is called by `grob`, `gTree`, `grid.edit` and `editGrob`. A method should be written for classes derived from grob or gTree to validate the values of slots specific to the new class. (e.g., see `grid:::validDetails.axis`).

Note that the standard slots for grobs and gTrees are automatically validated (e.g., `vp`, `gp` slots for grobs and, in addition, `children` and `childrenvp` slots for gTrees) so only slots specific to a new class need to be addressed.

Value

The function MUST return the validated grob.

Author(s)

Paul Murrell

See Also

`grid.edit`
vpPath

Concatenate Viewport Names

Description

This function can be used to generate a viewport path for use in `downViewport` or `seekViewport`.

A viewport path is a list of nested viewport names.

Usage

`vpPath(...)`

Arguments

... Character values which are viewport names.

Details

Viewport names must only be unique amongst viewports which share the same parent in the viewport tree.

This function can be used to generate a specification for a viewport that includes the viewport’s parent’s name (and the name of its parent and so on).

For interactive use, it is possible to directly specify a path, but it is strongly recommended that this function is used otherwise in case the path separator is changed in future versions of grid.

Value

A `vpPath` object.

See Also

`viewport`, `pushViewport`, `popViewport`, `downViewport`, `seekViewport`, `upViewport`

Examples

`vpPath("vp1", "vp2")`
widthDetails  Width and Height of a grid grob

Description
These generic functions are used to determine the size of grid grobs.

Usage
widthDetails(x)
heightDetails(x)

Arguments
x  A grid grob.

Details
These functions are called in the calculation of "grobwidth" and "grobheight" units. Methods should be written for classes derived from grob or gTree where the size of the grob can be determined (see, for example grid::widthDetails.frame).

Value
A unit object.

Author(s)
Paul Murrell

See Also
absolute.size.

Working with Viewports
Maintaining and Navigating the Grid Viewport Tree

Description
Grid maintains a tree of viewports — nested drawing contexts.
These functions provide ways to add or remove viewports and to navigate amongst viewports in the tree.

Usage
pushViewport(..., recording=TRUE)
popViewport(n, recording=TRUE)
downViewport(name, strict=FALSE, recording=TRUE)
seekViewport(name, recording=TRUE)
upViewport(n, recording=TRUE)
Working with Viewports

Arguments

... One or more objects of class "viewport".

n An integer value indicating how many viewports to pop or navigate up. The special value 0 indicates to pop or navigate viewports right up to the root viewport.

name A character value to identify a viewport in the tree.

strict A boolean indicating whether the vpPath must be matched exactly.

recording A logical value to indicate whether the viewport operation should be recorded on the Grid display list.

Details

Objects created by the viewport() function are only descriptions of a drawing context. A viewport object must be pushed onto the viewport tree before it has any effect on drawing.

The viewport tree always has a single root viewport (created by the system) which corresponds to the entire device (and default graphical parameter settings). Viewports may be added to the tree using pushViewport() and removed from the tree using popViewport().

There is only ever one current viewport, which is the current position within the viewport tree. All drawing and viewport operations are relative to the current viewport. When a viewport is pushed it becomes the current viewport. When a viewport is popped, the parent viewport becomes the current viewport. Use upViewport to navigate to the parent of the current viewport, without removing the current viewport from the viewport tree. Use downViewport to navigate to a viewport further down the viewport tree and seekViewport to navigate to a viewport anywhere else in the tree.

If a viewport is pushed and it has the same name as a viewport at the same level in the tree, then it replaces the existing viewport in the tree.

Value

downViewport returns the number of viewports it went down.

This can be useful for returning to your starting point by doing something like depth <- downViewport() then upViewport(depth).

pushViewport(viewport(x=0.5, width=0.4, height=0.8,
  just="left", name="C"))
grid.rect(gp=gpar(col="green"))
grid.text("4. Push Viewport C (in A)",
  y=unit(1, "npc") - unit(1, "lines"), gp=gpar(col="green"))
if (interactive()) Sys.sleep(1.0)
pushViewport(viewport(width=0.8, height=0.6, name="D"))
grid.rect()
grid.text("5. Push Viewport D (in C)",
  y=unit(1, "npc") - unit(1, "lines"))
if (interactive()) Sys.sleep(1.0)
upViewport(0)
grid.text("6. Up from D to top-level",
  y=unit(1, "npc") - unit(2, "lines"), gp=gpar(col="grey"))
if (interactive()) Sys.sleep(1.0)
downViewport("B")
grid.text("7. Down from top-level to D",
  y=unit(1, "npc") - unit(2, "lines"))
if (interactive()) Sys.sleep(1.0)
seekViewport("B")
grid.text("8. Seek from D to B",
  y=unit(1, "npc") - unit(2, "lines"), gp=gpar(col="red"))
pushViewport(viewport(width=0.9, height=0.5, name="A"))
grid.rect()
grid.text("9. Push Viewport A (in B)",
  y=unit(1, "npc") - unit(1, "lines"))
if (interactive()) Sys.sleep(1.0)
seekViewport("A")
grid.text("10. Seek from B to A (in ROOT)",
  y=unit(1, "npc") - unit(3, "lines"), gp=gpar(col="blue"))
if (interactive()) Sys.sleep(1.0)
seekViewport(vpPath("B", "A"))
grid.text("11. Seek from\nA (in ROOT)\nto A (in B)")
popViewport(0)
```
xDetails

Boundary of a grid grob

Description
These generic functions are used to determine a location on the boundary of a grid grob.

Usage

xDetails(x, theta)
yDetails(x, theta)

Arguments

x
A grid grob.
theta
A numeric angle, in degrees, measured anti-clockwise from the 3 o’clock or one of the following character strings: "north", "east", "west", "south".

Details
The location on the grob boundary is determined by taking a line from the centre of the grob at the angle theta and intersecting it with the convex hull of the grob (for the basic grob primitives, the centre is determined as half way between the minimum and maximum values in x and y directions). These functions are called in the calculation of "grobx" and "groby" units as produced by the grobX and grobY functions. Methods should be written for classes derived from grob or gTree where the boundary of the grob can be determined.

Value
A unit object.

grobX, grobY.
Chapter 6

The methods package

Description

Formally defined methods and classes for R objects, plus other programming tools, as described in the references.

Details

This package provides the “S4” or “S version 4” approach to methods and classes in a functional language.

For a complete list of functions and classes, use library(help="methods").

Author(s)

R Development Core Team

Maintainer: R Core Team (R-core@r-project.org)

References

The R package methods implements, with a few exceptions, the programming interface for classes and methods in the book Programming with Data (John M. Chambers, Springer, 1998), in particular sections 1.6, 2.7, 2.8, and chapters 7 and 8.

While the programming interface for the methods package follows the reference, the R software is an original implementation, so details in the reference that reflect the S4 implementation may appear differently in R. Also, there are extensions to the programming interface developed more recently than the reference. For a discussion of details see ?Methods and the links from that documentation.
.BasicFunsList  List of Builtin and Special Functions

Description

A named list providing instructions for turning builtin and special functions into generic functions.

Functions in R that are defined as .Primitive(<name>) are not suitable for formal methods, because they lack the basic reflectance property. You can’t find the argument list for these functions by examining the function object itself.

Future versions of R may fix this by attaching a formal argument list to the corresponding function. While generally the names of arguments are not checked by the internal code implementing the function, the number of arguments frequently is.

In any case, some definition of a formal argument list is needed if users are to define methods for these functions. In particular, if methods are to be merged from multiple packages, the different sets of methods need to agree on the formal arguments.

In the absence of reflectance, this list provides the relevant information via a dummy function associated with each of the known specials for which methods are allowed.

At the same, the list flags those specials for which methods are meaningless (e.g., for) or just a very bad idea (e.g., .Primitive).

A generic function created via setMethod, for example, for one of these special functions will have the argument list from .BasicFunsList. If no entry exists, the argument list (x, ...) is assumed.

as  Force an Object to Belong to a Class

Description

These functions manage the relations that allow coercing an object to a given class.

Usage

as(object, Class, strict=TRUE, ext)

as(object, Class) <- value

setAs(from, to, def, replace, where = topenv(parent.frame()))

Arguments

object  any R object.
Class  the name of the class to which object should be coerced.
strict logical flag. If TRUE, the returned object must be strictly from the target class (unless that class is a virtual class, in which case the object will be from the closest actual class (often the original object, if that class extends the virtual class directly).

If strict = FALSE, any simple extension of the target class will be returned, without further change. A simple extension is, roughly, one that just adds slots to an existing class.

value The value to use to modify object (see the discussion below). You should supply an object with class Class; some coercion is done, but you’re unwise to rely on it.

from, to The classes between which def performs coercion.
(In the case of the coerce function these are objects from the classes, not the names of the classes, but you’re not expected to call coerce directly.)

def function of one argument. It will get an object from class from and had better return an object of class to. (If you want to save setAs a little work, make the name of the argument from, but don’t worry about it, setAs will do the conversion.)

replace if supplied, the function to use as a replacement method.

where the position or environment in which to store the resulting method for coerce.

ext the optional object defining how Class is extended by the class of the object (as returned by possibleExtends). This argument is used internally (to provide essential information for non-public classes), but you are unlikely to want to use it directly.

Summary of Functions

**as:** Returns the version of this object coerced to be the given Class.

If the corresponding is(object, Class) relation is true, it will be used. In particular, if the relation has a coerce method, the method will be invoked on object. However, if the object’s class extends Class in a simple way (e.g, by including the superclass in the definition, then the actual coercion will be done only if strict is TRUE (non-strict coercion, is used in passing objects to methods).

Coerce methods are pre-defined for basic classes (including all the types of vectors, functions and a few others). See showMethods(coerce) for a list of these.

Beyond these two sources of methods, further methods are defined by calls to the setAs function.

**coerce:** Coerce from to be of the same class as to.

Not a function you should usually call explicitly. The function setAs creates methods for coerce for the as function to use.

**setAs:** The function supplied as the third argument is to be called to implement as(x, to) when x has class from. We need we add that the function should return a suitable object with class to.

How Functions ‘as’ and ‘setAs’ Work

The function as contrives to turn object into an object with class Class. In doing so, it uses information about classes and methods, but in a somewhat special way. Keep in mind that objects from one class can turn into objects from another class either automatically or by an explicit call to the as function. Automatic conversion is special, and comes from the designer of one class of objects asserting that this class extends another class (see setClass and setIs).
Because inheritance is a powerful assertion, it should be used sparingly (otherwise your computations may produce unexpected, and perhaps incorrect, results). But objects can also be converted explicitly, by calling as, and that conversion is designed to use any inheritance information, as well as explicit methods.

As a first step in conversion, the as function determines whether is(object, Class) is TRUE. This can be the case either because the class definition of object includes Class as a “super class” (directly or indirectly), or because a call to setIs established the relationship.

Either way, the inheritance relation defines a method to coerce object to Class. In the most common case, the method is just to extract from object the slots needed for Class, but it’s also possible to specify a method explicitly in a setIs call.

So, if inheritance applies, the as function calls the appropriate method. If inheritance does not apply, and coerceFlag is FALSE, NULL is returned.

By default, coerceFlag is TRUE. In this case the as function goes on to look for a method for the function coerce for the signature c(from = class(object), to = Class).

Method selection is used in the as function in two special ways.

First, inheritance is applied for the argument from but not for the argument to (if you think about it, you’ll probably agree that you wouldn’t want the result to be from some class other than the Class specified). Hence, you would typically use selectMethod("coerce", sig, useInherited= c(from=TRUE, to= FALSE)) for inspection of method selection of as().

Second, the function tries to use inheritance information to convert the object indirectly, by first converting it to an inherited class. It does this by examining the classes that the from class extends, to see if any of them has an explicit conversion method. Suppose class "by" does: Then the as function implicitly computes as(as(object, "by"), Class).

With this explanation as background, the function setAs does a fairly obvious computation: It constructs and sets a method for the function coerce with signature c(from, to), using the def argument to define the body of the method. The function supplied as def can have one argument (interpreted as an object to be coerced) or two arguments (the from object and the to class). Either way, setAs constructs a function of two arguments, with the second defaulting to the name of the to class. The method will be called from with the object as the only argument: The default for the second argument is provided so the method can know the intended to class.

The function coerce exists almost entirely as a repository for such methods, to be selected as described above by the as function. In fact, it would usually be a bad idea to call coerce directly, since then you would get inheritance on the to argument; as mentioned, this is not likely to be what you want.

The Function ‘as’ Used in Replacements

When as appears on the left of an assignment, the intuitive meaning is “Replace the part of object that was inherited from Class by the value on the right of the assignment.”

This usually has a straightforward interpretation, but you can control explicitly what happens, and sometimes you should to avoid possible corruption of objects.

When object inherits from Class in the usual way, by including the slots of Class, the default as method is to set the corresponding slots in object to those in value.

The default computation may be reasonable, but usually only if all other slots in object are unrelated to the slots being changed. Often, however, this is not the case. The class of object may have extended Class with a new slot whose value depends on the inherited slots. In this case, you may want to define a method for replacing the inherited information that recomputes all the dependent information. Or, you may just want to prohibit replacing the inherited information directly.
The way to control such replacements is through the replace argument to function setIs. This argument is a method that function as calls when used for replacement. It can do whatever you like, including calling stop if you want to prohibit replacements. It should return a modified object with the same class as the object argument to as.

In R, you can also explicitly supply a replacement method, even in the case that inheritance does not apply, through the replace argument to setAs. It works essentially the same way, but in this case by constructing a method for "coerce<-". (Replace methods for coercion without inheritance are not in the original description and so may not be compatible with S-Plus, at least not yet.)

When inheritance does apply, coerce and replace methods can be specified through either setIs or setAs; the effect is essentially the same.

Basic Coercion Methods

Methods are pre-defined for coercing any object to one of the basic datatypes. For example, as(x, "numeric") uses the existing as.numeric function. These built-in methods can be listed by showMethods("coerce").

References

The R package methods implements, with a few exceptions, the programming interface for classes and methods in the book Programming with Data (John M. Chambers, Springer, 1998), in particular sections 1.6, 2.7, 2.8, and chapters 7 and 8.

While the programming interface for the methods package follows the reference, the R software is an original implementation, so details in the reference that reflect the S4 implementation may appear differently in R. Also, there are extensions to the programming interface developed more recently than the reference. For a discussion of details see ?Methods and the links from that documentation.

If you think of using try(as(x, cl)), consider canCoerce(x, cl) instead.

Examples

## using the definition of class "track" from Classes

```r
setAs("track", "numeric", function(from) from@y)
```

```r
t1 <- new("track", x=1:20, y=(1:20)^2)
```

```r
as(t1, "numeric")
```

## The next example shows:
## 1. A virtual class to define setAs for several classes at once.
## 2. as() using inherited information

```r
setClass("ca", representation(a = "character", id = "numeric"))
```

```r
setClass("cb", representation(b = "character", id = "numeric"))
```

```r
setClass("id")
```
```r
setIs("ca", "id")
setIs("cb", "id")
setAs("id", "numeric", function(from) from@id)
CA <- new("ca", a = "A", id = 1)
CB <- new("cb", b = "B", id = 2)
setAs("cb", "ca", function(from, to )new(to, a=from@b, id = from@id))
as(CB, "numeric")
```

---

**BasicClasses**  
*Classes Corresponding to Basic Data Types*

**Description**

Formal classes exist corresponding to the basic R data types, allowing these types to be used in method signatures, as slots in class definitions, and to be extended by new classes.

**Usage**

```r
### The following are all basic vector classes.
### They can appear as class names in method signatures,  
### in calls to as(), is(), and new().
"character"
"complex"
"double"
"expression"
"integer"
"list"
"logical"
"numeric"
"single"
"raw"

### the class
"vector"
### is a virtual class, extended by all the above

### The following are additional basic classes
"NULL"  # NULL objects
"function" # function objects, including primitives
"externalptr" # raw external pointers for use in C code

"ANY" # virtual classes used by the methods package itself
"VIRTUAL"
"missing"
```
Objects from the Classes

Objects can be created by calls of the form `new(Class, ...)`, where `Class` is the quoted class name, and the remaining arguments if any are objects to be interpreted as vectors of this class. Multiple arguments will be concatenated.

The class "expression" is slightly odd, in that the ...arguments will not be evaluated; therefore, don’t enclose them in a call to `quote()`.

Extends

Class "vector", directly.

Methods

coerce  Methods are defined to coerce arbitrary objects to these classes, by calling the corresponding basic function, for example, `as(x, "numeric")` calls `as.numeric(x)`.

Description

A call to `callNextMethod` can only appear inside a method definition. It then results in a call to the first inherited method after the current method, with the arguments to the current method passed down to the next method. The value of that method call is the value of `callNextMethod`.

Usage

`callNextMethod(...)`

Arguments

... Optionally, the arguments to the function in its next call (but note that the dispatch is as in the detailed description below; the arguments have no effect on selecting the next method.)

If no arguments are included in the call to `callNextMethod`, the effect is to call the method with the current arguments. See the detailed description for what this really means.

Calling with no arguments is often the natural way to use `callNextMethod`; see the examples.

Details

The “next” method (i.e., the first inherited method) is defined to be that method which would have been called if the current method did not exist. This is more-or-less literally what happens: The current method (to be precise, the method with signature given by the defined slot of the method from which `callNextMethod` is called) is deleted from a copy of the methods for the current generic, and `selectMethod` is called to find the next method (the result is cached in a special object, so the search only typically happens once per session per combination of argument classes).

Note that the preceding definition means that the next method is defined uniquely when `setMethod` inserts the method containing the `callNextMethod` call, given the definitions of
the classes in the signature. The choice does not depend on the path that gets us to that method (for example, through inheritance or from another callNextMethod call). This definition was not enforced in versions of R prior to 2.3.0, where the method was selected based on the target signature, and so could vary depending on the actual arguments.

It is also legal, and often useful, for the method called by callNextMethod to itself have a call to callNextMethod. This generally works as you would expect, but for completeness be aware that it is possible to have ambiguous inheritance in the S structure, in the sense that the same two classes can appear as superclasses in the opposite order in two other class definitions. In this case the effect of a nested instance of callNextMethod is not well defined. Such inconsistent class hierarchies are both rare and nearly always the result of bad design, but they are possible, and currently undetected.

The statement that the method is called with the current arguments is more precisely as follows. Arguments that were missing in the current call are still missing (remember that "missing" is a valid class in a method signature). For a formal argument, say \( x \), that appears in the original call, there is a corresponding argument in the next method call equivalent to \( \text{"x = x"} \). In effect, this means that the next method sees the same actual arguments, but arguments are evaluated only once.

Value

The value returned by the selected method.

References

The R package methods implements, with a few exceptions, the programming interface for classes and methods in the book Programming with Data (John M. Chambers, Springer, 1998), in particular sections 1.6, 2.7, 2.8, and chapters 7 and 8.

While the programming interface for the methods package follows the reference, the R software is an original implementation, so details in the reference that reflect the S4 implementation may appear differently in R. Also, there are extensions to the programming interface developed more recently than the reference. For a discussion of details see ?Methods and the links from that documentation.

Methods for the general behavior of method dispatch

Examples

```r
## some class definitions with simple inheritance
setClass("B0", representation(b0 = "numeric"))
setClass("B1", representation(b1 = "character"), contains = "B0")
setClass("B2", representation(b2 = "logical"), contains = "B1")

## and a rather silly function to illustrate callNextMethod
f <- function(x) class(x)
setMethod("f", "B0", function(x) c(x@b0^2, callNextMethod()))
setMethod("f", "B1", function(x) c(paste(x@b1,":"), callNextMethod()))
setMethod("f", "B2", function(x) c(x@b2, callNextMethod()))

b1 <- new("B1", b0 = 2, b1 = "Testing")
```
b2 <- new("B2", b2 = FALSE, b1 = "More testing", b0 = 10)

f(b2)

f(b1)

---

canCoerce  

Can an Object be Coerced to a Certain S4 Class?

Description

Test if an object can be coerced to a given S4 class. Maybe useful inside if() to ensure that calling as(object, Class) will find a method.

Usage

canCoerce(object, Class)

Arguments

object  
any R object, typically of a formal S4 class.

Class  
an S4 class (see isClass).

Value

a scalar logical, TRUE if there is a coerce method (as defined by setAs, e.g.) for the signature (from = class(object), to = Class).

See Also

as, setAs, selectMethod, setClass.

Examples

m <- matrix(pi, 2, 3)
canCoerce(m, "numeric")  # TRUE
canCoerce(m, "array")    # TRUE
cbind2

Combine two Objects by Columns or Rows

Description

Combine two “matrix-like” R objects by columns (cbind2) or rows (rbind2). These are (S4) generic functions with default methods.

Usage

cbind2(x, y)

Arguments

x
any R object, typically “matrix-like”.
y
any R object, typically similar to x, or missing completely.

Details

The main use of cbind2(rbind2) is to be called by cbind() (rbind()) if these are activated. This allows cbind (rbind) to “work” for formally classed (aka ‘S4’) objects by providing S4 methods for these objects. Currently, a call

methods:::bind_activation(TRUE)

is needed to install a “cbind2-calling” version of cbind (into the base name space) and the same for rbind.

methods:::bind_activation(FALSE) reverts to the previous internal version of cbind which does not build on cbind2, see the examples.

Value

A matrix (or matrix like object) combining the columns (or rows) of x and y.

Methods

x = "ANY", y = "ANY" the default method using R’s internal code.

x = "ANY", y = "missing" the default method for one argument using R’s internal code.

See Also

cbind, rbind.

Examples

cbind2(1:3, 4)
m <- matrix(3:8, 2, 3, dimnames=list(c("a","b"), LETTERS[1:3]))
cbind2(1:2, m) # keeps dimnames from m

### Note: Use the following activation if you want cbind() to work
### ---- on S4 objects -- be careful otherwise!

methods:::bind_activation(on = TRUE)
trace("cbind2")
cbind(a=1:3)# no call to cbind2()
cbind(a=1:3, four=4, 7:9)# calling cbind2() twice
untrace("cbind2")

## The following fails currently,
## since cbind() works recursively from the tail:
try{ cbind(m, a=1, b=3) }

## turn off the 'special cbind()' :
methods:::bind_activation(FALSE)

---

**Classes**

**Class Definitions**

**Description**

Class definitions are objects that contain the formal definition of a class of R objects, usually referred to as an S4 class, to distinguish them from the informal S3 classes. This document gives an overview of S4 classes; for details of the class representation objects themselves, see `class?classRepresentation`.

**Details**

When a class is defined, an object is stored that contains the information about that class, including:

**Slots:** The data contained in an object from an S4 class is defined by the *slots* in the class definition. Each slot in an object is a component of the object; like components (that is, elements) of a list, these may be extracted and set, using the function `slot()` or more often the operator `@`. However, they differ from list components in important ways. First, slots can only be referred to by name, not by position, and there is no partial matching of names as with list elements.

All the objects from a particular class have the same set of slot names; specifically, the slot names that are contained in the class definition. Each slot in each object always has the same class; again, this is defined by the overall class definition. The phrase “has the same class” means that the class of the object in the slot must be the same as the class specified in the definition, or some class that extends the one in the definition.

One class name is special, `.Data`. This stands for the “data part” of the object. Any class that contains one of the basic data types in R, has implicitly a corresponding `.Data` slot of that type, allowing computations to extract or replace the data part while leaving other slots unchanged. The `.Data` slot also determines the type of the object; if `x` has a `.Data` slot, the type of the slot is the type of the object (that is, the value of `typeof(x)`). Otherwise the type of the object is "S4". Extending a basic type this way allows objects to use old-style code for the corresponding type as well as S4 methods. Any basic type can be used for `.Data`, with the exception of a few that do not behave like ordinary objects; namely, "NULL", environments, and external pointers.

Classes exist for which there are no actual objects, the *virtual* classes, in fact a very important programming tool. They are used to group together ordinary classes that want to share some
programming behavior, without necessarily restricting how the behavior is implemented. Virtual class definitions may if you want include slots (to provide some common behavior without fully defining the object—see `traceable-class` for an example).

A simple and useful form of virtual class is the class union, a virtual class that is defined in a call to `setClassUnion` by listing one or more of subclasses (classes that extend the class union). Class unions can include as subclasses basic data types (whose definition is otherwise sealed).

**Superclasses:** The definition of a class includes the superclasses—the classes that this class extends. A class `Fancy`, say, extends a class `Simple` if an object from the `Fancy` class has all the capabilities of the `Simple` class (and probably some more as well). In particular, and very usefully, any method defined to work for a `Simple` object can be applied to a `Fancy` object as well.

This relationship is expressed equivalently by saying that `Simple` is a superclass of `Fancy`, or that `Fancy` is a subclass of `Simple`.

The direct superclasses of a class are those superclasses explicitly defined. Direct superclasses can be defined in three ways. Most commonly, the superclasses are listed in the `contains=` argument in the call to `setClass` that creates the subclass. In this case the subclass will contain all the slots of the superclass, and the relation between the class is called simple, as it in fact is. Superclasses can also be defined explicitly by a call to `setIs`; in this case, the relation requires methods to be specified to go from subclass to superclass. Thirdly, a class union is a superclass of all the members of the union. In this case too the relation is simple, but notice that the relation is defined when the superclass is created, not when the subclass is created as with the `contains=` mechanism.

The definition of a superclass will also potentially contain its own direct superclasses. These are considered (and shown) as superclasses at distance 2 from the original class; their direct superclasses are at distance 3, and so on. All these are legitimate superclasses for purposes such as method selection.

When superclasses are defined by including the names of superclasses in the `contains=` argument to `setClass`, an object from the class will have all the slots defined for its own class and all the slots defined for all its superclasses as well.

The information about the relation between a class and a particular superclass is encoded as an object of class "SClassExtension" (see `SClassExtension-class`). A list of such objects for the superclasses (and sometimes for the subclasses) is included in the metadata object defining the class. If you need to compute with these objects (for example, to compare the distances), call the function `extends` with argument `fullInfo=TRUE`.

**Objects:** The objects from a class, typically created by a call to `new` or by assigning another object from the class, are defined by the `prototype` object for the class and by additional arguments in the call to `new`, which are passed to a method for that class for the function `initialize`.

Each class definition contains a prototype object for the class. This must have values for all the slots defined by the class definition. By default, these are the prototypes of all the slot classes, if those are not virtual classes. However, the definition of the class can specify any valid object for any of the slots.

There are a number of “basic” classes, corresponding to the ordinary kinds of data occurring in R. For example, "numeric" is a class corresponding to numeric vectors. There are also basic classes corresponding to objects in the language, such as "function" and "call", and for specialized objects, such as "environment". These classes are predefined and can then be used as slots or as superclasses for any other class definitions. The prototypes for the vector classes are vectors of length 0 of the corresponding type. Notice that basic classes are unusual in that the prototype object is from the class itself.

There are also a few basic virtual classes, the most important being "vector", grouping together all the vector classes; and "language", grouping together all the types of objects
making up the R language.

**classRepresentation-class**

*Class Objects*

**Description**

These are the objects that hold the definition of classes of objects. They are constructed and stored as meta-data by calls to the function `setClass`. Don’t manipulate them directly, except perhaps to look at individual slots.

**Details**

Class definitions are stored as metadata in various packages. Additional metadata supplies information on inheritance (the result of calls to `setIs`). Inheritance information implied by the class definition itself (because the class contains one or more other classes) is also constructed automatically.

When a class is to be used in an R session, this information is assembled to complete the class definition. The completion is a second object of class "classRepresentation", cached for the session or until something happens to change the information. A call to `getClass` returns the completed definition of a class; a call to `getClassDef` returns the stored definition (uncompleted).

In particular, completion fills in the upward- and downward-pointing inheritance information for the class, in slots `contains` and `subclasses` respectively. It’s in principle important to note that this information can depend on which packages are installed, since these may define additional subclasses or superclasses.

**Slots**

- **slots**: A named list of the slots in this class; the elements of the list are the classes to which the slots must belong (or extend), and the names of the list gives the corresponding slot names.
- **contains**: A named list of the classes this class “contains”; the elements of the list are objects of `SClassExtension-class`. The list may be only the direct extensions or all the currently known extensions (see the details).
- **virtual**: Logical flag, set to `TRUE` if this is a virtual class.
- **prototype**: The object that represents the standard prototype for this class; i.e., the data and slots returned by a call to `new` for this class with no special arguments. Don’t mess with the prototype object directly.
- **validity**: Optionally, a function to be used to test the validity of objects from this class. See `validObject`. 
access: Access control information. Not currently used.

className: The character string name of the class.

package: The character string name of the package to which the class belongs. Nearly always the package on which the metadata for the class is stored, but in operations such as constructing inheritance information, the internal package name rules.

subclasses: A named list of the classes known to extend this class; the elements of the list are objects of SClassExtension-class. The list is currently only filled in when completing the class definition (see the details).

versionKey: Object of class "externalptr"; eventually will perhaps hold some versioning information, but not currently used.

sealed: Object of class "logical"; is this class sealed? If so, no modifications are allowed.

Documentation

Using and Creating On-line Documentation for Classes and Methods

Description

Special documentation can be supplied to describe the classes and methods that are created by the software in the methods package. Techniques to access this documentation and to create it in R help files are described here.

Getting documentation on classes and methods

You can ask for on-line help for class definitions, for specific methods for a generic function, and for general discussion of methods for a generic function. These requests use the ? operator (see help for a general description of the operator). Of course, you are at the mercy of the implementer as to whether there is any documentation on the corresponding topics.

Documentation on a class uses the argument class on the left of the ?, and the name of the class on the right; for example,

class ? genericFunction

to ask for documentation on the class "genericFunction".

When you want documentation for the methods defined for a particular function, you can ask either for a general discussion of the methods or for documentation of a particular method (that is, the method that would be selected for a particular set of actual arguments).

Overall methods documentation is requested by calling the ? operator with methods as the left-side argument and the name of the function as the right-side argument. For example,

methods ? initialize

asks for documentation on the methods for the initialize function.

Asking for documentation on a particular method is done by giving a function call expression as the right-hand argument to the "?" operator. There are two forms, depending on whether you prefer to give the class names for the arguments or expressions that you intend to use in the actual call.
If you planned to evaluate a function call, say `myFun(x, sqrt(wt))` and wanted to find out something about the method that would be used for this call, put the call on the right of the "?" operator:

```
?myFun(x, sqrt(wt))
```

A method will be selected, as it would be for the call itself, and documentation for that method will be requested. If `myFun` is not a generic function, ordinary documentation for the function will be requested.

If you know the actual classes for which you would like method documentation, you can supply these explicitly in place of the argument expressions. In the example above, if you want method documentation for the first argument having class "maybeNumber" and the second "logical", call the "?" operator, this time with a left-side argument `method`, and with a function call on the right using the class names as arguments:

```
method ? myFun("maybeNumber", "logical")
```

Once again, a method will be selected, this time corresponding to the specified classes, and method documentation will be requested. This version only works with generic functions.

The two forms each have advantages. The version with actual arguments doesn’t require you to figure out (or guess at) the classes of the arguments. On the other hand, evaluating the arguments may take some time, depending on the example. The version with class names does require you to pick classes, but it’s otherwise unambiguous. It has a subtler advantage, in that the classes supplied may be virtual classes, in which case no actual argument will have specifically this class. The class "maybeNumber", for example, might be a class union (see the example for `setClassUnion`).

In either form, methods will be selected as they would be in actual computation, including use of inheritance and group generic functions. See `selectMethod` for the details, since it is the function used to find the appropriate method.

**Writing Documentation for Methods**

The on-line documentation for methods and classes uses some extensions to the R documentation format to implement the requests for class and method documentation described above. See the document *Writing R Extensions* for the available markup commands (you should have consulted this document already if you are at the stage of documenting your software).

In addition to the specific markup commands to be described, you can create an initial, overall file with a skeleton of documentation for the methods defined for a particular generic function:

```
promptMethods("myFun")
```

will create a file, `myFun-methods.Rd` with a skeleton of documentation for the methods defined for function `myFun`. The output from `promptMethods` is suitable if you want to describe all or most of the methods for the function in one file, separate from the documentation of the generic function itself. Once the file has been filled in and moved to the ‘`man`’ subdirectory of your source package, requests for methods documentation will use that file, both for specific methods documentation as described above, and for overall documentation requested by

```
methods ? myFun
```

You are not required to use `promptMethods`, and if you do, you may not want to use the entire file created:

- If you want to document the methods in the file containing the documentation for the generic function itself, you can cut-and-paste to move the `\alias` lines and the `Methods` section from the file created by `promptMethods` to the existing file.
• On the other hand, if these are auxiliary methods, and you only want to document the added or modified software, you should strip out all but the relevant \alias lines for the methods of interest, and remove all but the corresponding \item entries in the Methods section. Note that in this case you will usually remove the first \alias line as well, since that is the marker for general methods documentation on this function (in the example, \alias{myfun-methods}).

If you simply want to direct documentation for one or more methods to a particular R documentation file, insert the appropriate alias.

---

### environment-class

**Class "environment"**

**Description**

A formal class for R environments.

**Objects from the Class**

Objects can be created by calls of the form `new("environment", ...)`. The arguments in ..., if any, should be named and will be assigned to the newly created environment.

**Methods**

- **coerce** signature(from = "ANY", to = "environment"): calls as.environment.

- **initialize** signature(object = "environment"): Implements the assignments in the new environment. Note that the object argument is ignored; a new environment is always created, since environments are not protected by copying.

**See Also**

- new.env

---

### fixPre1.8

**Fix Objects Saved from R Versions Previous to 1.8**

**Description**

Beginning with R version 1.8.0, the class of an object contains the identification of the package in which the class is defined. The function `fixPre1.8` fixes and re-assigns objects missing that information (typically because they were loaded from a file saved with a previous version of R.)

**Usage**

`fixPre1.8(names, where)`
Arguments

names       Character vector of the names of all the objects to be fixed and re-assigned.
where      The environment from which to look for the objects, and for class definitions. Defaults to the top environment of the call to fixPre1.8, the global environment if the function is used interactively.

Details

The named object will be saved where it was found. Its class attribute will be changed to the full form required by R 1.8; otherwise, the contents of the object should be unchanged.

Objects will be fixed and re-assigned only if all the following conditions hold:

1. The named object exists.
2. It is from a defined class (not a basic datatype which has no actual class attribute).
3. The object appears to be from an earlier version of R.
4. The class is currently defined.
5. The object is consistent with the current class definition.

If any condition except the second fails, a warning message is generated.

Note that fixPre1.8 currently fixes only the change in class attributes. In particular, it will not fix binary versions of packages installed with earlier versions of R if these use incompatible features. Such packages must be re-installed from source, which is the wise approach always when major version changes occur in R.

Value

The names of all the objects that were in fact re-assigned.

---

genericFunction-class

Generic Function Objects

Description

Generic functions (objects from or extending class genericFunction) are extended function objects, containing information used in creating and dispatching methods for this function. They also identify the package associated with the function and its methods.

Objects from the Class

Generic functions are created and assigned by setGeneric or setGroupGeneric and, indirectly, by setMethod.

As you might expect setGeneric and setGroupGeneric create objects of class "genericFunction" and "groupGenericFunction" respectively.
GenericFunctions

Tools for Managing Generic Functions

Slots

.Data: Object of class "function", the function definition of the generic, usually created automatically as a call to standardGeneric.

generic: Object of class "character", the name of the generic function.

package: Object of class "character", the name of the package to which the function definition belongs (and not necessarily where the generic function is stored). If the package is not specified explicitly in the call to setGeneric, it is usually the package on which the corresponding non-generic function exists.

group: Object of class "list", the group or groups to which this generic function belongs. Empty by default.

valueClass: Object of class "character": if not an empty character vector, identifies one or more classes. It is asserted that all methods for this function return objects from these class (or from classes that extend them).

signature: Object of class "character", the vector of formal argument names that can appear in the signature of methods for this generic function. By default, it is all the formal arguments, except for .... Order matters for efficiency: the most commonly used arguments in specifying methods should come first.

default: Object of class "OptionalMethods", the default method for this function. Generated automatically and used to initialize method dispatch.

skeleton: Object of class "call", a slot used internally in method dispatch. Don’t expect to use it directly.

Extends

Class "function", from data part.
Class "OptionalMethods", by class "function".
Class "PossibleMethod", by class "function".

Methods

Generic function objects are used in the creation and dispatch of formal methods; information from the object is used to create methods list objects and to merge or update the existing methods for this generic.

Description

The functions documented here manage collections of methods associated with a generic function, as well as providing information about the generic functions themselves.

Usage

isGeneric(f, where, fdef, getName = FALSE)
isGroup(f, where, fdef)
removeGeneric(f, where)
dumpMethod(f, signature, file, where, def)
findFunction(f, generic = TRUE, where = topenv(parent.frame()))
dumpMethods(f, file, signature, methods, where)
signature(...)

removeMethods(f, where = topenv(parent.frame()), all = TRUE)
setReplaceMethod(f, ..., where = topenv(parent.frame()))

getGenerics(where, searchForm = FALSE)
allGenerics(where, searchForm = FALSE)
callGeneric(...)

Arguments

f The character string naming the function.
where The environment, namespace, or search-list position from which to search for objects. By default, start at the top-level environment of the calling function, typically the global environment (i.e., use the search list), or the namespace of a package from which the call came. It is important to supply this argument when calling any of these functions indirectly. With package namespaces, the default is likely to be wrong in such calls.
signature The class signature of the relevant method. A signature is a named or unnamed vector of character strings. If named, the names must be formal argument names for the generic function. If signature is unnamed, the default is to use the first length(signature) formal arguments of the function.
file The file on which to dump method definitions.
def The function object defining the method; if omitted, the current method definition corresponding to the signature.
... Named or unnamed arguments to form a signature.
generic In testing or finding functions, should generic functions be included. Supply as FALSE to get only non-generic functions.
fdef Optional, the generic function definition. Usually omitted in calls to isGeneric
getName If TRUE, isGeneric returns the name of the generic. By default, it returns TRUE.
methods The methods object containing the methods to be dumped. By default, the methods defined for this generic (optionally on the specified where location).
all in removeMethods, logical indicating if all (default) or only the first method found should be removed.
searchForm In getGenerics, if TRUE, the package slot of the returned result is in the form used by search(), otherwise as the simple package name (e.g. "package:base" vs "base").

Summary of Functions

isGeneric: Is there a function named f, and if so, is it a generic?

The getName argument allows a function to find the name from a function definition. If it is TRUE then the name of the generic is returned, or FALSE if this is not a generic function definition.

The behavior of isGeneric and getGeneric for primitive functions is slightly different. These functions don’t exist as formal function objects (for efficiency and historical reasons),
regardless of whether methods have been defined for them. A call to `isGeneric` tells you whether methods have been defined for this primitive function, anywhere in the current search list, or in the specified position `where`. In contrast, a call to `getGeneric` will return what the generic for that function would be, even if no methods have been currently defined for it.

**removeGeneric, removeMethods**: Remove all the methods for the generic function of this name. In addition, `removeGeneric` removes the function itself; `removeMethods` restores the non-generic function which was the default method. If there was no default method, `removeMethods` leaves a generic function with no methods.

**standardGeneric**: Dispatches a method from the current function call for the generic function `f`. It is an error to call `standardGeneric` anywhere except in the body of the corresponding generic function.

Note that `standardGeneric` is a primitive function in the `base` package for efficiency reasons, but rather documented here where it belongs naturally.

**dumpMethod**: Dump the method for this generic function and signature.

**findFirst**: return a list of either the positions on the search list, or the current top-level environment, on which a function object for `name` exists. The returned value is always a list, use the first element to access the first visible version of the function. See the example.

**NOTE**: Use this rather than `find` with `mode="function"`, which is not as meaningful, and has a few subtle bugs from its use of regular expressions. Also, `findFirst` works correctly in the code for a package when attaching the package via a call to `library`.

**dumpMethods**: Dump all the methods for this generic.

**signature**: Returns a named list of classes to be matched to arguments of a generic function.

**getGenerics**: Returns the names of the generic functions that have methods defined on `where`; this argument can be an environment or an index into the search list. By default, the whole search list is used.

The methods definitions are stored with package qualifiers; for example, methods for function "initialize" might refer to two different functions of that name, on different packages. The package names corresponding to the method list object are contained in the slot `package` of the returned object. The form of the returned name can be plain (e.g., "base"), or in the form used in the search list ("package:base") according to the value of `searchForm`.

**callGeneric**: In the body of a method, this function will make a call to the current generic function. If no arguments are passed to `callGeneric`, the arguments to the current call are passed down; otherwise, the arguments are interpreted as in a call to the generic function.

### Details

**setGeneric**: If there is already a non-generic function of this name, it will be used to define the generic unless `def` is supplied, and the current function will become the default method for the generic.

If `def` is supplied, this defines the generic function, and no default method will exist (often a good feature, if the function should only be available for a meaningful subset of all objects).

Arguments `group` and `valueClass` are retained for consistency with S-Plus, but are currently not used.

**isGeneric**: If the `fdef` argument is supplied, take this as the definition of the generic, and test whether it is really a generic, with `f` as the name of the generic. (This argument is not available in S-Plus.)

**removeGeneric**: If `where` supplied, just remove the version on this element of the search list; otherwise, removes the first version encountered.
**GenericFunctions**

**standardGeneric**: Generic functions should usually have a call to `standardGeneric` as their entire body. They can, however, do any other computations as well.

The usual `setGeneric` (directly or through calling `setMethod`) creates a function with a call to `standardGeneric`.

**dumpMethod**: The resulting source file will recreate the method.

**findFunction**: If `generic` is `FALSE`, ignore generic functions.

**dumpMethods**: If `signature` is supplied only the methods matching this initial signature are dumped. (This feature is not found in S-Plus: don’t use it if you want compatibility.)

**signature**: The advantage of using `signature` is to provide a check on which arguments you meant, as well as clearer documentation in your method specification. In addition, `signature` checks that each of the elements is a single character string.

**removeMethods**: Returns `TRUE` if `f` was a generic function, `FALSE` (silently) otherwise.

If there is a default method, the function will be re-assigned as a simple function with this definition. Otherwise, the generic function remains but with no methods (so any call to it will generate an error). In either case, a following call to `setMethod` will consistently re-establish the same generic function as before.

**References**

The R package `methods` implements, with a few exceptions, the programming interface for classes and methods in the book *Programming with Data* (John M. Chambers, Springer, 1998), in particular sections 1.6, 2.7, 2.8, and chapters 7 and 8.

While the programming interface for the methods package follows the reference, the R software is an original implementation, so details in the reference that reflect the S4 implementation may appear differently in R. Also, there are extensions to the programming interface developed more recently than the reference. For a discussion of details see `?Methods` and the links from that documentation.

**See Also**

`getMethod` (also for `selectMethod`), `setGeneric`, `setClass`, `showMethods`

**Examples**

```r
## get the function "myFun" -- throw an error if 0 or > 1 versions visible:
findFuncStrict <- function(fName) {
  allF <- findFunction(fName)
  if(length(allF) == 0)
    stop("No versions of ", fName, " visible")
  else if(length(allF) > 1)
    stop(fName," is ambiguous: ", length(allF), " versions")
  else
    get(fName, allF[[1]])
}

try(findFuncStrict("myFun")) # Error: no version
lm <- function(x) x+1
try(findFuncStrict("lm")) # Error: 2 versions
findFuncStrict("findFuncStrict") # just 1 version
rm(lm)
```
**getClass**

*Get Class Definition*

**Description**

Get the definition of a class.

**Usage**

```r
getClass(Class, .Force = FALSE, where)
getClassDef(Class, where, package)
```

**Arguments**

- **Class**: the character-string name of the class.
- **.Force**: if TRUE, return NULL if the class is undefined; otherwise, an undefined class results in an error.
- **where**: environment from which to begin the search for the definition; by default, start at the top-level (global) environment and proceed through the search list.
- **package**: the name of the package asserted to hold the definition. Supplied instead of where, with the distinction that the package need not be currently attached.

**Details**

A call to `getClass` returns the complete definition of the class supplied as a string, including all slots, etc. in classes that this class extends. A call to `getClassDef` returns the definition of the class from the environment where, unadorned. It’s usually `getClass` you want.

If you really want to know whether a class is formally defined, call `isClass`.

**Value**

The object defining the class. This is an object of class "classRepEnvironment". However, do not deal with the contents of the object directly unless you are very sure you know what you’re doing. Even then, it is nearly always better practice to use functions such as `setClass` and `setIs`. Messing up a class object will cause great confusion.

**References**

The R package `methods` implements, with a few exceptions, the programming interface for classes and methods in the book *Programming with Data* (John M. Chambers, Springer, 1998), in particular sections 1.6, 2.7, 2.8, and chapters 7 and 8.

While the programming interface for the methods package follows the reference, the R software is an original implementation, so details in the reference that reflect the S4 implementation may appear differently in R. Also, there are extensions to the programming interface developed more recently than the reference. For a discussion of details see `?Methods` and the links from that documentation.

getMethod

Examples

getClass("numeric") ## a built in class

cld <- getClass("thisIsAnUndefinedClass", .Force = TRUE)
cld ## a NULL prototype
## If you are really curious:
str(cld)
## Whereas these generate errors:
try(getClass("thisIsAnUndefinedClass"))
try(getClassDef("thisIsAnUndefinedClass"))

getMethod

Get or Test for the Definition of a Method

Description

The functions getMethod and selectMethod get the definition of a particular method; the functions existsMethod and hasMethod test for the existence of a method. In both cases the first function only gets direct definitions and the second uses inheritance. The function findMethod returns the package(s) in the search list (or in the packages specified by the where argument) that contain a method for this function and signature.

The other functions are support functions: see the details below.

Usage

getMethod(f, signature=character(), where, optional=FALSE, mlist, fdef)

findMethod(f, signature, where)

getMethods(f, where)

existsMethod(f, signature = character(), where)

hasMethod(f, signature=character(), where)

selectMethod(f, signature, optional = FALSE, useInherited = TRUE,
             mlist = (if (is.null(fdef)) NULL else
getMethodsForDispatch(f, fdef)),
             fdef = getGeneric(f, !optional), verbose = FALSE)

MethodsListSelect(f, env, mlist, fEnv, finalDefault, evalArgs,
                  useInherited, fdef, resetAllowed)

Arguments

f

The character-string name of the generic function.

signature

the signature of classes to match to the arguments of f. See the details below.

For selectMethod, the signature can optionally be an environment with classes assigned to the names of the corresponding arguments. Note: the names
correspond to the names of the classes, not to the objects supplied in a call to the
generic function. (You are not likely to find this approach convenient, but it
is used internally and is marginally more efficient.)

where
The position or environment in which to look for the method(s): by default, 
anywhere in the current search list.

optional
If the selection does not produce a unique result, an error is generated, unless this 
argument is TRUE. In that case, the value returned is either a MethodsList 
object, if more than one method matches this signature, or NULL if no method 
matches.

mlist
Optionally, the list of methods in which to search. By default, the function 
finds the methods for the corresponding generic function. To restrict the 
search to a particular package or environment, e.g., supply this argument as 
getMethodsMetaData(f,where). For selectMethod, see the discus-
sion of argument fdef.

fdef
Optionally, the generic function from which the method is to be retrieved. (Un-
likely to be used, except internally in the package source.)

verbose
logical indicating if method selection should print some info about its progress.

env
The environment in which argument evaluations are done in 
MethodsListSelect. Currently must be supplied, but should usually 
be sys.frame(sys.parent()) when calling the function explicitly for 
debugging purposes.

fEnv, finalDefault, evalArgs, useInherited, resetAllowed
Internal-use arguments for the function’s environment, the method to use as the 
overall default, whether to evaluate arguments, which arguments should use in-
heritance, and whether the cached methods are allowed to be reset.

Details
The signature argument specifies classes, in an extended sense, corresponding to formal argu-
ments of the generic function. As supplied, the argument may be a vector of strings identifying 
classes, and may be named or not. Names, if supplied, match the names of those formal arguments 
included in the signature of the generic. That signature is normally all the arguments except … .
However, generic functions can be specified with only a subset of the arguments permitted, or with 
the signature taking the arguments in a different order.

It’s a good idea to name the arguments in the signature to avoid confusion, if you’re dealing with 
a generic that does something special with its signature. In any case, the elements of the signature 
are matched to the formal signature by the same rules used in matching arguments in function calls 
(see match.call).

The strings in the signature may be class names, "missing" or "ANY". See Methods for the 
meaning of these in method selection. Arguments not supplied in the signature implicitly cor-
respond to class "ANY"; in particular, giving an empty signature means to look for the default 
method.

A call to getMethod returns the method for a particular function and signature. As with other 
get functions, argument where controls where the function looks (by default anywhere in the 
search list) and argument optional controls whether the function returns NULL or generates an 
error if the method is not found. The search for the method makes no use of inheritance.

The function selectMethod also looks for a method given the function and signature, but makes 
full use of the method dispatch mechanism; i.e., inherited methods and group generics are taken into 
account just as they would be in dispatching a method for the corresponding signature, with the one
exception that conditional inheritance is not used. Like `getMethod`, `selectMethod` returns NULL or generates an error if the method is not found, depending on the argument `optional`.

The functions `existsMethod` and `hasMethod` return TRUE or FALSE according to whether a method is found, the first corresponding to `getMethod` (no inheritance) and the second to `selectMethod`.

The function `getMethods` returns all the methods for a particular generic (in the form of a generic function with the methods information in its environment). The function is called from the evaluator to merge method information, and is not intended to be called directly. Note that it gets all the visible methods for the specified functions. If you want only the methods defined explicitly in a particular environment, use the function `getMethodsMetadata` instead.

The function `MethodsListSelect` performs a full search (including all inheritance and group generic information: see the `Methods` documentation page for details on how this works). The call returns a possibly revised methods list object, incorporating any method found as part of the `allMethods` slot.

Normally you won’t call `MethodsListSelect` directly, but it is possible to use it for debugging purposes (only for distinctly advanced users!).

Note that the statement that `MethodsListSelect` corresponds to the selection done by the evaluator is a fact, not an assertion, in the sense that the evaluator code constructs and executes a call to `MethodsListSelect` when it does not already have a cached method for this generic function and signature. (The value returned is stored by the evaluator so that the search is not required next time.)

**Value**

The call to `selectMethod` or `getMethod` returns a `MethodDefinition-class` object, the selected method, if a unique selection exists. (This class extends `function`, so you can use the result directly as a function if that is what you want.) Otherwise an error is thrown if `optional` is `FALSE`. If `optional` is `TRUE`, the value returned is `NULL` if no method matched, or a `MethodsList` object if multiple methods matched.

The call to `getMethods` returns the `MethodsList` object containing all the methods requested. If there are none, `NULL` is returned: `getMethods` does not generate an error in this case.

**References**

The R package `methods` implements, with a few exceptions, the programming interface for classes and methods in the book *Programming with Data* (John M. Chambers, Springer, 1998), in particular sections 1.6, 2.7, 2.8, and chapters 7 and 8.

While the programming interface for the `methods` package follows the reference, the R software is an original implementation, so details in the reference that reflect the S4 implementation may appear differently in R. Also, there are extensions to the programming interface developed more recently than the reference. For a discussion of details see `?Methods` and the links from that documentation.

`GenericFunctions`

**Examples**

```r
setGeneric("testFun", function(x) standardGeneric("testFun"))
setMethod("testFun", "numeric", function(x)x+1)
```
getPackageName

The Name associated with a Given Package

Description

The functions below produce the package associated with a particular environment or position on the search list, or of the package containing a particular function. They are primarily used to support computations that need to differentiate objects on multiple packages.

Usage

getPackageName(where)

packageSlot(object)
packageSlot(object) <- value

Arguments

where the environment or position on the search list associated with the desired package.

object object providing a character string name, plus the package in which this object is to be found.

value the name of the package.

Details

Package names are normally installed during loading of the package, by the INSTALL script or by the library function. (Currently, the name is stored as the object .packageName but don’t trust this for the future.)

Value

packageName return the character-string name of the package (without the extraneous "package:" found in the search list).

packageSlot returns or sets the package name slot (currently an attribute, not a formal slot, but this will likely change).

search
Examples

```r
## both the following usually return "base"
getPackageName(length(search()))
```

## Look for an Argument in the Call

### Description

Returns TRUE if `name` corresponds to an argument in the call, either a formal argument to the function, or a component of `. . .`, and FALSE otherwise.

### Usage

```r
hasArg(name)
```

### Arguments

- `name` The unquoted name of a potential argument.

### Details

The expression `hasArg(x)`, for example, is similar to `!missing(x)`, with two exceptions. First, `hasArg` will look for an argument named `x` in the call if `x` is not a formal argument to the calling function, but `...` is. Second, `hasArg` never generates an error if given a name as an argument, whereas `missing(x)` generates an error if `x` is not a formal argument.

### Value

Always TRUE or FALSE as described above.

### See Also

`missing`

### Examples

```r
ftest <- function(x1, ...) c(hasArg(x1), hasArg(y2))

ftest(1)  # c(TRUE, FALSE)
ftest(1, 2)  # c(TRUE, FALSE)
ftest(y2=2)  # c(FALSE, TRUE)
ftest(y=2)   # c(FALSE, FALSE) (no partial matching)
ftest(y2 = 2, x=1)  # c(TRUE, TRUE) partial match x1
```
initialize-methods  Methods to Initialize New Objects from a Class

Description

The arguments to function `new` to create an object from a particular class can be interpreted specially for that class, by the definition of a method for function `initialize` for the class. This documentation describes some existing methods, and also outlines how to write new ones.

Methods

:Object = "ANY"  The default method for `initialize` takes either named or unnamed arguments. Argument names must be the names of slots in this class definition, and the corresponding arguments must be valid objects for the slot (that is, have the same class as specified for the slot, or some superclass of that class). If the object comes from a superclass, it is not coerced strictly, so normally it will retain its current class (specifically, `as(object, Class, strict = FALSE)`).

Unnamed arguments must be objects of this class, of one of its superclasses, or one of its subclasses (from the class, from a class this class extends, or from a class that extends this class). If the object is from a superclass, this normally defines some of the slots in the object. If the object is from a subclass, the new object is that argument, coerced to the current class. Unnamed arguments are processed first, in the order they appear. Then named arguments are processed. Therefore, explicit values for slots always override any values inferred from superclass or subclass arguments.

:Object = "traceable"  Objects of a class that extends `traceable` are used to implement debug tracing (see `traceable-class` and `trace`).

The `initialize` method for these classes takes special arguments `def`, `tracer`, `exit`, `at`, and `print`. The first of these is the object to use as the original definition (e.g., a function). The others correspond to the arguments to `trace`.

:Object = "environment"  The `initialize` method for environments takes a named list of objects to be used to initialize the environment.

:Object = "signature"  This is a method for internal use only. It takes an optional `functionDef` argument to provide a generic function with a `signature` slot to define the argument names. See Methods for details.

Writing Initialization Methods

Initialization methods provide a general mechanism corresponding to generator functions in other languages.

The arguments to `initialize` are `.Object` and `. . .`. Nearly always, `initialize` is called from `new`, not directly. The `.Object` argument is then the prototype object from the class.

Two techniques are often appropriate for `initialize` methods: special argument names and `callNextMethod`.

You may want argument names that are more natural to your users than the (default) slot names. These will be the formal arguments to your method definition, in addition to `.Object` (always) and `. . .` (optionally). For example, the method for class "traceable" documented above would be created by a call to `setMethod` of the form:
setMethod("initialize", "traceable",
  function(.Object, def, tracer, exit, at, print) ... )

In this example, no other arguments are meaningful, and the resulting method will throw an error if other names are supplied.

When your new class extends another class, you may want to call the initialize method for this superclass (either a special method or the default). For example, suppose you want to define a method for your class, with special argument x, but you also want users to be able to set slots specifically. If you want x to override the slot information, the beginning of your method definition might look something like this:

    function(.Object, x, ...) {
    Object <- callNextMethod(.Object, ...)
    if(!missing(x)) { # do something with x

You could also choose to have the inherited method override, by first interpreting x, and then calling the next method.

---

**is**

*Is an Object from a Class*

**Description**

is: With two arguments, tests whether object can be treated as from class2.

With one argument, returns all the super-classes of this object’s class.

extends: Does the first class extend the second class? Returns maybe if the extension includes a test.

setIs: Defines class1 to be an extension of class2.

**Usage**

is(object, class2)

extends(class1, class2, maybe=TRUE, fullInfo = FALSE)

setIs(class1, class2, test=NULL, coerce=NULL, replace=NULL,
     by = character(), where = topenv(parent.frame()), classDef =,
     extensionObject = NULL, doComplete = TRUE)

**Arguments**

object any R object.

class1, class2

the names of the classes between which is relations are to be defined.

maybe, fullInfo

In a call to extends, maybe is a flag to include/exclude conditional relations, and fullInfo is a flag, which if TRUE causes object(s) of class classExtension to be returned, rather than just the names of the classes or a logical value. See the details below.
extensionObject
alternative to the test, coerce, replace, by arguments; an object
from class SClassExtension describing the relation. (Used in internal
calls.)
doComplete when TRUE, the class definitions will be augmented with indirect relations as
well. (Used in internal calls.)
test, coerce, replace
In a call to setIs, functions optionally supplied to test whether the relation
is defined, to coerce the object to class2, and to alter the object so that
is(object, class2) is identical to value.
by
In a call to setIs, the name of an intermediary class. Coercion will proceed by
first coercing to this class and from there to the target class. (The intermediate
coercions have to be valid.)
where
In a call to setIs, where to store the metadata defining the relationship. Default
is the global environment.
classDef Optional class definition for class, required internally when setIs is called
during the initial definition of the class by a call to setClass. Don’t use this
argument, unless you really know why you’re doing so.

Details
extends: Given two class names, extends by default says whether the first class extends the
second; that is, it does for class names what is does for an object and a class. Given one class
name, it returns all the classes that class extends (the “superclasses” of that class), including
the class itself. If the flag fullInfo is TRUE, the result is a list, each element of which is
an object describing the relationship; otherwise, and by default, the value returned is only the
names of the classes.
setIs: This function establishes an inheritance relation between two classes, by some means
other than having one class contain the other. It should not be used for ordinary relationships:
either include the second class in the contains= argument to setClass if the class is
contained in the usual way, or consider setClassUnion to define a virtual class that is
extended by several ordinary classes. A call to setIs makes sense, for example, if one class
ought to be automatically convertible into a second class, but they have different representations,
so that the conversion must be done by an explicit computation, not just be inheriting
slots, for example. In this case, you will typically need to provide both a coerce= and
replace= argument to setIs.
The coerce, replace, and by arguments behave as described for the setAs function. It’s
unlikely you would use the by argument directly, but it is used in defining cached information
about classes. The value returned (invisibly) by setIs is the extension information, as a list.
The coerce argument is a function that turns a class1 object into a class2 object. The
replace argument is a function of two arguments that modifies a class1 object (the first
argument) to replace the part of it that corresponds to class2 (supplied as value, the second
argument). It then returns the modified object as the value of the call. In other words, it acts as
a replacement method to implement the expression as(object, class2) <- value.
The easiest way to think of the coerce and replace functions is by thinking of the case
that class1 contains class2 in the usual sense, by including the slots of the second class.
(To repeat, in this situation you would not call setIs, but the analogy shows what happens
when you do.)
The coerce function in this case would just make a class2 object by extracting the corre-
spending slots from the class1 object. The replace function would replace in the
class1 object the slots corresponding to class2, and return the modified object as its value.

The relationship can also be conditional, if a function is supplied as the test argument. This should be a function of one argument that returns TRUE or FALSE according to whether the object supplied satisfies the relation is(object, class2). If you worry about such things, conditional relations between classes are slightly deprecated because they cannot be implemented as efficiently as ordinary relations and because they sometimes can lead to confusion (in thinking about what methods are dispatched for a particular function, for example). But they can correspond to useful distinctions, such as when two classes have the same representation, but only one of them obeys certain additional constraints.

Because only global environment information is saved, it rarely makes sense to give a value other than the default for argument where. One exception is where=0, which modifies the cached (i.e., session-scope) information about the class. Class completion computations use this version, but don’t use it yourself unless you are quite sure you know what you’re doing.

References

The R package methods implements, with a few exceptions, the programming interface for classes and methods in the book Programming with Data (John M. Chambers, Springer, 1998), in particular sections 1.6, 2.7, 2.8, and chapters 7 and 8.

While the programming interface for the methods package follows the reference, the R software is an original implementation, so details in the reference that reflect the S4 implementation may appear differently in R. Examples

```r
## a class definition (see setClass for the example)
setClass("trackCurve",
 representation("track", smooth = "numeric"))
## A class similar to "trackCurve", but with different structure
## allowing matrices for the "y" and "smooth" slots
setClass("trackMultiCurve",
 representation(x="numeric", y="matrix", smooth="matrix"),
 prototype = structure(list(), x=numeric(), y=matrix(0,0,0),
                      smooth= matrix(0,0,0)))
## Automatically convert an object from class "trackCurve" into
## "trackMultiCurve", by making the y, smooth slots into 1-column matrices
setIs("trackCurve", "trackMultiCurve",
 coerce = function(obj) {
  new("trackMultiCurve",
       x = obj@x,
       y = as.matrix(obj@y),
       curve = as.matrix(obj@smooth))
 -runtime-only
  return(obj)
},
 replace = function(obj, value) {
  obj@y <- as.matrix(value@y)
  obj@x <- value@x
  obj@smooth <- as.matrix(value@smooth)
  obj})
## Automatically convert the other way, but ONLY
```
## if the y data is one variable.
setIs("trackMultiCurve",
"trackCurve",
test = function(obj) {ncol(obj@y) == 1},
coerce = function(obj) {
  new("trackCurve",
    x = slot(obj, "x"),
    y = as.numeric(obj@y),
    smooth = as.numeric(obj@smooth))
},
replace = function(obj, value) {
  obj@y <- matrix(value@y, ncol=1)
  obj@x <- value@x
  obj@smooth <- value@smooth
  obj})

isSealedMethod  
Check for a Sealed Method or Class

Description
These functions check for either a method or a class that has been “sealed” when it was defined, and which therefore cannot be re-defined.

Usage
isSealedMethod(f, signature, fdef, where)
isSealedClass(Class, where)

Arguments
  f  The quoted name of the generic function.
  signature The class names in the method’s signature, as they would be supplied to setMethod.
  fdef Optional, and usually omitted: the generic function definition for f.
  Class The quoted name of the class.
  where where to search for the method or class definition. By default, searches from the top environment of the call to isSealedMethod or isSealedClass, typically the global environment or the namespace of a package containing a call to one of the functions.

Details
In the R implementation of classes and methods, it is possible to seal the definition of either a class or a method. The basic classes (numeric and other types of vectors, matrix and array data) are sealed. So also are the methods for the primitive functions on those data types. The effect is that programmers cannot re-define the meaning of these basic data types and computations. More precisely, for primitive functions that depend on only one data argument, methods cannot be specified for basic classes. For functions (such as the arithmetic operators) that depend on two arguments, methods can be specified if one of those arguments is a basic class, but not if both are.

Programmers can seal other class and method definitions by using the sealed argument to setClass or setMethod.
Value

The functions return FALSE if the method or class is not sealed (including the case that it is not defined); TRUE if it is.

References

The R package methods implements, with a few exceptions, the programming interface for classes and methods in the book Programming with Data (John M. Chambers, Springer, 1998), in particular sections 1.6, 2.7, 2.8, and chapters 7 and 8.

While the programming interface for the methods package follows the reference, the R software is an original implementation, so details in the reference that reflect the S4 implementation may appear differently in R. Also, there are extensions to the programming interface developed more recently than the reference. For a discussion of details see ?Methods and the links from that documentation.

Examples

```r
## these are both TRUE
isSealedMethod("+", c("numeric", "character"))
isSealedClass("matrix")

setClass("track",
         representation(x="numeric", y="numeric"))
## but this is FALSE
isSealedClass("track")
## and so is this
isSealedClass("A Name for an undefined Class")
## and so are these, because only one of the two arguments is basic
isSealedMethod("+", c("track", "numeric"))
isSealedMethod("+", c("numeric", "track"))
```

language-class

Classes to Represent Unevaluated Language Objects

Description

The virtual class "language" and the specific classes that extend it represent unevaluated objects, as produced for example by the parser or by functions such as quote.

Usage

```r
### each of these classes corresponds to an unevaluated object
### in the S language. The class name can appear in method signatures,
### and in a few other contexts (such as some calls to as()).

"(" 
"<-" 
"call" 
"for" 
"if"
```
### Each of the classes above extends the virtual class "language"

---

**LinearMethodsList-class**

**Class** "LinearMethodsList"

**Description**

A version of methods lists that has been “linearized” for producing summary information. The actual objects from class "MethodsList" used for method dispatch are defined recursively over the arguments involved.

**Objects from the Class**

The function `linearizeMlist` converts an ordinary methods list object into the linearized form.

**Slots**

- **methods**: Object of class "list", the method definitions.
- **arguments**: Object of class "list", the corresponding formal arguments, namely as many of the arguments in the signature of the generic function as are active in the relevant method table.
- **classes**: Object of class "list", the corresponding classes in the signatures.
- **generic**: Object of class "genericFunction"; the generic function to which the methods correspond.

**Objects from the Class**

"language" is a virtual class; no objects may be created from it.

Objects from the other classes can be generated by a call to `new(Class, ...)`, where `Class` is the quoted class name, and the ...arguments are either empty or a single object that is from this class (or an extension).

**Methods**

- **coerce** signature(from = "ANY", to = "call"). A method exists for `as(object, "call")`, calling `as.call()`. 

---

834
Future Note

The current version of `linearizeMlist` does not take advantage of the `MethodDefinition` class, and therefore does more work for less effect than it could. In particular, we may move to redefine both the function and the class to take advantage of the stored signatures. Don’t write code depending precisely on the present form, although all the current information will be obtainable in the future.

See Also

Function `linearizeMlist` for the computation, and `MethodsList-class` for the original recursive form.

makeClassRepresentation

Create a Class Definition

Description

Constructs a `classRepresentation-class` object to describe a particular class. Mostly a utility function, but you can call it to create a class definition without assigning it, as `setClass` would do.

Usage

`makeClassRepresentation(name, slots=list(), superClasses=character(), prototype=NULL, package, validity, access, version, sealed, virtual=NA, where)`

Arguments

- `name`: character string name for the class
- `slots`: named list of slot classes as would be supplied to `setClass`, but without the unnamed arguments for `superClasses` if any.
- `superClasses`: what classes does this class extend
- `prototype`: an object providing the default data for the class, e.g. the result of a call to `prototype`.
- `package`: The character string name for the package in which the class will be stored; see `getPackageName`.
- `access`: Access information. Not currently used.
- `version`: Optional version key for version control. Currently generated, but not used.
- `sealed`: Is the class sealed? See `setClass`.
- `virtual`: Is this known to be a virtual class?
- `where`: The environment from which to look for class definitions needed (e.g., for slots or superclasses). See the discussion of this argument under `GenericFunctions`. 
method.skeleton

References

setClass

method.skeleton  Create a Skeleton File for a New Method

Description

This function writes a source file containing a call to setMethod to define a method for the generic function and signature supplied. By default the method definition is in line in the call, but can be made an external function assigned in the same source file.

Usage

method.skeleton(generic, signature, file, external = FALSE)

Arguments

generic the character string name of the generic function, or the generic function itself. In the first case, the function need not currently be a generic, as it would not for the resulting call to setMethod.

signature the method signature, as it would be given to setMethod

file a character string name for the output file, or a writable connection. By default the generic function name and the classes in the signature are concatenated, with separating underscore characters. The file name should normally end in ".R".

external flag to control whether the function definition for the method should be a separate external object assigned in the source file, or included in line in the call to setMethod. If supplied as a character string, this will be used as the name for the external function; by default the name concatenates the generic and signature names, as in the example below.

Value

The file argument, invisibly, but the function is used for its side effect.

See Also

setMethod, package.skeleton
Examples

```r
## Not run:
setClass("track", representation(x="numeric", y="numeric"))
method.skeleton("show", "track")  ## writes show_track.R
method.skeleton("Ops", c("track", "track"))  ## writes "Ops_track_track.R"
## write multiple method skeletons to one file
con = file("./Math_track.R", "w")
method.skeleton("Math", "track", con)
method.skeleton("exp", "track", con)
method.skeleton("log", "track", con)
close(con)
## End(Not run)
```

### MethodDefinition-class

#### Classes to Represent Method Definitions

**Description**

These classes extend the basic class "function" when functions are to be stored and used as method definitions.

**Details**

Method definition objects are functions with additional information defining how the function is being used as a method. The `target` slot is the class signature for which the method will be dispatched, and the `defined` slot the signature for which the method was originally specified (that is, the one that appeared in some call to `setMethod`).

**Objects from the Class**

The action of setting a method by a call to `setMethod` creates an object of this class. It’s unwise to create them directly.

The class "SealedMethodDefinition" is created by a call to `setMethod` with argument `sealed = TRUE`. It has the same representation as "MethodDefinition".

**Slots**

- `.Data`: Object of class "function"; the data part of the definition.
- `target`: Object of class "signature"; the signature for which the method was wanted.
- `defined`: Object of class "signature"; the signature for which a method was found. If the method was inherited, this will not be identical to `target`.
- `generic`: Object of class "character"; the function for which the method was created.

**Extends**

- Class "function", from data part.
- Class "PossibleMethods", directly.
- Class "OptionalMethods", by class "function".
Methods

See Also
class MethodsList-class for the objects defining sets of methods associated with a particular generic function. The individual method definitions stored in these objects are from class MethodDefinition, or an extension. MethodWithNext-class for an extension used by callNextMethod.

Description
This documentation section covers some general topics on how methods work and how the methods package interacts with the rest of R. The information is usually not needed to get started with methods and classes, but may be helpful for moderately ambitious projects, or when something doesn’t work as expected.

The section How Methods Work describes the underlying mechanism; Dispatch and Method Selection provides more details on how class definitions determine which methods are used. For additional information specifically about class definitions, see ?Classes.

How Methods Work
A generic function is a function that has associated with it a collection of other functions (the methods), all of which agree in formal arguments with the generic.

Each R package will include methods metadata objects corresponding to each generic function for which methods have been defined in that package. When the package is loaded into an R session, the methods for each generic function are cached, that is, stored in the environment of the generic function along with the methods from previously loaded packages. This merged table of methods is used to dispatch or select methods from the generic, using class inheritance and possibly group generic functions to find an applicable method. See the Dispatch section below. The caching computations ensure that only one version of each generic function is visible globally; although different attached packages may contain a copy of the generic function, these are in fact identical.

The methods for a generic are stored according to the corresponding signature for which the method was defined, in a call to setMethod. The signature associates one class name with each of a subset of the formal arguments to the generic function. Which formal arguments are available, and the order in which they appear, are determined by the "signature" slot of the generic function. By default, the signature of the generic consists of all the formal arguments except . . . , in the order they appear in the function definition.

Trailing arguments in the signature will be inactive if no method has yet been specified that included those arguments. Inactive arguments are not needed or used in labeling the cached methods. (The distinction does not change which methods are dispatched, but ignoring inactive arguments does improve the efficiency of dispatch. Thus, defining the generic signature to contain the most useful arguments first can help efficiency somewhat.)

All arguments in the signature of the generic function will be evaluated when the function is called, rather than using the traditional lazy evaluation rules of S. Therefore, it’s important to exclude from the signature any arguments that need to be dealt with symbolically (such as the first argument to function substitute). Note that only actual arguments are evaluated, not default expressions. A missing argument enters into the method selection as class "missing" and non-missing arguments according to their actual class.

As of version 2.4.0 of R, the cached methods are stored in an environment object. The names used for assignment are a concatenation of the class names for the arguments in the active signature.
Dispatch and Method Selection

When a call to a generic function is evaluated, a method is selected corresponding to the classes of the actual arguments in the signature. First, the cached methods table is searched for a direct match; that is, a method stored under the direct class names. The direct class is the value of `class(x)` for each non-missing argument, and class "missing" for each missing argument. If no method is found directly for the actual arguments in a call to a generic function, an attempt is made to match the available methods to the arguments by using inheritance.

Each class definition potentially includes the names of one or more classes that the new class contains. (These are sometimes called the superclasses of the new class.) The S language has an additional, explicit mechanism for defining superclasses, the `setIs` mechanism. Also, a call to `setClassUnion` makes the union class a superclass of each of the members of the union. All three mechanisms are treated equivalently for purposes of inheritance: they define the direct superclasses of a particular class.

The direct superclasses themselves may contain other classes. Putting all this information together produces the full list of superclasses for this class. The superclass list is included in the definition of the class that is cached during the R session. Each element of the list describes the nature of the relationship (see `SClassExtension-class` for details). Included in the element is a distance slot giving a numeric distance between the two classes. The distance currently is the path length for the relationship: 1 for direct superclasses (regardless of which mechanism defined them), then 2 for the direct superclasses of those classes, and so on. In addition, any class implicitly has class "ANY" as a superclass. The distance to "ANY" is treated as larger than the distance to any actual class. The special class "missing" corresponding to missing arguments has only "ANY" as a superclass, while "ANY" has no superclasses.

The information about superclasses is summarized when a class definition is printed.

When a method is to be selected by inheritance, a search is made in the table for all methods directly corresponding to a combination of either the direct class or one of its superclasses, for each argument in the active signature. For an example, suppose there is only one argument in the signature and that the class of the corresponding object was "dgeMatrix" (from the `Matrix` package on CRAN). This class has two direct superclasses and through these 4 additional superclasses. Method selection finds all the methods in the table of directly specified methods labeled by one of these classes, or by "ANY".

When there are multiple arguments in the signature, each argument will generate a similar list of inherited classes. The possible matches are now all the combinations of classes from each argument (think of the function `outer` generating an array of all possible combinations). The search now finds all the methods matching any of this combination of classes. The computation of distances also has to combine distances for the individual arguments. There are many ways to combine the distances; the current implementation simply adds them. The result of the search is then a list of zero, one or more methods, and a parallel vector of distances between the target signature and the available methods.

If the list has more than one matching method, only those corresponding to the minimum distance are considered. There may still be multiple best methods. The dispatch software considers this an ambiguous case and warns the user (only on the first call for this selection). The method occurring first in the list of superclasses is selected. By the mechanism of producing the extension information, this orders the direct superclasses by the order they appeared in the original call to `setClass`, followed by classes specified in `setIs` calls, in the order those calls were evaluated, followed by classes specified in unions. Then the superclasses of those classes are appended (note that only the ordering of classes within a particular generation of superclasses counts, because only these will have the same distance). For further discussion of method selection, see the document http://developer.r-project.org/howMethodsWork.pdf.
All this detail about selection is less important than the realization that having ambiguous method selection usually means that you need to be more specific about intentions. It is likely that some consideration other than the ordering of superclasses in the class definition is more important in determining which method should be selected, and the preference may well be different for different generic functions. Where ambiguities arise, the best approach is usually to provide a specific method for the subclass.

When the inherited method has been selected, the selection is cached in the generic function so that future calls with the same class will not require repeating the search. Cached non-direct selections are not themselves used in inheritance searches, since that could result in invalid selections.

Besides being initiated through calls to the generic function, method selection can be done explicitly by calling the function `selectMethod`.

References

The R package `methods` implements, with a few exceptions, the programming interface for classes and methods in the book *Programming with Data* (John M. Chambers, Springer, 1998), in particular sections 1.6, 2.7, 2.8, and chapters 7 and 8.

While the programming interface for the `methods` package follows the reference, the R software is an original implementation, so details in the reference that reflect the S4 implementation may appear differently in R. Also, there are extensions to the programming interface developed more recently than the reference.

**MethodsList-class**

**Class MethodsList, Representation of Methods for a Generic Function**

**Description**

Objects from this class are generated and revised by the definition of methods for a generic function.

**Details**

Suppose a function \( f \) has formal arguments \( x \) and \( y \). The methods list object for that function has the object `as.name("x")` as its argument slot. An element of the methods named "track" is selected if the actual argument corresponding to \( x \) is an object of class "track". If there is such an element, it can generally be either a function or another methods list object.

In the first case, the function defines the method to use for any call in which \( x \) is of class "track". In the second case, the new methods list object defines the available methods depending on the remaining formal arguments, in this example, \( y \).

Each method corresponds conceptually to a *signature*; that is a named list of classes, with names corresponding to some or all of the formal arguments. In the previous example, if selecting class "track" for \( x \), finding that the selection was another methods list and then selecting class "numeric" for \( y \) would produce a method associated with the signature \( x = "track", y = "numeric" \).

You can see the methods arranged by signature by calling the function `showMethods`, A methods list can be converted into an ordinary list with the methods arranged this way (in two different forms) by calling the functions `listFromMlist` and `linearizeMlist`. 
Slots

- **argument**: Object of class "name". The name of the argument being used for dispatch at this level.
- **methods**: A named list of the methods (and method lists) defined *explicitly* for this argument. The names are the names of classes, and the corresponding element defines the method or methods to be used if the corresponding argument has that class. See the details below.
- **allMethods**: A named list, contains all the directly defined methods from the methods slot, plus any inherited methods. Ignored when methods tables are used for dispatch (see Methods)

Extends

Class "OptionalMethods", directly.

---

MethodWithNext-class

*Class MethodWithNext*

### Description

Class of method definitions set up for callNextMethod

### Objects from the Class

Objects from this class are generated as a side-effect of calls to callNextMethod.

### Slots

- **.Data**: Object of class "function"; the actual function definition.
- **nextMethod**: Object of class "PossibleMethod" the method to use in response to a callNextMethod() call.
- **excluded**: Object of class "list"; one or more signatures excluded in finding the next method.
- **target**: Object of class "signature", from class "MethodDefinition"
- **defined**: Object of class "signature", from class "MethodDefinition"
- **generic**: Object of class "character"; the function for which the method was created.

### Extends

Class "MethodDefinition", directly.
Class "function", from data part.
Class "PossibleMethod", by class "MethodDefinition".
Class "OptionalMethods", by class "MethodDefinition".

### Methods

- **findNextMethod signature(method = "MethodWithNext")**: used internally by method dispatch.
- **loadMethod signature(method = "MethodWithNext")**: used internally by method dispatch.
- **show signature(object = "MethodWithNext")**

new

Generate an Object from a Class

Description

Given the name or the definition of a class, plus optionally data to be included in the object, new returns an object from that class.

Usage

new(Class, ...)

initialize(.Object, ...)

Arguments

Class

Either the name of a class (the usual case) or the object describing the class (e.g., the value returned by getClass).

...

Data to include in the new object. Named arguments correspond to slots in the class definition. Unnamed arguments must be objects from classes that this class extends.

.Object

An object: see the Details section.

Details

The function new begins by copying the prototype object from the class definition. Then information is inserted according to the ... arguments, if any. As of version 2.4 of R, the type of the prototype object, and therefore of all objects returned by new(), is "S4" except for classes that extend one of the basic types, where the prototype has that basic type. User functions that depend on typeof(object) should be careful to handle "S4" as a possible type.

The interpretation of the ... arguments can be specialized to particular classes, if an appropriate method has been defined for the generic function "initialize". The new function calls initialize with the object generated from the prototype as the .Object argument to initialize.

By default, unnamed arguments in the ... are interpreted as objects from a superclass, and named arguments are interpreted as objects to be assigned into the correspondingly named slots. Thus, explicit slots override inherited information for the same slot, regardless of the order in which the arguments appear.

The initialize methods do not have to have ... as their second argument (see the examples), and generally it is better design not to have ... as a formal argument, if only a fixed set of arguments make sense.

For examples of initialize methods, see initialize-methods for existing methods for classes "traceable" and "environment", among others.

Note that the basic vector classes, "numeric", etc. are implicitly defined, so one can use new for these classes.

Classes

Examples

```r
## using the definition of class "track" from Classes

## a new object with two slots specified
new("track", x = seq(along=ydata), y = ydata)

# a new object including an object from a superclass, plus a slot
new("trackCurve", t1, smooth = ysmooth)

### define a method for initialize, to ensure that new objects have
### equal-length x and y slots.

setMethod("initialize",  
  "track",  
  function(.Object, x = numeric(0), y = numeric(0)) {  
    if(nargs() > 1) {  
      if(length(x) != length(y))  
        stop("specified x and y of different lengths")  
        .Object@x <- x  
        .Object@y <- y  
      }  
    .Object  
  })

### the next example will cause an error (x will be numeric(0)),
### because we didn't build in defaults for x,
### although we could with a more elaborate method for initialize

try(new("track", y = sort(rnorm(10))))

## a better way to implement the previous initialize method.
## Why? By using callNextMethod to call the default initialize method
## we don't inhibit classes that extend "track" from using the general
## form of the new() function. In the previous version, they could only
## use x and y as arguments to new, unless they wrote their own
## initialize method.

setMethod("initialize", "track", function(.Object, ...) {  
  .Object <- callNextMethod()  
  if(length(.Object@x) != length(.Object@y))  
    stop("specified x and y of different lengths")  
  .Object  
})
```
ObjectsWithPackage-class

A Vector of Object Names, with associated Package Names

**Description**

This class of objects is used to represent ordinary character string object names, extended with a `package` slot naming the package associated with each object.

**Objects from the Class**

The function `getGenerics` returns an object of this class.

**Slots**

- **.Data**: Object of class "character": the object names.
- **package**: Object of class "character" the package names.

**Extends**

Class "character", from data part.
Class "vector", by class "character".

Methods for general background.

---

**promptClass**

*Generate a Shell for Documentation of a Formal Class*

**Description**

Assembles all relevant slot and method information for a class, with minimal markup for Rd processing; no QC facilities at present.

**Usage**

`promptClass(clName, filename = NULL, type = "class", keywords = "classes", where = toopenv(parent.frame()))`

**Arguments**

- **clName**: a character string naming the class to be documented.
- **filename**: usually, a connection or a character string giving the name of the file to which the documentation shell should be written. The default corresponds to a file whose name is the topic name for the class documentation, followed by ".Rd". Can also be `NA` (see below).
- **type**: the documentation type to be declared in the output file.
- **keywords**: the keywords to include in the shell of the documentation. The keyword "classes" should be one of them.
- **where**: where to look for the definition of the class and of methods that use it.
The class definition is found on the search list. Using that definition, information about classes extended and slots is determined.

In addition, the currently available generics with methods for this class are found (using `getGenerics`). Note that these methods need not be in the same environment as the class definition; in particular, this part of the output may depend on which packages are currently in the search list.

As with other prompt-style functions, unless `filename` is NA, the documentation shell is written to a file, and a message about this is given. The file will need editing to give information about the meaning of the class. The output of `promptClass` can only contain information from the metadata about the formal definition and how it is used.

If `filename` is NA, a list-style representation of the documentation shell is created and returned. Writing the shell to a file amounts to `cat(unlist(x), file = filename, sep = " \n"),` where `x` is the list-style representation.

If `filename` is NA, a list-style representation of the documentation shell is created and returned. Writing the shell to a file amounts to `cat(unlist(x), file = filename, sep = "\n"),` where `x` is the list-style representation.

Value

If `filename` is NA, a list-style representation of the documentation shell. Otherwise, the name of the file written to is returned invisibly.

See Also

`prompt` for documentation of functions, `promptMethods` for documentation of method definitions.

For processing of the edited documentation, either use `R CMD Rdconv`, or include the edited file in the `man` subdirectory of a package.

Examples

```r
## Not run:
> promptClass("track")
A shell of class documentation has been written to the file "track-class.Rd".
## End(Not run)
```
promptMethods

Generate a Shell for Documentation of Formal Methods

Description

Generates a shell of documentation for the methods of a generic function.

Usage

```r
promptMethods(f, filename = NULL, methods)
```

Arguments

- `f`: a character string naming the generic function whose methods are to be documented.
- `filename`: usually, a connection or a character string giving the name of the file to which the documentation shell should be written. The default corresponds to the coded topic name for these methods (currently, `f` followed by `"-methods.Rd"`). Can also be `FALSE` or `NA` (see below).
- `methods`: Optional methods list object giving the methods to be documented. By default, the first methods object for this generic is used (for example, if the current global environment has some methods for `f`, these would be documented). If this argument is supplied, it is likely to be `getMethods(f, where)` with `where` some package containing methods for `f`.

Details

If `filename` is `FALSE`, the text created is returned, presumably to be inserted some other documentation file, such as the documentation of the generic function itself (see `prompt`).

If `filename` is `NA`, a list-style representation of the documentation shell is created and returned. Writing the shell to a file amounts to

```r
cat(unlist(x), file = filename, sep = "\n"),
```

where `x` is the list-style representation.

Otherwise, the documentation shell is written to the file specified by `filename`.

Value

If `filename` is `FALSE`, the text generated; if `filename` is `NA`, a list-style representation of the documentation shell. Otherwise, the name of the file written to is returned invisibly.

prompt and promptClass

representation Construct a Representation or a Prototype for a Class Definition

Description

In calls to setClass, these two functions construct, respectively, the representation and prototype arguments. They do various checks and handle special cases. You’re encouraged to use them when defining classes that, for example, extend other classes as a data part or have multiple superclasses, or that combine extending a class and slots.

Usage

representation(...)
prototype(...)

Arguments

... The call to representation takes arguments that are single character strings. Unnamed arguments are classes that a newly defined class extends; named arguments name the explicit slots in the new class, and specify what class each slot should have.

In the call to prototype, if an unnamed argument is supplied, it unconditionally forms the basis for the prototype object. Remaining arguments are taken to correspond to slots of this object. It is an error to supply more than one unnamed argument.

Details

The representation function applies tests for the validity of the arguments. Each must specify the name of a class.

The classes named don’t have to exist when representation is called, but if they do, then the function will check for any duplicate slot names introduced by each of the inherited classes.

The arguments to prototype are usually named initial values for slots, plus an optional first argument that gives the object itself. The unnamed argument is typically useful if there is a data part to the definition (see the examples below).

Value

The value of representation is just the list of arguments, after these have been checked for validity.

The value of prototype is the object to be used as the prototype. Slots will have been set consistently with the arguments, but the construction does not use the class definition to test validity of the contents (it hardly can, since the prototype object is usually supplied to create the definition).

         contains = "numeric",
         prototype = prototype(pi, comment = "Start with pi"))
```

**S4groupGeneric**  
*S4 Group Generic Functions*

**Description**

Methods can be defined for groups of functions known as *group generic functions*. These exist in both S3 (see *S3groupGeneric*) and S4 flavours, with different groups.

Methods are defined for the group of functions as a whole. A method defined for an individual member of the group takes precedence over a method defined for the group as a whole.

When package *methods* is attached there are objects visible with the names of the group generics: these functions should never be called directly (a suitable error message will result if they are).
S4 group generics:

Arith(e1, e2)
Compare(e1, e2)
Ops(e1, e2)
Logic(e1, e2)
Math(x)
Math2(x, digits)
Summary(x, ..., na.rm = FALSE)
Complex(z)

Arguments

x, z, e1, e2 objects.
digits number of digits to be used in round or signif.
... further arguments passed to or from methods.
na.rm logical: should missing values be removed?

Details

When package methods is attached (which it is by default), formal (S4) methods can be defined for the group generic functions (which are R objects which should never be called directly – a suitable error message will result if they are). There are also S3 groups Math, Ops, Summary and Complex, see ?S3groupGeneric, with no corresponding R objects.

The functions belonging to the various groups are as follows:

Arith "+", "-", "*", ", ^", ", %", ", %/%", "/"
Logic "&", "|", but not "!" since that has only one argument. Note that this is contrary to Chambers(1998), on purpose.

Ops "Arith", "Compare", "Logic"

Math2 "round", "signif"

Summary "max", "min", "range", "prod", "sum", "any", "all"

Complex "Arg", "Conj", "Im", "Mod", "Re"

Note that "Ops" merely consists of three sub groups. Functions with the group names exist in the methods package but should not be called directly.

All the functions in these groups (other than the group generics themselves) are basic functions in R. They are not by default S4 generic functions, and many of them are defined as primitives, meaning that they do not have formal arguments. However, you can still define formal methods for them. The effect of doing so is to create an S4 generic function with the appropriate arguments, in the environment where the method definition is to be stored. It all works more or less as you might expect, admittedly via a bit of trickery in the background.

Note: currently those members which are not primitive functions must have been converted to S4 generic functions (preferably before setting an S4 group generic method) as it only sets methods for known S4 generics. This can be done by a call to setGeneric, for example setGeneric("round", group="Math2").
References

See Also

[S3groupGeneric](#) for S3 group generics.

Examples

```r
setClass("testComplex", representation(zz = "complex"))
## method for whole group "Complex"
setMethod("Complex", "testComplex",
    function(z) c("groupMethod", callGeneric(z@zz)))
## exception for Arg() : setMethod("Arg", "testComplex",
    function(z) c("ArgMethod", Arg(z@zz)))
z1 <- 1+2i
z2 <- new("testComplex", zz = z1)
stopifnot(identical(Mod(z2), c("groupMethod", Mod(z1))))
stopifnot(identical(Arg(z2), c("ArgMethod", Arg(z1))))
```

SClassExtension-class

*Class to Represent Inheritance (Extension) Relations*

Description

An object from this class represents a single “is” relationship; lists of these objects are used to represent all the extensions (superclasses) and subclasses for a given class. The object contains information about how the relation is defined and methods to coerce, test, and replace correspondingly.

Objects from the Class

Objects from this class are generated by `setIs`, from direct calls and from the `contains=` information in a call to `setClass`, and from class unions created by `setClassUnion`. In the last case, the information is stored in defining the subclasses of the union class (allowing unions to contain sealed classes).

Slots

- `subClass, superClass`: The classes being extended: corresponding to the `from`, and `to` arguments to `setIs`.
- `package`: The package to which that class belongs.
- `coerce`: A function to carry out the `as()` computation implied by the relation. Note that these functions should not be used directly. They only deal with the `strict=TRUE` calls to the `as` function, with the full method constructed from this mechanically.
- `test`: The function that would test whether the relation holds. Except for explicitly specified `test` arguments to `setIs`, this function is trivial.
replace: The method used to implement `as(x, Class) <- value`.

simple: A "logical" flag, TRUE if this is a simple relation, either because one class is contained in the definition of another, or because a class has been explicitly stated to extend a virtual class. For simple extensions, the three methods are generated automatically.

by: If this relation has been constructed transitively, the first intermediate class from the subclass.

dataPart: A "logical" flag, TRUE if the extended class is in fact the data part of the subclass. In this case the extended class is a basic class (i.e., a type).

distance: The distance between the two classes, 1 for directly contained classes, plus the number of generations between otherwise.

Methods

No methods defined with class "SClassExtension" in the signature.

See Also

`is`, `as`, and `classRepresentation-class`.

seemsS4Object  Heuristic test for an object from an S4 class

Description

Returns TRUE if `object` has been generated from a formally defined ("S4") class. DEPRECATED: use `isS4(object)` instead.

Usage

`seemsS4Object(object)`

Arguments

object Any object.

Details

The class of the object is examined for the "package" attribute included when objects are generated from an S4 class. The test in this function has been superseded by an internal bit set when S4 objects are generated.

The `seemsS4Object` function is deprecated and will be removed.

The test can be fooled in at least two ways:

1. It will give TRUE incorrectly if someone puts a "package" string attribute on the class of an S3 object. Presumably unlikely.

2. It will give FALSE incorrectly for class definitions and certain other objects for packages that have not been `INSTALLed` since the `seemsS4Object` was added to R. See the Warning below.

Value

Always TRUE or FALSE for any object.
**Warnings**

One motivation for this function is to prevent standard S3 vector operations from being applied to S4 objects that are not vectors. Note that `seemsS4Object()` alone is *not* that test. One also needs to check that the object does not inherit from class "vector". See the examples.

The existence of a class definition for the object’s class is also not equivalent. S4 class definitions are recorded for S3 classes registered via `setOldClass`, but registering does not change the class of such objects, so they are not judged to be S4 objects (and should not be).

Certain other S4 objects used to be generated without the "package" attribute in earlier builds of R, notably class definitions. Packages using S4 objects *must* be reinstalled with a version of R recent enough to contain the `seemsS4Object` function (e.g., R 2.3.0 or later).

**Examples**

```r
seemsS4Object(1) # FALSE
seemsS4Object(getClass(class(1)))) # TRUE
```

```r
## how to test for an S4 object that is not a vector
S4NotVector <- function(object) seemsS4Object(object) && !is(object, "vector")
setClass("classNotNumeric", representation(x="numeric", y="numeric"))
setClass("classWithNumeric", representation(y="numeric"), contains = "numeric")
obj1 <- new("classNotNumeric", x=1, y=2)
obj2 <- new("classWithNumeric", 1, y=2)
seemsS4Object(obj1); seemsS4Object(obj2) # TRUE, TRUE
S4NotVector(obj1); S4NotVector(obj2) # TRUE, FALSE
```

---

**setClass**

Create a Class Definition

**Description**

Functions to create (`setClass`) and manipulate class definitions.

**Usage**

```r
setClass(Class, representation, prototype, contains=character(),
     validity, access, where, version, sealed, package)
removeClass(Class, where)
isClass(Class, formal=TRUE, where)
getClasses(where, inherits = missing(where))
```
setClass

findClass(Class, where, unique = "")
resetClass(Class, classDef, where)
sealClass(Class, where)

Arguments

Class character string name for the class. Other than setClass, the functions will usually take a class definition instead of the string (allowing the caller to identify the class uniquely).
representation the slots that the new class should have and/or other classes that this class extends. Usually a call to the representation function.
prototype an object (usually a list) providing the default data for the slots specified in the representation.
contains what classes does this class extend? (These are called superclasses in some languages.) When these classes have slots, all their slots will be contained in the new class as well.
where For setClass and removeClass, the environment in which to store or remove the definition. Defaults to the top-level environment of the calling function (the global environment for ordinary computations, but the environment or name space of a package when loading that package).
For other functions, where defines where to do the search for the class definition, and the default is to search from the top-level environment or name space of the caller to this function.
unique if findClass expects a unique location for the class, unique is a character string explaining the purpose of the search (and is used in warning and error messages). By default, multiple locations are possible and the function always returns a list.
inherits in a call to getClasses, should the value returned include all parent environments of where, or that environment only? Defaults to TRUE if where is omitted, and to FALSE otherwise.
validity if supplied, should be a validity-checking method for objects from this class (a function that returns TRUE if its argument is a valid object of this class and one or more strings describing the failures otherwise). See validObject for details.
access Access list for the class. Saved in the definition, but not currently used.
version A version indicator for this definition. Saved in the definition, but not currently used.
sealed If TRUE, the class definition will be sealed, so that another call to setClass will fail on this class name.
package An optional package name for the class. By default (and usually) the package where the class definition is assigned will be used.
formal Should a formal definition be required?
classDef For removeClass, the optional class definition (but usually it’s better for Class to be the class definition, and to omit classDef).
setClass

Details

These are the functions that create and manipulate formal class definitions. Brief documentation is provided below. See the references for an introduction and for more details.

**setClass**: Define Class to be an S-style class. The effect is to create an object, of class "classRepEnvironment", and store this (hidden) in the specified environment or database. Objects can be created from the class (e.g., by calling `new`), manipulated (e.g., by accessing the object’s slots), and methods may be defined including the class name in the signature (see `setMethod`).

**removeClass**: Remove the definition of this class, from the environment where if this argument is supplied; if not, `removeClass` will search for a definition, starting in the top-level environment of the call to `removeClass`, and remove the (first) definition found.

**isClass**: Is this the name of a formally defined class? (Argument `formal` is for compatibility and is ignored.)

**getClasses**: The names of all the classes formally defined on where. If called with no argument, all the classes visible from the calling function (if called from the top-level, all the classes in any of the environments on the search list). The `inherits` argument can be used to search a particular environment and all its parents, but usually the default setting is what you want.

**findClass**: The list of environments or positions on the search list in which a class definition of Class is found. If where is supplied, this is an environment (or name space) from which the search takes place; otherwise the top-level environment of the caller is used. If unique is supplied as a character string, `findClass` returns a single environment or position. By default, it always returns a list. The calling function should select, say, the first element as a position or environment for functions such as `get`. If unique is supplied as a character string, `findClass` will warn if there is more than one definition visible (using the string to identify the purpose of the call), and will generate an error if no definition can be found.

**resetClass**: Reset the internal definition of a class. Causes the complete definition of the class to be re-computed, from the representation and superclasses specified in the original call to `setClass`.

This function is called when aspects of the class definition are changed. You would need to call it explicitly if you changed the definition of a class that this class extends (but doing that in the middle of a session is living dangerously, since it may invalidate existing objects).

**sealClass**: Seal the current definition of the specified class, to prevent further changes. It is possible to seal a class in the call to `setClass`, but sometimes further changes have to be made (e.g., by calls to `setIs`). If so, call `sealClass` after all the relevant changes have been made.

Inheritance and Prototypes

Defining new classes that inherit from ("extend") other classes is a powerful technique, but has to be used carefully and not over-used. Otherwise, you will often get unintended results when you start to compute with objects from the new class.

As shown in the examples below, the simplest and safest form of inheritance is to start with an explicit class, with some slots, that does not extend anything else. It only does what we say it does. Then extensions will add some new slots and new behavior.

Another variety of extension starts with one of the built-in data types, perhaps with the intention of modifying R's standard behavior for that class. In this case, the new class inherits the built-in data type as its "data" part. See the "numWithId" example below.
When such a class definition is printed, the data part shows up as a pseudo-slot named ".Data".

**S3 Classes**

Earlier, informal classes of objects (usually referred to as "S3" classes) are used by many R functions. It’s natural to consider including them as the class for a slot in a formal class, or even as a class to be extended by the new class. This isn’t prohibited but there are some disadvantages, and if you do want to include S3 classes, they should be declared by including them in a call to `setOldClass`. Here are some considerations:

- Using S3 classes somewhat defeats the purpose of defining a formal class: An important advantage to your users is that a formal class provides guarantees of what the object contains (minimally, the classes of the slots and therefore what data they contain; optionally, any other requirements imposed by a validity method).

  But there is no guarantee whatever about the data in an object from an S3 class. It’s entirely up to the functions that create or modify such objects. If you want to provide guarantees to your users, you will need a validity method that explicitly checks the contents of S3-class objects.

- To get the minimal guarantee (that the object in a slot has, or extends, the class for the slot) you should ensure that the S3 classes are known to be S3 classes, with the possible inheritance. To do this, include a call to `setOldClass` for the S3 classes used.

  Otherwise, the S3 class is undefined (and the code used by `setClass` will issue a warning). Slot assignments, for example, will not then check for possible errors.

- These caveats apply to S3 classes; that is, objects with a class assigned by some R function but without a formal class definition. In contrast, the built-in data types (numeric, list, etc.) are generally fine as slots or for `contains=` classes (see the previous section). These data types don’t have formal slots, but the base code in the system essentially forces them to contain the type of data they claim to have.

  The data types `matrix` and `array` are somewhat in between. They do not have an explicit S3 class, but do have one or two attributes. There is no general problem in having these as slots, but because there is no guarantee of a dimnames slot, they don’t work as formal classes.

  The `ts` class is treated as a formal class, extending class `vector`.

**Note**

Certain slot names are not allowed in the current implementation, as they correspond to attributes which are treated specially. These are `class`, `comment`, `dim`, `dimnames`, `names`, (from R 2.4.0) `row.names` and `tsp`.

**References**

The R package `methods` implements, with a few exceptions, the programming interface for classes and methods in the book *Programming with Data* (John M. Chambers, Springer, 1998), in particular sections 1.6, 2.7, 2.8, and chapters 7 and 8.

While the programming interface for the `methods` package follows the reference, the R software is an original implementation, so details in the reference that reflect the S4 implementation may appear differently in R. Also, there are extensions to the programming interface developed more recently than the reference. For a discussion of details see `?Methods` and the links from that documentation.

`setClassUnion`, `Methods`, `makeClassRepresentation`
Examples

```r
## A simple class with two slots
setClass("track",
    representation(x="numeric", y="numeric"))

## A class extending the previous, adding one more slot
setClass("trackCurve",
    representation("track", smooth = "numeric"))

## A class similar to "trackCurve", but with different structure
## allowing matrices for the "y" and "smooth" slots
setClass("trackMultiCurve",
    representation(x="numeric", y="matrix", smooth="matrix"),
    prototype = list(x=numeric(), y=matrix(0,0,0),
                     smooth= matrix(0,0,0)))

## Suppose we want trackMultiCurve to be like trackCurve when there's
## only one column.
## First, the wrong way.
try(setIs("trackMultiCurve", "trackCurve",
    test = function(obj) {ncol(slot(obj, "y")) == 1}))

## Why didn't that work? You can only override the slots "x", "y",
## and "smooth" if you provide an explicit coerce function to correct
## any inconsistencies:

setIs("trackMultiCurve", "trackCurve",
    test = function(obj) {ncol(slot(obj, "y")) == 1},
    coerce = function(obj) {
        new("trackCurve",
            x = slot(obj, "x"),
            y = as.numeric(slot(obj,"y")),
            smooth = as.numeric(slot(obj, "smooth")))
    })

## A class that extends the built-in data type "numeric"

setClass("numWithId", representation(id = "character"),
         contains = "numeric")

new("numWithId", 1:3, id = "An Example")
```

setClassUnion Classes Defined as the Union of Other Classes

Description

A class may be defined as the union of other classes; that is, as a virtual class defined as a superclass of several other classes. Class unions are useful in method signatures or as slots in other classes, when we want to allow one of several classes to be supplied.

Usage

```r
setClassUnion(name, members, where)
isClassUnion(Class)
```
Arguments

name the name for the new union class.
members the classes that should be members of this union.
where where to save the new class definition; by default, the environment of the package in which the setClassUnion call appears, or the global environment if called outside of the source of a package.

Class the name or definition of a class.

Details

The classes in members must be defined before creating the union. However, members can be added later on to an existing union, as shown in the example below. Class unions can be members of other class unions.

Class unions are the only way to create a class that is extended by a class whose definition is sealed (for example, the basic datatypes or other classes defined in the base or methods package in R are sealed). You cannot say setIs("function", "other") unless "other" is a class union. In general, a setIs call of this form changes the definition of the first class mentioned (adding "other" to the list of superclasses contained in the definition of "function").

Class unions get around this by not modifying the first class definition, relying instead on storing information in the subclasses slot of the class union. In order for this technique to work, the internal computations for expressions such as extends(class1, class2) work differently for class unions than for regular classes; specifically, they test whether any class is in common between the superclasses of class1 and the subclasses of class2.

The different behavior for class unions is made possible because the class definition object for class unions has itself a special class, "ClassUnionRepresentation", an extension of "classRepresentation" (see classRepresentation-class).

References

The R package methods implements, with a few exceptions, the programming interface for classes and methods in the book Programming with Data (John M. Chambers, Springer, 1998), in particular sections 1.6, 2.7, 2.8, and chapters 7 and 8.

While the programming interface for the methods package follows the reference, the R software is an original implementation, so details in the reference that reflect the S4 implementation may appear differently in R. Also, there are extensions to the programming interface developed more recently than the reference. For a discussion of details see ?Methods and the links from that documentation.

Examples

### a class for either numeric or logical data
setClassUnion("maybeNumber", c("numeric", "logical"))

### use the union as the data part of another class
setClass("withId", representation("maybeNumber", id = "character"))

w1 <- new("withId", 1:10, id = "test 1")
w2 <- new("withId", sqrt(w1)%%1 < .01, id = "Perfect squares")

### add class "complex" to the union "maybeNumber"
setIs("complex", "maybeNumber")
setGeneric

Define a New Generic Function

Description
Create a new generic function of the given name, for which formal methods can then be defined. Typically, an existing non-generic function becomes the default method, but there is much optional control. See the details section.

Usage

setGeneric(name, def = , group=list(), valueClass=character(), where= ,
package= , signature= , useAsDefault= , genericFunction= )

setGroupGeneric(name, def = , group=list(), valueClass=character(),
knownMembers=list(), package= , where= )

Arguments

name  The character string name of the generic function. In the simplest and most common case, a function of this name is already defined. The existing function may be non-generic or already a generic (see the details).

def An optional function object, defining the generic. This argument is usually only needed (and is then required) if there is no current function of this name. In that case, the formal arguments and default values for the generic are taken from def. You can also supply this argument if you want the generic function to do something other than just dispatch methods (an advanced topic best left alone unless you are sure you want it).

Note that def is not the default method; use argument useAsDefault if you want to specify the default separately.

group Optionally, a character string giving the group of generic functions to which this function belongs. Methods can be defined for the corresponding group generic, and these will then define methods for this specific generic function, if no method has been explicitly defined for the corresponding signature. See the references for more discussion.

valueClass An optional character vector or unevaluated expression. The value returned by the generic function must have (or extend) this class, or one of the classes; otherwise, an error is generated. See the details section for supplying an expression.
**setGeneric**

package

The name of the package with which this function is associated. Usually determined automatically (as the package containing the non-generic version if there is one, or else the package where this generic is to be saved).

where

Where to store the resulting initial methods definition, and possibly the generic function; by default, stored into the top-level environment.

signature

Optionally, the signature of arguments in the function that can be used in methods for this generic. By default, all arguments other than ... can be used. The signature argument can prohibit methods from using some arguments. The argument, if provided, is a vector of formal argument names.

genericFunction

The object to be used as a (nonstandard) generic function definition. Supply this explicitly only if you know what you are doing!

useAsDefault

Override the usual choice of default argument (an existing non-generic function or no default if there is no such function). Argument useAsDefault can be supplied, either as a function to use for the default, or as a logical value. FALSE says not to have a default method at all, so that an error occurs if there is not an explicit or inherited method for a call. TRUE says to use the existing function as default, unconditionally (hardly ever needed as an explicit argument). See the section on details.

knownMembers

(For setGroupGeneric only) The names of functions that are known to be members of this group. This information is used to reset cached definitions of the member generics when information about the group generic is changed.

**Details**

The setGeneric function is called to initialize a generic function in an environment (usually the global environment), as preparation for defining some methods for that function.

The simplest and most common situation is that name is already an ordinary non-generic function, and you now want to turn this function into a generic. In this case you will most often supply only name. The existing function becomes the default method, and the special group and valueClass properties remain unspecified.

A second situation is that you want to create a new, generic function, unrelated to any existing function. In this case, you need to supply a skeleton of the function definition, to define the arguments for the function. The body of a generic function is usually a standard form, standardGeneric(name) where name is the quoted name of the generic function.

When calling setGeneric in this form, you would normally supply the def argument as a function of this form. If not told otherwise, setGeneric will try to find a non-generic version of the function to use as a default. If you don’t want this to happen, supply the argument useAsDefault. That argument can be the function you want to be the default method. You can supply the argument as FALSE to force no default (i.e., to cause an error if there is not direct or inherited method on call to the function).

The same no-default situation occurs if there is no non-generic form of the function, and useAsDefault=FALSE. Remember, though, you can also just assign the default you want (even one that generates an error) rather than relying on the prior situation.

You cannot (and never need to) create an explicit generic for the primitive functions in the base library. These are dispatched from C code for efficiency and are not to be redefined in any case.

As mentioned, the body of a generic function usually does nothing except for dispatching methods by a call to standardGeneric. Under some circumstances you might just want to do some additional computation in the generic function itself. As long as your function eventually calls
setGeneric

standardGeneric that is permissible (though perhaps not a good idea, in that it makes the behavior of your function different from the usual S model). If your explicit definition of the generic function does not call standardGeneric you are in trouble, because none of the methods for the function will ever be dispatched.

By default, the generic function can return any object. If valueClass is supplied, it should be a vector of class names; the value returned by a method is then required to satisfy is(object, Class) for one of the specified classes. An empty (i.e., zero length) vector of classes means anything is allowed. Note that more complicated requirements on the result can be specified explicitly, by defining a non-standard generic function.

The setGroupGeneric function behaves like setGeneric except that it constructs a group generic function, differing in two ways from an ordinary generic function. First, this function cannot be called directly, and the body of the function created will contain a stop call with this information. Second, the group generic function contains information about the known members of the group, used to keep the members up to date when the group definition changes, through changes in the search list or direct specification of methods, etc.

Value

The setGeneric function exists for its side effect: saving the generic function to allow methods to be specified later. It returns name.

Generic Functions and Primitive Functions

A number of the basic R functions are specially implemented as primitive functions, to be evaluated directly in the underlying C code rather than by evaluating an S language definition. Primitive functions are eligible to have methods, but are handled differently by setGeneric and setGroupGeneric. A call to setGeneric for a primitive function does not create a new definition of the function, and the call is allowed only to “turn on” methods for that function.

A call to setGeneric for a primitive causes the evaluator to look for methods for that generic; a call to setGroupGeneric for any of the groups that include primitives ("Arith", "Logic", "Compare", "Ops", "Math", "Math2", "Summary", and "Complex") does the same for each of the functions in that group.

You usually only need to use either function if the methods are being defined only for the group generic. Defining a method for a primitive function, say "+", by a call to setMethod turns on method dispatch for that function. But in R defining a method for the corresponding group generic, "Arith", does not currently turn on method dispatch (for efficiency reasons). If there are no non-group methods for the functions, you have two choices.

You can turn on method dispatch for all the functions in the group by calling setGroupGeneric("Arith"), or you can turn on method dispatch for only some of the functions by calling setGeneric("+"), etc. Note that in either case you should give the name of the generic function as the only argument.

References

The R package methods implements, with a few exceptions, the programming interface for classes and methods in the book Programming with Data (John M. Chambers, Springer, 1998), in particular sections 1.6, 2.7, 2.8, and chapters 7 and 8.

While the programming interface for the methods package follows the reference, the R software is an original implementation, so details in the reference that reflect the S4 implementation may appear differently in R. setMethod

See Also

Methods for a discussion of other functions to specify and manipulate the methods of generic functions.

Examples

### A non-standard generic function. It insists that the methods
### return a non-empty character vector (a stronger requirement than
### valueClass = "character" in the call to setGeneric)

```r
setGeneric("authorNames",
  function(text) {
    value <- standardGeneric("authorNames")
    if(!(is(value, "character") && any(nchar(value)>0)))
      stop("authorNames methods must return non-empty strings")
    value
  })
```

## An example of group generic methods, using the class
## "track"; see the documentation of setClass for its definition

## define a method for the Arith group

```r
setMethod("Arith", c("track", "numeric"),
  function(e1, e2) {
    e1@y <- callGeneric(e1@y , e2)
    e1
  })
```

```r
setMethod("Arith", c("numeric", "track"),
  function(e1, e2) {
    e2@y <- callGeneric(e1, e2@y)
    e2
  })
```

## now arithmetic operators will dispatch methods:

t1 <- new("track", x=1:10, y=sort(rnorm(10)))

t1 - 100

1/t1

---

setMethod  

Create and Save a Method

Description

Create and save a formal method for a given function and list of classes.
setMethod

Usage

```r
setMethod(f, signature=character(), definition,
          where = topenv(parent.frame()),
          valueClass = NULL, sealed = FALSE)
```

```r
removeMethod(f, signature, where)
```

Arguments

- **f**  
  A generic function or the character-string name of the function.

- **signature**  
  A match of formal argument names for `f` with the character-string names of corresponding classes. This argument can also just be the vector of class names, in which case the first name corresponds to the first formal argument, the next to the second formal argument, etc.

- **definition**  
  A function definition, which will become the method called when the arguments in a call to `f` match the classes in `signature`, directly or through inheritance.

- **where**  
  the database in which to store the definition of the method;  
  For `removeMethod`, the default is the location of the (first) instance of the method for this signature.

- **valueClass**  
  If supplied, this argument asserts that the method will return a value of this class.  
  (At present this argument is stored but not explicitly used.)

- **sealed**  
  If `TRUE`, the method so defined cannot be redefined by another call to `setMethod` (although it can be removed and then re-assigned). Note that this argument is an extension to the definition of `setMethod` in the reference.

Details

R methods for a particular generic function are stored in an object of class `MethodsList`. The effect of calling `setMethod` is to store `definition` in a `MethodsList` object on database `where`. If `f` doesn’t exist as a generic function, but there is an ordinary function of the same name and the same formal arguments, a new generic function is created, and the previous non-generic version of `f` becomes the default method. This is equivalent to the programmer calling `setGeneric` for the same function; it’s better practice to do the call explicitly, since it shows that you intend to turn `f` into a generic function.

Methods are stored in a hierarchical structure: see `Methods` for how the objects are used to select a method, and `MethodsList` for functions that manipulate the objects.

The class names in the signature can be any formal class, plus predefined basic classes such as "numeric", "character", and "matrix". Two additional special class names can appear: "ANY", meaning that this argument can have any class at all; and "missing", meaning that this argument must not appear in the call in order to match this signature. Don’t confuse these two: if an argument isn’t mentioned in a signature, it corresponds implicitly to class "ANY", not to "missing". See the example below. Old-style ("S3") classes can also be used, if you need compatibility with these, but you should definitely declare these classes by calling `setOldClass` if you want S3-style inheritance to work.

While `f` can correspond to methods defined on several packages or environments, the underlying model is that these together make up the definition for a single generic function. When R proceeds to select and evaluate methods for `f`, the methods on the current search list are merged to form a single generic function and associated methods list. When `f` is called and a method is “dispatched”, the evaluator matches the classes of the actual arguments to the signatures of the available methods. When a match is found, the body of the corresponding method is evaluated, but without rematching.
the arguments to \textit{f}. Aside from not rematching the arguments, the computation proceeds as if the call had been to the method. In particular, the lexical scope of the method is used.

Method definitions can have default expressions for arguments. If those arguments are then missing in the call to the generic function, the default expression in the method is used. If the method definition has no default for the argument, then the expression (if any) supplied in the definition of the generic function itself is used. But note that this expression will be evaluated in the environment defined by the method.

It is possible to have some differences between the formal arguments to a method supplied to \texttt{setMethod} and those of the generic. Roughly, if the generic has \ldots as one of its arguments, then the method may have extra formal arguments, which will be matched from the arguments matching \ldots in the call to \textit{f}. (What actually happens is that a local function is created inside the method, with its formal arguments, and the method is re-defined to call that local function.)

Method dispatch tries to match the class of the actual arguments in a call to the available methods collected for \textit{f}. Roughly, for each formal argument in turn, we look for the best match (the exact same class or the nearest element in the value of \texttt{extends} for that class) for which there is any possible method matching the remaining arguments. See \texttt{Methods} for more details.

\textbf{Value}

These functions exist for their side-effect, in setting or removing a method in the object defining methods for the specified generic.

The value returned by \texttt{removeMethod} is \texttt{TRUE} if a method was found to be removed.

\textbf{References}

The R package \texttt{methods} implements, with a few exceptions, the programming interface for classes and methods in the book \textit{Programming with Data} (John M. Chambers, Springer, 1998), in particular sections 1.6, 2.7, 2.8, and chapters 7 and 8.

While the programming interface for the \texttt{methods} package follows the reference, the R software is an original implementation, so details in the reference that reflect the S4 implementation may appear differently in R. Also, there are extensions to the programming interface developed more recently than the reference. For a discussion of details and ongoing development, see \texttt{?Methods} and the pointers from that documentation.

\textbf{Examples}

\begin{verbatim}
## methods for plotting track objects (see the example for setClass)
##
## First, with only one object as argument:
setMethod("plot", signature(x="track", y="missing"),
  function(x, y, ...) plot(slot(x, "x"), slot(x, "y"), ...)
)
## Second, plot the data from the track on the y-axis against anything
## as the x data.
setMethod("plot", signature(y = "track"),

##
## # set the method to return the class of the object
##
## setMethod("class", signature(x="track"),
##
## function(x, ...) class(slot(x, "x"))
##
## # replace the default method for class with a new one
##
## setMethod("class", signature(x="track"),
##
## function(x, ...) "other-class")
##
## # remove the method for class
##
## removeMethod("class")
\end{verbatim}
function(x, y, ...) plot(x, slot(y, "y"), ...) )
## and similarly with the track on the x-axis (using the short form of ## specification for signatures)
setMethod("plot", "track",
  function(x, y, ...) plot(slot(x, "y"), y, ...) )

```
t1 <- new("track", x=1:20, y=(1:20)^2)
tcl <- new("trackCurve", t1)
slot(tcl, "smooth") <- smooth.spline(slot(tcl, "x"), slot(tcl, "y"))$y
```

```r
plot(t1)
```
```
plot(qnorm(ppoints(20)), t1)
```

## An example of inherited methods, and of conforming method arguments
## (note the dotCurve argument in the method, which will be pulled out of ... in the generic.
setMethod("plot", c("trackCurve", "missing"),
  function(x, y, dotCurve = FALSE, ...) {
    plot(as(x, "track"))
    if(length(slot(x, "smooth")) > 0))
      lines(slot(x, "x"), slot(x, "smooth"), lty = if(dotCurve) 2 else 1)
  })

## the plot of tcl alone has an added curve; other uses of tcl ## are treated as if it were a "track" object.
plot(tcl, dotCurve = TRUE)
plot(qnorm(ppoints(20)), tcl)

## defining methods for a special function.
## Although "[" and "length" are not ordinary functions
## methods can be defined for them.
setMethod("[", "track",
  function(x, i, j, ..., drop) {
    x@x <- x@x[i]; x@y <- x@y[i]
    x
  })
  plot(t1[1:15])

setMethod("length", "track", function(x)length(x@y))
length(t1)

## methods can be defined for missing arguments as well
setGeneric("summary") ## make the function into a generic

## A method for summary()
## The method definition can include the arguments, but
## if they're omitted, class "missing" is assumed.
setMethod("summary", "missing", function() "<No Object>")
setOldClass

Description

Register an old-style (a.k.a. ‘S3’) class as a formally defined class. The Classes argument is the character vector used as the class attribute; in particular, if there is more than one string, old-style class inheritance is mimicked. Registering via setOldClass allows S3 classes to appear in method signatures, and as a slot in an S4 class if a prototype is included.

Usage

setOldClass(Classes, prototype, where, test = FALSE)

Arguments

Classes A character vector, giving the names for old-style classes, as they would appear on the right side of an assignment of the class attribute.

prototype An optional object to use as the prototype. This should be provided as the default S3 object for the class, if you plan to use the class as a slot in an S4 class. See the details section.

where Where to store the class definitions, the global or top-level environment by default. (When either function is called in the source for a package, the class definitions will be included in the package’s environment by default.)

test Flag, if TRUE, inheritance must be tested explicitly for each object, needed if the S3 class can have a different set of class strings, with the same first string. See the details below.

Details

Each of the names will be defined as an S4 class, extending the remaining classes in Classes, and the class oldClass, which is the “root” of all old-style classes. S3 classes have no formal definition, and therefore no formally defined slots. If a prototype argument is supplied in the call to setOldClass(), objects from the class can be generated. If the S3 class is to be a slot in an S4 class, providing a prototype is recommended. Otherwise, the class will be created as a virtual S4 class; method dispatch will still work and inheritance will follow the S3 class hierarchy, but actions that require a prototype object from the class will not. For example, using the class as a slot in an S4 class definition will set the corresponding slot to NULL in the prototype for the S4 class.

Providing a prototype allows the function new() to be called for this class, but optional arguments in this call are not meaningful, since the class has no formal slots. Extending an S3 class with an S4 class is formally legal, but discouraged. Since the S4 subclass will have a single character string in its class(), S3 inheritance will not work. Also, there is no safe way for a general object from the S3 class to be inserted when an object is generated from the subclass.

See Methods for the details of method dispatch and inheritance. See the section Register or Convert? for comments on the alternative of defining “real” S4 classes rather than using setOldClass.

Some S3 classes cannot be represented as an ordinary combination of S4 classes and superclasses, because objects from the S3 class can have a variable set of strings in the class. It is still possible to register such classes as S4 classes, but now the inheritance has to be verified for each object, and you must call setOldClass with argument test=TRUE once for each superclass.

For example, ordered factors always have the S3 class c("ordered", "factor"). This is proper behavior, and maps simply into two S4 classes, with "ordered" extending "factor".
But objects whose class attribute has "POSIXt" as the first string may have either (or neither) of "POSIXct" or "POSIXlt" as the second string. This behavior can be mapped into S4 classes but now to evaluate is(x, "POSIXlt"), for example, requires checking the S3 class attribute on each object. Supplying the test=TRUE argument to setOldClass causes an explicit test to be included in the class definitions. It’s never wrong to have this test, but since it adds significant overhead to methods defined for the inherited classes, you should only supply this argument if it’s known that object-specific tests are needed.

The list .OldClassesList contains the old-style classes that are defined by the methods package. Each element of the list is an old-style list, with multiple character strings if inheritance is included. Each element of the list was passed to setOldClass when creating the methods package; therefore, these classes can be used in setMethod calls, with the inheritance as implied by the list.

Register or Convert?

A call to setOldClass creates formal classes corresponding to S3 classes, allows these to be used as slots in other classes or in a signature in setMethod, and mimics the S3 inheritance.

Supplying the prototype and optionally the generator arguments allows the S4 class created to be non-virtual, making it a candidate to be a slot in S4 class definitions and to be extended by S4 classes. The class still does not have formally defined slots. Because R implements slots as attributes, an S3 class that uses attributes (factor, for example) can in principle be defined as an S4 class with slots. However, a class such as lm that uses components of a list in a similar role cannot have formal slots. The slots would not be interpreted by S3 code written for lm objects.

If your class does in fact have a consistent set of attributes, so that every object from the class has the same structure, you may prefer to take some extra time to write down a specific definition in a call to setClass to convert the class to a fully functional formal class. On the other hand, if the actual contents of the class vary from one object to another, such a definition will not generally be possible. You should still register the class via setOldClass, unless its class attribute is hopelessly unpredictable.

An S3 class has consistent structure if each object has the same set of attributes, both the names and the classes of the attributes being the same for every object in the class. In practice, you can convert classes that are slightly less well behaved. If a few attributes appear in some but not all objects, you can include these optional attributes as slots that always appear in the objects, if you can supply a default value that is equivalent to the attribute being missing. Sometimes NULL can be that value: A slot (but not an attribute) can have the value NULL. If version, for example, was an optional attribute, the old test is.null(attr(x,"version")) for a missing version attribute could turn into is.null(x@version) for the formal class.

The requirement that slots have a fixed class can be satisfied indirectly as well. Slots can be specified with class "ANY", allowing an arbitrary object. However, this eliminates an important benefit of formal class definitions; namely, automatic validation of objects assigned to a slot. If just a few different classes are possible, consider using setClassUnion to define valid objects for a slot.

setClass, setMethod

Examples

setOldClass(c("mlm", "lm"))
setGeneric("dfResidual", function(model)standardGeneric("dfResidual"))
setMethod("dfResidual", "lm", function(model)model$df.residual)
## dfResidual will work on mlm objects as well as lm objects
myData <- data.frame(time = 1:10, y = (1:10)^.5)
myLm <- lm(cbind(y, y^3) ~ time, myData)
rm(myData, myLm)
removeGeneric("dfResidual")
## Not run: setOldClass("data.frame", prototype = data.frame())
## End(Not run)

### show

#### Show an Object

**Description**

Display the object, by printing, plotting or whatever suits its class. This function exists to be specialized by methods. The default method calls `showDefault`.

Formal methods for `show` will usually be invoked for automatic printing (see the details).

**Usage**

```r
show(object)
```

**Arguments**

- `object` Any R object

**Details**

The `methods` package overrides the base definition of `print.default` to arrange for automatic printing to honor methods for the function `show`. This does not quite manage to override old-style printing methods, since the automatic printing in the evaluator will look first for the old-style method.

If you have a class `myClass` and want to define a method for `show`, all will be well unless there is already a function named `print.myClass`. In that case, to get your method dispatched for automatic printing, it will have to be a method for `print`. A slight cheat is to override the function `print.myClass` yourself, and then call that function also in the method for `show` with signature "myClass".

**Value**

`show` returns an invisible `NULL`.

**See Also**

`showMethods` prints all the methods for one or more functions; `showMlist` prints individual methods lists; `showClass` prints class definitions. Neither of the latter two normally needs to be called directly.
Examples

```r
## following the example shown in the setMethod documentation ...
setClass("track",
          representation(x="numeric", y="numeric"))
setClass("trackCurve",
          representation("track", smooth = "numeric"))
t1 <- new("track", x=1:20, y=(1:20)^2)
tcl <- new("trackCurve", t1)
setMethod("show", "track",
          function(object)
            print(rbind(x = object@x, y=object@y))
)
## The method will now be used for automatic printing of t1
t1
## Not run:
x  1  2  3  4  5  6  7  8  9  10  11  12
y  1  4  9 16 25 36 49 64 81 100 121 144
x 13 14 15 16 17 18 19 20
y 169 196 225 256 289 324 361 400
## End(Not run)
## and also for tcl, an object of a class that extends "track"
tcl
## Not run:
x  1  2  3  4  5  6  7  8  9  10  11  12
y  1  4  9 16 25 36 49 64 81 100 121 144
x 13 14 15 16 17 18 19 20
y 169 196 225 256 289 324 361 400
## End(Not run)
```

showMethods

Show all the methods for the specified function(s)

Description

Show a summary of the methods for one or more generic functions, possibly restricted to those involving specified classes.

Usage

```r
showMethods(f = character(), where = topenv(parent.frame()),
            classes = NULL, includeDefs = FALSE, inherited = TRUE,
            showEmpty, printTo = stdout())
```
showMethods

Arguments

- **f**: one or more function names. If omitted, all functions will be shown that match the other arguments.

- **where**: Used only when `f` is missing, or length 0, to determine which generic functions to examine. If `where` is supplied, only the generic functions returned by `getGenerics(where)` are eligible for printing. If `where` is also missing, all the cached generic functions are considered.

- **classes**: If argument `classes` is supplied, it is a vector of class names that restricts the displayed results to those methods whose signatures include one or more of those classes.

- **includeDefs**: If `includeDefs` is `TRUE`, include the definitions of the individual methods in the printout.

- **inherited**: If `inherited` is `TRUE`, then methods that have been found by inheritance, so far in the session, will be included and marked as inherited. Note that an inherited method will not usually appear until it has been used in this session. See `selectMethod` if you want to know what method is dispatched for particular classes of arguments.

- **showEmpty**: logical indicating whether methods with no defined methods matching the other criteria should be shown at all. By default, `TRUE` if and only if argument `f` is not missing.

- **printTo**: The connection on which the printed information will be written; by default, standard output. If `printTo` is `FALSE`, the output will be collected as a character vector and returned as the value of the call to `showMethod`. See `show`.

Details

The name and package of the generic are followed by the list of signatures for which methods are currently defined, according to the criteria determined by the various arguments. Note that the package refers to the source of the generic function. Individual methods for that generic can come from other packages as well.

Value

If `printTo` is `FALSE`, the character vector that would have been printed is returned; otherwise the value is the connection or filename, via `invisible`.

References

The R package `methods` implements, with a few exceptions, the programming interface for classes and methods in the book *Programming with Data* (John M. Chambers, Springer, 1998), in particular sections 1.6, 2.7, 2.8, and chapters 7 and 8.

While the programming interface for the `methods` package follows the reference, the R software is an original implementation, so details in the reference that reflect the S4 implementation may appear differently in R. Also, there are extensions to the programming interface developed more recently than the reference. See `Methods` and references from there.

See Also

`setMethod`, and `GenericFunctions` for other tools involving methods; `selectMethod` will show you the method dispatched for a particular function and signature of classes for the arguments.
signature-class

Class "signature" For Method Definitions

Description

This class represents the mapping of some of the formal arguments of a function onto the names of some classes. It is used as one of two slots in the MethodDefinition-class.

Objects from the Class

Objects can be created by calls of the form new("signature", functionDef, ...). The functionDef argument, if it is supplied as a function object, defines the formal names. The other arguments define the classes.

Slots

.Data: Object of class "character" the classes.
.names: Object of class "character" the corresponding argument names.

Extends

Class "character", from data part. Class "vector", by class "character".

Methods

initialize signature(object = "signature"): see the discussion of objects from the class, above.

See Also

MethodDefinition-class for the use of this class
The Slots in an Object from a Formal Class

Description
These functions return or set information about the individual slots in an object.

Usage

object@name
object@name <- value

slot(object, name)
slot(object, name, check = TRUE) <- value

slotNames(x)

Arguments

object An object from a formally defined class.
name The character-string name of the slot. The name must be a valid slot name: see Details below.
value A new value for the named slot. The value must be valid for this slot in this object’s class.
x Either the name of a class or an object from that class. Print getClass(class) to see the full description of the slots.
check If TRUE, check the assigned value for validity as the value of this slot. You should never set this to FALSE in normal use, since the result can create invalid objects.

Details
The "@" operator and the slot function extract or replace the formally defined slots for the object. The operator takes a fixed name, which can be unquoted if it is syntactically a name in the language. A slot name can be any non-empty string, but if the name is not made up of letters, numbers, and ., it needs to be quoted (by backticks or single or double quotes).

In the case of the slot function, name can be any expression that evaluates to a valid slot in the class definition. Generally, the only reason to use the functional form rather than the simpler operator is because the slot name has to be computed.

The definition of the class contains the names of all slots directly and indirectly defined. Each slot has a name and an associated class. Extracting a slot returns an object from that class. Setting a slot first coerces the value to the specified slot and then stores it.

Unlike attributes, slots are not partially matched, and asking for (or trying to set) a slot with an invalid name for that class generates an error.

Note that currently, slotNames() behaves particularly for class representation objects – this is considered bogus and likely to be changed.

Currently the @ extraction operator and slot function do no checking, neither that object has a formal class nor that name is a valid slot name for the class. (They will extract the attribute of the given name if it exists from any R object.) The replacement forms do check (at least if check=TRUE).

Examples

```r
setClass("track", representation(x="numeric", y="numeric"))
myTrack <- new("track", x = -4:4, y = exp(-4:4))
slot(myTrack, "x")
slot(myTrack, "y") <- log(slot(myTrack, "y"))
str(myTrack)

slotNames("track") # is the same as
slotNames(myTrack)
```

StructureClasses  Classes Corresponding to Basic Structures

Description

The virtual class structure and classes that extend it are formal classes analogous to S language structures such as arrays and time-series

Usage

```r
## The following class names can appear in method signatures, 
## as the class in as() and is() expressions, and, except for 
## the classes commented as VIRTUAL, in calls to new()

"matrix"
"array"
"ts"

"structure"  ## VIRTUAL
```
Objects from the Classes

Objects can be created by calls of the form `new(Class, ...),` where `Class` is the quoted name of the specific class (e.g., "matrix"), and the other arguments, if any, are interpreted as arguments to the corresponding function, e.g., to function `matrix()`. There is no particular advantage over calling those functions directly, unless you are writing software designed to work for multiple classes, perhaps with the class name and the arguments passed in.

Extends

The specific classes all extend class "structure", directly, and class "vector", by class "structure".

Methods

`coerce` Methods are defined to coerce arbitrary objects to these classes, by calling the corresponding basic function, for example, `as(x, "matrix")` calls `as.matrix(x).

### Objects from the following classes are generated

### by calling `trace()` on an object from the corresponding
### class without the "WithTrace" in the name.

"functionWithTrace"
"MethodDefinitionWithTrace"
"MethodWithNextWithTrace"
"genericFunctionWithTrace"
"groupGenericFunctionWithTrace"

### the following is a virtual class extended by each of the
### classes above

"traceable"

Description

The classes described here are used by the R function `trace` to create versions of functions and methods including browser calls, etc., and also to `untrace` the same objects.

Usage

```
### Objects from the following classes are generated
### by calling trace() on an object from the corresponding
### class without the "WithTrace" in the name.

"functionWithTrace"
"MethodDefinitionWithTrace"
"MethodWithNextWithTrace"
"genericFunctionWithTrace"
"groupGenericFunctionWithTrace"

### the following is a virtual class extended by each of the
### classes above

"traceable"
```

Objects from the Class

Objects will be created from these classes by calls to `trace`. (There is an `initialize` method for class "traceable", but you are unlikely to need it directly.)

Slots

`.Data`: The data part, which will be "function" for class "functionWithTrace", and similarly for the other classes.

`original`: Object of the original class; e.g., "function" for class "functionWithTrace".

validObject

Extends

Each of the classes extends the corresponding untraced class, from the data part; e.g., "functionWithTrace" extends "function". Each of the specific classes extends "traceable", directly, and class "VIRTUAL", by class "traceable".

Methods

The point of the specific classes is that objects generated from them, by function trace(), remain callable or dispatchable, in addition to their new trace information.

See Also

function trace

validObject Test the Validity of an Object

Description

The validity of object related to its class definition is tested. If the object is valid, TRUE is returned; otherwise, either a vector of strings describing validity failures is returned, or an error is generated (according to whether test is TRUE). Optionally, all slots in the object can also be validated.

The function setValidity sets the validity method of a class (but more normally, this method will be supplied as the validity argument to setClass). The method should be a function of one object that returns TRUE or a description of the non-validity.

Usage

validObject(object, test = FALSE, complete = FALSE)

setValidity(Class, method, where = topenv(parent.frame()) )

Arguments

object any object, but not much will happen unless the object's class has a formal definition.

test logical; if TRUE and validity fails, the function returns a vector of strings describing the problems. If test is FALSE (the default) validity failure generates an error.

complete logical; if TRUE, validity methods will be applied recursively to any of the slots that have such methods.

Class the name or class definition of the class whose validity method is to be set.

method a validity method; that is, either NULL or a function of one argument (the object). Like validObject, the function should return TRUE if the object is valid, and one or more descriptive strings if any problems are found. Unlike validObject, it should never generate an error.
where the modified class definition will be stored in this environment.

Note that validity methods do not have to check validity of superclasses: the logic of `validObject` ensures these tests are done once only. As a consequence, if one validity method wants to use another, it should extract and call the method from the other definition of the other class by calling `getValidity`: it should not call `validObject`.

**Details**

Validity testing takes place “bottom up”: Optionally, if `complete=TRUE`, the validity of the object’s slots, if any, is tested. Then, in all cases, for each of the classes that this class extends (the “superclasses”), the explicit validity method of that class is called, if one exists. Finally, the validity method of `object`’s class is called, if there is one.

Testing generally stops at the first stage of finding an error, except that all the slots will be examined even if a slot has failed its validity test.

The standard validity test (with `complete=FALSE`) is applied when an object is created via `new` with any optional arguments (without the extra arguments the result is just the class prototype object).

**Value**

`validObject` returns `TRUE` if the object is valid. Otherwise a vector of strings describing problems found, except that if `test` is `FALSE`, validity failure generates an error, with the corresponding strings in the error message.

**References**

The R package `methods` implements, with a few exceptions, the programming interface for classes and methods in the book *Programming with Data* (John M. Chambers, Springer, 1998), in particular sections 1.6, 2.7, 2.8, and chapters 7 and 8.

While the programming interface for the `methods` package follows the reference, the R software is an original implementation, so details in the reference that reflect the S4 implementation may appear differently in R. Also, there are extensions to the programming interface developed more recently than the reference. For a discussion of details see `?Methods` and the links from that documentation.

**See Also**

`setClass`.

**Examples**

```r
setClass("track",
    representation(x= "numeric", y = "numeric"))
t1 <- new("track", x=1:10, y=sort(rnorm(10)))
## A valid "track" object has the same number of x, y values
validTrackObject <- function(x){
  if(length(x@x) == length(x@y)) TRUE
  else paste("Unequal x,y lengths: ", length(x@x), ",", length(x@y), sep="")
}
## assign the function as the validity method for the class
setValidity("track", validTrackObject)
## t1 should be a valid "track" object
```

validObject(t1)
## Now we do something bad
t2 <- t1
t2@x <- 1:20
## This should generate an error
## Not run: try(validObject(t2))

setClass("trackCurve",
    representation("track", smooth = "numeric"))
## all superclass validity methods are used when validObject
## is called from initialize() with arguments, so this fails
## Not run: trynew("trackCurve", t2)

setClass("twoTrack", representation(tr1 = "track", tr2 = "track"))
## validity tests are not applied recursively by default,
## so this object is created (invalidly)
tT <- new("twoTrack", tr2 = t2)
## A stricter test detects the problem
## Not run: try(validObject(tT, complete = TRUE))

**.checkMFClasses** *Functions to Check the Type of Variables passed to Model Frames*

**Description**

`.checkMFClasses` checks if the variables used in a predict method agree in type with those used for fitting.

`.MFclass` categorizes variables for this purpose.

**Usage**

`.checkMFClasses(cl, m, ordNotOK = FALSE)`

`.MFclass(x)`

`.getXlevels(Terms, m)`
Arguments

cl a character vector of class descriptions to match.
m a model frame.
x any R object.
ordNotOK logical: are ordered factors different?
Terms a terms object.

Details

For applications involving model.matrix such as linear models we do not need to differentiate between ordered factors and factors as although these affect the coding, the coding used in the fit is already recorded and imposed during prediction. However, other applications may treat ordered factors differently: rpart does, for example.

Value

.MFclass returns a character string, one of "logical", "ordered", "factor", "numeric", "nmatrix.*" (a numeric matrix with a number of columns appended) or "other".
.getXlevels returns a named character vector, or NULL.

acf

Auto- and Cross- Covariance and -Correlation Function Estimation

Description

The function acf computes (and by default plots) estimates of the autocovariance or autocorrelation function. Function pacf is the function used for the partial autocorrelations. Function ccf computes the cross-correlation or cross-covariance of two univariate series.

Usage

acf(x, lag.max = NULL,
    type = c("correlation", "covariance", "partial"),
    plot = TRUE, na.action = na.fail, demean = TRUE, ...)

pacf(x, lag.max, plot, na.action, ...)

## Default S3 method:
pacf(x, lag.max = NULL, plot = TRUE, na.action = na.fail, 
    ...)

ccf(x, y, lag.max = NULL, type = c("correlation", "covariance"),
    plot = TRUE, na.action = na.fail, ...)

## S3 method for class 'acf':
x[i, j]
acf

Arguments

- **x, y**
  
a univariate or multivariate (not ccf) numeric time series object or a numeric vector or matrix, or an "acf" object.

- **lag.max**
  
  maximum lag at which to calculate the acf. Default is \(10 \log_{10}(N/m)\) where \(N\) is the number of observations and \(m\) the number of series. Will be automatically limited to one less than the number of observations in the series.

- **type**
  
  character string giving the type of acf to be computed. Allowed values are "correlation" (the default), "covariance" or "partial".

- **plot**
  
  logical. If TRUE (the default) the acf is plotted.

- **na.action**
  
  function to be called to handle missing values. na.pass can be used.

- **demean**
  
  logical. Should the covariances be about the sample means?

- **...**
  
  further arguments to be passed to plot.acf.

- **i**
  
  a set of lags (time differences) to retain.

- **j**
  
  a set of series (names or numbers) to retain.

Details

For type = "correlation" and "covariance", the estimates are based on the sample covariance. (The lag 0 autocorrelation is fixed at 1 by convention.)

By default, no missing values are allowed. If the na.action function passes through missing values (as na.pass does), the covariances are computed from the complete cases. This means that the estimate computed may well not be a valid autocorrelation sequence, and may contain missing values. Missing values are not allowed when computing the PACF of a multivariate time series.

The partial correlation coefficient is estimated by fitting autoregressive models of successively higher orders up to lag.max.

The generic function plot has a method for objects of class "acf".

The lag is returned and plotted in units of time, and not numbers of observations.

There are print and subsetting methods for objects of class "acf".

Value

An object of class "acf", which is a list with the following elements:

- **lag**
  
  A three dimensional array containing the lags at which the acf is estimated.

- **acf**
  
  An array with the same dimensions as lag containing the estimated acf.

- **type**
  
  The type of correlation (same as the type argument).

- **n.used**
  
  The number of observations in the time series.

- **series**
  
  The name of the series x.

- **snames**
  
  The series names for a multivariate time series.

The lag k value returned by ccf(x,y) estimates the correlation between x[t+k] and y[t]. The result is returned invisibly if plot is TRUE.

acf(1deaths, ci.type = "ma")
acf(ts.union(mdeaths, fdeaths))
ccf(mdeaths, fdeaths, ylab="cross-correlation") # just the cross-correlations.

presidents # contains missing values
acf(presidents, na.action = na.pass)
pacf(presidents, na.action = na.pass)

acf2AR

Compute an AR Process Exactly Fitting an ACF

Description

Compute an AR process exactly fitting an autocorrelation function.

Usage

acf2AR(acf)

Arguments

acf An autocorrelation or autocovariance sequence.

Value

A matrix, with one row for the computed AR(p) coefficients for 1 <= p <= length(acf).

See Also

ARMAacf, ar.yw which does this from an empirical ACF.

Examples

(Acf <- ARMAacf(c(0.6, 0.3, -0.2)))
acf2AR(Acf)
Description

Compute all the single terms in the scope argument that can be added to or dropped from the model, fit those models and compute a table of the changes in fit.

Usage

```
add1(object, scope, ...)  
```

## Default S3 method:
```
add1(object, scope, scale = 0, test = c("none", "Chisq"),  
      k = 2, trace = FALSE, ...)  
```

## S3 method for class 'lm':  
```
add1(object, scope, scale = 0, test = c("none", "Chisq", "F"),  
      x = NULL, k = 2, ...)  
```

## S3 method for class 'glm':  
```
add1(object, scope, scale = 0, test = c("none", "Chisq", "F"),  
      x = NULL, k = 2, ...)  
```

```
drop1(object, scope, ...)  
```

## Default S3 method:
```
drop1(object, scope, scale = 0, test = c("none", "Chisq"),  
       k = 2, trace = FALSE, ...)  
```

## S3 method for class 'lm':  
```
drop1(object, scope, scale = 0, all.cols = TRUE,  
       test = c("none", "Chisq", "F"), k = 2, ...)  
```

## S3 method for class 'glm':  
```
drop1(object, scope, scale = 0, test = c("none", "Chisq", "F"),  
       k = 2, ...)  
```

Arguments

- **object**: a fitted model object.
- **scope**: a formula giving the terms to be considered for adding or dropping.
- **scale**: an estimate of the residual mean square to be used in computing $C_p$. Ignored if 0 or NULL.
- **test**: should the results include a test statistic relative to the original model? The F test is only appropriate for lm and aov models or perhaps for glm fits with estimated dispersion. The $\chi^2$ test can be an exact test (lm models with known scale) or a likelihood-ratio test or a test of the reduction in scaled deviance depending on the method.
- **k**: the penalty constant in AIC / $C_p$. 
trace if TRUE, print out progress reports.

add1 a model matrix containing columns for the fitted model and all terms in the upper scope. Useful if add1 is to be called repeatedly. **Warning**: no checks are done on its validity.

all.cols (Provided for compatibility with S.) Logical to specify whether all columns of the design matrix should be used. If FALSE then non-estimable columns are dropped, but the result is not usually statistically meaningful.

... further arguments passed to or from other methods.

**Details**

For drop1 methods, a missing scope is taken to be all terms in the model. The hierarchy is respected when considering terms to be added or dropped: all main effects contained in a second-order interaction must remain, and so on.

In a scope formula, * means 'what is already there'.

The methods for lm and glm are more efficient in that they do not recompute the model matrix and call the fit methods directly.

The default output table gives AIC, defined as minus twice log likelihood plus 2p where p is the rank of the model (the number of effective parameters). This is only defined up to an additive constant (like log-likelihoods). For linear Gaussian models with fixed scale, the constant is chosen to give Mallows’ C_p, RSS/scale + 2p − n. Where C_p is used, the column is labelled as Cp rather than AIC.

The F tests for the "glm" methods are based on analysis of deviance tests, so if the dispersion is estimated it is based on the residual deviance, unlike the F tests of anova.glm.

**Value**

An object of class "anova" summarizing the differences in fit between the models.

**Warning**

The model fitting must apply the models to the same dataset. Most methods will attempt to use a subset of the data with no missing values for any of the variables if na.action=na.omit, but this may give biased results. Only use these functions with data containing missing values with great care.

**Note**

These are not fully equivalent to the functions in S. There is no keep argument, and the methods used are not quite so computationally efficient.

Their authors’ definitions of Mallows’ C_p and Akaike’s AIC are used, not those of the authors of the models chapter of S.

**Author(s)**

The design was inspired by the S functions of the same names described in Chambers (1992).

addmargins Puts Arbitrary Margins on Multidimensional Tables or Arrays

Description
For a given table one can specify which of the classifying factors to expand by one or more levels to
hold margins to be calculated. One may for example form sums and means over the first dimension
and medians over the second. The resulting table will then have two extra levels for the first dimen-
sion and one extra level for the second. The default is to sum over all margins in the table. Other
possibilities may give results that depend on the order in which the margins are computed. This is
flagged in the printed output from the function.

Usage
addmargins(A, margin = 1:length(dim(A)), FUN = sum, quiet = FALSE)

Arguments
A    table or array. The function uses the presence of the "dim" and "dimnames"
     attributes of A.
margin vector of dimensions over which to form margins. Margins are formed in the
     order in which dimensions are specified in margin.
FUN    list of the same length as margin, each element of the list being either a func-
     tion or a list of functions. Names of the list elements will appear as levels in
dimnames of the result. Unnamed list elements will have names constructed:
     the name of a function or a constructed name based on the position in the table.
quiet    logical which suppresses the message telling the order in which the margins
     were computed.

Details
If the functions used to form margins are not commutative the result depends on the order in which
margins are computed. Annotation of margins is done via naming the FUN list.

Value
A table or array with the same number of dimensions as A, but with extra levels of the dimensions
mentioned in margin. The number of levels added to each dimension is the length of the entries
in FUN. A message with the order of computation of margins is printed.
aggregate

Compute Summary Statistics of Data Subsets

Description

Splits the data into subsets, computes summary statistics for each, and returns the result in a convenient form.
aggregate

Usage

aggregate(x, ...)

### Default S3 method:
aggregate(x, ...)

### S3 method for class 'data.frame':
aggregate(x, by, FUN, ...)

### S3 method for class 'ts':
aggregate(x, nfrequency = 1, FUN = sum, ndeltat = 1,
          ts.eps = getOption("ts.eps"), ...)

Arguments

x
   an R object.

by
   a list of grouping elements, each as long as the variables in x. Names for the
grouping variables are provided if they are not given. The elements of the list
will be coerced to factors (if they are not already factors).

FUN
   a scalar function to compute the summary statistics which can be applied to all
data subsets.

nfrequency
   new number of observations per unit of time; must be a divisor of the frequency
   of x.

ndeltat
   new fraction of the sampling period between successive observations; must be a
divisor of the sampling interval of x.

ts.eps
   tolerance used to decide if nfrequency is a sub-multiple of the original fre-
   quency.

... further arguments passed to or used by methods.

Details

aggregate is a generic function with methods for data frames and time series.
The default method aggregate.default uses the time series method if x is a time series, and
otherwise coerces x to a data frame and calls the data frame method.

aggregate.data.frame is the data frame method. If x is not a data frame, it is coerced to
one. Then, each of the variables (columns) in x is split into subsets of cases (rows) of identical
combinations of the components of by, and FUN is applied to each such subset with further argu-
ments in ... passed to it. (i.e. tapply(VAR, by, FUN, ..., simplify = FALSE) is
done for each variable VAR in x, conveniently wrapped into one call to lapply().) Empty subsets
are removed, and the result is reformatted into a data frame containing the variables in by and x.
The ones arising from by contain the unique combinations of grouping values used for determining
the subsets, and the ones arising from x the corresponding summary statistics for the subset of the
respective variables in x.

aggregate.ts is the time series method. If x is not a time series, it is coerced to one. Then, the
variables in x are split into appropriate blocks of length frequency(x) / nfrequency, and
FUN is applied to each such block, with further (named) arguments in ... passed to it. The result
returned is a time series with frequency nfrequency holding the aggregated values.

Examples

```r
## Compute the averages for the variables in 'state.x77', grouped
## according to the region (Northeast, South, North Central, West) that
## each state belongs to.
aggregate(state.x77, list(Region = state.region), mean)

## Compute the averages according to region and the occurrence of more
## than 130 days of frost.
aggregate(state.x77,
    list(Region = state.region,
         Cold = state.x77[,"Frost"] > 130),
    mean)
## (Note that no state in 'South' is THAT cold.)

## Compute the average annual approval ratings for American presidents.
aggregate(presidents, nf = 1, FUN = mean)
## Give the summer less weight.
aggregate(presidents, nf = 1, FUN = weighted.mean, w = c(1, 1, 0.5, 1))
```

AIC

Akaike’s An Information Criterion

Description

Generic function calculating the Akaike information criterion for one or several fitted model objects
for which a log-likelihood value can be obtained, according to the formula $-2 \text{log-likelihood} + k n_{par}$, where $n_{par}$ represents the number of parameters in the fitted model, and $k = 2$ for the
usual AIC, or $k = \log(n)$ ($n$ the number of observations) for the so-called BIC or SBC (Schwarz’s
Bayesian criterion).

Usage

```r
AIC(object, ..., k = 2)
```

Arguments

- `object`: a fitted model object, for which there exists a `logLik` method to extract the
  corresponding log-likelihood, or an object inheriting from class `logLik`.
- `...`: optionally more fitted model objects.
- `k`: numeric, the “penalty” per parameter to be used; the default $k = 2$ is the classical AIC.
The default method for AIC, \texttt{AIC.default()} entirely relies on the existence of a \texttt{logLik} method computing the log-likelihood for the given class.

When comparing fitted objects, the smaller the AIC, the better the fit.

The log-likelihood and hence the AIC is only defined up to an additive constant. Different constants have conventionally be used for different purposes and so \texttt{extractAIC} and \texttt{AIC} may give different values (and do for models of class "lm": see the help for \texttt{extractAIC}).

Value

If just one object is provided, returns a numeric value with the corresponding AIC (or BIC, or ..., depending on \(k\)); if more than one object are provided, returns a \texttt{data.frame} with rows corresponding to the objects and columns representing the number of parameters in the model (df) and the AIC.

\texttt{extractAIC}, \texttt{logLik}.

Examples

\begin{verbatim}
lm1 <- lm(Fertility ~ . , data = swiss)
AIC(lm1)
stopifnot(all.equal(AIC(lm1),
                    AIC(logLik(lm1))))
## a version of BIC or Schwarz' BC :
AIC(lm1, k = log(nrow(swiss)))
\end{verbatim}
Usage

alias(object, ...)  
## S3 method for class 'formula':
alias(object, data, ...)  
## S3 method for class 'lm':
alias(object, complete = TRUE, partial = FALSE,  
       partial.pattern = FALSE, ...)  

Arguments

object A fitted model object, for example from lm or aov, or a formula for alias.formula.
data Optionally, a data frame to search for the objects in the formula.
complete Should information on complete aliasing be included?
partial Should information on partial aliasing be included?
partial.pattern Should partial aliasing be presented in a schematic way? If this is done, the results are presented in a more compact way, usually giving the deciles of the coefficients.
... further arguments passed to or from other methods.

Details

Although the main method is for class "lm", alias is most useful for experimental designs and so is used with fits from aov. Complete aliasing refers to effects in linear models that cannot be estimated independently of the terms which occur earlier in the model and so have their coefficients omitted from the fit. Partial aliasing refers to effects that can be estimated less precisely because of correlations induced by the design.

Value

A list (of class "listof") containing components

Model Description of the model; usually the formula.
Complete A matrix with columns corresponding to effects that are linearly dependent on the rows.
Partial The correlations of the estimable effects, with a zero diagonal. An object of class "mtable" which has its own print method.

Note

The aliasing pattern may depend on the contrasts in use: Helmert contrasts are probably most useful.
The defaults are different from those in S.

Author(s)

The design was inspired by the S function of the same name described in Chambers et al. (1992).
References

Examples

```r
data(npk, package="MASS")

op <- options(contrasts=c("contr.helmert", "contr.poly"))
npk.aov <- aov(yield ~ block + N*P*K, npk)
alias(npk.aov)
options(op)# reset
```

### Description

Compute analysis of variance (or deviance) tables for one or more fitted model objects.

### Usage

```r
anova(object, ...)
```

### Arguments

- **object**: an object containing the results returned by a model fitting function (e.g., `lm` or `glm`).
- **...**: additional objects of the same type.

### Value

This (generic) function returns an object of class `anova`. These objects represent analysis-of-variance and analysis-of-deviance tables. When given a single argument it produces a table which tests whether the model terms are significant.

When given a sequence of objects, `anova` tests the models against one another in the order specified.

The print method for `anova` objects prints tables in a “pretty” form.

### Warning

The comparison between two or more models will only be valid if they are fitted to the same dataset. This may be a problem if there are missing values and R’s default of `na.action = na.omit` is used.

### References

**anova.glm**

**Analysis of Deviance for Generalized Linear Model Fits**

**Description**

Compute an analysis of deviance table for one or more generalized linear model fits.

**Usage**

```r
## S3 method for class 'glm':
anova(object, ..., dispersion = NULL, test = NULL)
```

**Arguments**

- `object, ...`
  objects of class `glm`, typically the result of a call to `glm`, or a list of objects for the "glmlist" method.
- `dispersion`
  the dispersion parameter for the fitting family. By default it is obtained from the object(s).
- `test`
  a character string, (partially) matching one of "Chisq", "F" or "Cp". See `stat.anova`.

**Details**

Specifying a single object gives a sequential analysis of deviance table for that fit. That is, the reductions in the residual deviance as each term of the formula is added in turn are given in as the rows of a table, plus the residual deviances themselves.

If more than one object is specified, the table has a row for the residual degrees of freedom and deviance for each model. For all but the first model, the change in degrees of freedom and deviance is also given. (This only makes statistical sense if the models are nested.) It is conventional to list the models from smallest to largest, but this is up to the user.

The table will optionally contain test statistics (and P values) comparing the reduction in deviance for the row to the residuals. For models with known dispersion (e.g., binomial and Poisson fits) the chi-squared test is most appropriate, and for those with dispersion estimated by moments (e.g., `gaussian`, `quasibinomial` and `quasipoisson` fits) the F test is most appropriate. Mallows' $C_p$ statistic is the residual deviance plus twice the estimate of $\sigma^2$ times the residual degrees of freedom, which is closely related to AIC (and a multiple of it if the dispersion is known).

The dispersion estimate will be taken from the largest model, using the value returned by `summary.glm`. As this will in most cases use a Chisquared-based estimate, the F tests are not based on the residual deviance in the analysis of deviance table shown.

**Value**

An object of class "anova" inheriting from class "data.frame".

**See Also**

`coefficients`, `effects`, `fitted.values`, `residuals`, `summary`, `drop1`, `add1`.
Warning

The comparison between two or more models by `anova` or `anova.glmlist` will only be valid if they are fitted to the same dataset. This may be a problem if there are missing values and R’s default of `na.action = na.omit` is used, and `anova.glmlist` will detect this with an error.

References

See Also

glm, anova.
drop1 for so-called ‘type II’ anova where each term is dropped one at a time respecting their hierarchy.

Examples

```r
## --- Continuing the Example from '?glm':
aova(glm.D93)
aova(glm.D93, test = "Cp")
aova(glm.D93, test = "Chisq")
```
Details

Specifying a single object gives a sequential analysis of variance table for that fit. That is, the reductions in the residual sum of squares as each term of the formula is added in turn are given in as the rows of a table, plus the residual sum of squares.

The table will contain F statistics (and P values) comparing the mean square for the row to the residual mean square.

If more than one object is specified, the table has a row for the residual degrees of freedom and sum of squares for each model. For all but the first model, the change in degrees of freedom and sum of squares is also given. (This only make statistical sense if the models are nested.) It is conventional to list the models from smallest to largest, but this is up to the user.

Optionally the table can include test statistics. Normally the F statistic is most appropriate, which compares the mean square for a row to the residual sum of squares for the largest model considered. If scale is specified chi-squared tests can be used. Mallows’ $C_p$ statistic is the residual sum of squares plus twice the estimate of $\sigma^2$ times the residual degrees of freedom.

Value

An object of class "anova" inheriting from class "data.frame".

Warning

The comparison between two or more models will only be valid if they are fitted to the same dataset. This may be a problem if there are missing values and R’s default of na.action = na.omit is used, and anova.lmList will detect this with an error.

Note

Versions of R prior to 1.2.0 based F tests on pairwise comparisons, and this behaviour can still be obtained by a direct call to anova.lmList.

The model fitting function lm, anova.

drop1 for so-called ‘type II’ anova where each term is dropped one at a time respecting their hierarchy.

Examples

```r
## sequential table
fit <- lm(sr ~ ., data = LifeCycleSavings)
anova(fit)

## same effect via separate models
fit0 <- lm(sr ~ 1, data = LifeCycleSavings)
fit1 <- update(fit0, . ~ . + pop15)
fit2 <- update(fit1, . ~ . + pop75)
fit3 <- update(fit2, . ~ . + dpi)
fit4 <- update(fit3, . ~ . + ddpi)
```
anova.mlm

## S3 method for class 'mlm':
anova(object, ..., 
  test = c("Pillai", "Wilks", "Hotelling-Lawley", "Roy", "Spherical"), 
  Sigma = diag(nrow = p), 
  T = Thin.row(proj(M) - proj(X)), M = diag(nrow = p), X = ~0, 
  idata = data.frame(index = seq_len(p)))

Arguments

object an object of class "mlm".
...
... further objects of class "mlm".
test choice of test statistic (see below).
Sigma (only relevant if test == "Spherical"). Covariance matrix assumed propor-
tional to Sigma.
T transformation matrix. By default computed from M and X.
M formula or matrix describing the outer projection (see below).
X formula or matrix describing the inner projection (see below).
idata data frame describing intra-block design.

Details

The anova.mlm method uses either a multivariate test statistic for the summary table, or a test 
based on sphericity assumptions (i.e. that the covariance is proportional to a given matrix).

For the multivariate test, Wilks’ statistic is most popular in the literature, but the default Pillai– 
Bartlett statistic is recommended by Hand and Taylor (1987). See summary.manova for further 
details.

For the "Spherical" test, proportionality is usually with the identity matrix but a different matrix 
can be specified using Sigma). Corrections for asphericity known as the Greenhouse–Geisser, 
respectively Huynh–Feldt, epsilons are given and adjusted $F$ tests are performed.

It is common to transform the observations prior to testing. This typically involves transformation 
to intra-block differences, but more complicated within-block designs can be encountered, making 
more elaborate transformations necessary. A transformation matrix $T$ can be given directly or spec-
ified as the difference between two projections onto the spaces spanned by $M$ and $X$, which in turn 
can be given as matrices or as model formulas with respect to $idata$ (the tests will be invariant to 
parametrization of the quotient space $M/X$).
As with `anova.lm`, all test statistics use the SSD matrix from the largest model considered as the (generalized) denominator.

Contrary to other `anova` methods, the intercept is not excluded from the display in the single-model case. When contrast transformations are involved, it often makes good sense to test for a zero intercept.

**Value**

An object of class "anova" inheriting from class "data.frame"

**Note**

The Huynh–Feldt epsilon differs from that calculated by SAS (as of v. 8.2) except when the DF is equal to the number of observations minus one. This is believed to be a bug in SAS, not in R.

## Using MANOVA techniques on contrasts:
anova(mlmfit, mlmfit0, X=~1)

## Assuming sphericity
anova(mlmfit, mlmfit0, X=~1, test="Spherical")

### tests using intra-subject 3x2 design
idata <- data.frame(deg=gl(3,1,6,labels=c(0,4,8)),
                      noise=gl(2,3,6,labels=c("A","B"))
                      )
anova(mlmfit, mlmfit0, X = ~ deg + noise, idata = idata, test = "Spherical")
anova(mlmfit, mlmfit0, M = ~ deg + noise, X = ~ noise, idata = idata,
               test="Spherical")
anova(mlmfit, mlmfit0, M = ~ deg + noise, X = ~ deg, idata = idata,
               test="Spherical")

f <- factor(rep(1:2,5))  # bogus, just for illustration
mlmfit2 <- update(mlmfit, ~f)
anova(mlmfit2, mlmfit, mlmfit0, X=~1, test="Spherical")
anova(mlmfit2, X=~1, test="Spherical")  # one-model form, equiv. to previous

### There seems to be a strong interaction in these data
plot(colMeans(reacttime))
```
Description

Performs the Ansari-Bradley two-sample test for a difference in scale parameters.

Usage

ansari.test(x, y, alternative = c("two.sided", "less", "greater"),
            exact = NULL, conf.int = FALSE, conf.level = 0.95, ...)

Arguments

x numeric vector of data values.
y numeric vector of data values.
alternative indicates the alternative hypothesis and must be one of "two.sided",
            "greater" or "less". You can specify just the initial letter.
exact a logical indicating whether an exact p-value should be computed.
conf.int a logical, indicating whether a confidence interval should be computed.
conf.level confidence level of the interval.
formula a formula of the form lhs ~ rhs where lhs is a numeric variable giving the
data values and rhs a factor with two levels giving the corresponding groups.
data an optional matrix or data frame (or similar: see model.frame) containing
        the variables in the formula formula. By default the variables are taken from
        environment(formula).
subset an optional vector specifying a subset of observations to be used.
nlaction a function which indicates what should happen when the data contain NAs. De-
        fault to getOption("na.action").
... further arguments to be passed to or from methods.

Details

Suppose that x and y are independent samples from distributions with densities \( f((t - m)/s)/s \)
and \( f(t - m) \), respectively, where \( m \) is an unknown nuisance parameter and \( s \), the ratio of scales,
is the parameter of interest. The Ansari-Bradley test is used for testing the null that \( s \) equals 1, the
two-sided alternative being that \( s \neq 1 \) (the distributions differ only in variance), and the one-sided
alternatives being \( s > 1 \) (the distribution underlying x has a larger variance, "greater") or \( s < 1 \)
("less").

By default (if exact is not specified), an exact p-value is computed if both samples contain less
than 50 finite values and there are no ties. Otherwise, a normal approximation is used.
Optionally, a nonparametric confidence interval and an estimator for $s$ are computed. If exact $p$-values are available, an exact confidence interval is obtained by the algorithm described in Bauer (1972), and the Hodges-Lehmann estimator is employed. Otherwise, the returned confidence interval and point estimate are based on normal approximations.

Note that mid-ranks are used in the case of ties rather than average scores as employed in Hollander & Wolfe (1973). See, e.g., Hajek, Sidak and Sen (1999), pages 131ff, for more information.

**Value**

A list with class "htest" containing the following components:

- **statistic** the value of the Ansari-Bradley test statistic.
- **p.value** the $p$-value of the test.
- **null.value** the ratio of scales $s$ under the null, 1.
- **alternative** a character string describing the alternative hypothesis.
- **method** the string "Ansari-Bradley test".
- **data.name** a character string giving the names of the data.
- **conf.int** a confidence interval for the scale parameter. (Only present if argument `conf.int = TRUE`.)
- **estimate** an estimate of the ratio of scales. (Only present if argument `conf.int = TRUE`.)

**Note**

To compare results of the Ansari-Bradley test to those of the F test to compare two variances (under the assumption of normality), observe that $s$ is the ratio of scales and hence $s^2$ is the ratio of variances (provided they exist), whereas for the F test the ratio of variances itself is the parameter of interest. In particular, confidence intervals are for $s$ in the Ansari-Bradley test but for $s^2$ in the F test.

ansari.test(rnorm(10), rnorm(10, 0, 2), conf.int = TRUE)
```

### try more points - failed in 2.4.1

```r
ansari.test(rnorm(100), rnorm(100, 0, 2), conf.int = TRUE)
```

---

**aov**  
*Fit an Analysis of Variance Model*

**Description**

Fit an analysis of variance model by a call to `lm` for each stratum.

**Usage**

```r
aov(formula, data = NULL, projections = FALSE, qr = TRUE,
    contrasts = NULL, ...)
```

**Arguments**

- `formula` A formula specifying the model.
- `data` A data frame in which the variables specified in the formula will be found. If missing, the variables are searched for in the standard way.
- `projections` Logical flag: should the projections be returned?
- `qr` Logical flag: should the QR decomposition be returned?
- `contrasts` A list of contrasts to be used for some of the factors in the formula. These are not used for any `Error` term, and supplying contrasts for factors only in the `Error` term will give a warning.
- `...` Arguments to be passed to `lm`, such as `subset` or `na.action`.

**Details**

This provides a wrapper to `lm` for fitting linear models to balanced or unbalanced experimental designs.

The main difference from `lm` is in the way `print`, `summary` and so on handle the fit: this is expressed in the traditional language of the analysis of variance rather than that of linear models.

If the formula contains a single `Error` term, this is used to specify error strata, and appropriate models are fitted within each error stratum.

The formula can specify multiple responses.

Weights can be specified by a `weights` argument, but should not be used with an `Error` term, and are incompletely supported (e.g., not by `model.tables`).
Value

An object of class c("aov", "lm") or for multiple responses of class c("maov", "aov", "mlm", "lm") or for multiple error strata of class "aovlist". There are print and summary methods available for these.

Note

aov is designed for balanced designs, and the results can be hard to interpret without balance: beware that missing values in the response(s) will likely lose the balance. If there are two or more error strata, the methods used are statistically inefficient without balance, and it may be better to use lme.

Balance can be checked with the replications function.

The default ‘contrasts’ in R are not orthogonal contrasts, and aov and its helper functions will work better with such contrasts: see the examples for how to select these.

Author(s)

The design was inspired by the S function of the same name described in Chambers et al. (1992).

Examples

data(npk, package="MASS")

## Set orthogonal contrasts.
op <- options(contrasts=c("contr.helmert", "contr.poly"))
(npk.aov <- aov(yield ~ block + N*P*K, npk))
summary(npk.aov)
coefficients(npk.aov)

## to show the effects of re-ordering terms contrast the two fits
aov(yield ~ block + N * P + K, npk)
aov(terms(yield ~ block + N * P + K, keep.order=TRUE), npk)

## as a test, not particularly sensible statistically
npk.aovE <- aov(yield ~ N*P*K + Error(block), npk)
npk.aovE
summary(npk.aovE)
options(op)# reset to previous
**Description**

Return a list of points which linearly interpolate given data points, or a function performing the linear (or constant) interpolation.

**Usage**

```r
approx (x, y = NULL, xout, method="linear", n=50,
        yleft, yright, rule = 1, f = 0, ties = mean)
approxfun(x, y = NULL, method="linear",
          yleft, yright, rule = 1, f = 0, ties = mean)
```

**Arguments**

- `x, y` vectors giving the coordinates of the points to be interpolated. Alternatively a single plotting structure can be specified: see `xy.coords`.
- `xout` an optional set of values specifying where interpolation is to take place.
- `method` specifies the interpolation method to be used. Choices are "linear" or "constant".
- `n` If `xout` is not specified, interpolation takes place at `n` equally spaced points spanning the interval `[min(x), max(x)]`.
- `yleft` the value to be returned when input `x` values are less than `min(x)`. The default is defined by the value of `rule` given below.
- `yright` the value to be returned when input `x` values are greater than `max(x)`. The default is defined by the value of `rule` given below.
- `rule` an integer describing how interpolation is to take place outside the interval `[min(x), max(x)]`. If `rule` is 1 then NAs are returned for such points and if it is 2, the value at the closest data extreme is used.
- `f` For `method="constant"` a number between 0 and 1 inclusive, indicating a compromise between left- and right-continuous step functions. If `y0` and `y1` are the values to the left and right of the point then the value is `y0*(1-f)+y1*f` so that `f=0` is right-continuous and `f=1` is left-continuous.
- `ties` Handling of tied `x` values. Either a function with a single vector argument returning a single number result or the string "ordered".

**Details**

The inputs can contain missing values which are deleted, so at least two complete `(x, y)` pairs are required (for `method = "linear"`, one otherwise). If there are duplicated (tied) `x` values and `ties` is a function it is applied to the `y` values for each distinct `x` value. Useful functions in this context include `mean`, `min`, and `max`. If `ties="ordered"` the `x` values are assumed to be already ordered. The first `y` value will be used for interpolation to the left and the last one for interpolation to the right.
Value

approx returns a list with components \( x \) and \( y \), containing \( n \) coordinates which interpolate the given data points according to the method (and rule) desired.

The function approxfun returns a function performing (linear or constant) interpolation of the given data points. For a given set of \( x \) values, this function will return the corresponding interpolated values. This is often more useful than approx.

spline and splinefun for spline interpolation.

Examples

```r
x <- 1:10
y <- rnorm(10)
par(mfrow = c(2,1))
plot(x, y, main = "approx(.) and approxfun(.)")
points(approx(x, y), col = 2, pch = "*")
points(approx(x, y, method = "constant"), col = 4, pch = "+")

f <- approxfun(x, y)
curve(f(x), 0, 10, col = "green")
points(x, y)
is.function(fc <- approxfun(x, y, method = "const")) # TRUE
curve(fc(x), 0, 10, col = "darkblue", add = TRUE)

## Show treatment of 'ties' :
x <- c(2,2:4,4,5,7,7,7)
y <- c(1:6, 5:4, 3:1)
approx(x,y, xout=x)$y # warning
(ay <- approx(x,y, xout=x, ties = "ordered")$y)
stopifnot(ay == c(2,2,3,6,6,4,4,1,1,1))
approx(x,y, xout=x, ties = min)$y
approx(x,y, xout=x, ties = max)$y
```

ar

Fit Autoregressive Models to Time Series

Description

Fit an autoregressive time series model to the data, by default selecting the complexity by AIC.
Usage

ar(x, aic = TRUE, order.max = NULL, 
method=c("yule-walker", "burg", "ols", "mle", "yw"), 
na.action, series, ...)

ar.burg(x, ...) 
## Default S3 method: 
ar.burg(x, aic = TRUE, order.max = NULL, 
na.action = na.fail, demean = TRUE, series, 
var.method = 1, ...)
## S3 method for class 'mts'

ar.burg(x, aic = TRUE, order.max = NULL, 
na.action = na.fail, demean = TRUE, series, 
var.method = 1, ...)

ar.yw(x, ...) 
## Default S3 method: 
ar.yw(x, aic = TRUE, order.max = NULL, 
na.action = na.fail, demean = TRUE, series, ...)
## S3 method for class 'mts'

ar.yw(x, aic = TRUE, order.max = NULL, 
na.action = na.fail, demean = TRUE, series, 
var.method = 1, ...)

ar.mle(x, aic = TRUE, order.max = NULL, na.action = na.fail, 
demean = TRUE, series, ...)

## S3 method for class 'ar': 
predict(object, newdata, n.ahead = 1, se.fit = TRUE, ...)

Arguments

x A univariate or multivariate time series.
aic Logical flag. If TRUE then the Akaike Information Criterion is used to 
choose the order of the autoregressive model. If FALSE, the model of order 
order.max is fitted.
order.max Maximum order (or order) of model to fit. Defaults to $10 \log_{10}(N)$ where $N$ is the number of observations except for method="mle" where it is the mini-
mum of this quantity and 12.
method Character string giving the method used to fit the model. Must be one of the 
strings in the default argument (the first few characters are sufficient). Defaults 
to "yule-walker".
na.action function to be called to handle missing values.
demean should a mean be estimated during fitting?
series names for the series. Defaults to deparse(substitute(x)).
var.method the method to estimate the innovations variance (see Details).
... additional arguments for specific methods.
object a fit from ar.
newdata data to which to apply the prediction.
n.ahead number of steps ahead at which to predict.
se.fit logical: return estimated standard errors of the prediction error?

Details
For definiteness, note that the AR coefficients have the sign in
\[ x_t - \mu = a_1(x_{t-1} - \mu) + \cdots + a_p(x_{t-p} - \mu) + \epsilon_t \]

ar is just a wrapper for the functions ar.yw, ar.burg, ar.ols and ar.mle.
Order selection is done by AIC if aic is true. This is problematic, as of the methods here only
ar.mle performs true maximum likelihood estimation. The AIC is computed as if the variance
estimate were the MLE, omitting the determinant term from the likelihood. Note that this is not
the same as the Gaussian likelihood evaluated at the estimated parameter values. In ar.yw the
variance matrix of the innovations is computed from the fitted coefficients and the autocovariance
of \( x \).

ar.burg allows two methods to estimate the innovations variance and hence AIC. Method 1 is
to use the update given by the Levinson-Durbin recursion (Brockwell and Davis, 1991, (8.2.6) on
page 242), and follows S-PLUS. Method 2 is the mean of the sum of squares of the forward and
backward prediction errors (as in Brockwell and Davis, 1996, page 145). Percival and Walden
(1998) discuss both. In the multivariate case the estimated coefficients will depend (slightly) on the
variance estimation method.
Remember that ar includes by default a constant in the model, by removing the overall mean of \( x \)
before fitting the AR model, or (ar.mle) estimating a constant to subtract.

Value
For ar and its methods a list of class "ar" with the following elements:

order The order of the fitted model. This is chosen by minimizing the AIC if
aic=TRUE, otherwise it is order.max.
ar Estimated autoregression coefficients for the fitted model.
var.pred The prediction variance: an estimate of the portion of the variance of the time
series that is not explained by the autoregressive model.
x.mean The estimated mean of the series used in fitting and for use in prediction.
x.intercept (ar.ols only.) The intercept in the model for \( x - x.mean \).
aic The value of the aic argument.
n.used The number of observations in the time series.
order.max The value of the order.max argument.
partialacf The estimate of the partial autocorrelation function up to lag order.max.
resid residuals from the fitted model, conditioning on the first order observations.
The first order residuals are set to NA. If \( x \) is a time series, so is resid.
method The value of the method argument.
series The name(s) of the time series.
frequency The frequency of the time series.
call The matched call.
asy.var.coef (univariate case, order > 0.) The asymptotic-theory variance matrix of the
coefficient estimates.

For predict.ar, a time series of predictions, or if se.fit = TRUE, a list with components
pred, the predictions, and se, the estimated standard errors. Both components are time series.
Note

Only the univariate case of \texttt{ar.mle} is implemented.

Fitting by \texttt{method="mle"} to long series can be very slow.

  ar(ts.union(BJsales, BJsales.lead), method="burg")
\end{verbatim}

\section*{Description}

Fit an autoregressive time series model to the data by ordinary least squares, by default selecting the complexity by AIC.

Usage

\begin{verbatim}
ar.ols(x, aic = TRUE, order.max = NULL, na.action = na.fail,
       demean = TRUE, intercept = demean, series, ...)
\end{verbatim}
Arguments

- **x**: A univariate or multivariate time series.
- **aic**: Logical flag. If `TRUE` then the Akaike Information Criterion is used to choose the order of the autoregressive model. If `FALSE`, the model of order `order.max` is fitted.
- **order.max**: Maximum order (or order) of model to fit. Defaults to $10 \log_{10}(N)$ where $N$ is the number of observations.
- **na.action**: function to be called to handle missing values.
- **demean**: should the AR model be for $x$ minus its mean?
- **intercept**: should a separate intercept term be fitted?
- **series**: names for the series. Defaults to `deparse(substitute(x))`.
- **...**: further arguments to be passed to or from methods.

Details

`ar.ols` fits the general AR model to a possibly non-stationary and/or multivariate system of series `x`. The resulting unconstrained least squares estimates are consistent, even if some of the series are non-stationary and/or co-integrated. For definiteness, note that the AR coefficients have the sign in

$$x_t - \mu = a_0 + a_1(x_{t-1} - \mu) + \cdots + a_p(x_{t-p} - \mu) + e_t$$

where $a_0$ is zero unless `intercept` is true, and $\mu$ is the sample mean if `demean` is true, zero otherwise.

Order selection is done by AIC if `aic` is true. This is problematic, as `ar.ols` does not perform true maximum likelihood estimation. The AIC is computed as if the variance estimate (computed from the variance matrix of the residuals) were the MLE, omitting the determinant term from the likelihood. Note that this is not the same as the Gaussian likelihood evaluated at the estimated parameter values.

Some care is needed if `intercept` is true and `demean` is false. Only use this if the series are roughly centred on zero. Otherwise the computations may be inaccurate or fail entirely.

Value

A list of class "ar" with the following elements:

- **order**: The order of the fitted model. This is chosen by minimizing the AIC if `aic=TRUE`, otherwise it is `order.max`.
- **ar**: Estimated autoregression coefficients for the fitted model.
- **var.pred**: The prediction variance: an estimate of the portion of the variance of the time series that is not explained by the autoregressive model.
- **x.mean**: The estimated mean (or zero if `demean` is false) of the series used in fitting and for use in prediction.
- **x.intercept**: The intercept in the model for $x - x.mean$, or zero if `intercept` is false.
- **aic**: The value of the `aic` argument.
- **n.used**: The number of observations in the time series.
- **order.max**: The value of the `order.max` argument.
- **partialacf**: NULL. For compatibility with `ar`. 
resid residuals from the fitted model, conditioning on the first order observations. The first order residuals are set to NA. If \( x \) is a time series, so is resid.

method The character string "Unconstrained LS".

series The name(s) of the time series.

frequency The frequency of the time series.

call The matched call.

asy.se.coef The asymptotic-theory standard errors of the coefficient estimates.

ar.ols(x, order.max=6, demean=FALSE, intercept=TRUE)

---

**arima**

**ARIMA Modelling of Time Series**

Description

Fit an ARIMA model to a univariate time series.

Usage

```
arima(x, order = c(0, 0, 0), seasonal = list(order = c(0, 0, 0), period = NA), xreg = NULL, include.mean = TRUE, transform.pars = TRUE, fixed = NULL, init = NULL, method = c("CSS-ML", "ML", "CSS"), n.cond, optim.control = list(), kappa = 1e6)
```
Arguments

x a univariate time series

order A specification of the non-seasonal part of the ARIMA model: the three components \((p, d, q)\) are the AR order, the degree of differencing, and the MA order.

seasonal A specification of the seasonal part of the ARIMA model, plus the period (which defaults to \texttt{frequency(x)}). This should be a list with components \texttt{order} and \texttt{period}, but a specification of just a numeric vector of length 3 will be turned into a suitable list with the specification as the \texttt{order}.

xreg Optionally, a vector or matrix of external regressors, which must have the same number of rows as \(x\).

include.mean Should the ARIMA model include a mean term? The default is \texttt{TRUE} for undifferenced series, \texttt{FALSE} for differenced ones (where a mean would not affect the fit nor predictions).

transform.pars Logical. If true, the AR parameters are transformed to ensure that they remain in the region of stationarity. Not used for \texttt{method = "CSS"}.

fixed optional numeric vector of the same length as the total number of parameters. If supplied, only NA entries in \texttt{fixed} will be varied. \texttt{transform.pars = TRUE} will be overridden (with a warning) if any AR parameters are fixed. It may be wise to set \texttt{transform.pars = FALSE} when fixing MA parameters, especially near non-invertibility.

init optional numeric vector of initial parameter values. Missing values will be filled in, by zeroes except for regression coefficients. Values already specified in \texttt{fixed} will be ignored.

method Fitting method: maximum likelihood or minimize conditional sum-of-squares. The default (unless there are missing values) is to use conditional-sum-of-squares to find starting values, then maximum likelihood.

n.cond Only used if fitting by conditional-sum-of-squares: the number of initial observations to ignore. It will be ignored if less than the maximum lag of an AR term.

optim.control List of control parameters for \texttt{optim}.

cappa the prior variance (as a multiple of the innovations variance) for the past observations in a differenced model. Do not reduce this.

Details

Different definitions of ARMA models have different signs for the AR and/or MA coefficients. The definition here has

\[
X_t = a_1X_{t-1} + \cdots + a_pX_{t-p} + e_t + b_1e_{t-1} + \cdots + b_qe_{t-q}
\]

and so the MA coefficients differ in sign from those of S-PLUS. Further, if \texttt{include.mean} is true, this formula applies to \(X - m\) rather than \(X\). For ARIMA models with differencing, the differenced series follows a zero-mean ARMA model. If a \texttt{xreg} term is included, a linear regression (with a constant term if \texttt{include.mean} is true) is fitted with an ARMA model for the error term.

The variance matrix of the estimates is found from the Hessian of the log-likelihood, and so may only be a rough guide.

Optimization is done by \texttt{optim}. It will work best if the columns in \texttt{xreg} are roughly scaled to zero mean and unit variance, but does attempt to estimate suitable scalings.
Value

A list of class "Arima" with components:

- **coef**: a vector of AR, MA and regression coefficients, which can be extracted by the `coef` method.
- **sigma2**: the MLE of the innovations variance.
- **var.coef**: the estimated variance matrix of the coefficients `coef`, which can be extracted by the `vcov` method.
- **loglik**: the maximized log-likelihood (of the differenced data), or the approximation to it used.
- **arma**: A compact form of the specification, as a vector giving the number of AR, MA, seasonal AR and seasonal MA coefficients, plus the period and the number of non-seasonal and seasonal differences.
- **aic**: the AIC value corresponding to the log-likelihood. Only valid for `method = "ML"` fits.
- **residuals**: the fitted innovations.
- **call**: the matched call.
- **series**: the name of the series `x`.
- **code**: the convergence value returned by `optim`.
- **n.cond**: the number of initial observations not used in the fitting.
- **model**: A list representing the Kalman Filter used in the fitting. See `KalmanLike`.

Fitting methods

The exact likelihood is computed via a state-space representation of the ARIMA process, and the innovations and their variance found by a Kalman filter. The initialization of the differenced ARMA process uses stationarity and is based on Gardner *et al.* (1980). For a differenced process the non-stationary components are given a diffuse prior (controlled by `kappa`). Observations which are still controlled by the diffuse prior (determined by having a Kalman gain of at least `1e4`) are excluded from the likelihood calculations. (This gives comparable results to `arima0` in the absence of missing values, when the observations excluded are precisely those dropped by the differencing.)

Missing values are allowed, and are handled exactly in method "ML".

If `transform.pars` is true, the optimization is done using an alternative parametrization which is a variation on that suggested by Jones (1980) and ensures that the model is stationary. For an AR(p) model the parametrization is via the inverse tanh of the partial autocorrelations: the same procedure is applied (separately) to the AR and seasonal AR terms. The MA terms are not constrained to be invertible during optimization, but they will be converted to invertible form after optimization if `transform.pars` is true.

Conditional sum-of-squares is provided mainly for expositional purposes. This computes the sum of squares of the fitted innovations from observation `n.cond` on, (where `n.cond` is at least the maximum lag of an AR term), treating all earlier innovations to be zero. Argument `n.cond` can be used to allow comparability between different fits. The “part log-likelihood” is the first term, half the log of the estimated mean square. Missing values are allowed, but will cause many of the innovations to be missing.

When regressors are specified, they are orthogonalized prior to fitting unless any of the coefficients is fixed. It can be helpful to roughly scale the regressors to zero mean and unit variance.
Note

The results are likely to be different from S-PLUS’s `arima.mle`, which computes a conditional likelihood and does not include a mean in the model. Further, the convention used by `arima.mle` reverses the signs of the MA coefficients.

`arima` is very similar to `arima0` for ARMA models or for differenced models without missing values, but handles differenced models with missing values exactly. It is somewhat slower than `arima0`, particularly for seasonally differenced models.

tsdiag(fit3)
```
Simulate from an ARIMA Model

Description

Simulate from an ARIMA model.

Usage

arima.sim(model, n, rand.gen = rnorm, innov = rand.gen(n, ...),
          n.start = NA, start.innov = rand.gen(n.start, ...), ...)

Arguments

model  A list with component ar and/or ma giving the AR and MA coefficients respectively. Optionally a component order can be used. An empty list gives an ARIMA(0, 0, 0) model, that is white noise.
n  length of output series, before un-differencing.
rand.gen  optional: a function to generate the innovations.
innov  an optional times series of innovations. If not provided, rand.gen is used.
n.start  length of “burn-in” period. If NA, the default, a reasonable value is computed.
start.innov  an optional times series of innovations to be used for the burn-in period. If supplied there must be at least n.start values (and n.start is by default computed inside the function).
...  additional arguments for rand.gen. Most usefully, the standard deviation of the innovations generated by rnorm can be specified by sd.

Details

See arima for the precise definition of an ARIMA model.

The ARMA model is checked for stationarity.

ARIMA models are specified via the order component of model, in the same way as for arima. Other aspects of the order component are ignored, but inconsistent specifications of the MA and AR orders are detected. The un-differencing assumes previous values of zero, and to remind the user of this, those values are returned.

Random inputs for the “burn-in” period are generated by calling rand.gen.

Value

A time-series object of class "ts".

ts.plot(ts.sim)

---

**arima0**

**ARIMA Modelling of Time Series – Preliminary Version**

**Description**

Fit an ARIMA model to a univariate time series, and forecast from the fitted model.

**Usage**

```r
arima0(x, order = c(0, 0, 0),
  seasonal = list(order = c(0, 0, 0), period = NA),
  xreg = NULL, include.mean = TRUE, delta = 0.01,
  transform.pars = TRUE, fixed = NULL, init = NULL,
  method = c("ML", "CSS"), n.cond, optim.control = list())
```

**Arguments**

- `x` a univariate time series
- `order` A specification of the non-seasonal part of the ARIMA model: the three components \((p, d, q)\) are the AR order, the degree of differencing, and the MA order.
- `seasonal` A specification of the seasonal part of the ARIMA model, plus the period (which defaults to `frequency(x)`). This should be a list with components `order` and `period`, but a specification of just a numeric vector of length 3 will be turned into a suitable list with the specification as the `order`.
- `xreg` Optionally, a vector or matrix of external regressors, which must have the same number of rows as `x`.
- `include.mean` Should the ARIMA model include a mean term? The default is `TRUE` for undifferenced series, `FALSE` for differenced ones (where a mean would not affect the fit nor predictions).
- `delta` A value to indicate at which point ‘fast recursions’ should be used. See the Details section.
- `transform.pars` Logical. If true, the AR parameters are transformed to ensure that they remain in the region of stationarity. Not used for `method = "CSS"`.

---

### S3 method for class 'arima0':
```r
predict(object, n.ahead = 1, newxreg, se.fit = TRUE, ...)
```
fixed
optional numeric vector of the same length as the total number of parameters. If supplied, only NA entries in fixed will be varied. transform.pars = TRUE will be overridden (with a warning) if any ARMA parameters are fixed.

init
optional numeric vector of initial parameter values. Missing values will be filled in, by zeroes except for regression coefficients. Values already specified in fixed will be ignored.

method
Fitting method: maximum likelihood or minimize conditional sum-of-squares.

n.cond
Only used if fitting by conditional-sum-of-squares: the number of initial observations to ignore. It will be ignored if less than the maximum lag of an AR term.

optim.control
List of control parameters for optim.

object
The result of an arima0 fit.

newxreg
New values of xreg to be used for prediction. Must have at least n.ahead rows.

n.ahead
The number of steps ahead for which prediction is required.

se.fit
Logical: should standard errors of prediction be returned?

... arguments passed to or from other methods.

Details
Different definitions of ARMA models have different signs for the AR and/or MA coefficients. The definition here has

\[ X_t = a_1 X_{t-1} + \cdots + a_p X_{t-p} + \epsilon_t + b_1 \epsilon_{t-1} + \cdots + b_q \epsilon_{t-q} \]

and so the MA coefficients differ in sign from those of S-PLUS. Further, if include.mean is true, this formula applies to \( X - m \) rather than \( X \). For ARIMA models with differencing, the differenced series follows a zero-mean ARMA model.

The variance matrix of the estimates is found from the Hessian of the log-likelihood, and so may only be a rough guide, especially for fits close to the boundary of invertibility.

Optimization is done by optim. It will work best if the columns in xreg are roughly scaled to zero mean and unit variance, but does attempt to estimate suitable scalings.

Finite-history prediction is used. This is only statistically efficient if the MA part of the fit is invertible, so predict.arima0 will give a warning for non-invertible MA models.

Value
For arima0, a list of class "arima0" with components:

coef a vector of AR, MA and regression coefficients,
sigma2 the MLE of the innovations variance.
var.coef the estimated variance matrix of the coefficients coef.
loglik the maximized log-likelihood (of the differenced data), or the approximation to it used.
arma A compact form of the specification, as a vector giving the number of AR, MA, seasonal AR and seasonal MA coefficients, plus the period and the number of non-seasonal and seasonal differences.
arima0

aic  the AIC value corresponding to the log-likelihood. Only valid for method = "ML" fits.
residuals  the fitted innovations.
call  the matched call.
series  the name of the series x.
convergence  the value returned by optim.
n.cond  the number of initial observations not used in the fitting.

For predict.arima0, a time series of predictions, or if se.fit = TRUE, a list with components pred, the predictions, and se, the estimated standard errors. Both components are time series.

Fitting methods

The exact likelihood is computed via a state-space representation of the ARMA process, and the innovations and their variance found by a Kalman filter based on Gardner et al. (1980). This has the option to switch to ‘fast recursions’ (assume an effectively infinite past) if the innovations variance is close enough to its asymptotic bound. The argument delta sets the tolerance: at its default value the approximation is normally negligible and the speed-up considerable. Exact computations can be ensured by setting delta to a negative value.

If transform.pars is true, the optimization is done using an alternative parametrization which is a variation on that suggested by Jones (1980) and ensures that the model is stationary. For an AR(p) model the parametrization is via the inverse tanh of the partial autocorrelations: the same procedure is applied (separately) to the AR and seasonal AR terms. The MA terms are also constrained to be invertible during optimization by the same transformation if transform.pars is true. Note that the MLE for MA terms does sometimes occur for MA polynomials with unit roots: such models can be fitted by using transform.pars = FALSE and specifying a good set of initial values (often obtainable from a fit with transform.pars = TRUE).

As from R 1.5.0 missing values are allowed, but any missing values will force delta to be ignored and full recursions used. Note that missing values will be propagated by differencing, so the procedure used in this function is not fully efficient in that case.

Conditional sum-of-squares is provided mainly for expositional purposes. This computes the sum of squares of the fitted innovations from observation n.cond on, (where n.cond is at least the maximum lag of an AR term), treating all earlier innovations to be zero. Argument n.cond can be used to allow comparability between different fits. The “part log-likelihood” is the first term, half the log of the estimated mean square. Missing values are allowed, but will cause many of the innovations to be missing.

When regressors are specified, they are orthogonalized prior to fitting unless any of the coefficients is fixed. It can be helpful to roughly scale the regressors to zero mean and unit variance.

Note

This is a preliminary version, and will be replaced by arima.

The standard errors of prediction exclude the uncertainty in the estimation of the ARMA model and the regression coefficients.

The results are likely to be different from S-PLUS’s arima.mle, which computes a conditional likelihood and does not include a mean in the model. Further, the convention used by arima.mle reverses the signs of the MA coefficients.

ARMAacf

Compute Theoretical ACF for an ARMA Process

Description

Compute the theoretical autocorrelation function or partial autocorrelation function for an ARMA process.

Usage

```r
ARMAacf(ar = numeric(0), ma = numeric(0), lag.max = r, pacf = FALSE)
```
ARMAtoMA

Convert ARMA Process to Infinite MA Process

Description

Convert ARMA process to infinite MA process.

Usage

ARMAtoMA(ar = numeric(0), ma = numeric(0), lag.max)
as.hclust

Arguments

ar  numeric vector of AR coefficients
ma  numeric vector of MA coefficients
lag.max Largest MA(Inf) coefficient required.

Value

A vector of coefficients.

References

See Also

arima, ARMAacf.

Examples

ARMAtoMA(c(1.0, -0.25), 1.0, 10)
## Example from Brockwell & Davis (1991, p.92)
## answer (1 + 3*n)*2^(-n)
n <- 1:10; (1 + 3*n)*2^(-n)

as.hclust        Convert Objects to Class hclust

Description

Converts objects from other hierarchical clustering functions to class "hclust".

Usage

as.hclust(x, ...)

Arguments

x  Hierarchical clustering object
...
     further arguments passed to or from other methods.

Details

Currently there is only support for converting objects of class "twins" as produced by the functions diana and agnes from the package cluster. The default method throws an error unless passed an "hclust" object.

Value

An object of class "hclust".
Convert to One-Sided Formula

Description

Names, expressions, numeric values, and character strings are converted to one-sided formulae. If object is a formula, it must be one-sided, in which case it is returned unaltered.

Usage

asOneSidedFormula(object)

Arguments

object a one-sided formula, an expression, a numeric value, or a character string.

Value

a one-sided formula representing object

Author(s)

Jose Pinheiro and Douglas Bates

Examples

asOneSidedFormula("age")
asOneSidedFormula(~ age)
ave

Group Averages Over Level Combinations of Factors

Description
Subsets of \( x[] \) are averaged, where each subset consist of those observations with the same factor levels.

Usage
\[
\text{ave}(x, \ldots, \text{FUN} = \text{mean})
\]

Arguments
\[
\begin{align*}
x & \quad \text{A numeric.} \\
\ldots & \quad \text{Grouping variables, typically factors, all of the same length as } x. \\
\text{FUN} & \quad \text{Function to apply for each factor level combination.}
\end{align*}
\]

Value
A numeric vector, say \( y \) of length \( \text{length}(x) \). If \( \ldots \) is \( g1,g2 \), e.g., \( y[i] \) is equal to \( \text{FUN}(x[j], \text{for all } j \text{ with } g1[j] == g1[i] \text{ and } g2[j] == g2[i]) \).

See Also
\text{mean, median}.

Examples
\[

\]
\[
\text{plot(breaks, main =}
\]
\[
\"\text{\"ave(Warpbreaks ) for wool x tension combinations\")}
\]
\[
\text{lines(ave(breaks, wool, tension, FUN=\text{mean}), type='s', col = \"blue\")}
\]
\[
\text{lines(ave(breaks, wool, tension, FUN=\text{median}), type='s', col = \"green\")}
\]
\[
\text{legend(40,70, c("mean","median"), lty=1,col=c("blue","green"), bg=\text{gray90})}
\]
\[
\text{detach()}
\]
Description

Bandwidth selectors for gaussian windows in density.

Usage

bw.nrd0(x)

bw.nrd(x)

bw.ucv(x, nb = 1000, lower = 0.1 * hmax, upper = hmax)

bw.bcv(x, nb = 1000, lower = 0.1 * hmax, upper = hmax)

bw.SJ(x, nb = 1000, lower = 0.1 * hmax, upper = hmax,
method = c("ste", "dpi"))

Arguments

x  A data vector.

nb  number of bins to use.

lower, upper Range over which to minimize. The default is almost always satisfactory. hmax is calculated internally from a normal reference bandwidth.

method  Either "ste" ("solve-the-equation") or "dpi" ("direct plug-in").

Details

bw.nrd0 implements a rule-of-thumb for choosing the bandwidth of a Gaussian kernel density estimator. It defaults to 0.9 times the minimum of the standard deviation and the interquartile range divided by 1.34 times the sample size to the negative one-fifth power (= Silverman’s “rule of thumb”, Silverman (1986, page 48, eqn (3.31)) unless the quartiles coincide when a positive result will be guaranteed.

bw.nrd is the more common variation given by Scott (1992), using factor 1.06.

bw.ucv and bw.bcv implement unbiased and biased cross-validation respectively.

bw.SJ implements the methods of Sheather & Jones (1991) to select the bandwidth using pilot estimation of derivatives.

Value

A bandwidth on a scale suitable for the bw argument of density.
**References**

**See Also**

`density`, `bandwidth.nrd`, `ucv`, `bcv` and `width.SJ` in package MASS, which are all scaled to the `width` argument of `density` and so give answers four times as large.

**Examples**

```r
plot(density(precip, n = 1000))
rug(precip)
lines(density(precip, bw="nrd"), col = 2)
lines(density(precip, bw="ucv"), col = 3)
lines(density(precip, bw="bcv"), col = 4)
lines(density(precip, bw="SJ-ste"), col = 5)
lines(density(precip, bw="SJ-dpi"), col = 6)
legend(55, 0.035,
  legend = c("nrd0", "nrd", "ucv", "bcv", "SJ-ste", "SJ-dpi"),
  col = 1:6, lty = 1)
```

---

**bartlett.test**

**Bartlett Test of Homogeneity of Variances**

**Description**

Performs Bartlett’s test of the null that the variances in each of the groups (samples) are the same.

**Usage**

```r
bartlett.test(x, ...)
```

**Arguments**

- `x`: a numeric vector of data values, or a list of numeric data vectors representing the respective samples, or fitted linear model objects (inheriting from class "lm").
- `g`: a vector or factor object giving the group for the corresponding elements of `x`. Ignored if `x` is a list.

---

**Examples**

```r
plot(density(precip, n = 1000))
rug(precip)
lines(density(precip, bw="nrd"), col = 2)
lines(density(precip, bw="ucv"), col = 3)
lines(density(precip, bw="bcv"), col = 4)
lines(density(precip, bw="SJ-ste"), col = 5)
lines(density(precip, bw="SJ-dpi"), col = 6)
legend(55, 0.035,
  legend = c("nrd0", "nrd", "ucv", "bcv", "SJ-ste", "SJ-dpi"),
  col = 1:6, lty = 1)
```
formula a formula of the form lhs ~ rhs where lhs gives the data values and rhs the corresponding groups.
data an optional matrix or data frame (or similar: see model.frame) containing the variables in the formula formula. By default the variables are taken from environment(formula).
subset an optional vector specifying a subset of observations to be used.
na.action a function which indicates what should happen when the data contain NAs. Defaults to getOption("na.action").
... further arguments to be passed to or from methods.

Details

If x is a list, its elements are taken as the samples or fitted linear models to be compared for homogeneity of variances. In this case, the elements must either all be numeric data vectors or fitted linear model objects, g is ignored, and one can simply use bartlett.test(x) to perform the test. If the samples are not yet contained in a list, use bartlett.test(list(x, ...)). Otherwise, x must be a numeric data vector, and g must be a vector or factor object of the same length as x giving the group for the corresponding elements of x.

Value

A list of class "htest" containing the following components:

statistic Bartlett’s K-squared test statistic.
parameter the degrees of freedom of the approximate chi-squared distribution of the test statistic.
p.value the p-value of the test.
method the character string "Bartlett test of homogeneity of variances".
data.name a character string giving the names of the data.

References

See Also

Examples

plot(count ~ spray, data = InsectSprays)
bartlett.test(InsectSprays$count, InsectSprays$spray)
bartlett.test(count ~ spray, data = InsectSprays)
Description

Density, distribution function, quantile function and random generation for the Beta distribution with parameters `shape1` and `shape2` (and optional non-centrality parameter `ncp`).

Usage

```r
dbeta(x, shape1, shape2, ncp = 0, log = FALSE)
pbeta(q, shape1, shape2, ncp = 0, lower.tail = TRUE, log.p = FALSE)
qbeta(p, shape1, shape2, ncp = 0, lower.tail = TRUE, log.p = FALSE)
rbeta(n, shape1, shape2, ncp = 0)
```

Arguments

- `x, q` vector of quantiles.
- `p` vector of probabilities.
- `n` number of observations. If `length(n) > 1`, the length is taken to be the number required.
- `shape1, shape2` positive parameters of the Beta distribution.
- `ncp` non-centrality parameter.
- `log, log.p` logical; if TRUE, probabilities `p` are given as log(`p`).
- `lower.tail` logical; if TRUE (default), probabilities are \( P[X \leq x] \), otherwise, \( P[X > x] \).

Details

The Beta distribution with parameters `shape1 = a` and `shape2 = b` has density

\[
f(x) = \frac{\Gamma(a + b)}{\Gamma(a)\Gamma(b)}x^a(1-x)^b
\]

for \( a > 0, b > 0 \) and \( 0 \leq x \leq 1 \) where the boundary values at \( x = 0 \) or \( x = 1 \) are defined as by continuity (as limits).

The mean is \( a/(a + b) \) and the variance is \( ab/((a + b)^2(a + b + 1)) \).

`pbeta` is closely related to the incomplete beta function. As defined by Abramowitz and Stegun 6.6.1

\[
B_x(a,b) = \int_0^x t^{a-1}(1 - t)^{b-1}dt,
\]

and 6.6.2 \( I_x(a,b) = B_x(a,b)/B(a,b) \) where \( B(a,b) = B_1(a,b) \) is the Beta function (`.beta`).

\( I_x(a,b) \) is `pbeta(x, a, b)`.

The non-central Beta distribution is defined (Johnson et al, 1995, pp. 502) as the distribution of \( X/(X + Y) \) where \( X \sim \chi^2_{a}(\lambda) \) and \( Y \sim \chi^2_{b} \).
Value

dbeta gives the density, pbeta the distribution function, qbeta the quantile function, and rbeta generates random deviates.

Invalid arguments will result in return value NaN, with a warning.

Source

The central dbeta is based on a binomial probability, using code contributed by Catherine Loader (see dbinom) if either shape parameter is larger than one, otherwise directly from the definition. The non-central case is based on the derivation as a Poisson mixture of betas (Johnson et al, 1995, pp. 502–3).

The central pbeta uses a C translation of

The non-central pbeta uses a C translation of

qbeta is based on a C translation of

rbeta is based on a C translation of

Examples

x <- seq(0, 1, length=21)
dbeta(x, 1, 1)
pbeta(x, 1, 1)
binom.test

Exact Binomial Test

Description

Performs an exact test of a simple null hypothesis about the probability of success in a Bernoulli experiment.

Usage

binom.test(x, n, p = 0.5, 
alternative = c("two.sided", "less", "greater"), 
conf.level = 0.95)

Arguments

x
number of successes, or a vector of length 2 giving the numbers of successes and failures, respectively.
n
number of trials; ignored if x has length 2.
p
hypothesized probability of success.
alternative
indicates the alternative hypothesis and must be one of "two.sided", "greater" or "less". You can specify just the initial letter.
conf.level
confidence level for the returned confidence interval.

Details

Confidence intervals are obtained by a procedure first given in Clopper and Pearson (1934). This guarantees that the confidence level is at least conf.level, but in general does not give the shortest-length confidence intervals.

Value

A list with class "htest" containing the following components:

statistic
the number of successes.

parameter
the number of trials.

p.value
the p-value of the test.

conf.int
a confidence interval for the probability of success.

estimate
the estimated probability of success.

null.value
the probability of success under the null, p.

alternative
a character string describing the alternative hypothesis.

method
the character string "Exact binomial test".

data.name
a character string giving the names of the data.
References

See Also

`prop.test` for a general (approximate) test for equal or given proportions.

Examples

```r
## Under (the assumption of) simple Mendelian inheritance, a cross
## between plants of two particular genotypes produces progeny 1/4 of
## which are "dwarf" and 3/4 of which are "giant", respectively.
## In an experiment to determine if this assumption is reasonable, a
## cross results in progeny having 243 dwarf and 682 giant plants.
## If "giant" is taken as success, the null hypothesis is that \( p = \frac{3}{4} \) and the alternative that \( p \neq \frac{3}{4} \).
##
## binom.test(c(682, 243), p = 3/4)
## binom.test(682, 682 + 243, p = 3/4)  # The same.
## => Data are in agreement with the null hypothesis.
```

Binomial

**The Binomial Distribution**

Description

Density, distribution function, quantile function and random generation for the binomial distribution with parameters `size` and `prob`.

Usage

```r
dbinom(x, size, prob, log = FALSE)
pbinom(q, size, prob, lower.tail = TRUE, log.p = FALSE)
qbinom(p, size, prob, lower.tail = TRUE, log.p = FALSE)
rbinom(n, size, prob)
```

Arguments

- `x, q` vector of quantiles.
- `p` vector of probabilities.
- `n` number of observations. If `length(n) > 1`, the length is taken to be the number required.
- `size` number of trials (zero or more).
- `prob` probability of success on each trial.
- `log, log.p` logical; if TRUE, probabilities p are given as \( \log(p) \).
- `lower.tail` logical; if TRUE (default), probabilities are \( P[X \leq x] \), otherwise, \( P[X > x] \).

Binomial
Binomial

Details

The binomial distribution with \( \text{size} = n \) and \( \text{prob} = p \) has density

\[
p(x) = \binom{n}{x} p^x (1 - p)^{n-x}
\]

for \( x = 0, \ldots, n \).

If an element of \( x \) is not integer, the result of \( \text{dbinom} \) is zero, with a warning. \( p(x) \) is computed using Loader’s algorithm, see the reference below.

The quantile is defined as the smallest value \( x \) such that \( F(x) \geq p \), where \( F \) is the distribution function.

Value

\( \text{dbinom} \) gives the density, \( \text{pbinom} \) gives the distribution function, \( \text{qbinom} \) gives the quantile function and \( \text{rbinom} \) generates random deviates.

If \( \text{size} \) is not an integer, \( \text{NaN} \) is returned.

Source

For \( \text{dbinom} \) a saddle-point expansion is used: see

\( \text{pbinom} \) uses \( \text{pbeta} \).

\( \text{qbinom} \) uses the Cornish–Fisher Expansion to include a skewness correction to a normal approximation, followed by a search.

\( \text{rbinom} \) is based on

See Also

\( \text{dnbinom} \) for the negative binomial, and \( \text{dpois} \) for the Poisson distribution.

Examples

```r
# Compute P(45 < X < 55) for X Binomial(100,0.5)
sum(dbinom(46:54, 100, 0.5))

## Using "log = TRUE" for an extended range :
n <- 2000
k <- seq(0, n, by = 20)
plot (k, dbinom(k, n, pi/10, log=TRUE), type='l', ylab="log density",
     main = "\text{dbinom}(\ast, \log=\text{TRUE}) \text{ is better than} \log(\text{dbinom}(\ast))")
lines(k, log(dbinom(k, n, pi/10)), col='red', lwd=2)
## extreme points are omitted since \text{dbinom} gives 0.
mtext("\text{dbinom}(k, \log=\text{TRUE})", adj=0)
mtext("\text{extended range}", adj=0, line = -1, font=4)
mtext("\text{log(dbinom(k))}", col="red", adj=1)
```
## biplot

**Biplot of Multivariate Data**

### Description
Plot a biplot on the current graphics device.

### Usage

```r
biplot(x, ...)  # Default S3 method:
biplot(x, y, var.axes = TRUE, col, cex = rep(par("cex"), 2),
       xlabs = NULL, ylabs = NULL, expand = 1,
       xlim = NULL, ylim = NULL, arrow.len = 0.1,
       main = NULL, sub = NULL, xlab = NULL, ylab = NULL, ...)
```

### Arguments

- **x**: The biplot, a fitted object. For `biplot.default`, the first set of points (a two-column matrix), usually associated with observations.
- **y**: The second set of points (a two-column matrix), usually associated with variables.
- **var.axes**: If `TRUE` the second set of points have arrows representing them as (unscaled) axes.
- **col**: A vector of length 2 giving the colours for the first and second set of points respectively (and the corresponding axes). If a single colour is specified it will be used for both sets. If missing the default colour is looked for in the `palette`; if there it and the next colour as used, otherwise the first two colours of the palette are used.
- **cex**: The character expansion factor used for labelling the points. The labels can be of different sizes for the two sets by supplying a vector of length two.
- **xlabs**: A vector of character strings to label the first set of points: the default is to use the row dimname of `x`, or `1:n` if the dimname is `NULL`.
- **ylabs**: A vector of character strings to label the second set of points: the default is to use the row dimname of `y`, or `1:n` if the dimname is `NULL`.
- **expand**: An expansion factor to apply when plotting the second set of points relative to the first. This can be used to tweak the scaling of the two sets to a physically comparable scale.
- **arrow.len**: The length of the arrow heads on the axes plotted in `var.axes` is true. The arrow head can be suppressed by `arrow.len = 0`.
- **xlim, ylim**: Limits for the x and y axes in the units of the first set of variables.
- **main, sub, xlab, ylab, ...**: graphical parameters.
biplot.princomp

Details

A biplot is plot which aims to represent both the observations and variables of a matrix of multivariate data on the same plot. There are many variations on biplots (see the references) and perhaps the most widely used one is implemented by biplot.princomp. The function biplot.default merely provides the underlying code to plot two sets of variables on the same figure.

Graphical parameters can also be given to biplot: the size of xlabs and ylabs is controlled by cex.

Side Effects

a plot is produced on the current graphics device.

References

See Also

biplot.princomp, also for examples.

---

biplot.princomp  Biplot for Principal Components

Description

Produces a biplot (in the strict sense) from the output of princomp or prcomp.

Usage

## S3 method for class 'prcomp':
biplot(x, choices = 1:2, scale = 1, pc.biplot = FALSE, ...)

## S3 method for class 'princomp':
biplot(x, choices = 1:2, scale = 1, pc.biplot = FALSE, ...)

Arguments

x       an object of class "princomp".
choices length 2 vector specifying the components to plot. Only the default is a biplot in the strict sense.
scale   The variables are scaled by lambda ^ scale and the observations are scaled by lambda ^ (1-scale) where lambda are the singular values as computed by princomp. Normally 0 <= scale <= 1, and a warning will be issued if the specified scale is outside this range.
pc.biplot If true, use what Gabriel (1971) refers to as a "principal component biplot", with lambda = 1 and observations scaled up by sqrt(n) and variables scaled down by sqrt(n). Then inner products between variables approximate covariances and distances between observations approximate Mahalanobis distance.
...     optional arguments to be passed to biplot.default.
This is a method for the generic function `biplot`. There is considerable confusion over the precise definitions: those of the original paper, Gabriel (1971), are followed here. Gabriel and Odoroff (1990) use the same definitions, but their plots actually correspond to `pc.biplot = TRUE`.

Side Effects

A plot is produced on the current graphics device.

References

`biplot`, `princomp`.

Examples

```r
biplot(princomp(USArrests))
```

### birthday

<table>
<thead>
<tr>
<th>Probability of coincidences</th>
</tr>
</thead>
</table>

#### Description

Computes approximate answers to a generalised “birthday paradox” problem. `pbirthday` computes the probability of a coincidence and `qbirthday` computes the number of observations needed to have a specified probability of coincidence.

#### Usage

```r
qbirthday(prob = 0.5, classes = 365, coincident = 2)
pbirthday(n, classes = 365, coincident = 2)
```

#### Arguments

- `classes` How many distinct categories the people could fall into
- `prob` The desired probability of coincidence
- `n` The number of people
- `coincident` The number of people to fall in the same category

#### Details

The birthday paradox is that a very small number of people, 23, suffices to have a 50-50 chance that two of them have the same birthday. This function generalises the calculation to probabilities other than 0.5, numbers of coincident events other than 2, and numbers of classes other than 365.

This formula is approximate, as the example below shows. For `coincident=2` the exact computation is straightforward and may be preferable.
Value

qbirthday  Number of people needed for a probability prob that k of them have the same
          one out of classes equiprobable labels.

pbirthday  Probability of the specified coincidence

References

Diaconis P, Mosteller F. "Methods for studying coincidences". JASA 84:853-861

Examples

```r
## the standard version
qbirthday()
## same 4-digit PIN number
qbirthday(classes=10^4)
## 0.9 probability of three coincident birthdays
qbirthday(coincident=3, prob=0.9)
## Chance of 4 coincident birthdays in 150 people
pbirthday(150, coincident=4)
## 100 coincident birthdays in 1000 people: *very* rare:
pbirthday(1000, coincident=100)
## Accuracy compared to exact calculation
x1 <- sapply(10:100, pbirthday)
x2 <- 1 - sapply(10:100, function(n) prod((365:(365-n+1))/rep(365,n)))
par(mfrow=c(2,2))
plot(x1, x2, xlab="approximate", ylab="exact")
abline(0,1)
plot(x1, x1-x2, xlab="approximate", ylab="error")
abline(h=0)
plot(x1, x2, log="xy", xlab="approximate", ylab="exact")
abline(0,1)
plot(1-x1, 1-x2, log="xy", xlab="approximate", ylab="exact")
abline(0,1)
```

Box.test

**Box-Pierce and Ljung-Box Tests**

Description

Compute the Box–Pierce or Ljung–Box test statistic for examining the null hypothesis of independence in a given time series.

Usage

```r
Box.test(x, lag = 1, type = c("Box-Pierce", "Ljung-Box"))
```

Arguments

- `x`  a numeric vector or univariate time series.
- `lag`  the statistic will be based on lag autocorrelation coefficients.
- `type`  test to be performed: partial matching is used.
Value

A list with class "htest" containing the following components:

- **statistic** the value of the test statistic.
- **parameter** the degrees of freedom of the approximate chi-squared distribution of the test statistic.
- **p.value** the p-value of the test.
- **method** a character string indicating which type of test was performed.
- **data.name** a character string giving the name of the data.

Note

Missing values are not handled.

Author(s)

A. Trapletti

References

Examples

```r
x <- rnorm (100)
Box.test (x, lag = 1)
Box.test (x, lag = 1, type="Ljung")
```

---

C

Sets Contrasts for a Factor

Description

Sets the "contrasts" attribute for the factor.

Usage

```r
C(object, contr, how.many, ...)
```

Arguments

- **object** a factor or ordered factor
- **contr** which contrasts to use. Can be a matrix with one row for each level of the factor or a suitable function like `contr.poly` or a character string giving the name of the function
- **how.many** the number of contrasts to set, by default one less than `nlevels(object)`.
- **...** additional arguments for the function `contr`.  

cancor

Details

For compatibility with S, contr can be treatment, helmert, sum or poly (without quotes) as shorthand for contr.treatment and so on.

Value

The factor object with the "contrasts" attribute set.

References

See Also

contrasts, contr.sum, etc.

Examples

```r
## reset contrasts to defaults
options(contrasts=c("contr.treatment", "contr.poly"))
tens <- with(warpbreaks, C(tension, poly, 1))
attributes(tens)
## tension SHOULD be an ordered factor, but as it is not we can use
aov(breaks ~ wool + tens + tension, data=warpbreaks)

## show the use of ... The default contrast is contr.treatment here
summary(lm(breaks ~ wool + C(tension, base=2), data=warpbreaks))

# following on from help(esoph)
model3 <- glm(cbind(ncases, ncontrols) ~ agegp + C(tobgp, , 1) +
               C(alcgp, , 1), data = esoph, family = binomial())
summary(model3)
```

cancor

**Canonical Correlations**

Description

Compute the canonical correlations between two data matrices.

Usage

```r
cancor(x, y, xcenter = TRUE, ycenter = TRUE)
```

Arguments

- **x** numeric matrix \((n \times p_1)\), containing the x coordinates.
- **y** numeric matrix \((n \times p_2)\), containing the y coordinates.
- **xcenter** logical or numeric vector of length \(p_1\), describing any centering to be done on the x values before the analysis. If TRUE (default), subtract the column means. If FALSE, do not adjust the columns. Otherwise, a vector of values to be subtracted from the columns.
- **ycenter** analogous to xcenter, but for the y values.
The canonical correlation analysis seeks linear combinations of the $y$ variables which are well explained by linear combinations of the $x$ variables. The relationship is symmetric as 'well explained' is measured by correlations.

Value

A list containing the following components:

- **cor**: correlations.
- **xcoef**: estimated coefficients for the $x$ variables.
- **ycoef**: estimated coefficients for the $y$ variables.
- **xcenter**: the values used to adjust the $x$ variables.
- **ycenter**: the values used to adjust the $x$ variables.

References

See Also

- **qr**,
- **svd**.

Examples

```r
pop <- LifeCycleSavings[, 2:3]
oec <- LifeCycleSavings[, -(2:3)]
cancor(pop, oec)

x <- matrix(rnorm(150), 50, 3)
y <- matrix(rnorm(250), 50, 5)
(cxy <- cancor(x, y))

all(abs(cor(x %*% cxy$xcoef, y %*% cxy$ycoef)[,1:3] - diag(cxy$cor)) < 1e-15)
all(abs(cor(x %*% cxy$xcoef) - diag(3)) < 1e-15)
all(abs(cor(y %*% cxy$ycoef) - diag(5)) < 1e-15)
```

---

**Case and Variable Names of Fitted Models**

Description

Simple utilities returning (non-missing) case names, and (non-eliminated) variable names.
Usage

case.names(object, ...)  
## S3 method for class 'lm':  
case.names(object, full = FALSE, ...)

variable.names(object, ...)  
## S3 method for class 'lm':  
variable.names(object, full = FALSE, ...)

Arguments

object  
an R object, typically a fitted model.

full  
logical; if TRUE, all names (including zero weights, ...) are returned.

...  
further arguments passed to or from other methods.

Value

A character vector.

See Also

lm; further, all.names, all.vars for functions with a similar name but only slightly related purpose.

Examples

x <- 1:20  
y <- x + (x/4 - 2)^3 + rnorm(20, s=3)  
names(y) <- paste("O",x,sep=".")  
ww <- rep(1,20); ww[13] <- 0  
summary(lmxy <- lm(y ~ x + I(x^2)+I(x^3) + I((x-10)^2),  
                      weights = ww), cor = TRUE)  
variable.names(lmxy)  
variable.names(lmxy, full= TRUE)# includes the last  
case.names(lmxy)  
case.names(lmxy, full = TRUE)# includes the 0-weight case

---

Cauchy

The Cauchy Distribution

Description

Density, distribution function, quantile function and random generation for the Cauchy distribution with location parameter location and scale parameter scale.

Usage

dcauchy(x, location = 0, scale = 1, log = FALSE)  
pcauchy(q, location = 0, scale = 1, lower.tail = TRUE, log.p = FALSE)  
qcauchy(p, location = 0, scale = 1, lower.tail = TRUE, log.p = FALSE)  
rcauchy(n, location = 0, scale = 1)
Arguments

\(x, q\)  vector of quantiles.
\(p\)  vector of probabilities.
\(n\)  number of observations. If length\((n) > 1\), the length is taken to be the number required.
location, scale

location and scale parameters.
log, log.p  logical; if TRUE, probabilities p are given as log(p).
lower.tail  logical; if TRUE (default), probabilities are \(P[X \leq x]\), otherwise, \(P[X > x]\).

Details

If location or scale are not specified, they assume the default values of 0 and 1 respectively.

The Cauchy distribution with location \(l\) and scale \(s\) has density

\[ f(x) = \frac{1}{\pi s} \left( 1 + \left( \frac{x - l}{s} \right)^2 \right)^{-1} \]

for all \(x\).

Value
dcauchy, pcauchy, and qcauchy are respectively the density, distribution function and quantile function of the Cauchy distribution. rcauchy generates random deviates from the Cauchy.

Source
dcauchy, pcauchy and qcauchy are all calculated from numerically stable versions of the definitions.
rcauchy uses inversion.

References

See Also
dt for the t distribution which generalizes dcauchy(*, l = 0, s = 1).

Examples
dcauchy(-1:4)
chisq.test

Pearson’s Chi-squared Test for Count Data

Description

chisq.test performs chi-squared contingency table tests and goodness-of-fit tests.

Usage

chisq.test(x, y = NULL, correct = TRUE, 
            p = rep(1/length(x), length(x)), rescale.p = FALSE, 
            simulate.p.value = FALSE, B = 2000)

Arguments

  x               a vector or matrix.
  y               a vector; ignored if x is a matrix.
  correct         a logical indicating whether to apply continuity correction when computing the
                  test statistic for 2x2 tables: one half is subtracted from all |O - E| differences.
                  No correction is done if simulate.p.value = TRUE.
  p               a vector of probabilities of the same length of x. An error is given if any entry
                  of p is negative.
  rescale.p       a logical scalar; if TRUE then p is rescaled (if necessary) to sum to 1. If
                  rescale.p is FALSE, and p does not sum to 1, an error is given.
  simulate.p.value a logical indicating whether to compute p-values by Monte Carlo simulation.
  B               an integer specifying the number of replicates used in the Monte Carlo test.

Details

If x is a matrix with one row or column, or if x is a vector and y is not given, then a “goodness-of-fit test” is performed (“x is treated as a one-dimensional contingency table”). The entries of x must be non-negative integers. In this case, the hypothesis tested is whether the population probabilities equal those in p, or are all equal if p is not given.

If x is a matrix with at least two rows and columns, it is taken as a two-dimensional contingency table. Again, the entries of x must be non-negative integers. Otherwise, x and y must be vectors or factors of the same length; incomplete cases are removed, the objects are coerced into factor objects, and the contingency table is computed from these. Then, Pearson’s chi-squared test of the null hypothesis that the joint distribution of the cell counts in a 2-dimensional contingency table is the product of the row and column marginals is performed.

If simulate.p.value is FALSE, the p-value is computed from the asymptotic chi-squared distribution of the test statistic; continuity correction is only used in the 2-by-2 case (if correct is TRUE, the default). Otherwise the p-value is computed for a Monte Carlo test (Hope, 1968) with B replicates.

In the contingency table case simulation is done by random sampling from the set of all contingency tables with given marginals, and works only if the marginals are strictly positive. (A C translation of the algorithm of Patefield (1981) is used.) Continuity correction is never used, and the statistic is quoted without it. Note that this is not the usual sampling situation for the chi-squared test but rather that for Fisher’s exact test.
In the goodness-of-fit case simulation is done by random sampling from the discrete distribution specified by \( p \), each sample being of size \( n = \text{sum}(x) \). This simulation is done in \( R \) and may be slow.

**Value**

A list with class "htest" containing the following components:

- **statistic** \( \) the value the chi-squared test statistic.
- **parameter** \( \) the degrees of freedom of the approximate chi-squared distribution of the test statistic, \( \text{NA} \) if the p-value is computed by Monte Carlo simulation.
- **p.value** \( \) the p-value for the test.
- **method** \( \) a character string indicating the type of test performed, and whether Monte Carlo simulation or continuity correction was used.
- **data.name** \( \) a character string giving the name(s) of the data.
- **observed** \( \) the observed counts.
- **expected** \( \) the expected counts under the null hypothesis.
- **residuals** \( \) the Pearson residuals, \( \frac{(\text{observed} - \text{expected})}{\sqrt{\text{expected}}} \).

**References**

**Examples**

```r
## Not really a good example
chisq.test(InsectSprays$count > 7, InsectSprays$spray) # Prints test summary
chisq.test(InsectSprays$count > 7, InsectSprays$spray)$obs # Counts observed
chisq.test(InsectSprays$count > 7, InsectSprays$spray)$exp # Counts expected under the null hypothesis.

## Effect of simulating p-values
x <- matrix(c(12, 5, 7, 7), nc = 2)
chisq.test(x)$p.value # 0.4233
chisq.test(x, simulate.p.value = TRUE, B = 10000)$p.value # around 0.29!

## Testing for population probabilities
## Case A. Tabulated data
x <- c(A = 20, B = 15, C = 25)
chisq.test(x)
chisq.test(as.table(x)) # the same
x <- c(89,37,30,28,2)
p <- c(40,20,20,15,5)
try{
  chisq.test(x, p = p) # gives an error
}
```
```r
chisq.test(x, p = p, rescale.p = TRUE)
# works
p <- c(0.40, 0.20, 0.20, 0.19, 0.01)
# Expected count in category 5
# is 1.86 < 5 ==> chi square approx.
chisq.test(x, p = p)
# maybe doubtful, but is ok!
chisq.test(x, p = p, simulate.p.value = TRUE)

## Case B. Raw data
x <- trunc(5 * runif(100))
chisq.test(table(x))
# NOT 'chisq.test(x)'
```

---

**Chisquare**

*The (non-central) Chi-Squared Distribution*

**Description**

Density, distribution function, quantile function and random generation for the chi-squared ($\chi^2$) distribution with `df` degrees of freedom and optional non-centrality parameter `ncp`.

**Usage**

```r
dchisq(x, df, ncp=0, log = FALSE)
pchisq(q, df, ncp=0, lower.tail = TRUE, log.p = FALSE)
qchisq(p, df, ncp=0, lower.tail = TRUE, log.p = FALSE)
rchisq(n, df, ncp=0)
```

**Arguments**

- `x, q` vector of quantiles.
- `p` vector of probabilities.
- `n` number of observations. If `length(n)` > 1, the length is taken to be the number required.
- `df` degrees of freedom (non-negative, but can be non-integer).
- `ncp` non-centrality parameter (non-negative).
- `log, log.p` logical; if TRUE, probabilities `p` are given as log(p).
- `lower.tail` logical; if TRUE (default), probabilities are $P[X \leq x]$, otherwise, $P[X > x]$.

**Details**

The chi-squared distribution with `df=n > 0` degrees of freedom has density

$$f_n(x) = \frac{1}{2^{n/2}\Gamma(n/2)}x^{n/2-1}e^{-x/2}$$

for $x > 0$. The mean and variance are $n$ and $2n$.

The non-central chi-squared distribution with `df=n` degrees of freedom and non-centrality parameter `ncp = \lambda` has density

$$f(x) = e^{-\lambda/2}\sum_{r=0}^{\infty} \frac{(\lambda/2)^r}{r!} f_{n+2r}(x)$$
for $x \geq 0$. For integer $n$, this is the distribution of the sum of squares of $n$ normals each with variance one, $\lambda$ being the sum of squares of the normal means; further, $E(X) = n + \lambda$, $Var(X) = 2(n + 2 \cdot \lambda)$, and $E((X - E(X))^2) = 8(n + 3 \cdot \lambda)$.

Note that the degrees of freedom $df = n$, can be non-integer, and for non-centrality $\lambda > 0$, even $n = 0$; see Johnson et al. (1995, chapter 29).

Note that ncp values larger than about 1e5 may give inaccurate results with many warnings for pchisq and qchisq.

**Value**

- `dchisq` gives the density,
- `pchisq` gives the distribution function,
- `qchisq` gives the quantile function,
- and `rchisq` generates random deviates.

Invalid arguments will result in return value NaN, with a warning.

**Source**

The central cases are computed via the gamma distribution.

The non-central `dchisq` and `rchisq` are computed as a Poisson mixture central of chi-squares (Johnson et al, 1995, p.436).

which computes the lower tail only (so the upper tail suffers from cancellation).

The non-central `qchisq` is based on inversion of `pchisq`.

**References**

**See Also**

A central chi-squared distribution with $n$ degrees of freedom is the same as a Gamma distribution with shape $\alpha = n/2$ and scale $\sigma = 2$. Hence, see `dgamma` for the Gamma distribution.

**Examples**

```r
dchisq(1, df=1:3)
pchisq(1, df= 3)
pchisq(1, df= 3, ncp = 0:4)# includes the above

x <- 1:10
## Chi-squared(df = 2) is a special exponential distribution
all.equal(dchisq(x, df=2), dexp(x, 1/2))
all.equal(pchisq(x, df=2), pexp(x, 1/2))

## non-central RNG -- df=0 is ok for ncp > 0: Z0 has point mass at 0!
Z0 <- rchisq(100, df = 0, ncp = 2.)
graphics:::stem(Z0)
```
clearNames

Remove the Names from an Object

Description

This function sets the names attribute of object to NULL and returns the object.

Usage

clearNames(object)

Arguments

object an object that may have a names attribute

Value

An object similar to object but without names.

Author(s)

Douglas Bates and Saikat DebRoy

See Also

setName

Examples

lapply( women, mean ) # has a names attribute
clearNames( lapply( women, mean ) ) # removes the names
Description

Classical multidimensional scaling of a data matrix. Also known as *principal coordinates analysis* (Gower, 1966).

Usage

```r
cmdscale(d, k = 2, eig = FALSE, add = FALSE, x.ret = FALSE)
```

Arguments

d  a distance structure such as that returned by `dist` or a full symmetric matrix containing the dissimilarities.

k  the dimension of the space which the data are to be represented in; must be in \{1, 2, ..., n - 1\}.

eig  indicates whether eigenvalues should be returned.

add  logical indicating if an additive constant $c*$ should be computed, and added to the non-diagonal dissimilarities such that all $n - 1$ eigenvalues are non-negative.

x.ret  indicates whether the doubly centred symmetric distance matrix should be returned.

Details

Multidimensional scaling takes a set of dissimilarities and returns a set of points such that the distances between the points are approximately equal to the dissimilarities.

The functions `isoMDS` and `sammon` in package `MASS` provide alternative ordination techniques.

When `add = TRUE`, an additive constant $c*$ is computed, and the dissimilarities $d_{ij} + c*$ are used instead of the original $d_{ij}$’s.

Whereas S (Becker et al., 1988) computes this constant using an approximation suggested by Torgerson, R uses the analytical solution of Cailliez (1983), see also Cox and Cox (1994).

Value

If `eig = FALSE` and `x.ret = FALSE` (default), a matrix with $k$ columns whose rows give the coordinates of the points chosen to represent the dissimilarities.

Otherwise, a list containing the following components.

points  a matrix with $k$ columns whose rows give the coordinates of the points chosen to represent the dissimilarities.

eig  the $n - 1$ eigenvalues computed during the scaling process if `eig` is true.

x  the doubly centered distance matrix if `x.ret` is true.

GOF  a numeric vector of length 2, equal to say $(g_1, g_2)$, where $g_i = (\sum_{j=1}^{k} \lambda_j)/(\sum_{j=1}^{n} T_1(\lambda_j))$, where $\lambda_j$ are the eigenvalues (sorted decreasingly), $T_1(v) = |v|$, and $T_2(v) = max(v, 0)$.
References

See Also

dist. Also isoMDS and sammon in package MASS.

Examples

```r
loc <- cmdscale(eurodist)
   x <- loc[,1]
   y <- -loc[,2]
plot(x, y, type="n", xlab="", ylab="", main="cmdscale(eurodist))"
   text(x, y, rownames(loc), cex=0.8)
cmdsE <- cmdscale(eurodist, k=20, add = TRUE, eig = TRUE, x.ret = TRUE)
   str(cmdsE)
```

ccoef

**Extract Model Coefficients**

**Description**

ccoef is a generic function which extracts model coefficients from objects returned by modeling functions. coefficients is an alias for it.

**Usage**

ccoef(object, ...)
   coefficients(object, ...)

**Arguments**

object
   an object for which the extraction of model coefficients is meaningful.

... other arguments.

**Details**

All object classes which are returned by model fitting functions should provide a coef method or use the default one. (Note that the method is for coef and not coefficients.)

Class "aov" has a coef method that does not report aliased coefficients (see alias).
Value

Coefficients extracted from the model object object.

References

See Also

*fitted.values* and *residuals* for related methods; *glm, lm* for model fitting.

Examples

\[
x <- 1:5; \text{coef(lm(c(1:3,7,6) ~ x))}
\]

---

**complete.cases**  
*Find Complete Cases*

Description

Return a logical vector indicating which cases are complete, i.e., have no missing values.

Usage

```
complete.cases(...)  
```

Arguments

...  
a sequence of vectors, matrices and data frames.

Value

A logical vector specifying which observations/rows have no missing values across the entire sequence.

See Also

*is.na, na.omit, na.fail*.

Examples

\[
x <- \text{airquality[, -1]} \# \text{x is a regression design matrix}
y <- \text{airquality[, 1]} \# \text{y is the corresponding response}
\]

\[
\text{stopifnot(complete.cases(y) != is.na(y))}
\]

\[
\text{ok <- complete.cases(x,y)}
\]

\[
\text{sum(!ok)} \# \text{how many are not "ok" ?}
\]

\[
x <- x[\text{ok,}]
y <- y[\text{ok}]
\]
**Description**

Computes confidence intervals for one or more parameters in a fitted model. There is a default and a method for objects inheriting from class "lm".

**Usage**

```r
confint(object, parm, level = 0.95, ...)
```

**Arguments**

- `object`: a fitted model object.
- `parm`: a specification of which parameters are to be given confidence intervals, either a vector of numbers or a vector of names. If missing, all parameters are considered.
- `level`: the confidence level required.
- `...`: additional argument(s) for methods.

**Details**

`confint` is a generic function. The default method assumes asymptotic normality, and needs suitable `coef` and `vcov` methods to be available. The default method can be called directly for comparison with other methods.

For objects of class "lm" the direct formulae based on t values are used.

There are stub methods for classes "glm" and "nls" which invoke those in package MASS which are based on profile likelihoods.

**Value**

A matrix (or vector) with columns giving lower and upper confidence limits for each parameter. These will be labelled as (1-level)/2 and 1 - (1-level)/2 in % (by default 2.5% and 97.5%).

**See Also**

- `confint.glm` and `confint.nls` in package MASS.

**Examples**

```r
fit <- lm(100/mpg ~ disp + hp + wt + am, data=mtcars)
confint(fit)
confint(fit, "wt")
```

```r
## from example(glm) (needs MASS to be present on the system)
counts <- c(18,17,15,20,10,20,25,13,12)
outcome <- gl(3,1,9); treatment <- gl(3,3)
glm.D93 <- glm(counts ~ outcome + treatment, family=poisson())
confint(glm.D93)
confint.default(glm.D93)  # based on asymptotic normality
```
constrOptim  

Linearly constrained optimisation

Description
Minimise a function subject to linear inequality constraints using an adaptive barrier algorithm.

Usage
constrOptim(theta, f, grad, ui, ci, mu = 1e-04, control = list(),
method = if(is.null(grad)) "Nelder-Mead" else "BFGS",
outer.iterations = 100, outer.eps = 1e-05, ...)

Arguments
theta  Starting value: must be in the feasible region.
f  Function to minimise.
grad  Gradient of f.
ui  Constraints (see below).
ci  Constraints (see below).
mu  (Small) tuning parameter.
control  Passed to optim.
method  Passed to optim.
outer.iterations  Iterations of the barrier algorithm.
outer.eps  Criterion for relative convergence of the barrier algorithm.
...  Other arguments passed to optim, which will pass them to f and grad if it does not use them.

Details
The feasible region is defined by $\mathbf{u} \mathbf{i} \%\% \mathbf{t} heta - \mathbf{c} i \geq 0$. The starting value must be in the interior of the feasible region, but the minimum may be on the boundary.

A logarithmic barrier is added to enforce the constraints and then optim is called. The barrier function is chosen so that the objective function should decrease at each outer iteration. Minima in the interior of the feasible region are typically found quite quickly, but a substantial number of outer iterations may be needed for a minimum on the boundary.

The tuning parameter $\mu$ multiplies the barrier term. Its precise value is often relatively unimportant. As $\mu$ increases the augmented objective function becomes closer to the original objective function but also less smooth near the boundary of the feasible region.

Any optim method that permits infinite values for the objective function may be used (currently all but "L-BFGS-B"). The gradient function must be supplied except with method="Nelder-Mead".

As with optim, the default is to minimise and maximisation can be performed by setting control$fnscale to a negative value.
Value

As for \texttt{optim}, but with two extra components: \texttt{barrier.value} giving the value of the barrier function at the optimum and \texttt{outer.iterations} gives the number of outer iterations (calls to \texttt{optim}).

References

K. Lange \textit{Numerical Analysis for Statisticians}. Springer 2001, p185ff

See Also

\texttt{optim}, especially method="L-BFGS-B" which does box-constrained optimisation.

Examples

```r
## from optim
fr <- function(x) { ## Rosenbrock Banana function
  x1 <- x[1]
  x2 <- x[2]
  100 * (x2 - x1 * x1)^2 + (1 - x1)^2
}
grr <- function(x) { ## Gradient of 'fr'
  x1 <- x[1]
  x2 <- x[2]
  c(-400 * x1 * (x2 - x1 * x1) - 2 * (1 - x1),
     200 * (x2 - x1 * x1))
}
optim(c(-1.2,1), fr, grr)
#Box-constraint, optimum on the boundary
constrOptim(c(-1.2,0.9), fr, grr, ui=rbind(c(-1,0),c(0,-1)), ci=c(-1,-1))
# x<=0.9, y-x>0.1
constrOptim(c(.5,0), fr, grr, ui=rbind(c(-1,0),c(1,-1)), ci=c(-0.9,0.1))

## Solves linear and quadratic programming problems
## but needs a feasible starting value
#
# from example(solve.QP) in 'quadprog'
# no derivative
fQP <- function(b) {-sum(c(0,5,0)*b)+0.5*sum(b*b)}
Amat <- matrix(c(-4,-3,0,2,1,0,0,-2,1),3,3)
bvec <- c(-8,2,0)
constrOptim(c(2,-1,-1), fQP, NULL, ui=t(Amat),ci=bvec)
# derivative
gQP <- function(b) {-c(0,5,0)+b}
constrOptim(c(2,-1,-1), fQP, gQP, ui=t(Amat), ci=bvec)

## Now with maximisation instead of minimisation
hQP <- function(b) {sum(c(0,5,0)*b)-0.5*sum(b*b)}
constrOptim(c(2,-1,-1), hQP, NULL, ui=t(Amat), ci=bvec, control=list(fnscale=-1))
```
Contrast Matrices

Description

Return a matrix of contrasts.

Usage

contr.helmert(n, contrasts = TRUE)
contr.poly(n, scores = 1:n, contrasts = TRUE)
contr.sum(n, contrasts = TRUE)
contr.treatment(n, base = 1, contrasts = TRUE)
contr.SAS(n, contrasts = TRUE)

Arguments

n a vector of levels for a factor, or the number of levels.
contrasts a logical indicating whether contrasts should be computed.
scores the set of values over which orthogonal polynomials are to be computed.
base an integer specifying which group is considered the baseline group. Ignored if contrasts is FALSE.

Details

These functions are used for creating contrast matrices for use in fitting analysis of variance and regression models. The columns of the resulting matrices contain contrasts which can be used for coding a factor with n levels. The returned value contains the computed contrasts. If the argument contrasts is FALSE a square indicator matrix (the dummy coding) is returned except for contr.poly (which include the 0-degree, i.e. constant, polynomial when contrasts = FALSE).

contr.helmert returns Helmert contrasts, which contrast the second level with the first, the third with the average of the first two, and so on. contr.poly returns contrasts based on orthogonal polynomials. contr.sum uses 'sum to zero contrasts'.

contr.treatment contrasts each level with the baseline level (specified by base); the baseline level is omitted. Note that this does not produce 'contrasts' as defined in the standard theory for linear models as they are not orthogonal to the intercept.

contr.SAS is a wrapper for contr.treatment that sets the base level to be the last level of the factor. The coefficients produced when using these contrasts should be equivalent to those produced by many (but not all) SAS procedures.

Value

A matrix with n rows and k columns, with k=n-1 if contrasts is TRUE and k=n if contrasts is FALSE.

References

See Also  
contrasts, C, and aov, glm, lm.

Examples

(cH <- contr.helmert(4))
apply(cH, 2, sum) # column sums are 0!
crossprod(cH) # diagonal -- columns are orthogonal
contr.helmert(4, contrasts = FALSE) # just the 4 x 4 identity matrix

(cT <- contr.treatment(5))
all(crossprod(cT) == diag(4)) # TRUE: even orthonormal

(cP <- contr.SAS(5))
all(crossprod(cP) == diag(4)) # TRUE: even orthonormal

(cP <- contr.poly(3)) # Linear and Quadratic
zapsmall(crossprod(cP), dig=15) # orthonormal up to fuzz

Description

Set and view the contrasts associated with a factor.

Usage

contrasts(x, contrasts = TRUE)
contrasts(x, how.many) <- value

Arguments

x            a factor or a logical variable.
contrasts    logical. See Details.
how.many     How many contrasts should be made. Defaults to one less than the number of
              levels of x. This need not be the same as the number of columns of ctr.
value        either a numeric matrix whose columns give coefficients for contrasts in the
              levels of x, or the (quoted) name of a function which computes such matrices.

Details

If contrasts are not set for a factor the default functions from options("contrasts") are used.

A logical vector x is converted into a two-level factor with levels c(FALSE, TRUE) (regardless
of which levels occur in the variable).

The argument contrasts is ignored if x has a matrix contrasts attribute set. Otherwise if
contrasts = TRUE it is passed to a contrasts function such as contr.treatment and if
contrasts = FALSE an identity matrix is returned.

C, contr.helmert, contr.poly, contr.sum, contr.treatment; glm, aov, lm.

Examples

```r
example(factor)
fff <- ff[, drop=TRUE]  # reduce to 5 levels.
contrasts(fff) # treatment contrasts by default
contrasts(C(fff, sum))
contrasts(fff, contrasts = FALSE) # the 5x5 identity matrix

contrasts(fff) <- contr.sum(5); contrasts(fff) # set sum contrasts
contrasts(fff, 2) <- contr.sum(5); contrasts(fff) # set 2 contrasts
# supply 2 contrasts, compute 2 more to make full set of 4.
contrasts(fff) <- contr.sum(5)[,1:2]; contrasts(fff)
```

convolve

**Fast Convolution**

**Description**

Use the Fast Fourier Transform to compute the several kinds of convolutions of two sequences.

**Usage**

```r
convolve(x, y, conj = TRUE, type = c("circular", "open", "filter"))
```

**Arguments**

- `x, y`: numeric sequences of the same length to be convolved.
- `conj`: logical; if TRUE, take the complex conjugate before back-transforming (default, and used for usual convolution).
- `type`: character; one of "circular", "open", "filter" (beginning of word is ok). For circular, the two sequences are treated as circular, i.e., periodic. For open and filter, the sequences are padded with 0s (from left and right) first; "filter" returns the middle sub-vector of "open", namely, the result of running a weighted mean of `x` with weights `y`.

**Details**

The Fast Fourier Transform, `fft`, is used for efficiency.

The input sequences `x` and `y` must have the same length if circular is true.

Note that the usual definition of convolution of two sequences `x` and `y` is given by `convolve(x, rev(y), type = "o")`. 

cophenetic

Value

If \( r \leftarrow \text{convolve}(x, y, \text{type} = \text{"open"}) \) and \( n \leftarrow \text{length}(x), \ m \leftarrow \text{length}(y) \), then

\[
\begin{align*}
  r_k &= \sum_i x_{k-m+i} y_i \\
\end{align*}
\]

where the sum is over all valid indices \( i \), for \( k = 1, \ldots, n + m - 1 \).

If \( \text{type} = \text{"circular"}, \ n = m \) is required, and the above is true for \( i, k = 1, \ldots, n \) when \( x_j := x_{n+j} \) for \( j < 1 \).

References

fft, nextn, and particularly filter (from the stats package) which may be more appropriate.

Examples

```r
x <- c(0, 0, 0, 100, 0, 0, 0)
y <- c(0, 0, 1, 2, 1, 0, 0)/4
zapsmall(convolve(x, y)) # *NOT* what you first thought.
zapsmall(convolve(x, y[3:5], type="f")) # rather
x <- rnorm(50)
y <- rnorm(50)
# Circular convolution *has* this symmetry:
all.equal(convolve(x, y, conj = FALSE), rev(convolve(rev(y), x)))
```

```r
n <- length(x <- -20:24)
y <- (x-10)^2/1000 + rnorm(x)/8
Han <- function(y) # Hanning
  convolve(y, c(1, 2, 1)/4, type = "filter")
plot(x, y, main="Using convolve(.) for Hanning filters")
lines(x[-c(1, n)], Han(y), col="red")
lines(x[-c(1:2, (n-1):n)], Han(Han(y)), lwd=2, col="dark blue")
```

cophenetic

*Cophenetic Distances for a Hierarchical Clustering*

Description

Computes the cophenetic distances for a hierarchical clustering.

Usage

```r
cophenetic(x)
## Default S3 method:
cophenetic(x)
## S3 method for class 'dendrogram':
cophenetic(x)
```
cophenetic

Arguments

x an R object representing a hierarchical clustering. For the default method, an object of class hclust or with a method for as.hclust() such as agnes.

Details

The cophenetic distance between two observations that have been clustered is defined to be the intergroup dissimilarity at which the two observations are first combined into a single cluster. Note that this distance has many ties and restrictions.

It can be argued that a dendrogram is an appropriate summary of some data if the correlation between the original distances and the cophenetic distances is high. Otherwise, it should simply be viewed as the description of the output of the clustering algorithm.

cophenetic is a generic function. Support for classes which represent hierarchical clusterings (total indexed hierarchies) can be added by providing an as.hclust() or, more directly, a cophenetic() method for such a class.

The method for objects of class "dendrogram" requires that all leaves of the dendrogram object have non-null labels.

Value

An object of class dist.

Examples

d1 <- dist(USArrests)
hc <- hclust(d1, "ave")
d2 <- cophenetic(hc)
cor(d1,d2) # 0.7659

## Example from Sneath & Sokal, Fig. 5-29, p.279

d0 <- c(1,3.8,4.4,5.1, 4,4.2,5, 2.6,5.3, 5.4)
attributes(d0) <- list(Size = 5, diag=TRUE)
class(d0) <- "dist"
names(d0) <- letters[1:5]
d0
str(upgma <- hclust(d0, method = "average"))
plot(upgma, hang = -1)

# (d.coph <- cophenetic(upgma))
cor(d0, d.coph) # 0.9911
Description

`var`, `cov` and `cor` compute the variance of `x` and the covariance or correlation of `x` and `y` if these are vectors. If `x` and `y` are matrices then the covariances (or correlations) between the columns of `x` and the columns of `y` are computed.

`cov2cor` scales a covariance matrix into the corresponding correlation matrix efficiently.

Usage

```r
var(x, y = NULL, na.rm = FALSE, use)
cov(x, y = NULL, use = "all.obs", method = c("pearson", "kendall", "spearman"))
cor(x, y = NULL, use = "all.obs", method = c("pearson", "kendall", "spearman"))
cov2cor(V)
```

Arguments

- `x` a numeric vector, matrix or data frame.
- `y` NULL (default) or a vector, matrix or data frame with compatible dimensions to `x`. The default is equivalent to `y = x` (but more efficient).
- `na.rm` logical. Should missing values be removed?
- `use` an optional character string giving a method for computing covariances in the presence of missing values. This must be (an abbreviation of) one of the strings "all.obs", "complete.obs" or "pairwise.complete.obs".
- `method` a character string indicating which correlation coefficient (or covariance) is to be computed. One of "pearson" (default), "kendall", or "spearman", can be abbreviated.
- `V` symmetric numeric matrix, usually positive definite such as a covariance matrix.

Details

For `cov` and `cor` one must either give a matrix or data frame for `x` or give both `x` and `y`.

`var` is just another interface to `cov`, where `na.rm` is used to determine the default for `use` when that is unspecified. If `na.rm` is TRUE then the complete observations (rows) are used (use = "complete") to compute the variance. Otherwise (use = "all"), `var` will give an error if there are missing values.

If `use` is "all.obs", then the presence of missing observations will produce an error. If `use` is "complete.obs" then missing values are handled by casewise deletion. Finally, if `use` has the value "pairwise.complete.obs" then the correlation between each pair of variables is computed using all complete pairs of observations on those variables. This can result in covariance or correlation matrices which are not positive semi-definite. "pairwise.complete.obs" only works with the "pearson" method for `cov` and `var`.

The denominator \( n - 1 \) is used which gives an unbiased estimator of the (co)variance for i.i.d. observations. These functions return \( \text{NA} \) when there is only one observation (whereas S-PLUS has been returning \( \text{NaN} \)), and fail if \( x \) has length zero.

For \( \text{cor}() \), if \text{method} is "kendall" or "spearman", Kendall's \( \tau \) or Spearman's \( \rho \) statistic is used to estimate a rank-based measure of association. These are more robust and have been recommended if the data do not necessarily come from a bivariate normal distribution.

For \( \text{cov}() \), a non-Pearson method is unusual but available for the sake of completeness. Note that "spearman" basically computes \( \text{cor}(\text{R}(x), \text{R}(y)) \) (or \( \text{cov}(.,.) \)) where \( \text{R}(u) := \text{rank}(u, \text{na.last}="\text{keep})" \). In the case of missing values, the ranks are calculated depending on the value of \text{use}, either based on complete observations, or based on pairwise completeness with reranking for each pair.

Scaling a covariance matrix into a correlation one can be achieved in many ways, mathematically most appealing by multiplication with a diagonal matrix from left and right, or more efficiently by using \( \text{sweep}(., \text{FUN} = "/") \) twice. The \( \text{cov2cor} \) function is even a bit more efficient, and provided mostly for didactical reasons.

**Value**

For \( r \leftarrow \text{cor}(\ast, \text{use} = \"\text{all.obs}\") \), it is now guaranteed that \( \text{all}(r \leq 1) \).

**References**

**See Also**

- \( \text{cor.test} \) for confidence intervals (and tests).

\quad \text{## How much do they differ?} \\
i & \leftarrow \text{lower.tri(Cl)} \\
\text{cor(cbind(P = Cl[i], S = clS[i], K = clK[i]))} \\
\quad \text{## \text{cov2cor}() scales a covariance matrix by its diagonal} \\
\quad \text{## to become the correlation matrix.}
\end{align*}
\]
**cor.test**

Test for Association/Correlation Between Paired Samples

**Description**

Test for association between paired samples, using one of Pearson’s product moment correlation coefficient, Kendall’s \( \tau \) or Spearman’s \( \rho \).

**Usage**

```r
cor.test(x, y, ...)
```

**Arguments**

- `x, y` numeric vectors of data values. `x` and `y` must have the same length.
- `alternative` indicates the alternative hypothesis and must be one of "two.sided", "greater" or "less". You can specify just the initial letter. "greater" corresponds to positive association, "less" to negative association.
- `method` a character string indicating which correlation coefficient is to be used for the test. One of "pearson", "kendall", or "spearman". can be abbreviated.
- `exact` a logical indicating whether an exact p-value should be computed. Used for Kendall’s \( \tau \) and Spearman’s \( \rho \). See the Details for the meaning of NULL (the default).
conf.level: confidence level for the returned confidence interval. Currently only used for the Pearson product moment correlation coefficient if there are at least 4 complete pairs of observations.

formula: a formula of the form \( u + v \), where each of \( u \) and \( v \) are numeric variables giving the data values for one sample. The samples must be of the same length.

data: an optional matrix or data frame (or similar: see model.frame) containing the variables in the formula formula. By default the variables are taken from environment(formula).

subset: an optional vector specifying a subset of observations to be used.

na.action: a function which indicates what should happen when the data contain NAs. Defaults to getOption("na.action").

... further arguments to be passed to or from methods.

Details

The three methods each estimate the association between paired samples and compute a test of the value being zero. They use different measures of association, all in the range \([-1, 1]\) with 0 indicating no association. These are sometimes referred to as tests of no correlation, but that term is often confined to the default method.

If method is "pearson", the test statistic is based on Pearson’s product moment correlation coefficient \( \text{cor}(x, y) \) and follows a t distribution with \( \text{length}(x)-2 \) degrees of freedom if the samples follow independent normal distributions. If there are at least 4 complete pairs of observations, an asymptotic confidence interval is given based on Fisher’s Z transform.

If method is "kendall" or "spearman", Kendall’s \( \tau \) or Spearman’s \( \rho \) statistic is used to estimate a rank-based measure of association. These tests may be used if the data do not necessarily come from a bivariate normal distribution.

For Kendall’s test, by default (if exact is NULL), an exact p-value is computed if there are less than 50 paired samples containing finite values and there are no ties. Otherwise, the test statistic is the estimate scaled to zero mean and unit variance, and is approximately normally distributed.

For Spearman’s test, p-values are computed using algorithm AS 89.

Value

A list with class "htest" containing the following components:

- statistic: the value of the test statistic.
- parameter: the degrees of freedom of the test statistic in the case that it follows a t distribution.
- p.value: the p-value of the test.
- estimate: the estimated measure of association, with name "cor", "tau", or "rho" corresponding to the method employed.
- null.value: the value of the association measure under the null hypothesis, always 0.
- alternative: a character string describing the alternative hypothesis.
- method: a character string indicating how the association was measured.
- data.name: a character string giving the names of the data.
- conf.int: a confidence interval for the measure of association. Currently only given for Pearson’s product moment correlation coefficient in case of at least 4 complete pairs of observations.
cov.wt

Weighted Covariance Matrices

Description

Returns a list containing estimates of the weighted covariance matrix and the mean of the data, and optionally of the (weighted) correlation matrix.

Usage

```r
cov.wt(x, wt = rep(1/nrow(x), nrow(x)), cor = FALSE, center = TRUE, method = c("unbiased", "ML"))
```

Arguments

- `x` a matrix or data frame. As usual, rows are observations and columns are variables.

References

Examples

```r
## Assessment of tuna quality. We compare the Hunter L measure of
## lightness to the averages of consumer panel scores (recoded as
## integer values from 1 to 6 and averaged over 80 such values) in
## 9 lots of canned tuna.

x <- c(44.4, 45.9, 41.9, 53.3, 44.7, 44.1, 50.7, 45.2, 60.1)
y <- c( 2.6,  3.1,  2.5,  5.0,  3.6,  4.0,  5.2,  2.8,  3.8)

## The alternative hypothesis of interest is that the
## Hunter L value is positively associated with the panel score.

cor.test(x, y, method = "kendall", alternative = "greater")
## => p=0.05972

cor.test(x, y, method = "kendall", alternative = "greater",
exact = FALSE) # using large sample approximation
## => p=0.04765

## Compare this to

cor.test(x, y, method = "spearman", alternative = "g")
cor.test(x, y, alternative = "g")

## Formula interface.
pairs(USJudgeRatings)
cor.test(~ CONT + INTG, data = USJudgeRatings)
```
wt  a non-negative and non-zero vector of weights for each observation. Its length must equal the number of rows of x.
cor a logical indicating whether the estimated correlation weighted matrix will be returned as well.
center either a logical or a numeric vector specifying the centers to be used when computing covariances. If TRUE, the (weighted) mean of each variable is used, if FALSE, zero is used. If center is numeric, its length must equal the number of columns of x.
method string specifying how the result is scaled, see Details below.

Details

By default, method = "unbiased", The covariance matrix is divided by one minus the sum of squares of the weights, so if the weights are the default (1/n) the conventional unbiased estimate of the covariance matrix with divisor (n – 1) is obtained. This differs from the behaviour in S-PLUS which corresponds to method = "ML" and does not divide.

Value

A list containing the following named components:
cov the estimated (weighted) covariance matrix
center an estimate for the center (mean) of the data.
n.obs the number of observations (rows) in x.
wt the weights used in the estimation. Only returned if given as an argument.
cor the estimated correlation matrix. Only returned if cor is TRUE.

See Also
cov and var.

Examples

(xy <- cbind(x = 1:10, y = c(1:3, 8:5, 8:10)))
w1 <- c(0,0,0,1,1,1,1,1,0,0)
cov.wt(xy, wt = w1) # i.e. method = "unbiased"
cov.wt(xy, wt = w1, method = "ML", cor = TRUE)

Description

Plots a cumulative periodogram.

Usage

cpgram(ts, taper = 0.1,
       main = paste("Series: ", deparse(substitute(ts))),
       ci.col = "blue")

Plot Cumulative Periodogram
**cutree**

**Arguments**

- `ts`: a univariate time series
- `taper`: proportion tapered in forming the periodogram
- `main`: main title
- `ci.col`: colour for confidence band.

**Value**

None.

**Side Effects**

Plots the cumulative periodogram in a square plot.

**Note**

From package MASS.

**Author(s)**

B.D. Ripley

**Examples**

```r
par(pty = "s", mfrow = c(1,2))
cpgram(lh)
lh.ar <- ar(lh, order.max = 9)
cpgram(lh.ar$resid, main = "AR(3) fit to lh")
cpgram(ldeaths)
```

---

**Description**

Cuts a tree, e.g., as resulting from `hclust`, into several groups either by specifying the desired number(s) of groups or the cut height(s).

**Usage**

```r
cutree(tree, k = NULL, h = NULL)
```

**Arguments**

- `tree`: a tree as produced by `hclust`. `cutree()` only expects a list with components `merge`, `height`, and `labels`, of appropriate content each.
- `k`: an integer scalar or vector with the desired number of groups
- `h`: numeric scalar or vector with heights where the tree should be cut.

At least one of `k` or `h` must be specified, `k` overrides `h` if both are given.
Value

cutree returns a vector with group memberships if \(k\) or \(h\) are scalar, otherwise a matrix with group memberships is returned where each column corresponds to the elements of \(k\) or \(h\), respectively (which are also used as column names).

References

See Also

hclust, dendrogram for cutting trees themselves.

Examples

\[
\text{hc} \leftarrow \text{hclust}(\text{dist(USArrests)})
\]

cutree(hc, \(k=1:5\)) # \(k = 1\) is trivial

cutree(hc, \(h=250\))

## Compare the 2 and 3 grouping:

g24 \leftarrow \text{cutree}(\text{hc, } k = c(2,4))

table(g24[,"2"], g24[,"4"])
Value

An object of class "decomposed.ts" with following components:

- **seasonal**: The seasonal component (i.e., the repeated seasonal figure)
- **figure**: The estimated seasonal figure only
- **trend**: The trend component
- **random**: The remainder part
- **type**: The value of type

Note

The function `stl` provides a much more sophisticated decomposition.

Author(s)

David Meyer (David.Meyer@wu-wien.ac.at)

- `stl`

Examples

```r
m <- decompose(co2)
m$figure
plot(m)
```

---

**delete.response**  *Modify Terms Objects*

Description

`delete.response` returns a `terms` object for the same model but with no response variable.

`drop.terms` removes variables from the right-hand side of the model. There is also a `\[.terms` method to perform the same function (with `keep.response=TRUE`).

`reformulate` creates a formula from a character vector.

Usage

```r
delete.response(termobj)
reformulate(termlabels, response = NULL)
drop.terms(termobj, dropx = NULL, keep.response = FALSE)
```
Arguments

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>termobj</td>
<td>A terms object</td>
</tr>
<tr>
<td>termlabels</td>
<td>character vector giving the right-hand side of a model formula. Cannot be zero-length.</td>
</tr>
<tr>
<td>response</td>
<td>character string, symbol or call giving the left-hand side of a model formula, or NULL.</td>
</tr>
<tr>
<td>dropx</td>
<td>vector of positions of variables to drop from the right-hand side of the model.</td>
</tr>
<tr>
<td>keep.response</td>
<td>Keep the response in the resulting object?</td>
</tr>
</tbody>
</table>

Value

delete.response and drop.terms return a terms object. reformulate returns a formula.

See Also

terms

Examples

```
ff <- y ~ z + x + w
tt <- terms(ff)
tt
delete.response(tt)
drop.terms(tt, 2:3, keep.response = TRUE)
tt[-1]
tt[2:3]
reformulate(attr(tt, "term.labels"))

## keep LHS :
reformulate("x*w", ff[[2]])
fs <- surv(ft, case) ~ a + b
reformulate(c("a", "b*f"), fs[[2]])

stopifnot(identical(~ var, reformulate("var")),
identical(~ a + b + c, reformulate(letters[1:3])),
identical( y ~ a + b, reformulate(letters[1:2], "y"))
)
```

dendrapply  

Apply a Function to All Nodes of a Dendrogram

Description

Apply function FUN to each node of a dendrogram recursively. When y <- dendrapply(x, fn), then y is a dendrogram of the same graph structure as x and each for each node, y.node[j] <- FUN( x.node[j], ...) (where y.node[j] is an (invalid!) notation for the j-th node of y.  

```r
dendrapply
```

Apply a Function to All Nodes of a Dendrogram

Description

Apply function FUN to each node of a dendrogram recursively. When y <- dendrapply(x, fn), then y is a dendrogram of the same graph structure as x and each for each node, y.node[j] <- FUN( x.node[j], ...) (where y.node[j] is an (invalid!) notation for the j-th node of y.
Usage

dendrapply(X, FUN, ...)

Arguments

X an object of class "dendrogram".
FUN an R function to be applied to each dendrogram node, typically working on its attributes alone, returning an altered version of the same node.
... potential further arguments passed to FUN.

Value

Usually a dendrogram of the same (graph) structure as X. For that, the function must be conceptually of the form FUN <- function(X) { attributes(X) <- ......; X }, i.e. returning the node with some attributes added or changed.

Note

this is still somewhat experimental, and suggestions for enhancements (or nice examples of usage) are very welcome.

dendrogram  General Tree Structures

Description

Class "dendrogram" provides general functions for handling tree-like structures. It is intended as a replacement for similar functions in hierarchical clustering and classification/regression trees, such that all of these can use the same engine for plotting or cutting trees.

The code is still in testing stage and the API may change in the future.

Usage

as.dendrogram(object, ...)
## S3 method for class 'hclust':
as.dendrogram(object, hang = -1, ...)

## S3 method for class 'dendrogram':
plot(x, type = c("rectangle", "triangle"),
     center = FALSE,
     edge.root = is.leaf(x) || !is.null(attr(x,"edgetext")),
     nodePar = NULL, edgePar = list(),
     leaflab = c("perpendicular", "textlike", "none"),
     dLeaf = NULL, xlab = "", ylab = "", xaxt = "n", yaxt = "s",
     horiz = FALSE, frame.plot = FALSE, ...)

## S3 method for class 'dendrogram':
cut(x, h, ...)

## S3 method for class 'dendrogram':
print(x, digits, ...)

## S3 method for class 'dendrogram':
rev(x)

## S3 method for class 'dendrogram':
str(object, max.level = NA, digits.d = 3,
     give.attr = FALSE, wid =getOption("width"),
     nest.lev = 0, indent.str = "", stem = "--", ...)

is.leaf(object)

Arguments

object  any R object that can be made into one of class "dendrogram".

x  object of class "dendrogram".

hang  numeric scalar indicating how the height of leaves should be computed from the heights of their parents; see plot.hclust.
dendrogram

- **type**: type of plot.
- **center**: logical; if TRUE, nodes are plotted centered with respect to the leaves in the branch. Otherwise (default), plot them in the middle of all direct child nodes.
- **edge.root**: logical; if true, draw an edge to the root node.
- **nodePar**: a list of plotting parameters to use for the nodes (see `points`) or NULL by default which does not draw symbols at the nodes. The list may contain components named `pch`, `cex`, `col`, and/or `bg` each of which can have length two for specifying separate attributes for inner nodes and leaves.
- **edgePar**: a list of plotting parameters to use for the edge segments and labels (if there's an `edgetext`). The list may contain components named `col`, `lty`, and `lwd` (for the segments), `p.col`, `p.lwd`, and `p.lty` (for the polygon around the text) and `t.col` for the text color. As with `nodePar`, each can have length two for differentiating leaves and inner nodes.
- **leaflab**: a string specifying how leaves are labeled. The default "perpendicular" writes text vertically (by default). "textlike" writes text horizontally (in a rectangle), and "none" suppresses leaf labels.
- **dLeaf**: a number specifying the distance in user coordinates between the tip of a leaf and its label. If NULL as per default, 3/4 of a letter width or height is used.
- **horiz**: logical indicating if the dendrogram should be drawn horizontally or not.
- **frame.plot**: logical indicating if a box around the plot should be drawn, see `plot.default`.
- **h**: height at which the tree is cut.
- **digits**: integer specifying the precision for printing, see `print.default`.
- **max.level**, `digits.d`, `give.attr`, `wid`, `nest.lev`, `indent.str` arguments to `str`, see `str.default()`. Note that `give.attr = FALSE` still shows `height` and `members` attributes for each node.
- **stem**: a string used for `str()` specifying the `stem` to use for each dendrogram branch.

### Details

Warning: This documentation is preliminary.

The dendrogram is directly represented as a nested list where each component corresponds to a branch of the tree. Hence, the first branch of tree `z` is `z[[1]]`, the second branch of the corresponding subtree is `z[[1]][[2]]` etc.. Each node of the tree carries some information needed for efficient plotting or cutting as attributes, of which only `members`, `height` and `leaf` for leaves are compulsory:

- **members**: total number of leaves in the branch
- **height**: numeric non-negative height at which the node is plotted.
- **midpoint**: numeric horizontal distance of the node from the left border (the leftmost leaf) of the branch (unit 1 between all leaves). This is used for `plot(*, center=FALSE)`.
- **label**: character; the label of the node
- **x.member**: for `cut()` $Supper$, the number of former `members`; more generally a substitute for the `members` component used for "horizontal" (when `horiz = FALSE, else "vertical") alignment.
edgetext character; the label for the edge leading to the node

nodePar a named list (of length-1 components) specifying node-specific attributes for points plotting, see the nodePar argument above.

dendrogram

eedgePar a named list (of length-1 components) specifying attributes for segments plotting of the edge leading to the node, and drawing of the edgetext if available, see the edgePar argument above.

leaf logical, if TRUE, the node is a leaf of the tree.

cut.dendrogram() returns a list with components $upper and $lower, the first is a truncated version of the original tree, also of class dendrogram, the latter a list with the branches obtained from cutting the tree, each a dendrogram.

There are [[,print, and str methods for "dendrogram" objects where the first one (extraction) ensures that selecting sub-branches keeps the class.

Objects of class "hclust" can be converted to class "dendrogram" using method as.dendrogram.

rev.dendrogram simply returns the dendrogram x with reversed nodes, see also reorder.dendrogram.

is.leaf(object) is logical indicating if object is a leaf (the most simple dendrogram).

plotNode() and plotNodeLimit() are helper functions.

Warning

Some operations on dendrograms (including plotting) make use of recursion. For very deep trees it may be necessary to increase options("expressions"): if you do you are likely to need to set the C stack size larger than the OS default if possible (which it is not on Windows).

Note

When using type = "triangle", center = TRUE often looks better.

See Also

order.dendrogram also on the labels method for dendrograms.

Examples

hc <- hclust(dist(USArrests), "ave")
dend1 <- as.dendrogram(hc)) # "print()" method
str(dend1) # "str()" method
str(dend1, max = 2) # only the first two sub-levels

op <- par(mfrow= c(2,2), mar = c(5,2,1,4))
plot(dend1)
## "triangle" type and show inner nodes:
plot(dend1, nodePar=list(pch = c(1,NA), cex=0.8, lab.cex = 0.8),
     type = "t", center=TRUE)
plot(dend1, edgePar=list(col = 1:2, lty = 2:3), dLeaf=1, edge.root = TRUE)
plot(dend1, nodePar=list(pch = 2:1,cex=.4*2:1, col = 2:3), horiz=TRUE)

dend2 <- cut(dend1, h=70)
plot(dend2$upper)
## leaves are wrong horizontally:
plot(dend2$upper, nodePar=list(pch = c(1,7), col = 2:1))
density

Kernel Density Estimation

density

Description

The (S3) generic function density computes kernel density estimates. Its default method does so with the given kernel and bandwidth for univariate observations.

Usage

density(x, ...)  

## Default S3 method:  
density(x, bw = "nrd0", adjust = 1,  
kernel = c("gaussian", "epanechnikov", "rectangular",  
"triangular", "biweight", "cosine", "optcosine"),  
weights = NULL, window = kernel, width,  
give.Rkern = FALSE,  
n = 512, from, to, cut = 3, na.rm = FALSE, ...)

Arguments

x

the data from which the estimate is to be computed.

bw

the smoothing bandwidth to be used. The kernels are scaled such that this is the standard deviation of the smoothing kernel. (Note this differs from the reference books cited below, and from S-PLUS.)

bw can also be a character string giving a rule to choose the bandwidth. See bw.nrd.

The specified (or computed) value of bw is multiplied by adjust.
adjust the bandwidth used is actually adjust*bw. This makes it easy to specify values like “half the default” bandwidth.

kernel, window

a character string giving the smoothing kernel to be used. This must be one of "gaussian", "rectangular", "triangular", "epanechnikov", "biweight", "cosine" or "optcosine", with default "gaussian", and may be abbreviated to a unique prefix (single letter).

"cosine" is smoother than "optcosine", which is the usual “cosine” kernel in the literature and almost MSE-efficient. However, "cosine" is the version used by S.

weights numeric vector of non-negative observation weights, hence of same length as x. The default NULL is equivalent to weights = rep(1/nx, nx) where nx is the length of (the finite entries of) x[].

width this exists for compatibility with S; if given, and bw is not, will set bw to width if this is a character string, or to a kernel-dependent multiple of width if this is numeric.

give.Rkern logical; if true, no density is estimated, and the “canonical bandwidth” of the chosen kernel is returned instead.

n the number of equally spaced points at which the density is to be estimated. When n > 512, it is rounded up to the next power of 2 for efficiency reasons (fft).

from,to the left and right-most points of the grid at which the density is to be estimated.

cut by default, the values of left and right are cut bandwidths beyond the extremes of the data. This allows the estimated density to drop to approximately zero at the extremes.

na.rm logical; if TRUE, missing values are removed from x. If FALSE any missing values cause an error.

... further arguments for (non-default) methods.

Details

The algorithm used in density.default disperses the mass of the empirical distribution function over a regular grid of at least 512 points and then uses the fast Fourier transform to convolve this approximation with a discretized version of the kernel and then uses linear approximation to evaluate the density at the specified points.

The statistical properties of a kernel are determined by \( \sigma_K^2 = \int t^2 K(t) dt \) which is always = 1 for our kernels (and hence the bandwidth bw is the standard deviation of the kernel) and \( R(K) = \int K^2(t) dt \).

MSE-equivalent bandwidths (for different kernels) are proportional to \( \sigma_K R(K) \) which is scale invariant and for our kernels equal to \( R(K) \). This value is returned when give.Rkern = TRUE. See the examples for using exact equivalent bandwidths.

Infinite values in x are assumed to correspond to a point mass at +/-Inf and the density estimate is of the sub-density on (-Inf, +Inf).

Value

If give.Rkern is true, the number \( R(K) \), otherwise an object with class "density" whose underlying structure is a list containing the following components.

x the n coordinates of the points where the density is estimated.
density

\[ y \]
the estimated density values. These will be non-negative, but can be zero.

\[ bw \]
the bandwidth used.

\[ n \]
the sample size after elimination of missing values.

\[ call \]
the call which produced the result.

\[ data.name \]
the deparsed name of the \( x \) argument.

\[ has.na \]
logical, for compatibility (always FALSE).

---

Symbolic and Algorithmic Derivatives of Simple Expressions

Description

Compute derivatives of simple expressions, symbolically.

Usage

D (expr, name)
deriv(expr, ...)
deriv3(expr, ...)

## Default S3 method:
deriv(expr, namevec, function.arg = NULL, tag = ".expr",
hessian = FALSE, ...)
## S3 method for class 'formula':
deriv(expr, namevec, function.arg = NULL, tag = ".expr",
hessian = FALSE, ...)

## Default S3 method:
deriv3(expr, namevec, function.arg = NULL, tag = ".expr",
hessian = TRUE, ...)
## S3 method for class 'formula':
deriv3(expr, namevec, function.arg = NULL, tag = ".expr",
hessian = TRUE, ...)

Arguments

expr A expression or call or (except D) a formula with no lhs.
name, namevec character vector, giving the variable names (only one for D()) with respect to
which derivatives will be computed.
function.arg If specified and non-NULL, a character vector of arguments for a function return,
or a function (with empty body) or TRUE, the latter indicating that a function
with argument names namevec should be used.
tag character; the prefix to be used for the locally created variables in result.
hessian a logical value indicating whether the second derivatives should be calculated
and incorporated in the return value.
...
arguments to be passed to or from methods.

Details

D is modelled after its S namesake for taking simple symbolic derivatives.
deriv is a generic function with a default and a formula method. It returns a call for computing
the expr and its (partial) derivatives, simultaneously. It uses so-called "algorithmic derivatives". If function.arg is a function, its arguments can have default values, see the fx example
below.
Currently, deriv.formula just calls deriv.default after extracting the expression to the
right of ~.
deriv3 and its methods are equivalent to deriv and its methods except that hessian defaults
to TRUE for deriv3.
The internal code knows about the arithmetic operators +, -, *, / and ^, and the single-variable
functions exp, log, sin, cos, tan, sinh, cosh, sqrt, pnorm, dnorm, asin, acos, atan,
gamma and lgamma. (Note that only the standard normal distribution is considered.)

Value

D returns a call and therefore can easily be iterated for higher derivatives.
deriv and deriv3 normally return an expression object whose evaluation returns the function
values with a "gradient" attribute containing the gradient matrix. If hessian is TRUE
the evaluation also returns a "hessian" attribute containing the Hessian array.
If `function.arg` is not `NULL`, `deriv` and `deriv3` return a function with those arguments rather than an expression.

References

See Also

`nlm` and `optim` for numeric minimization which could make use of derivatives.

Examples

```r
## formula argument :
dx2x <- deriv(~ x^2, "x") ; dx2x
## Not run:  
expression({
  .value <- x^2
  .grad <- array(0, c(length(.value), 1), list(NULL, c("x")))
  .grad[, "x"] <- 2 * x
  attr(.value, "gradient") <- .grad
  .value
})
## End(Not run)
mode(dx2x)
x <- -1:2
eval(dx2x)

## Something 'tougher':
trig.exp <- expression(sin(cos(x + y^2)))
(D.sc <- D(trig.exp, "x") )
all.equal(D(trig.exp[[[1]]], "x"), D.sc)

( dxy <- deriv(trig.exp, c("x","y")) )
y <- 1
eval(dxy)
eval(D.sc)

## function returned:
deriv(y ~ sin(cos(x) * y)), c("x","y"), func = TRUE)

## function with defaulted arguments:
(fx <- deriv(y ~ b0 + b1 * 2^(-x/th), c("b0","b1","th"),
function(b0, b1, th, x = 1:7){} ) )
fx(2,3,4)

## Higher derivatives
deriv3(y ~ b0 + b1 * 2^(-x/th), c("b0","b1","th"),
c("b0","b1","th","x") )

## Higher derivatives:
DD <- function(expr,name, order = 1) {
  if(order < 1) stop("'order' must be >= 1")
}
```

deviance

```r
if(order == 1) D(expr, name)
else DD(D(expr, name), name, order - 1)
}
```

```r
DD(expression(sin(x^2)), "x", 3)
```

## showing the limits of the internal "simplify()"

```r
-\sin(x^2) * (2 * x) * 2 + ((\cos(x^2) * (2 * x) * (2 * x) + \sin(x^2) * 2) * (2 * x) + \sin(x^2) * (2 * x) * 2)
```

## End(Not run)

---

<table>
<thead>
<tr>
<th>deviance</th>
<th>Model Deviance</th>
</tr>
</thead>
</table>

### Description

Returns the deviance of a fitted model object.

#### Usage

```r
deviance(object, ...)
```

#### Arguments

- **object**: an object for which the deviance is desired.
- **...**: additional optional argument.

#### Details

This is a generic function which can be used to extract deviances for fitted models. Consult the individual modeling functions for details on how to use this function.

#### Value

The value of the deviance extracted from the object `object`.

#### References

#### See Also

`df.residual`, `extractAIC`, `glm`, `lm`.
df.residual

**Residual Degrees-of-Freedom**

**Description**

Returns the residual degrees-of freedom extracted from a fitted model object.

**Usage**

```r
df.residual(object, ...)
```

**Arguments**

- `object`: an object for which the degrees-of freedom are desired.
- `...`: additional optional arguments.

**Details**

This is a generic function which can be used to extract residual degrees-of freedom for fitted models. Consult the individual modeling functions for details on how to use this function.

The default method just extracts the `df.residual` component.

**Value**

The value of the residual degrees-of freedom extracted from the object `x`.

**See Also**

deviance, glm, lm.

diffinv

**Discrete Integration: Inverse of Differencing**

**Description**

Computes the inverse function of the lagged differences function `diff`.

**Usage**

```r
diffinv(x, ...)
```

```r
## Default S3 method:
diffinv(x, lag = 1, differences = 1, xi, ...)
```

```r
## S3 method for class 'ts':
diffinv(x, lag = 1, differences = 1, xi, ...)
```
Arguments

- **x**: a numeric vector, matrix, or time series.
- **lag**: a scalar lag parameter.
- **differences**: an integer representing the order of the difference.
- **xi**: a numeric vector, matrix, or time series containing the initial values for the integrals. If missing, zeros are used.
- **...**: arguments passed to or from other methods.

Details

diffinv is a generic function with methods for class "ts" and default for vectors and matrices.

Missing values are not handled.

Value

A numeric vector, matrix, or time series (the latter for the "ts" method) representing the discrete integral of x.

diff

Examples

```r
s <- 1:10
d <- diff(s)
diffinv(d, xi = 1)
```

---

**dist**

*Distance Matrix Computation*

Description

This function computes and returns the distance matrix computed by using the specified distance measure to compute the distances between the rows of a data matrix.

Usage

```r
dist(x, method = "euclidean", diag = FALSE, upper = FALSE, p = 2)
```

```r
as.dist(m, diag = FALSE, upper = FALSE)
```

```r
## Default S3 method:
as.dist(m, diag = FALSE, upper = FALSE)

## S3 method for class 'dist':
```

```r
```
print(x, diag = NULL, upper = NULL,
       digits =getOption("digits"), justify = "none", right = TRUE, ...)

## S3 method for class 'dist':
as.matrix(x, ...)

Arguments

x  
a numeric matrix, data frame or "dist" object.

method  
the distance measure to be used. This must be one of "euclidean", "maximum", "manhattan", "canberra", "binary" or "minkowski". Any unambiguous substring can be given.

diag  
logical value indicating whether the diagonal of the distance matrix should be printed by print.dist.

upper  
logical value indicating whether the upper triangle of the distance matrix should be printed by print.dist.

p  
The power of the Minkowski distance.

m  
An object with distance information to be converted to a "dist" object. For the default method, a "dist" object, or a matrix (of distances) or an object which can be coerced to such a matrix using as.matrix(). (Only the lower triangle of the matrix is used, the rest is ignored).

digits, justify  
passed to format inside of print().

right, ...  
further arguments, passed to other methods.

Details

Available distance measures are (written for two vectors x and y):

euclidean: Usual square distance between the two vectors (2 norm).

maximum: Maximum distance between two components of x and y (supremum norm)

manhattan: Absolute distance between the two vectors (1 norm).

canberra: \[\sum |x_i - y_i| / |x_i + y_i|\]. Terms with zero numerator and denominator are omitted from the sum and treated as if the values were missing.

binary: (aka asymmetric binary): The vectors are regarded as binary bits, so non-zero elements are 'on' and zero elements are 'off'. The distance is the proportion of bits in which only one is on amongst those in which at least one is on.

minkowski: The p norm, the pth root of the sum of the pth powers of the differences of the components.

Missing values are allowed, and are excluded from all computations involving the rows within which they occur. Further, when Inf values are involved, all pairs of values are excluded when their contribution to the distance gave NaN or NA.

If some columns are excluded in calculating a Euclidean, Manhattan, Canberra or Minkowski distance, the sum is scaled up proportionally to the number of columns used. If all pairs are excluded when calculating a particular distance, the value is NA.

The "dist" method of as.matrix() and as.dist() can be used for conversion between objects of class "dist" and conventional distance matrices.

as.dist() is a generic function. Its default method handles objects inheriting from class "dist", or coercible to matrices using as.matrix(). Support for classes representing distances (also known as dissimilarities) can be added by providing an as.matrix() or, more directly, an as.dist method for such a class.
Value

`dist` returns an object of class "dist".

The lower triangle of the distance matrix stored by columns in a vector, say `do`. If `n` is the number of observations, i.e., `n <- attr(do, "Size")`, then for `i < j <= n`, the dissimilarity between (row) `i` and `j` is `do[n*(i-1) - i*(i-1)/2 + j-i]`. The length of the vector is `n*(n-1)/2`, i.e., of order `n^2`.

The object has the following attributes (besides "class" equal to "dist"):

- **Size**: integer, the number of observations in the dataset.
- **Labels**: optionally, contains the labels, if any, of the observations of the dataset.
- **Diag, Upper**: logicals corresponding to the arguments `diag` and `upper` above, specifying how the object should be printed.
- **call**: optionally, the `call` used to create the object.
- **method**: optionally, the distance method used; resulting from `dist()`, the `(match.arg())`ed method argument.

References

See Also

`daisy` in the `cluster` package with more possibilities in the case of mixed (continuous / categorical) variables. `hclust`.

Examples

```r
x <- matrix(rnorm(100), nrow=5)
dist(x)
dist(x, diag = TRUE)
dist(x, upper = TRUE)
m <- as.matrix(dist(x))
d <- as.dist(m)
stopifnot(d == dist(x))

## Use correlations between variables `as distance`

dd <- as.dist((1 - cor(USJudgeRatings))/2)
round(1000 * dd)  # (prints more nicely)
plot(hclust(dd))  # to see a dendrogram of clustered variables

## example of binary and canberra distances.
x <- c(0, 0, 1, 1, 1, 1)
y <- c(1, 0, 1, 1, 0, 1)
dist(rbind(x,y), method= "binary")
## answer 0.4 == 2/5

dist(rbind(x,y), method= "canberra")
## answer 2 * (6/5)
```
## To find the names
labels(eurodist)

## Examples involving "Inf" :
## 1)
x[6] <- Inf
(m2 <- rbind(x,y))
dist(m2, method="binary") # warning, answer 0.5 = 2/4
## These all give "Inf":
stopifnot(Inf == dist(m2, method= "euclidean"),
    Inf == dist(m2, method= "maximum"),
    Inf == dist(m2, method= "manhattan"))
## "Inf" is same as very large number:
x1 <- x; x1[6] <- 1e100
stopifnot(dist(cbind(x ,y), method="canberra") ==
       print(dist(cbind(x1,y), method="canberra")))

## 2)
y[6] <- Inf #-> 6-th pair is excluded
dist(rbind(x,y), method="binary") # warning; 0.5
dist(rbind(x,y), method="canberra") # 3
dist(rbind(x,y), method="maximum") # 1
dist(rbind(x,y), method="manhattan")# 2.4

dummy.coef

### Extract Coefficients in Original Coding

#### Description

This extracts coefficients in terms of the original levels of the coefficients rather than the coded variables.

#### Usage

dummy.coef(object, ...)

### S3 method for class 'lm':
dummy.coef(object, use.na = FALSE, ...)

### S3 method for class 'aovlist':
dummy.coef(object, use.na = FALSE, ...)

#### Arguments

- **object** a linear model fit.
- **use.na** logical flag for coefficients in a singular model. If use.na is true, undetermined coefficients will be missing; if false they will get one possible value.
- **...** arguments passed to or from other methods.
Details

A fitted linear model has coefficients for the contrasts of the factor terms, usually one less in number than the number of levels. This function re-expresses the coefficients in the original coding; as the coefficients will have been fitted in the reduced basis, any implied constraints (e.g., zero sum for `contr.helmert` or `contr.sum` will be respected. There will be little point in using `dummy.coef` for `contr.treatment` contrasts, as the missing coefficients are by definition zero.

The method used has some limitations, and will give incomplete results for terms such as `poly(x, 2)`). However, it is adequate for its main purpose, `aov` models.

Value

A list giving for each term the values of the coefficients. For a multistratum `aov` model, such a list for each stratum.

Warning

This function is intended for human inspection of the output: it should not be used for calculations. Use coded variables for all calculations.

The results differ from S for singular values, where S can be incorrect.

See Also

`aov`, `model.tables`

Examples

```r
options(contrasts=c("contr.helmert", "contr.poly"))
data(npk, package="MASS")
npk.aov <- aov(yield ~ block + N*P*K, npk)
dummy.coef(npk.aov)

npk.aovE <- aov(yield ~ N*P*K + Error(block), npk)
dummy.coef(npk.aovE)
```

ecdf

Empirical Cumulative Distribution Function

Description

Compute or plot an empirical cumulative distribution function.

Usage

```r
ecdf(x)
```

Examples

```r
## S3 method for class 'ecdf':
plot(x, ..., ylab="Fn(x)", verticals = FALSE, col.01line = "gray70")

## S3 method for class 'ecdf':
print(x, digits=getOption("digits") - 2, ...)
```
Arguments

- `x`: numeric vector of "observations" in `ecdf`; for the methods, an object of class "ecdf", typically.
- `...`: arguments to be passed to subsequent methods, i.e., `plot.stepfun` for the plot method.
- `ylab`: label for the y-axis.
- `verticals`: see `plot.stepfun`.
- `col.01line`: numeric or character specifying the color of the horizontal lines at y = 0 and 1, see `colors`.
- `digits`: number of significant digits to use, see `print`.

Details

The c.c.d.f. (empirical cumulative distribution function) $F_n$ is a step function with jumps $i/n$ at observation values, where $i$ is the number of tied observations at that value. Missing values are ignored.

For observations $x = (x_1, x_2, \ldots, x_n)$, $F_n$ is the fraction of observations less or equal to $t$, i.e.,

$$F_n(t) = \#\{x_i \leq t\} / n = \frac{1}{n} \sum_{i=1}^{n} 1[x_i \leq t].$$

The function `plot.ecdf` which implements the `plot` method for `ecdf` objects, is implemented via a call to `plot.stepfun`; see its documentation.

Value

For `ecdf`, a function of class "ecdf", inheriting from the "stepfun" class.

Author(s)

Martin Maechler, (maechler@stat.math.ethz.ch).
Corrections by R-core.

See Also

`stepfun`, the more general class of step functions, `approxfun` and `splinefun`.

Examples

```r
##-- Simple didactical ecdf example:
Fn <- ecdf(rnorm(12))
Fn
tt <- seq(-2,2, by = 0.1)
12* Fn(tt) # Fn is a 'simple' function {with values k/12}
summary(Fn)
knots(Fn)# the unique data values {12 of them if there were no ties}

y <- round(rnorm(12),1); y[3] <- y[1]
Fn12 <- ecdf(y)
Fn12

eff.aovlist

Compute Efficiencies of Multistratum Analysis of Variance

Description

Computes the efficiencies of fixed-effect terms in an analysis of variance model with multiple strata.

Usage

eff.aovlist(aovlist)

Arguments

aovlist The result of a call to aov with an Error term.

Details

Fixed-effect terms in an analysis of variance model with multiple strata may be estimable in more than one stratum, in which case there is less than complete information in each. The efficiency for a term is the fraction of the maximum possible precision (inverse variance) obtainable by estimating
effects

in just that stratum. Under the assumption of balance, this is the same for all contrasts involving
that term.

This function is used to pick strata in which to estimate terms in model.tables.aovlist and
se.contrast.aovlist.

In many cases terms will only occur in one stratum, when all the efficiencies will be one: this is
detected and no further calculations are done.

The calculation used requires orthogonal contrasts for each term, and will throw an error if non-
orthogonal contrasts (e.g. treatment contrasts or an unbalanced design) are detected.

Value

A matrix giving for each non-pure-error stratum (row) the efficiencies for each fixed-effect term in
the model.

References

See Also

aov, model.tables.aovlist, se.contrast.aovlist

Examples

## An example of Yates (1932), a 2^3 design in 2 blocks replicated 4 times

Block <- gl(8, 4)
A <- factor(c(0, 1, 0, 1, 0, 1, 0, 1, 0, 1, 0, 1, 0, 1, 0, 1, 0, 1, 0, 1, 0, 1, 0, 1))
B <- factor(c(0, 0, 1, 1, 0, 0, 1, 1, 0, 0, 1, 1, 0, 0, 1, 1, 0, 0, 1, 1, 0, 0, 1, 1))
C <- factor(c(0, 1, 0, 1, 0, 1, 0, 1, 0, 1, 0, 1, 0, 1, 0, 1, 0, 1, 0, 1, 0, 1, 0, 1))
Yield <- c(101, 373, 398, 291, 312, 106, 265, 450, 106, 306, 324, 449,
           272, 89, 407, 338, 87, 324, 279, 471, 323, 128, 423, 334,
           131, 103, 445, 437, 324, 361, 302, 272)
aovdat <- data.frame(Block, A, B, C, Yield)

old <- getOption("contrasts")
options(contrasts = c("contr.helmert", "contr.poly"))
(fit <- aov(Yield ~ A*B*C + Error(Block), data = aovdat))

options(contrasts = old)
effects

Usage

effects(object, ...)  
## S3 method for class 'lm':  
effects(object, set.sign = FALSE, ...)

Arguments

object an R object; typically, the result of a model fitting function such as lm.
set.sign logical. If TRUE, the sign of the effects corresponding to coefficients in the model will be set to agree with the signs of the corresponding coefficients, otherwise the sign is arbitrary.
... arguments passed to or from other methods.

Details

For a linear model fitted by lm or aov, the effects are the uncorrelated single-degree-of-freedom values obtained by projecting the data onto the successive orthogonal subspaces generated by the QR decomposition during the fitting process. The first \( r \) (the rank of the model) are associated with coefficients and the remainder span the space of residuals (but are not associated with particular residuals).

Empty models do not have effects.

Value

A (named) numeric vector of the same length as residuals, or a matrix if there were multiple responses in the fitted model, in either case of class "coef".

The first \( r \) rows are labelled by the corresponding coefficients, and the remaining rows are unlabelled. Note that in rank-deficient models the “corresponding” coefficients will be in a different order if pivoting occurred.

coeff

Examples

y <- c(1:3,7,5)
x <- c(1:3,6:7)
( ee <- effects(lm(y ~ x)) )
c(round(ee - effects(lm(y+10 ~ I(x-3.8))),3))# just the first is different
**embed**  
*Embedding a Time Series*

**Description**

Embeds the time series $x$ into a low-dimensional Euclidean space.

**Usage**

```r
embed(x, dimension = 1)
```

**Arguments**

- `x` : a numeric vector, matrix, or time series.
- `dimension` : a scalar representing the embedding dimension.

**Details**

Each row of the resulting matrix consists of sequences $x[t], x[t-1], ..., x[t-dimension+1]$, where $t$ is the original index of $x$. If $x$ is a matrix, i.e., $x$ contains more than one variable, then $x[t]$ consists of the $t$th observation on each variable.

**Value**

A matrix containing the embedded time series $x$.

**Author(s)**

A. Trapletti, B.D. Ripley

**Examples**

```r
x <- 1:10
embed(x, 3)
```

**expand.model.frame**  
*Add new variables to a model frame*

**Description**

Evaluates new variables as if they had been part of the formula of the specified model. This ensures that the same `na.action` and `subset` arguments are applied and allows, for example, $x$ to be recovered for a model using $\sin(x)$ as a predictor.

**Usage**

```r
expand.model.frame(model, extras, 
                  envir = environment(formula(model)),
                  na.expand = FALSE)
```
Exponential

Arguments

model a fitted model
eXtras one-sided formula or vector of character strings describing new variables to be added
e nvir an environment to evaluate things in
na.expand logical; see below

Details

If na.expand=FALSE then NA values in the extra variables will be passed to the na.action function used in model. This may result in a shorter data frame (with na.omit) or an error (with na.fail). If na.expand=TRUE the returned data frame will have precisely the same rows as model.frame(model), but the columns corresponding to the extra variables may contain NA.

Value

A data frame.

See Also

model.frame, predict

Examples

model <- lm(log(Volume) ~ log(Girth) + log(Height), data=trees)
expand.model.frame(model, ~ Girth) # prints data.frame like

dd <- data.frame(x=1:5, y=rnorm(5), z=c(1,2,NA,4,5))
model <- glm(y ~ x, data=dd, subset=1:4, na.action=na.omit)
expand.model.frame(model, "z", na.expand=FALSE) # = default
expand.model.frame(model, "z", na.expand=TRUE)

---

Exponential

The Exponential Distribution

Description

Density, distribution function, quantile function and random generation for the exponential distribution with rate rate (i.e., mean 1/rate).

Usage

dexp(x, rate = 1, log = FALSE)
pexp(q, rate = 1, lower.tail = TRUE, log.p = FALSE)
qexp(p, rate = 1, lower.tail = TRUE, log.p = FALSE)
rexp(n, rate = 1)
Arguments

x, q  vector of quantiles.
p  vector of probabilities.
n  number of observations. If length(n) > 1, the length is taken to be the number required.
rate  vector of rates.
log, log.p  logical; if TRUE, probabilities p are given as log(p).
lower.tail  logical; if TRUE (default), probabilities are \( P[X \leq x] \), otherwise, \( P[X > x] \).

Details

If rate is not specified, it assumes the default value of 1.
The exponential distribution with rate \( \lambda \) has density
\[
  f(x) = \lambda e^{-\lambda x}
\]
for \( x \geq 0 \).

Value
dexp gives the density, pexp gives the distribution function, qexp gives the quantile function, and rexp generates random deviates.

Note

The cumulative hazard \( H(t) = -\log(1 - F(t)) \) is \( -\text{pexp}(t, r, \text{lower} = \text{FALSE}, \text{log} = \text{TRUE}) \).

Source
dexp, pexp and qexp are all calculated from numerically stable versions of the definitions.
rexp uses

References

See Also
dexp for the exponential function, dgamma for the gamma distribution and dweibull for the Weibull distribution, both of which generalize the exponential.

Examples

dexp(1) - exp(-1) #-> 0
extractAIC

Extract AIC from a Fitted Model

Description

Computes the (generalized) Akaike Information Criterion for a fitted parametric model.

Usage

extractAIC(fit, scale, k = 2, ...)

Arguments

fit  fitted model, usually the result of a fitter like lm.
scale optional numeric specifying the scale parameter of the model, see scale in step. Currently only used in the "lm" method, where scale specifies the estimate of the error variance, and scale = 0 indicates that it is to be estimated by maximum likelihood.
k numeric specifying the "weight" of the equivalent degrees of freedom (≡ edf) part in the AIC formula.
... further arguments (currently unused in base R).

Details

This is a generic function, with methods in base R for "aov", "coxph", "glm", "lm", "negbin" and "survreg" classes.

The criterion used is

\[ AIC = -2 \log L + k \times \text{edf}, \]

where \( L \) is the likelihood and \( \text{edf} \) the equivalent degrees of freedom (i.e., the number of free parameters for usual parametric models) of \( \text{fit} \).

For linear models with unknown scale (i.e., for \( \text{lm} \) and \( \text{aov} \)), \(-2 \log L\) is computed from the deviance and uses a different additive constant to logLik and hence AIC. If RSS denotes the (weighted) residual sum of squares then extractAIC uses for \(-2 \log L\) the formulae \( RSS/s - n \) (corresponding to Mallows’ \( C_p \)) in the case of known scale \( s \) and \( n \log(RSS/n) \) for unknown scale. AIC only handles unknown scale and uses the formula \( n \log(RSS/n) - n + n \log 2\pi - \sum \log w \) where \( w \) are the weights.

For glm fits the family’s \( \text{aic}() \) function to compute the AIC: see the note under logLik about the assumptions this makes.

\( k = 2 \) corresponds to the traditional AIC, using \( k = \log(n) \) provides the BIC (Bayesian IC) instead.

Value

A numeric vector of length 2, giving

\[ \text{edf} \] the “equivalent degrees of freedom” for the fitted model \( \text{fit} \).
\[ \text{AIC} \] the (generalized) Akaike Information Criterion for \( \text{fit} \).
Note

This function is used in `add1`, `drop1` and `step` and similar functions in package MASS from which it was adopted.

Author(s)

B. D. Ripley

Examples

```r
example(glm)
extractAIC(glm.D93)#>> 5 15.129
```

---

**factanal**

Factor Analysis

**Description**

Perform maximum-likelihood factor analysis on a covariance matrix or data matrix.

**Usage**

```r
factanal(x, factors, data = NULL, covmat = NULL, n.obs = NA,
subset, na.action,
start = NULL, scores = c("none", "regression", "Bartlett"),
rotation = "varimax", control = NULL, ...)
```

**Arguments**

- **x**: A formula or a numeric matrix or an object that can be coerced to a numeric matrix.
- **factors**: The number of factors to be fitted.
- **data**: An optional data frame (or similar: see `model.frame`), used only if `x` is a formula. By default the variables are taken from `environment(formula)`.
- **covmat**: A covariance matrix, or a covariance list as returned by `cov.wt`. Of course, correlation matrices are covariance matrices.
- **n.obs**: The number of observations, used if `covmat` is a covariance matrix.
- **subset**: A specification of the cases to be used, if `x` is used as a matrix or formula.
- **na.action**: The `na.action` to be used if `x` is used as a formula.
- **start**: NULL or a matrix of starting values, each column giving an initial set of uniquenesses.
scores Type of scores to produce, if any. The default is none, "regression" gives Thompson's scores, "Bartlett" given Bartlett's weighted least-squares scores. Partial matching allows these names to be abbreviated.

rotation character. "none" or the name of a function to be used to rotate the factors: it will be called with first argument the loadings matrix, and should return a list with component loadings giving the rotated loadings, or just the rotated loadings.

control A list of control values,

   nstart The number of starting values to be tried if start = NULL. Default 1.
   trace logical. Output tracing information? Default FALSE.
   lower The lower bound for uniquenesses during optimization. Should be > 0. Default 0.005.
   opt A list of control values to be passed to optim's control argument.
   rotate a list of additional arguments for the rotation function.

... Components of control can also be supplied as named arguments to factanal.

Details

The factor analysis model is

\[ x = \Lambda f + e \]

for a \( p \)-element row-vector \( x \), a \( p \times k \) matrix of loadings, a \( k \)-element vector of scores and a \( p \)-element vector of errors. None of the components other than \( x \) is observed, but the major restriction is that the scores be uncorrelated and of unit variance, and that the errors be independent with variances \( \Phi \), the uniquenesses. Thus factor analysis is in essence a model for the covariance matrix of \( x \),

\[ \Sigma = \Lambda'\Lambda + \Psi \]

There is still some indeterminacy in the model for it is unchanged if \( \Lambda \) is replaced by \( GA \) for any orthogonal matrix \( G \). Such matrices \( G \) are known as rotations (although the term is applied also to non-orthogonal invertible matrices).

If covmat is supplied it is used. Otherwise \( x \) is used if it is a matrix, or a formula \( x \) is used with data to construct a model matrix, and that is used to construct a covariance matrix. (It makes no sense for the formula to have a response, and all the variables must be numeric.) Once a covariance matrix is found or calculated from \( x \), it is converted to a correlation matrix for analysis. The correlation matrix is returned as component correlation of the result.

The fit is done by optimizing the log likelihood assuming multivariate normality over the uniquenesses. (The maximizing loadings for given uniquenesses can be found analytically: Lawley & Maxwell (1971, p. 27).) All the starting values supplied in start are tried in turn and the best fit obtained is used. If start = NULL then the first fit is started at the value suggested by Jöreskog (1963) and given by Lawley & Maxwell (1971, p. 31), and then control$nstart - 1 other values are tried, randomly selected as equal values of the uniquenesses.

The uniquenesses are technically constrained to lie in [0, 1], but near-zero values are problematical, and the optimization is done with a lower bound of control$lower, default 0.005 (Lawley & Maxwell, 1971, p. 32).

Scores can only be produced if a data matrix is supplied and used. The first method is the regression method of Thomson (1951), the second the weighted least squares method of Bartlett (1937, 8).
Both are estimates of the unobserved scores \( f \). Thomson’s method regresses (in the population) the unknown \( f \) on \( x \) to yield

\[
\hat{f} = \Lambda \Sigma^{-1} x
\]

and then substitutes the sample estimates of the quantities on the right-hand side. Bartlett’s method minimizes the sum of squares of standardized errors over the choice of \( f \), given (the fitted) \( \Lambda \).

If \( x \) is a formula then the standard NA-handling is applied to the scores (if requested): see \texttt{napredict}.

Value

An object of class "\texttt{factanal}" with components

- \texttt{loadings}: A matrix of loadings, one column for each factor. The factors are ordered in decreasing order of sums of squares of loadings, and given the sign that will make the sum of the loadings positive.
- \texttt{uniquenesses}: The uniquenesses computed.
- \texttt{correlation}: The correlation matrix used.
- \texttt{criteria}: The results of the optimization: the value of the negative log-likelihood and information on the iterations used.
- \texttt{factors}: The argument \texttt{factors}.
- \texttt{dof}: The number of degrees of freedom of the factor analysis model.
- \texttt{method}: The method: always "\texttt{mle}".
- \texttt{scores}: If requested, a matrix of scores. \texttt{napredict} is applied to handle the treatment of values omitted by the \texttt{na.action}.
- \texttt{n.obs}: The number of observations if available, or \texttt{NA}.
- \texttt{call}: The matched call.
- \texttt{na.action}: If relevant.
- \texttt{STATISTIC, PVAL}: The significance-test statistic and \( P \) value, if if can be computed.

Note

There are so many variations on factor analysis that it is hard to compare output from different programs. Further, the optimization in maximum likelihood factor analysis is hard, and many other examples we compared had less good fits than produced by this function. In particular, solutions which are Heywood cases (with one or more uniquenesses essentially zero) are much often common than most texts and some other programs would lead one to believe.

\section*{factor.scope}

\textit{Compute Allowed Changes in Adding to or Dropping from a Formula}

\subsection*{Description}

\texttt{add.scope} and \texttt{drop.scope} compute those terms that can be individually added to or dropped from a model while respecting the hierarchy of terms.

\subsection*{Usage}

\begin{verbatim}
add.scope(terms1, terms2)

drop.scope(terms1, terms2)

factor.scope(factor, scope)
\end{verbatim}

\subsection*{Arguments}

\texttt{terms1} the terms or formula for the base model.

\texttt{terms2} the terms or formula for the upper (\texttt{add.scope}) or lower (\texttt{drop.scope}) scope. If missing for \texttt{drop.scope} it is taken to be the null formula, so all terms (except any intercept) are candidates to be dropped.
factor

scope

the "factor" attribute of the terms of the base object.
a list with one or both components drop and add giving the "factor" attribute of the lower and upper scopes respectively.

Details

factor.scope is not intended to be called directly by users.

Value

For add.scope and drop.scope a character vector of terms labels. For factor.scope, a list with components drop and add, character vectors of terms labels.

See Also

add1, drop1, aov, lm

Examples

add.scope(~ a + b + c + a:b, ~ (a + b + c)^3)
# [1] "a:c"  "b:c"
drop.scope(~ a + b + c + a:b)
# [1] "c"  "a:b"

family

Family Objects for Models

Description

Family objects provide a convenient way to specify the details of the models used by functions such as glm. See the documentation for glm for the details on how such model fitting takes place.

Usage

family(object, ...)

binomial(link = "logit")
 gaussian(link = "identity")
 Gamma(link = "inverse")
 inverse.gaussian(link = "1/mu^2")
 poisson(link = "log")
 quasi(link = "identity", variance = "constant")
 quasibinomial(link = "logit")
 quasipoisson(link = "log")
Arguments

link

A specification for the model link function. This can be a name/expression, a literal character string, a length-one character vector or an object of class "link-glm" (provided it is not specified via one of the standard names given next).

The gaussian family accepts the links "identity", "log" and "inverse"; the binomial family the links "logit", "probit", "cauchit", (corresponding to logistic, normal and Cauchy CDFs respectively) "log" and "cloglog" (complementary log-log); the Gamma family the links "inverse", "identity" and "log"; the poisson family the links "log", "identity", and "sqrt" and the inverse.gaussian family the links "1/mu^2", "inverse", "identity" and "log".

The quasi family accepts the links "logit", "probit", "cloglog", "identity", "inverse", "log", "1/mu^2" and "sqrt", and the function power can be used to create a power link function.

variance

For all families other than quasi, the variance function is determined by the family. The quasi family will accept the literal character string (or unquoted as a name/expression) specifications "constant", "mu(1-mu)", "mu", "mu^2" and "mu^3", a length-one character vector taking one of those values, or a list containing components varfun, validmu, dev.resids, initialize and name.

object

The function family accesses the family objects which are stored within objects created by modelling functions (e.g., glm).

... further arguments passed to methods.

Details

family is a generic function with methods for classes "glm" and "lm" (the latter returning gaussian()).

The quasibinomial and quasipoisson families differ from the binomial and poisson families only in that the dispersion parameter is not fixed at one, so they can “model” over-dispersion. For the binomial case see McCullagh and Nelder (1989, pp. 124–8). Although they show that there is (under some restrictions) a model with variance proportional to mean as in the quasi-binomial model, note that glm does not compute maximum-likelihood estimates in that model. The behaviour of S is closer to the quasi-variants.

Value

An object of class "family" (which has a concise print method). This is a list with elements

family character: the family name.
link character: the link name.
linkfun function: the link.
linkinv function: the inverse of the link function.
variance function: the variance as a function of the mean.
dev.resids function giving the deviance residuals as a function of (y, mu, wt).
aic function giving the AIC value if appropriate (but NA for the quasi-families). See logLik for the assumptions made about the dispersion parameter.
mu.eta function: derivative function(eta) dμ/dη.
family

initialize expression. This needs to set up whatever data objects are needed for the family as well as n (needed for AIC in the binomial family) and mustart (see glm.

valid.mu logical function. Returns TRUE if a mean vector mu is within the domain of variance.

valid.eta logical function. Returns TRUE if a linear predictor eta is within the domain of linkinv.

Note

The link and variance arguments have rather awkward semantics for back-compatibility. The recommended way is to supply them as quoted character strings, but they can also be supplied unquoted (as names or expressions). In addition, they can also be supplied as a length-one character vector giving the name of one of the options, or as a list (for link, of class "link-glm").

This is potentially ambiguous: supplying link=logit could mean the unquoted name of a link or the value of object logit. It is interpreted if possible as the name of an allowed link, then as an object. (You can force the interpretation to always be the value of an object via logit[1].)

Author(s)

The design was inspired by S functions of the same names described in Hastie & Pregibon (1992) (except quasibinomial and quasipoisson).

References

glm, power, make.link.

Examples

nf <- gaussian() # Normal family
nf
str(nf) # internal STRucture

gf <- Gamma()
gf
str(gf)
gf$linkinv
gf$variance(-3:4) # - == (.)^2

### quasipoisson. compare with example(glm)
counts <- c(18,17,15,20,10,20,25,13,12)
outcome <- gl(3,1,9)
treatment <- gl(3,3)
d.AD <- data.frame(treatment, outcome, counts)
glm.qD93 <- glm(counts ~ outcome + treatment, family=quasipoisson())
The F Distribution

Density, distribution function, quantile function and random generation for the F distribution with
df1 and df2 degrees of freedom (and optional non-centrality parameter ncp).

Usage

df(x, df1, df2, ncp, log = FALSE)
pf(q, df1, df2, ncp, lower.tail = TRUE, log.p = FALSE)
qf(p, df1, df2, ncp, lower.tail = TRUE, log.p = FALSE)
rf(n, df1, df2, ncp)
Arguments

- \(x, q\) vector of quantiles.
- \(p\) vector of probabilities.
- \(n\) number of observations. If \(\text{length}(n) > 1\), the length is taken to be the number required.
- \(df1, df2\) degrees of freedom. \(\text{Inf}\) is allowed.
- \(ncp\) non-centrality parameter. If omitted the central F is assumed.
- \(\text{log}, \text{log.p}\) logical; if TRUE, probabilities \(p\) are given as \(\log(p)\).
- \(\text{lower.tail}\) logical; if TRUE (default), probabilities are \(P[X \leq x]\), otherwise, \(P[X > x]\).

Details

The F distribution with \(df1 = n1\) and \(df2 = n2\) degrees of freedom has density

\[
f(x) = \frac{\Gamma(n1/2 + n2/2)}{\Gamma(n1/2)\Gamma(n2/2)} \left(\frac{1}{2}\right)^{n1/2} \left(1 + \frac{n1x}{n2}\right)^{-(n1+n2)/2}
\]

for \(x > 0\).

It is the distribution of the ratio of the mean squares of \(n1\) and \(n2\) independent standard normals, and hence of the ratio of two independent chi-squared variates each divided by its degrees of freedom. Since the ratio of a normal and the root mean-square of \(m\) independent normals has a Student’s \(t\) \(m\) distribution, the square of a \(t\) \(m\) variate has a F distribution on 1 and \(m\) degrees of freedom.

The non-central F distribution is again the ratio of mean squares of independent normals of unit variance, but those in the numerator are allowed to have non-zero means and \(ncp\) is the sum of squares of the means. See Chisquare for further details on non-central distributions.

Value

- \(\text{df}\) gives the density, \(\text{pf}\) gives the distribution function \(\text{qf}\) gives the quantile function, and \(\text{rf}\) generates random deviates.

Invalid arguments will result in return value NaN, with a warning.

Source

For \(\text{df}\), and \(\text{cdf} == 0\), computed via a binomial probability, code contributed by Catherine Loader (see \texttt{dbinom}); for \(\text{cdf} \neq 0\), computed via a \texttt{dbeta}, code contributed by Peter Ruckdeschel.

For \(\text{pf}\), via \texttt{pbeta} (or for large \(df2\), via \texttt{pchisq}).

For \(\text{qf}\), via \texttt{qchisq} for large \(df2\), else via \texttt{qbeta}.

References

- \texttt{dchisq} for chi-squared and \texttt{dt} for Student’s t distributions.
Examples

```r
## the density of the square of a t_m is 2*dt(x, m)/(2*x)
# check this is the same as the density of F_{1,m}
x <- seq(0.001, 5, len=100)
all.equal(df(x^2, 1, 5), dt(x, 5)/x)

## Identity: qf(2*p - 1, 1, df)) == qt(p, df)^2) for p >= 1/2
p <- seq(1/2, .99, length=50); df <- 10
rel.err <- function(x,y) ifelse(x==y,0, abs(x-y)/mean(abs(c(x,y))))
quantile(rel.err(qf(2*p - 1, df1=1, df2=df), qt(p, df)^2), .90)# ~= 7e-9
```

fft

Fast Discrete Fourier Transform

Description

Performs the Fast Fourier Transform of an array.

Usage

```r
fft(z, inverse = FALSE)
mvfft(z, inverse = FALSE)
```

Arguments

- `z`: a real or complex array containing the values to be transformed.
- `inverse`: if `TRUE`, the unnormalized inverse transform is computed (the inverse has a + in the exponent of e, but here, we do not divide by 1/length(x)).

Value

When `z` is a vector, the value computed and returned by `fft` is the unnormalized univariate Fourier transform of the sequence of values in `z`. When `z` contains an array, `fft` computes and returns the multivariate (spatial) transform. If `inverse` is `TRUE`, the (unnormalized) inverse Fourier transform is returned, i.e., if `y <- fft(z)`, then `z` is `fft(y, inverse = TRUE) / length(y)`.

By contrast, `mvfft` takes a real or complex matrix as argument, and returns a similar shaped matrix, but with each column replaced by its discrete Fourier transform. This is useful for analyzing vector-valued series.

The FFT is fastest when the length of the series being transformed is highly composite (i.e., has many factors). If this is not the case, the transform may take a long time to compute and will use a large amount of memory.

convolve, nextn.

Examples

```r
x <- 1:4
g gasesf(x)
g gasesftt(f(x), inverse = TRUE)/length(x)
```

filter

Linear Filtering on a Time Series

Description

Applies linear filtering to a univariate time series or to each series separately of a multivariate time series.

Usage

```r
filter(x, filter, method = c("convolution", "recursive"),
sides = 2, circular = FALSE, init)
```

Arguments

- `x`: a univariate or multivariate time series.
- `filter`: a vector of filter coefficients in reverse time order (as for AR or MA coefficients).
- `method`: Either "convolution" or "recursive" (and can be abbreviated). If "convolution" a moving average is used: if "recursive" an autoregression is used.
- `sides`: for convolution filters only. If sides=1 the filter coefficients are for past values only; if sides=2 they are centred around lag 0. In this case the length of the filter should be odd, but if it is even, more of the filter is forward in time than backward.
- `circular`: for convolution filters only. If TRUE, wrap the filter around the ends of the series, otherwise assume external values are missing (NA).
- `init`: for recursive filters only. Specifies the initial values of the time series just prior to the start value, in reverse time order. The default is a set of zeros.

Details

Missing values are allowed in `x` but not in `filter` (where they would lead to missing values everywhere in the output).

Note that there is an implied coefficient 1 at lag 0 in the recursive filter, which gives

```
y_i = x_i + f_1 y_{i-1} + \cdots + f_p y_{i-p}
```

No check is made to see if recursive filter is invertible: the output may diverge if it is not.

The convolution filter is

```
y_i = f_1 x_{i+o} + \cdots + f_p x_{i+o-(p-1)}
```

where `o` is the offset: see `sides` for how it is determined.
Value

A time series object.

Note

convolve(, type="filter") uses the FFT for computations and so may be faster for long filters on univariate series, but it does not return a time series (and so the time alignment is unclear), nor does it handle missing values. filter is faster for a filter of length 100 on a series of length 1000, for example.

Examples

x <- 1:100
filter(x, rep(1, 3))
filter(x, rep(1, 3), sides = 1)
filter(x, rep(1, 3), sides = 1, circular = TRUE)
filter(presidents, rep(1,3))

Fisher's Exact Test for Count Data

Description

Performs Fisher's exact test for testing the null of independence of rows and columns in a contingency table with fixed marginals.

Usage

fisher.test(x, y = NULL, workspace = 200000, hybrid = FALSE,
control = list(), or = 1, alternative = "two.sided",
conf.int = TRUE, conf.level = 0.95,
simulate.p.value = FALSE, B = 2000)

Arguments

x
either a two-dimensional contingency table in matrix form, or a factor object.
y
a factor object: ignored if x is a matrix.
workspace
an integer specifying the size of the workspace used in the network algorithm. In units of 4 bytes. Only used for non-simulated p-values larger than 2 × 2 tables.
hybrid
a logical. Only used for larger than 2 × 2 tables, in which cases it indicated whether the exact probabilities (default) or a hybrid approximation thereof should be computed. See Details.
control
a list with named components for low level algorithm control. At present the only one used is "mult", a positive integer >= 2 with default 30 used only for larger than 2 × 2 tables. This says how many times as much space should be allocated to paths as to keys: see file 'fexact.c' in the sources of this package.
the hypothesized odds ratio. Only used in the $2 \times 2$ case.

*alternative* indicates the alternative hypothesis and must be one of "two.sided", "greater" or "less". You can specify just the initial letter. Only used in the $2 \times 2$ case.

*conf.int* logical indicating if a confidence interval should be computed (and returned).

*conf.level* confidence level for the returned confidence interval. Only used in the $2 \times 2$ case if conf.int = TRUE.

*simulate.p.value* a logical indicating whether to compute p-values by Monte Carlo simulation, in larger than $2 \times 2$ tables.

*B* an integer specifying the number of replicates used in the Monte Carlo test.

**Details**

If $x$ is a matrix, it is taken as a two-dimensional contingency table, and hence its entries should be nonnegative integers. Otherwise, both $x$ and $y$ must be vectors of the same length. Incomplete cases are removed, the vectors are coerced into factor objects, and the contingency table is computed from these.

For $2 \times 2$ cases, p-values are obtained directly using the (central or non-central) hypergeometric distribution. Otherwise, computations are based on a C version of the FORTRAN subroutine FEXACT which implements the network developed by Mehta and Patel (1986) and improved by Clarkson, Fan and Joe (1993). The FORTRAN code can be obtained from [http://www.netlib.org/toms/643](http://www.netlib.org/toms/643). Note this fails (with an error message) when the entries of the table are too large. (It transposes the table if necessary so it has no more rows than columns. One constraint is that the product of the row marginals be less than $2^{31} - 1$.)

For $2 \times 2$ tables, the null of conditional independence is equivalent to the hypothesis that the odds ratio equals one. ‘Exact’ inference can be based on observing that in general, given all marginal totals fixed, the first element of the contingency table has a non-central hypergeometric distribution with non-centrality parameter given by the odds ratio (Fisher, 1935). The alternative for a one-sided test is based on the odds ratio, so alternative = "greater" is a test of the odds ratio being bigger than or.

Two-sided tests are based on the probabilities of the tables, and take as ‘more extreme’ all tables with probabilities less than or equal to that of the observed table, the p-value being the sum of such probabilities.

For larger than $2 \times 2$ tables and hybrid = TRUE, asymptotic chi-squared probabilities are only used if the “Cochran conditions” are satisfied, that is if no cell has count zero, and more than 80% of the cells have counts at least 5.

Simulation is done conditional on the row and column marginals, and works only if the marginals are strictly positive. (A C translation of the algorithm of Patefield (1981) is used.)

**Value**

A list with class "htest" containing the following components:

- *p.value* the p-value of the test.
- *conf.int* a confidence interval for the odds ratio. Only present in the $2 \times 2$ case if argument conf.int = TRUE.
- *estimate* an estimate of the odds ratio. Note that the conditional Maximum Likelihood Estimate (MLE) rather than the unconditional MLE (the sample odds ratio) is used. Only present in the $2 \times 2$ case.
null.value  the odds ratio under the null, or. Only present in the 2 × 2 case.
alternative a character string describing the alternative hypothesis.
method     the character string "Fisher’s Exact Test for Count Data".
data.name   a character string giving the names of the data.

fitted  Extract Model Fitted Values

Description

fitted is a generic function which extracts fitted values from objects returned by modeling functions. fitted.values is an alias for it.

All object classes which are returned by model fitting functions should provide a fitted method. (Note that the generic is fitted and not fitted.values.)

Methods can make use of napredict methods to compensate for the omission of missing values. The default and nls methods do.

Usage

fitted(object, ...)
fitted.values(object, ...)

Arguments

object            an object for which the extraction of model fitted values is meaningful.
...
other arguments.

Value

Fitted values extracted from the object x.

References

See Also

coefficients, glm, lm, residuals.
**Tukey Five-Number Summaries**

**Description**

Returns Tukey’s five number summary (minimum, lower-hinge, median, upper-hinge, maximum) for the input data.

**Usage**

```r
fivenum(x, na.rm = TRUE)
```

**Arguments**

- `x`: numeric, maybe including `NA`s and `±Inf`s.
- `na.rm`: logical; if `TRUE`, all `NA` and `NaN`s are dropped, before the statistics are computed.

**Value**

A numeric vector of length 5 containing the summary information. See `boxplot.stats` for more details.

**See Also**

`IQR, boxplot.stats, median, quantile, range`.

**Examples**

```r
fivenum(c(rnorm(100),-1:1/0))
```

---

**Fligner-Killeen Test of Homogeneity of Variances**

**Description**

Performs a Fligner-Killeen (median) test of the null that the variances in each of the groups (samples) are the same.

**Usage**

```r
fligner.test(x, ...)  
```

```r
## Default S3 method:  
fligner.test(x, g, ...)  
```

```r
## S3 method for class 'formula':  
fligner.test(formula, data, subset, na.action, ...)
```

---
Arguments

- **x**: a numeric vector of data values, or a list of numeric data vectors.
- **g**: a vector or factor object giving the group for the corresponding elements of x. Ignored if x is a list.
- **formula**: a formula of the form `lhs ~ rhs` where `lhs` gives the data values and `rhs` the corresponding groups.
- **data**: an optional matrix or data frame (or similar: see `model.frame`) containing the variables in the formula `formula`. By default the variables are taken from `environment(formula)`.
- **subset**: an optional vector specifying a subset of observations to be used.
- **na.action**: a function which indicates what should happen when the data contain NA's. Defaults to `getOption("na.action")`.
- **...**: further arguments to be passed to or from methods.

Details

If x is a list, its elements are taken as the samples to be compared for homogeneity of variances, and hence have to be numeric data vectors. In this case, g is ignored, and one can simply use `fligner.test(x)` to perform the test. If the samples are not yet contained in a list, use `fligner.test(list(x, ...))`.

Otherwise, x must be a numeric data vector, and g must be a vector or factor object of the same length as x giving the group for the corresponding elements of x.

The Fligner-Killeen (median) test has been determined in a simulation study as one of the many tests for homogeneity of variances which is most robust against departures from normality, see Conover, Johnson & Johnson (1981). It is a k-sample simple linear rank which uses the ranks of the absolute values of the centered samples and weights \( a(i) = \frac{\text{qnorm}\left(\frac{1+i}{n+1}\right)}{2} \). The version implemented here uses median centering in each of the samples (F-K:med \( X^2 \) in the reference).

Value

A list of class "htest" containing the following components:

- **statistic**: the Fligner-Killeen:med \( X^2 \) test statistic.
- **parameter**: the degrees of freedom of the approximate chi-squared distribution of the test statistic.
- **p.value**: the p-value of the test.
- **method**: the character string "Fligner-Killeen test of homogeneity of variances".
- **data.name**: a character string giving the names of the data.

References

See Also

- `ansari.test` and `mood.test` for rank-based two-sample test for a difference in scale parameters; `var.test` and `bartlett.test` for parametric tests for the homogeneity of variances.
Examples

```r
plot(count ~ spray, data = InsectSprays)
fligner.test(InsectSprays$count, InsectSprays$spray)
fligner.test(count ~ spray, data = InsectSprays)
## Compare this to bartlett.test()
```

### formula

**Model Formulae**

**Description**

The generic function `formula` and its specific methods provide a way of extracting formulae which have been included in other objects.

`as.formula` is almost identical, additionally preserving attributes when `object` already inherits from "formula". The default value of the `env` argument is used only when the formula would otherwise lack an environment.

**Usage**

```r
formula(x, ...)
as.formula(object, env = parent.frame())
```

**Arguments**

- `x, object` R object.
- `...` further arguments passed to or from other methods.
- `env` the environment to associate with the result.

**Details**

The models fit by, e.g., the `lm` and `glm` functions are specified in a compact symbolic form. The `~` operator is basic in the formation of such models. An expression of the form `y ~ model` is interpreted as a specification that the response `y` is modelled by a linear predictor specified symbolically by `model`. Such a model consists of a series of terms separated by `+` operators. The terms themselves consist of variable and factor names separated by `:` operators. Such a term is interpreted as the interaction of all the variables and factors appearing in the term.

In addition to `+` and `:`, a number of other operators are useful in model formulae. The `*` operator denotes factor crossing: `a*b` interpreted as `a+b+a:b`. The `%in%` operator indicates crossing to the specified degree. For example `(a+b+c)^2` is identical to `(a+b+c)*(a+b+c)` which in turn expands to a formula containing the main effects for `a, b` and `c` together with their second-order interactions. The `%in%` operator indicates that the terms on its left are nested within those on the right. For example `a + b %in% a` expands to the formula `a + a:b`. The `-` operator removes the specified terms, so that `(a+b+c)^2 - a:b` is identical to `a + b + c + b:c + a:c`. It can also used to remove the intercept term: `y ~ x - 1` is a line through the origin. A model with no intercept can be also specified as `y ~ x + 0` or `y ~ 0 + x`.

While formulae usually involve just variable and factor names, they can also involve arithmetic expressions. The formula `log(y) ~ a + log(x)` is quite legal. When such arithmetic expressions involve operators which are also used symbolically in model formulae, there can be confusion between arithmetic and symbolic operator use.
To avoid this confusion, the function `I()` can be used to bracket those portions of a model formula where the operators are used in their arithmetic sense. For example, in the formula \( y \sim a + I(b+c) \), the term \( b+c \) is to be interpreted as the sum of \( b \) and \( c \).

Variable names can be quoted by backticks `like this` in formulae, although there is no guarantee that all code using formulae will accept such non-syntactic names.

When `formula` is called on a fitted model object, either a specific method is used (such as that for class "nls") of the default method. The default first looks for a "formula" component of the object (and evaluates it), then a "terms" component, then a `formula` parameter of the call (and evaluates its value) and finally a "formula" attribute.

**Value**

All the functions above produce an object of class "formula" which contains a symbolic model formula.

**Environments**

A formula object has an associated environment, and this environment (rather than the parent environment) is used by `model.frame` to evaluate variables that are not found in the supplied `data` argument.

Formulas created with the `~` operator use the environment in which they were created. Formulas created with `as.formula` will use the `env` argument for their environment. Pre-existing formulas extracted with `as.formula` will only have their environment changed if `env` is given explicitly.

**References**

**See Also**

`I`.

For formula manipulation: `terms` and `all.vars`; for typical use: `lm`, `glm`, and `coplot`.

**Examples**

```r
class(fo <- y ~ x1*x2) # "formula"
fo
typeof(fo)# R internal : "language"
terms(fo)

environment(fo)
environment(as.formula("y ~ x"))
environment(as.formula("y ~ x", env=new.env()))

## Create a formula for a model with a large number of variables:
xnam <- paste("x", 1:25, sep="")
(fmla <- as.formula(paste("y ~ ", paste(xnam, collapse= " "))))
```

formula.nls  

Extract Model Formula from nls Object

Description

Returns the model used to fit object.

Usage

## S3 method for class 'nls':
formula(x, ...)

Arguments

x  
an object inheriting from class "nls", representing a nonlinear least squares fit.

...  
further arguments passed to or from other methods.

Value

a formula representing the model used to obtain object.

Author(s)

Jose Pinheiro and Douglas Bates

formula(fm1)

friedman.test  

Friedman Rank Sum Test

Description

Performs a Friedman rank sum test with unreplicated blocked data.

Usage

friedman.test(y, ...)

## Default S3 method:
friedman.test(y, groups, blocks, ...)

## S3 method for class 'formula':
friedman.test(formula, data, subset, na.action, ...)
friedman.test

Arguments

- **y**: either a numeric vector of data values, or a data matrix.
- **groups**: a vector giving the group for the corresponding elements of `y` if this is a vector; ignored if `y` is a matrix. If not a factor object, it is coerced to one.
- **blocks**: a vector giving the block for the corresponding elements of `y` if this is a vector; ignored if `y` is a matrix. If not a factor object, it is coerced to one.
- **formula**: a formula of the form `a ~ b | c`, where `a`, `b` and `c` give the data values and corresponding groups and blocks, respectively.
- **data**: an optional matrix or data frame (or similar: see `model.frame`) containing the variables in the formula `formula`. By default the variables are taken from `environment(formula)`.
- **subset**: an optional vector specifying a subset of observations to be used.
- **na.action**: a function which indicates what should happen when the data contain `NA`'s. Defaults to `getOption("na.action")`.
- **...**: further arguments to be passed to or from methods.

Details

`friedman.test` can be used for analyzing unreplicated complete block designs (i.e., there is exactly one observation in `y` for each combination of levels of `groups` and `blocks`) where the normality assumption may be violated.

The null hypothesis is that apart from an effect of `blocks`, the location parameter of `y` is the same in each of the `groups`.

If `y` is a matrix, `groups` and `blocks` are obtained from the column and row indices, respectively. `NA`'s are not allowed in `groups` or `blocks`; if `y` contains `NA`'s, corresponding blocks are removed.

Value

A list with class "htest" containing the following components:

- **statistic**: the value of Friedman’s chi-squared statistic.
- **parameter**: the degrees of freedom of the approximate chi-squared distribution of the test statistic.
- **p.value**: the p-value of the test.
- **method**: the character string "Friedman rank sum test".
- **data.name**: a character string giving the names of the data.

ftable

---

FTable

Description

Create “flat” contingency tables.
Usage

ftable(x, ...)

## Default S3 method:
ftable(..., exclude = c(NA, NaN), row.vars = NULL, col.vars = NULL)

Arguments

x, ...  R objects which can be interpreted as factors (including character strings), or a
list (or data frame) whose components can be so interpreted, or a contingency
table object of class "table" or "ftable".
exclude  values to use in the exclude argument of factor when interpreting non-factor
objects.
row.vars  a vector of integers giving the numbers of the variables, or a character vector
giving the names of the variables to be used for the rows of the flat contingency
table.
col.vars  a vector of integers giving the numbers of the variables, or a character vector giv-
ing the names of the variables to be used for the columns of the flat contingency
table.

Details

ftable creates “flat” contingency tables. Similar to the usual contingency tables, these contain
the counts of each combination of the levels of the variables (factors) involved. This information
is then re-arranged as a matrix whose rows and columns correspond to unique combinations of the
levels of the row and column variables (as specified by row.vars and col.vars, respectively).
The combinations are created by looping over the variables in reverse order (so that the levels of the
“left-most” variable vary the slowest). Displaying a contingency table in this flat matrix form (via
print.ftable, the print method for objects of class "ftable") is often preferable to showing
it as a higher-dimensional array.

ftable is a generic function. Its default method, ftable.default, first creates a contingency
table in array form from all arguments except row.vars and col.vars. If the first argument
is of class "table", it represents a contingency table and is used as is; if it is a flat table of
class "ftable", the information it contains is converted to the usual array representation using
as.ftable. Otherwise, the arguments should be R objects which can be interpreted as factors
(including character strings), or a list (or data frame) whose components can be so interpreted,
which are cross-tabulated using table. Then, the arguments row.vars and col.vars are used
to collapse the contingency table into flat form. If neither of these two is given, the last variable is
used for the columns. If both are given and their union is a proper subset of all variables involved,
the other variables are summed out.

When the arguments are R expressions interpreted as factors, additional arguments will be passed
to table to control how the variable names are displayed; see the last example below.

Function ftable.formula provides a formula method for creating flat contingency tables.
There are methods for as.table and as.data.frame.

Value

ftable returns an object of class "ftable", which is a matrix with counts of each combina-
tion of the levels of variables with information on the names and levels of the (row and columns)
variables stored as attributes "row.vars" and "col.vars".
ftable.formula

See Also

ftable.formula for the formula interface (which allows a data = . argument); read.ftable for information on reading, writing and coercing flat contingency tables; table for "ordinary" cross-tabulation; xtabs for formula-based cross-tabulation.

Examples

## Start with a contingency table.
ftable(Titanic, row.vars = 1:3)
ftable(Titanic, row.vars = 1:2, col.vars = "Survived")
ftable(Titanic, row.vars = 2:1, col.vars = "Survived")

## Start with a data frame.
  x <- ftable(mtcars[c("cyl", "vs", "am", "gear")])
  x
ftable(x, row.vars = c(2, 4))

## Start with expressions, use table()'s "dnn" to change labels
ftable(mtcars$cyl, mtcars$vs, mtcars$am, mtcars$gear, row.vars = c(2, 4),
       dnn = c("Cylinders", "V/S", "Transmission", "Gears"))

ftable.formula Formula Notation for Flat Contingency Tables

Description

Produce or manipulate a flat contingency table using formula notation.

Usage

## S3 method for class 'formula':
ftable(formula, data = NULL, subset, na.action, ...)

Arguments

formulaa a formula object with both left and right hand sides specifying the column and row variables of the flat table.
dataa a data frame, list or environment (or similar: see model.frame) containing the variables to be cross-tabulated, or a contingency table (see below).
subsetan optional vector specifying a subset of observations to be used. Ignored if data is a contingency table.
na.actiona function which indicates what should happen when the data contain NAs. Ignored if data is a contingency table.
...further arguments to the default ftable method may also be passed as arguments, see ftable.default.
Details

This is a method of the generic function `ftable`.

The left and right hand side of `formula` specify the column and row variables, respectively, of the flat contingency table to be created. Only the `+` operator is allowed for combining the variables. A `.`, may be used once in the formula to indicate inclusion of all the “remaining” variables.

If `data` is an object of class "table" or an array with more than 2 dimensions, it is taken as a contingency table, and hence all entries should be nonnegative. Otherwise, if it is not a flat contingency table (i.e., an object of class "ftable"), it should be a data frame or matrix, list or environment containing the variables to be cross-tabulated. In this case, `na.action` is applied to the data to handle missing values, and, after possibly selecting a subset of the data as specified by the `subset` argument, a contingency table is computed from the variables.

The contingency table is then collapsed to a flat table, according to the row and column variables specified by `formula`.

Value

A flat contingency table which contains the counts of each combination of the levels of the variables, collapsed into a matrix for suitably displaying the counts.

Examples

Titanic

```r
x <- ftable(Survived ~ ., data = Titanic)
x
ftable(Sex ~ Class + Age, data = x)
```

GammaDist

The Gamma Distribution

Description

Density, distribution function, quantile function and random generation for the Gamma distribution with parameters `shape` and `scale`.

Usage

```r
dgamma(x, shape, rate = 1, scale = 1/rate, log = FALSE)
pgamma(q, shape, rate = 1, scale = 1/rate, lower.tail = TRUE, log.p = FALSE)
qgamma(p, shape, rate = 1, scale = 1/rate, lower.tail = TRUE, log.p = FALSE)
rgamma(n, shape, rate = 1, scale = 1/rate)
```
Arguments

\(x, q\) vector of quantiles.
\(p\) vector of probabilities.
\(n\) number of observations. If \(\text{length}(n) > 1\), the length is taken to be the number required.
\(\text{rate}\) an alternative way to specify the scale.
\(\text{shape}, \text{scale}\) shape and scale parameters. Must be strictly positive.
\(\text{log}, \text{log.p}\) logical; if \(\text{TRUE}\), probabilities/densities \(p\) are returned as \(\log(p)\).
\(\text{lower.tail}\) logical; if \(\text{TRUE}\) (default), probabilities are \(P[X \leq x]\), otherwise, \(P[X > x]\).

Details

If \(\text{scale}\) is omitted, it assumes the default value of 1.

The Gamma distribution with parameters \(\text{shape} = \alpha\) and \(\text{scale} = \sigma\) has density

\[f(x) = \frac{1}{\sigma^\alpha \Gamma(\alpha)} x^{\alpha-1} e^{-x/\sigma}\]

for \(x \geq 0\), \(\alpha > 0\) and \(\sigma > 0\). (Here \(\Gamma(\alpha)\) is the function implemented by R’s \(\text{gamma()}\) and defined in its help.)

The mean and variance are \(E(X) = \alpha \sigma\) and \(\text{Var}(X) = \alpha^2 \sigma^2\).

The cumulative hazard \(H(t) = -\log(1 - F(t))\) is \(-\text{pgamma}(t, \ldots, \text{lower} = \text{FALSE}, \text{log} = \text{TRUE})\).

Note that for smallish values of \(\text{shape}\) (and moderate scale) a large parts of the mass of the Gamma distribution is on values of \(x\) so near zero that they will be represented as zero in computer arithmetic. So \(\text{rgamma}\) can well return values which will be represented as zero. (This will also happen for very large values of \(\text{scale}\) since the actual generation is done for \(\text{scale}=1\).)

Value

d\(\text{gamma}\) gives the density, \(\text{pgamma}\) gives the distribution function, \(\text{qgamma}\) gives the quantile function, and \(\text{rgamma}\) generates random deviates.

Invalid arguments will result in return value \(\text{NaN}\), with a warning.

Note

The S parametrization is via \(\text{shape}\) and \(\text{rate}\): S has no \(\text{scale}\) parameter.

\(\text{pgamma}\) is closely related to the incomplete gamma function. As defined by Abramowitz and Stegun 6.5.1

\[P(a, x) = \frac{1}{\Gamma(a)} \int_0^x t^{a-1} e^{-t} dt\]

\(P(a, x)\) is \(\text{pgamma}(x, a)\). Other authors (for example Karl Pearson in his 1922 tables) omit the normalizing factor, defining the incomplete gamma function as \(\text{pgamma}(x, a) \ast \text{gamma}(a)\).
Source

dgamma is computed via the Poisson density, using code contributed by Catherine Loader (see dbinom).

Prior to R 2.1.0 pgamma used AS239 (Shea, 1988). It currently uses an unpublished (and not otherwise documented) algorithm ‘mainly by Morten Welinder’.

qgamma is based on a C translation of

plus a final Newton step to improve the approximation.

rgamma for shape >= 1 uses

and for 0 < shape < 1 uses

References

See Also

gamma for the gamma function, dbeta for the Beta distribution and dchisq for the chi-squared distribution which is a special case of the Gamma distribution.

Examples

```r
-log(dgamma(1:4, shape=1))
p <- (1:9)/10
pgamma(qgamma(p, shape=2), shape=2)
1 - 1/exp(qgamma(p, shape=1))
```

# even for shape = 0.001 about half the mass is on numbers
# that cannot be represented accurately (and most of those as zero)
pgamma(.Machine$double.xmin, 0.001)
pgamma(5e-324, 0.001)  # on most machines this is the smallest
# representable non-zero number

table(rgamma(1e4, 0.001) == 0)/1e4
Geometric

The Geometric Distribution

Description

Density, distribution function, quantile function and random generation for the geometric distribution with parameter prob.

Usage

dgeom(x, prob, log = FALSE)
pgeom(q, prob, lower.tail = TRUE, log.p = FALSE)
qgeom(p, prob, lower.tail = TRUE, log.p = FALSE)
rgeom(n, prob)

Arguments

x, q
vector of quantiles representing the number of failures in a sequence of Bernoulli trials before success occurs.
p
vector of probabilities.
n
number of observations. If length(n) > 1, the length is taken to be the number required.
prob
probability of success in each trial. 0 < prob <= 1.
log, log.p
logical; if TRUE, probabilities p are given as log(p).
lower.tail
logical; if TRUE (default), probabilities are P[X ≤ x], otherwise, P[X > x].

Details

The geometric distribution with prob = p has density

\[ p(x) = p(1 - p)^x \]

for \( x = 0, 1, 2, \ldots, 0 < p \leq 1. \)

If an element of x is not integer, the result of pgeom is zero, with a warning.

The quantile is defined as the smallest value \( x \) such that \( F(x) \geq p \), where \( F \) is the distribution function.

Value

dgeom gives the density, pgeom gives the distribution function, qgeom gives the quantile function, and rgeom generates random deviates.

Invalid prob will result in return value NaN, with a warning.

Source

dgeom computes via dbinom, using code contributed by Catherine Loader (see dbinom).
pgeom and qgeom are based on the closed-form formulae.
rgeom uses the derivation as an exponential mixture of Poissons, see

See Also
dnbinom for the negative binomial which generalizes the geometric distribution.

Examples

qgeom((1:9)/10, prob = .2)
Ni <- rgeom(20, prob = 1/4); table(factor(Ni, 0:max(Ni)))

getInitial

Get Initial Parameter Estimates

Description

This function evaluates initial parameter estimates for a nonlinear regression model. If data is a parameterized data frame or pframe object, its parameters attribute is returned. Otherwise the object is examined to see if it contains a call to a selfStart object whose initial attribute can be evaluated.

Usage

getInitial(object, data, ...)

Arguments

object a formula or a selfStart model that defines a nonlinear regression model
data a data frame in which the expressions in the formula or arguments to the selfStart model can be evaluated
... optional additional arguments

Value

A named numeric vector or list of starting estimates for the parameters. The construction of many selfStart models is such that these "starting" estimates are, in fact, the converged parameter estimates.

Author(s)

Jose Pinheiro and Douglas Bates

See Also

nls, selfStart, selfStart.default, selfStart.formula

Examples

PurTrt <- Puromycin[ Puromycin$state == "treated", ]
getInitial( rate ~ SSmicmen( conc, Vm, K ), PurTrt )
glm is used to fit generalized linear models, specified by giving a symbolic description of the linear predictor and a description of the error distribution.

### Usage

```r
glm(formula, family = gaussian, data, weights, subset, 
    na.action, start = NULL, etastart, mustart, 
    offset, control = glm.control(...), model = TRUE, 
    method = "glm.fit", x = FALSE, y = TRUE, contrasts = NULL, ...)

glm.fit(x, y, weights = rep(1, nobs), 
    start = NULL, etastart = NULL, mustart = NULL, 
    offset = rep(0, nobs), family = gaussian(), 
    control = glm.control(), intercept = TRUE)

## S3 method for class 'glm':
weights(object, type = c("prior", "working"), ...)
```

### Arguments

- **formula**: an object of class "formula" (or one that can be coerced to that class): a symbolic description of the model to be fitted. The details of model specification are given under Details.

- **family**: a description of the error distribution and link function to be used in the model. This can be a character string naming a family function, a family function or the result of a call to a family function. (See family for details of family functions.)

- **data**: an optional data frame, list or environment (or object coercible by `as.data.frame` to a data frame) containing the variables in the model. If not found in `data`, the variables are taken from `environment(formula)`, typically the environment from which `glm` is called.

- **weights**: an optional vector of weights to be used in the fitting process. Should be `NULL` or a numeric vector.

- **subset**: an optional vector specifying a subset of observations to be used in the fitting process.

- **na.action**: a function which indicates what should happen when the data contain NAs. The default is set by the `na.action` setting of `options`, and is `na.fail` if that is unset. The “factory-fresh” default is `na.omit`. Another possible value is `NULL`, no action. Value `na.exclude` can be useful.

- **start**: starting values for the parameters in the linear predictor.

- **etastart**: starting values for the linear predictor.

- **mustart**: starting values for the vector of means.
offset  
this can be used to specify an *a priori* known component to be included in the 
linear predictor during fitting. This should be NULL or a numeric vector of 
length either one or equal to the number of cases. One or more offset terms 
can be included in the formula instead or as well, and if both are specified their 
sum is used. See `model.offset`.

control  
a list of parameters for controlling the fitting process. See the documentation for 
glm.control for details.

model  
a logical value indicating whether *model frame* should be included as a compo- 
nent of the returned value.

method  
the method to be used in fitting the model. The default method "glm.fit" 
uses iteratively reweighted least squares (IWLS). The only current alternative is 
"model.frame" which returns the model frame and does no fitting.

x, y  
For glm: logical values indicating whether the response vector and model ma- 
trix used in the fitting process should be returned as components of the returned 
value.
For glm.fit: x is a design matrix of dimension n * p, and y is a vector of 
observations of length n.

contrasts  
an optional list. See the contrasts.arg of model.matrix.default.

object  
an object inheriting from class "glm".

type  
character, partial matching allowed. Type of weights to extract from the fitted 
model object.

intercept  
logical. Should an intercept be included in the *null* model?

...  
further arguments passed to or from other methods.

Details

A typical predictor has the form `response ~ terms` where `response` is the (numeric) re- 
sponse vector and `terms` is a series of terms which specifies a linear predictor for `response`. 
For binomial and quasibinomial families the response can also be specified as a *factor* 
(when the first level denotes failure and all others success) or as a two-column matrix with the 
columns giving the numbers of successes and failures. A terms specification of the form `first + 
second` indicates all the terms in `first` together with all the terms in `second` with duplicates 
removed. The terms in the formula will be re-ordered so that main effects come first, followed by 
the interactions, all second-order, all third-order and so on: to avoid this pass a *terms* object as the 
formula.

A specification of the form `first:second` indicates the the set of terms obtained by tak- 
ing the interactions of all terms in `first` with all terms in `second`. The specification 
`first*second` indicates the *cross* of `first` and `second`. This is the same as `first + 
second + first:second`.

glm.fit is the workhorse function.

If more than one of etastart, start and mustart is specified, the first in the list will be used. 
It is often advisable to supply starting values for a *quasi* family, and also for families with unusual 
links such as gaussian("log").

All of weights, subset, offset, etastart and mustart are evaluated in the same way as 
variables in formula, that is first in data and then in the environment of formula.
**Value**

`glm` returns an object of class inheriting from "glm" which inherits from the class "lm". See later in this section.

The function `summary` (i.e., `summary.glm`) can be used to obtain or print a summary of the results and the function `anova` (i.e., `anova.glm`) to produce an analysis of variance table.

The generic accessor functions `coefficients`, `effects`, `fitted.values` and `residuals` can be used to extract various useful features of the value returned by `glm`.

`weights` extracts a vector of weights, one for each case in the fit (after subsetting and `na.action`).

An object of class "glm" is a list containing at least the following components:

- `coefficients`: a named vector of coefficients
- `residuals`: the working residuals, that is the residuals in the final iteration of the IWLS fit. Since cases with zero weights are omitted, their working residuals are `NA`.
- `fitted.values`: the fitted mean values, obtained by transforming the linear predictors by the inverse of the link function.
- `rank`: the numeric rank of the fitted linear model.
- `family`: the `family` object used.
- `linear.predictors`: the linear fit on link scale.
- `deviance`: up to a constant, minus twice the maximized log-likelihood. Where sensible, the constant is chosen so that a saturated model has deviance zero.
- `aic`: Akaike’s *An Information Criterion*, minus twice the maximized log-likelihood plus twice the number of coefficients (so assuming that the dispersion is known).
- `null.deviance`: The deviance for the null model, comparable with `deviance`. The null model will include the offset, and an intercept if there is one in the model. Note that this will be incorrect if the link function depends on the data other than through the fitted mean: specify a zero offset to force a correct calculation.
- `iter`: the number of iterations of IWLS used.
- `weights`: the working weights, that is the weights in the final iteration of the IWLS fit.
- `prior.weights`: the case weights initially supplied.
- `df.residual`: the residual degrees of freedom.
- `df.null`: the residual degrees of freedom for the null model.
- `y`: the `y` vector used. (It is a vector even for a binomial model.)
- `converged`: logical. Was the IWLS algorithm judged to have converged?
- `boundary`: logical. Is the fitted value on the boundary of the attainable values?
- `call`: the matched call.
- `formula`: the formula supplied.
- `terms`: the `terms` object used.
- `data`: the `data` argument.
- `offset`: the offset vector used.
glm

control  the value of the control argument used.
method   the name of the fitter function used, currently always "glm.fit".
contrasts (where relevant) the contrasts used.
xlevels  (where relevant) a record of the levels of the factors used in fitting.

In addition, non-empty fits will have components qr, R and effects relating to the final weighted linear fit.

Objects of class "glm" are normally of class c("glm", "lm"), that is inherit from class "lm", and well-designed methods for class "lm" will be applied to the weighted linear model at the final iteration of IWLS. However, care is needed, as extractor functions for class "glm" such as residuals and weights do not just pick out the component of the fit with the same name.

If a binomial glm model was specified by giving a two-column response, the weights returned by prior.weights are the total numbers of cases (factored by the supplied case weights) and the component y of the result is the proportion of successes.

Author(s)

The original R implementation of glm was written by Simon Davies working for Ross Ihaka at the University of Auckland, but has since been extensively re-written by members of the R Core team.

The design was inspired by the S function of the same name described in Hastie & Pregibon (1992).

### glm.control

**Auxiliary for Controlling GLM Fitting**

**Description**

Auxiliary function as user interface for `glm` fitting. Typically only used when calling `glm` or `glm.fit`.

**Usage**

```r
glm.control(epsilon = 1e-8, maxit = 25, trace = FALSE)
```

**Arguments**

- **epsilon**: positive convergence tolerance \( \epsilon \); the iterations converge when \(|\text{dev} - \text{dev}_{\text{old}}|/(|\text{dev}| + 0.1) < \epsilon\).
- **maxit**: integer giving the maximal number of IWLS iterations.
- **trace**: logical indicating if output should be produced for each iteration.

**Details**

If `epsilon` is small, it is also used as the tolerance for the least squares solution.

When `trace` is true, calls to `cat` produce the output for each IWLS iteration. Hence, `options(digits = *)` can be used to increase the precision, see the example.

**Value**

A list with the arguments as components.
References

See Also

glm.fit, the fitting procedure used by glm.

Examples

### A variation on example(glm):

```r
## Annette Dobson's example ...
counts <- c(18,17,15,20,10,20,25,13,12)
outcome <- gl(3,1,9)
treatment <- gl(3,3)

oo <- options(digits = 12) # to see more when tracing :
glm.D93X <- glm(counts ~ outcome + treatment, family=poisson(),
                trace = TRUE, epsilon = 1e-14)

options(oo)

coef(glm.D93X) # the last two are closer to 0 than in ?glm's glm.D93
```

---

**glm.summaries**

**Accessing Generalized Linear Model Fits**

**Description**

These functions are all methods for class glm or summary.glm objects.

**Usage**

```r
## S3 method for class 'glm':
family(object, ...)

## S3 method for class 'glm':
residuals(object, type = c("deviance", "pearson", "working",
                         "response", "partial"), ...)
```

**Arguments**

- `object`: an object of class glm, typically the result of a call to glm.
- `type`: the type of residuals which should be returned. The alternatives are: "deviance" (default), "pearson", "working", "response", and "partial".
- `...`: further arguments passed to or from other methods.
Details

The references define the types of residuals: Davison & Snell is a good reference for the usages of each.

The partial residuals are a matrix of working residuals, with each column formed by omitting a term from the model.

How residuals treats cases with missing values in the original fit is determined by the na.action argument of that fit. If na.action = na.omit omitted cases will not appear in the residuals, whereas if na.action = na.exclude they will appear, with residual value NA. See also na resid.

For fits done with y = FALSE the response values are computed from other components.

References

See Also

glm for computing glm.obj. anova.glm: the corresponding generic functions,
summary.glm, coef, deviance, df.residual, effects, fitted, residuals.
influence.measures for deletion diagnostics, including standardized (rstandard) and studentized (rstudent) residuals.

hclust

Hierarchical Clustering

Description

Hierarchical cluster analysis on a set of dissimilarities and methods for analyzing it.

Usage

hclust(d, method = "complete", members=NULL)

## S3 method for class 'hclust':
plot(x, labels = NULL, hang = 0.1,
    axes = TRUE, frame.plot = FALSE, ann = TRUE,
    main = "Cluster Dendrogram",
    sub = NULL, xlab = NULL, ylab = "Height", ...)

plclust(tree, hang = 0.1, unit = FALSE, level = FALSE, hmin = 0,
    square = TRUE, labels = NULL, plot. = TRUE,
    axes = TRUE, frame.plot = FALSE, ann = TRUE,
    main = ",", sub = NULL, xlab = NULL, ylab = "Height")
Arguments

- **d**: a dissimilarity structure as produced by `dist`.
- **method**: the agglomeration method to be used. This should be (an unambiguous abbreviation of) one of "ward", "single", "complete", "average", "mcquitty", "median" or "centroid".
- **members**: NULL or a vector with length size of d. See the Details section.
- **x, tree**: an object of the type produced by `hclust`.
- **hang**: The fraction of the plot height by which labels should hang below the rest of the plot. A negative value will cause the labels to hang down from 0.
- **labels**: A character vector of labels for the leaves of the tree. By default the row names or row numbers of the original data are used. If `labels=FALSE` no labels at all are plotted.
- **axes, frame.plot, ann**: logical flags as in `plot.default`.
- **main, sub, xlab, ylab**: character strings for `title`. `sub` and `xlab` have a non-NULL default when there’s a `tree$call`.
- **...**: Further graphical arguments.
- **unit**: logical. If true, the splits are plotted at equally-spaced heights rather than at the height in the object.
- **hmin**: numeric. All heights less than `hmin` are regarded as being `hmin`: this can be used to suppress detail at the bottom of the tree.
- **level, square, plot**: as yet unimplemented arguments of `plclust` for S-PLUS compatibility.

Details

This function performs a hierarchical cluster analysis using a set of dissimilarities for the n objects being clustered. Initially, each object is assigned to its own cluster and then the algorithm proceeds iteratively, at each stage joining the two most similar clusters, continuing until there is just a single cluster. At each stage distances between clusters are recomputed by the Lance–Williams dissimilarity update formula according to the particular clustering method being used.

A number of different clustering methods are provided. Ward’s minimum variance method aims at finding compact, spherical clusters. The complete linkage method finds similar clusters. The single linkage method (which is closely related to the minimal spanning tree) adopts a ‘friends of friends’ clustering strategy. The other methods can be regarded as aiming for clusters with characteristics somewhere between the single and complete link methods. Note however, that methods "median" and "centroid" are not leading to a monotone distance measure, or equivalently the resulting dendrograms can have so called inversions (which are hard to interpret).

If `members!=NULL`, then d is taken to be a dissimilarity matrix between clusters instead of dissimilarities between singletons and members gives the number of observations per cluster. This way the hierarchical cluster algorithm can be “started in the middle of the dendrogram”, e.g., in order to reconstruct the part of the tree above a cut (see examples). Dissimilarities between clusters can be efficiently computed (i.e., without `hclust` itself) only for a limited number of distance/linkage combinations, the simplest one being squared Euclidean distance and centroid linkage. In this case the dissimilarities between the clusters are the squared Euclidean distances between cluster means.

In hierarchical cluster displays, a decision is needed at each merge to specify which subtree should go on the left and which on the right. Since, for n observations there are n − 1 merges, there are
hclust

$2^{(n-1)}$ possible orderings for the leaves in a cluster tree, or dendrogram. The algorithm used in hclust is to order the subtree so that the tighter cluster is on the left (the last, i.e., most recent, merge of the left subtree is at a lower value than the last merge of the right subtree). Single observations are the tightest clusters possible, and merges involving two observations place them in order by their observation sequence number.

Value

An object of class hclust which describes the tree produced by the clustering process. The object is a list with components:

merge
an $n-1$ by 2 matrix. Row $i$ of merge describes the merging of clusters at step $i$ of the clustering. If an element $j$ in the row is negative, then observation $-j$ was merged at this stage. If $j$ is positive then the merge was with the cluster formed at the (earlier) stage $j$ of the algorithm. Thus negative entries in merge indicate agglomerations of singletons, and positive entries indicate agglomerations of non-singletons.

height
a set of $n-1$ non-decreasing real values. The clustering height: that is, the value of the criterion associated with the clustering method for the particular agglomeration.

order
a vector giving the permutation of the original observations suitable for plotting, in the sense that a cluster plot using this ordering and matrix merge will not have crossings of the branches.

labels
labels for each of the objects being clustered.

call
the call which produced the result.

method
the cluster method that has been used.

dist.method
the distance that has been used to create d (only returned if the distance object has a "method" attribute).

There are print, plot and identify (see identify.hclust) methods and the rect.hclust() function for hclust objects. The plotclust() function is basically the same as the plot method, plot.hclust, primarily for back compatibility with S-plus. Its extra arguments are not yet implemented.

Author(s)

The hclust function is based on Fortran code contributed to STATLIB by F. Murtagh.

Examples

hc <- hclust(dist(USArrests), "ave")
plot(hc)
plot(hc, hang = -1)
## Do the same with centroid clustering and squared Euclidean distance,
## cut the tree into ten clusters and reconstruct the upper part of the
## tree from the cluster centers.
hc <- hclust(dist(USArrests)^2, "cen")
memb <- cutree(hc, k = 10)
cent <- NULL
for(k in 1:10){
cent <- rbind(cen, colMeans(USArrests[memb == k, , drop = FALSE]))
}
hc1 <- hclust(dist(cen)^2, method = "cen", members = table(memb))
opar <- par(mfrow = c(1, 2))
plot(hc, labels = FALSE, hang = -1, main = "Original Tree")
plot(hc1, labels = FALSE, hang = -1, main = "Re-start from 10 clusters")
par(opar)

heatmap

**Description**

A heat map is a false color image (basically image(t(x))) with a dendrogram added to the left side and to the top. Typically, reordering of the rows and columns according to some set of values (row or column means) within the restrictions imposed by the dendrogram is carried out.

**Usage**

heatmap(x, Rowv=NULL, Colv=if(symm)"Rowv" else NULL,
distfun = dist, hclustfun = hclust,
reorderfun = function(d,w) reorder(d,w),
add.expr, symm = FALSE, revC = identical(Colv, "Rowv"),
scale=c("row", "column", "none"), na.rm = TRUE,
margins = c(5, 5), ColSideColors, RowSideColors,
cexRow = 0.2 + 1/log10(nr), cexCol = 0.2 + 1/log10(nc),
labRow = NULL, labCol = NULL, main = NULL,
xlab = NULL, ylab = NULL,
keep.dendro = FALSE, verbose = getOption("verbose"), ...)
Arguments

- **x**: numeric matrix of the values to be plotted.
- **Rowv**: determines if and how the row dendrogram should be computed and reordered. Either a `dendrogram` or a vector of values used to reorder the row dendrogram or NA to suppress any row dendrogram (and reordering) or by default, NULL, see Details below.
- **Colv**: determines if and how the column dendrogram should be reordered. Has the same options as the Rowv argument above and additionally when x is a square matrix, Colv = "Rowv" means that columns should be treated identically to the rows.
- **distfun**: function used to compute the distance (dissimilarity) between both rows and columns. Defaults to `dist`.
- **hclustfun**: function used to compute the hierarchical clustering when Rowv or Colv are not dendrograms. Defaults to `hclust`. Should take as argument a result of distfun and return an object to which as.dendrogram can be applied.
- **reorderfun**: function(d,w) of dendrogram and weights for reordering the row and column dendrograms. The default uses reorder.dendrogram.
- **add.expr**: expression that will be evaluated after the call to `image`. Can be used to add components to the plot.
- **symm**: logical indicating if x should be treated symmetrically; can only be true when x is a square matrix.
- **revC**: logical indicating if the column order should be reversed for plotting, such that e.g., for the symmetric case, the symmetry axis is as usual.
- **scale**: character indicating if the values should be centered and scaled in either the row direction or the column direction, or none. The default is "row" if symm false, and "none" otherwise.
- **na.rm**: logical indicating whether NA’s should be removed.
- **margins**: numeric vector of length 2 containing the margins (see `par(mar= *)`) for column and row names, respectively.
- **ColSideColors**: (optional) character vector of length ncol(x) containing the color names for a horizontal side bar that may be used to annotate the columns of x.
- **RowSideColors**: (optional) character vector of length nrow(x) containing the color names for a vertical side bar that may be used to annotate the rows of x.
- **cexRow**, **cexCol**: positive numbers, used as cex.axis in for the row or column axis labeling. The defaults currently only use number of rows or columns, respectively.
- **labRow**, **labCol**: character vectors with row and column labels to use; these default to rownames(x) or colnames(x), respectively.
- **main**, **xlab**, **ylab**: main, x- and y-axis titles; defaults to none.
- **keep.dendro**: logical indicating if the dendrogram(s) should be kept as part of the result (when Rowv and/or Colv are not NA).
- **verbose**: logical indicating if information should be printed.
- **...**: additional arguments passed on to `image`, e.g., `col` specifying the colors.
**Details**

If either `Rowv` or `Colv` are dendrograms they are honored (and not reordered). Otherwise, dendrograms are computed as `dd <- as.dendrogram(hclustfun(distfun(X)))` where `X` is either `x` or `t(x)`.

If either is a vector (of “weights”) then the appropriate dendrogram is reordered according to the supplied values subject to the constraints imposed by the dendrogram, by `reorder(dd, Rowv)` in the row case. If either is missing, as by default, then the ordering of the corresponding dendrogram is by the mean value of the rows/columns, i.e., in the case of rows, `Rowv <- rowMeans(x, na.rm=na.rm)`. If either is `NULL`, *no reordering* will be done for the corresponding side.

By default (`scale = "row"`) the rows are scaled to have mean zero and standard deviation one. There is some empirical evidence from genomic plotting that this is useful.

The default colors are not pretty. Consider using enhancements such as the `RColorBrewer` package, [http://cran.r-project.org/src/contrib/PACKAGES.html#RColorBrewer](http://cran.r-project.org/src/contrib/PACKAGES.html#RColorBrewer).

**Value**

Invisibly, a list with components

- `rowInd` row index permutation vector as returned by `order.dendrogram`.
- `colInd` column index permutation vector.
- `Rowv` the row dendrogram; only if input `Rowv` was not NA and `keep.dendro` is true.
- `Colv` the column dendrogram; only if input `Colv` was not NA and `keep.dendro` is true.

**Note**

Unless `Rowv = NA` (or `Colv = NA`), the original rows and columns are reordered *in any case* to match the dendrogram, e.g., the rows by `order.dendrogram(Rowv)` where `Rowv` is the (possibly `reorder()` ed) row dendrogram.

`heatmap()` uses `layout` and draws the `image` in the lower right corner of a 2x2 layout. Consequently, it can *not* be used in a multi column/row layout, i.e., when `par(mfrow= *)` or `(mfcol= *)` has been called.

HoltWinters

Holt-Winters Filtering

Description

Computes Holt-Winters Filtering of a given time series. Unknown parameters are determined by minimizing the squared prediction error.

Usage

HoltWinters(x, alpha = NULL, beta = NULL, gamma = NULL, seasonal = c("additive", "multiplicative"), start.periods = 3, l.start = NULL, b.start = NULL, s.start = NULL, optim.start = c(alpha = 0.3, beta = 0.1, gamma = 0.1), optim.control = list())

Arguments

x An object of class ts
alpha alpha parameter of Holt-Winters Filter
beta beta parameter of Holt-Winters Filter. If set to 0, the function will do exponential smoothing.
gamma  

`gamma` parameter used for the seasonal component. If set to 0, an non-seasonal model is fitted.

seasonal  

Character string to select an "additive" (the default) or "multiplicative" seasonal model. The first few characters are sufficient. (Only takes effect if `gamma` is non-zero).

start.periods  

Start periods used in the autodetection of start values. Must be at least 3.

l.start  

Start value for level (`a[0]`).

b.start  

Start value for trend (`b[0]`).

s.start  

Vector of start values for the seasonal component (`s[1][0]...s[p][0]`).

optim.start  

Vector with named components `alpha`, `beta`, and `gamma` containing the starting values for the optimizer. Only the values needed must be specified.

optim.control  

Optional list with additional control parameters passed to `optim`.

**Details**

The additive Holt-Winters prediction function (for time series with period length `p`) is

\[ \hat{Y}[t+h] = a[t] + hb[t] + s[t+1 + (h-1) \mod p], \]

where `a[t]`, `b[t]` and `s[t]` are given by

\[ a[t] = \alpha(Y[t] - s[t-p]) + (1 - \alpha)(a[t-1] + b[t-1]) \]
\[ b[t] = \beta(a[t] - a[t-1]) + (1 - \beta)b[t-1] \]
\[ s[t] = \gamma(\frac{Y[t]}{a[t]}) + (1 - \gamma)s[t-p] \]

The multiplicative Holt-Winters prediction function (for time series with period length `p`) is

\[ \hat{Y}[t+h] = (a[t] + hb[t]) \times s[t+1 + (h-1) \mod p], \]

where `a[t]`, `b[t]` and `s[t]` are given by

\[ a[t] = \alpha(Y[t]/s[t-p]) + (1 - \alpha)(a[t-1] + b[t-1]) \]
\[ b[t] = \beta(a[t] - a[t-1]) + (1 - \beta)b[t-1] \]
\[ s[t] = \gamma(\frac{Y[t]}{a[t]}) + (1 - \gamma)s[t-p] \]

The function tries to find the optimal values of `alpha` and/or `beta` and/or `gamma` by minimizing the squared one-step prediction error if they are omitted.

For seasonal models, start values for `a`, `b` and `s` are detected by performing a simple decomposition in trend and seasonal component using moving averages (see function `decompose`) on the `start.periods` first periods (a simple linear regression on the trend component is used for starting level and trend.). For level/trend-models (no seasonal component), start values for `a` and `b` are `x[2]` and `x[2] - x[1]`, respectively. For level-only models (ordinary exponential smoothing), the start value for `a` is `x[1]`. 
**Value**

An object of class "HoltWinters", a list with components:

- **fitted**: A multiple time series with one column for the filtered series as well as for the level, trend and seasonal components, estimated contemporaneously (that is at time t and not at the end of the series).
- **x**: The original series
- **alpha**: alpha used for filtering
- **beta**: beta used for filtering
- **coefficients**: A vector with named components a, b, s1, ..., sp containing the estimated values for the level, trend and seasonal components
- **seasonal**: The specified seasonal-parameter
- **SSE**: The final sum of squared errors achieved in optimizing
- **call**: The call used

The Hypergeometric Distribution

Description

Density, distribution function, quantile function and random generation for the hypergeometric distribution.

Usage

dhyper(x, m, n, k, log = FALSE)
phyper(q, m, n, k, lower.tail = TRUE, log.p = FALSE)
qhyper(p, m, n, k, lower.tail = TRUE, log.p = FALSE)
rhyper(nn, m, n, k)

Arguments

x, q  vector of quantiles representing the number of white balls drawn without replacement from an urn which contains both black and white balls.
m  the number of white balls in the urn.
n  the number of black balls in the urn.
k  the number of balls drawn from the urn.
p  probability, it must be between 0 and 1.
nn  number of observations. If length(nn) > 1, the length is taken to be the number required.
log, log.p  logical; if TRUE, probabilities p are given as log(p).
lower.tail  logical; if TRUE (default), probabilities are \( P[X \leq x] \), otherwise, \( P[X > x] \).

Details

The hypergeometric distribution is used for sampling without replacement. The density of this distribution with parameters \( m, n \) and \( k \) (named \( Np, N - Np, \) and \( n \), respectively in the reference below) is given by

\[
p(x) = \frac{\binom{m}{x} \binom{n}{k-x}}{\binom{m+n}{k}}
\]

for \( x = 0, \ldots, k \).

Value

dhyper gives the density, phyper gives the distribution function, qhyper gives the quantile function, and rhyper generates random deviates.

Invalid arguments will result in return value \( NaN \), with a warning.
identify.hclust

Source

dhyper computes via binomial probabilities, using code contributed by Catherine Loader (see dbinom).

phyper is based on calculating dhyper and phyper(...) / dhyper(...) (as a summation), based on ideas of Ian Smith and Morten Welinder.

qhyper is based on inversion.

rhyper is based on a corrected version of

Examples

m <- 10; n <- 7; k <- 8
x <- 0:(k+1)
rbind(phyper(x, m, n, k), dhyper(x, m, n, k))
all(phyper(x, m, n, k) == cumsum(dhyper(x, m, n, k))) # FALSE
## but error is very small:
signif(phyper(x, m, n, k) - cumsum(dhyper(x, m, n, k)), dig=3)

identify.hclust  Identify Clusters in a Dendrogram

Description

identify.hclust reads the position of the graphics pointer when the (first) mouse button is pressed. It then cuts the tree at the vertical position of the pointer and highlights the cluster containing the horizontal position of the pointer. Optionally a function is applied to the index of data points contained in the cluster.

Usage

## S3 method for class 'hclust':
identify(x, FUN = NULL, N = 20, MAXCLUSTER = 20, DEV.FUN = NULL, ...)

Arguments

x
 an object of the type produced by hclust.

FUN
 (optional) function to be applied to the index numbers of the data points in a cluster (see Details below).

N
 the maximum number of clusters to be identified.

MAXCLUSTER
 the maximum number of clusters that can be produced by a cut (limits the effective vertical range of the pointer).

DEV.FUN
 (optional) integer scalar. If specified, the corresponding graphics device is made active before FUN is applied.

... further arguments to FUN.
By default clusters can be identified using the mouse and an invisible list of indices of the respective data points is returned.

If FUN is not NULL, then the index vector of data points is passed to this function as first argument, see the examples below. The active graphics device for FUN can be specified using DEV.FUN.

The identification process is terminated by pressing any mouse button other than the first, see also identify.

Value

Either a list of data point index vectors or a list of return values of FUN.

          hat = infl$hat, ...)

## S3 method for class 'glm':
cooks.distance(model, infl = influence(model, do.coef = FALSE),  
         res = infl$pear.res,  
         dispersion = summary(model)$dispersion,  
         hat = infl$hat, ...)

covratio(model, infl = lm.influence(model, do.coef = FALSE),  
        res = weighted.residuals(model))

cooks.distance(model, ...)
## S3 method for class 'lm':
cooks.distance(model, infl = lm.influence(model, do.coef = FALSE),  
          res = weighted.residuals(model),  
          sd = sqrt(deviance(model)/df.residual(model)),  
          hat = infl$hat, ...)

## S3 method for class 'glm':
cooks.distance(model, infl = influence(model, do.coef = FALSE),  
         res = infl$pear.res,  
         dispersion = summary(model)$dispersion,  
         hat = infl$hat, ...)

hatvalues(model, ...)
## S3 method for class 'lm':
hatvalues(model, infl = lm.influence(model, do.coef = FALSE), ...

hat(x, intercept = TRUE)

Arguments

model an R object, typically returned by lm or glm.
influence.measures

infl influence structure as returned by lm.influence or influence (the latter only for the glm method of rstudent and cooks.distance).
res (possibly weighted) residuals, with proper default.
std standard deviation to use, see default.
dispersion dispersion (for glm objects) to use, see default.
hat hat values $H_{ii}$, see default.
x the $X$ or design matrix.
intercept should an intercept column be prepended to $x$?
... further arguments passed to or from other methods.

Details

The primary high-level function is influence.measures which produces a class "infl" object tabular display showing the DFBETAS for each model variable, DFFITS, covariance ratios, Cook's distances and the diagonal elements of the hat matrix. Cases which are influential with respect to any of these measures are marked with an asterisk.

The functions dfbetas, dfits, covratio and cooks.distance provide direct access to the corresponding diagnostic quantities. Functions rstandard and rstudent give the standardized and Studentized residuals respectively. (These re-normalize the residuals to have unit variance, using an overall and leave-one-out measure of the error variance respectively.)

Values for generalized linear models are approximations, as described in Williams (1987) (except that Cook’s distances are scaled as $F$ rather than as chi-square values). The approximations can be poor when some cases have large influence.

The optional infl, res and sd arguments are there to encourage the use of these direct access functions, in situations where, e.g., the underlying basic influence measures (from lm.influence or the generic influence) are already available.

Note that cases with weights == 0 are dropped from all these functions, but that if a linear model has been fitted with na.action = na.exclude, suitable values are filled in for the cases excluded during fitting.

The function hat() exists mainly for S (version 2) compatibility; we recommend using hatvalues() instead.

Note

For hatvalues, dfbeta, and dfbetas, the method for linear models also works for generalized linear models.

Author(s)

Several R core team members and John Fox, originally in his ‘car’ package.

References

**integrate**

**Integration of One-Dimensional Functions**

**Description**

Adaptive quadrature of functions of one variable over a finite or infinite interval.

**Usage**

```r
integrate(f, lower, upper, subdivisions=100, rel.tol = .Machine$double.eps^0.25, abs.tol = rel.tol, stop.on.error = TRUE, keep.xy = FALSE, aux = NULL, ...)
```

**Arguments**

- `f`: an R function taking a numeric first argument and returning a numeric vector of the same length. Returning a non-finite element will generate an error.
- `subdivisions`: the maximum number of subintervals.
rel.tol relative accuracy requested.
abs.tol absolute accuracy requested.
stop.on.error logical. If true (the default) an error stops the function. If false some errors will
give a result with a warning in the message component.
keep.xy unused. For compatibility with S.
aux unused. For compatibility with S.
... additional arguments to be passed to f. Remember to use argument names not
matching those of integrate().

Details
If one or both limits are infinite, the infinite range is mapped onto a finite interval.
For a finite interval, globally adaptive interval subdivision is used in connection with extrapolation
by the Epsilon algorithm.
rel.tol cannot be less than max(50*.Machine$double.eps, 0.5e-28) if abs.tol
<= 0.

Value
A list of class "integrate" with components
value the final estimate of the integral.
abs.error estimate of the modulus of the absolute error.
subdivisions the number of subintervals produced in the subdivision process.
message "OK" or a character string giving the error message.
call the matched call.

Note
Like all numerical integration routines, these evaluate the function on a finite set of points. If the
function is approximately constant (in particular, zero) over nearly all its range it is possible that the
result and error estimate may be seriously wrong.
When integrating over infinite intervals do so explicitly, rather than just using a large number as
the endpoint. This increases the chance of a correct answer -- any function whose integral over an
infinite interval is finite must be near zero for most of that interval.
f must accept a vector of inputs and produce a vector of function evaluations at those points. The
Vectorize function may be helpful to convert f to this form.

integrate(dnorm, -1.96, 1.96)
integrate(dnorm, -Inf, Inf)

## a slowly-convergent integral
integrand <- function(x) {1/((x+1) *sqrt(x))}
integrate(integrand, lower = 0, upper = Inf)

## don't do this if you really want the integral from 0 to Inf
integrate(integrand, lower = 0, upper = 10)
integrate(integrand, lower = 0, upper = 100000)
integrate(integrand, lower = 0, upper = 1000000, stop.on.error = FALSE)

## some functions do not handle vector input properly
f <- function(x) 2
try(integrate(f, 0, 1))
integrate(Vectorize(f), 0, 1) ## correct
integrate(function(x) rep(2, length(x)), 0, 1) ## correct

## integrate can fail if misused
integrate(dnorm, 0, 2)
integrate(dnorm, 0, 20)
integrate(dnorm, 0, 200)
integrate(dnorm, 0, 2000)
integrate(dnorm, 0, 20000) ## fails on many systems
integrate(dnorm, 0, Inf) ## works
```

interaction.plot

Two-way Interaction Plot

Description

Plots the mean (or other summary) of the response for two-way combinations of factors, thereby illustrating possible interactions.

Usage

```r
interaction.plot(x.factor, trace.factor, response, fun = mean,
                 type = c("l", "p", "b"), legend = TRUE,
                 trace.label = deparse(substitute(trace.factor)),
                 fixed = FALSE,
                 xlab = deparse(substitute(x.factor)),
                 ylab = ylabel,
                 ylim = range(cells, na.rm=TRUE),
                 lty = nc:1, col = 1, pch = c(1:9, 0, letters),
                 xpd = NULL, leg.bg = par("bg"), leg.bty = "n",
                 xtick = FALSE, xaxt = par("xaxt"), axes = TRUE,
                 ...
)
```

Arguments

- **x.factor**: a factor whose levels will form the x axis.
interaction.plot

trace.factor: another factor whose levels will form the traces.
response: a numeric variable giving the response
fun: the function to compute the summary. Should return a single real value.
type: the type of plot: lines or points.
legend: logical. Should a legend be included?
trace.label: overall label for the legend.
fixed: logical. Should the legend be in the order of the levels of trace.factor or in the order of the traces at their right-hand ends?
xlab,ylab: the x and y label of the plot each with a sensible default.
ylim: numeric of length 2 giving the y limits for the plot.
lty: line type for the lines drawn, with sensible default.
col: the color to be used for plotting.
pch: a vector of plotting symbols or characters, with sensible default.
xpd: determines clipping behaviour for the legend, see par(xpd). Per default, the legend is not clipped at the figure border.

leg.bg, leg.bty: arguments passed to legend().
xlick: logical. Should tick marks be used on the x axis?
xaxt, axes: ... graphics parameters to be passed to the plotting routines.

Details

By default the levels of x.factor are plotted on the x axis in their given order, with extra space left at the right for the legend (if specified). If x.factor is an ordered factor and the levels are numeric, these numeric values are used for the x axis.

The response and hence its summary can contain missing values. If so, the missing values and the line segments joining them are omitted from the plot (and this can be somewhat disconcerting).

The graphics parameters xlab, ylab, ylim, lty, col and pch are given suitable defaults (and xlim and xaxs are set and cannot be overridden). The defaults are to cycle through the line types, use the foreground colour, and to use the symbols 1:9, 0, and the capital letters to plot the traces.

Note

Some of the argument names and the precise behaviour are chosen for S-compatibility.

References

Examples

```R
with(ToothGrowth, {
  interaction.plot(dose, supp, len, fixed=TRUE)
  dose <- ordered(dose)
  interaction.plot(dose, supp, len, fixed=TRUE, col = 2:3, leg.bty = "o")
  interaction.plot(dose, supp, len, fixed=TRUE, col = 2:3, type = "p")
```
IQR

The Interquartile Range

Description

computes interquartile range of the x values.

Usage

IQR(x, na.rm = FALSE)

Arguments

x

a numeric vector.

na.rm

logical. Should missing values be removed?

Details

Note that this function computes the quartiles using the quantile function rather than following Tukey’s recommendations, i.e., $\text{IQR}(x) = \text{quantile}(x, 3/4) - \text{quantile}(x, 1/4)$.

For normally $N(m, 1)$ distributed $X$, the expected value of $\text{IQR}(X)$ is $2\times qnorm(3/4) = 1.3490$, i.e., for a normal-consistent estimate of the standard deviation, use $\text{IQR}(x) / 1.349$. 

with(OrchardSprays, {
  interaction.plot(treatment, rowpos, decrease)
  interaction.plot(rowpos, treatment, decrease, cex.axis=0.8)
  ## order the rows by their mean effect
  rowpos <- factor(rowpos, levels=sort.list(tapply(decrease, rowpos, mean)))
  interaction.plot(rowpos, treatment, decrease, col = 2:9, lty = 1)
})

with(esoph, {
  interaction.plot(agegp, alcgp, ncases/ncontrols, main = "'esoph' Data")
  interaction.plot(agegp, tobgp, ncases/ncontrols, trace.label="tobacco",
                  fixed=TRUE, xaxt = "n")
  ## deal with NAs:
  esophNA <- esoph; esophNA$ncases[66] <- NA
  with(esophNA, {
    interaction.plot(agegp, alcgp, ncases/ncontrols, col= 2:5)
    # doesn't show *last* group either
    interaction.plot(agegp, alcgp, ncases/ncontrols, col= 2:5, type = "b")
    ## alternative take non-NA's ("cheating")
    interaction.plot(agegp, alcgp, ncases/ncontrols, col= 2:5,
                     fun = function(x) mean(x, na.rm=TRUE),
                     sub = "function(x) mean(x, na.rm=TRUE)")
  })
  rm(esophNA) # to clear up
is.empty.model

Check if a Model is Empty

Description

R model notation allows models with no intercept and no predictors. These require special handling internally. `is.empty.model()` checks whether an object describes an empty model.

Usage

`is.empty.model(x)`

Arguments

`x` A `terms` object or an object with a `terms` method.

Value

`TRUE` if the model is empty

See Also

`lm`, `glm`

Examples

```r
y <- rnorm(20)
is.empty.model(y ~ 0)
is.empty.model(y ~ -1)
is.empty.model(lm(y ~ 0))
```
isoreg

Isotonic / Monotone Regression

Description
Compute the isotonic (monotonely increasing nonparametric) least squares regression which is piecewise constant.

Usage
isoreg(x, y = NULL)

Arguments
x, y
in isoreg, coordinate vectors of the regression points. Alternatively a single “plotting” structure can be specified: see xy.coords.

Details
The algorithm determines the convex minorant \( m(x) \) of the cumulative data (i.e., \( \text{cumsum}(y) \)) which is piecewise linear and the result is \( m'(x) \), a step function with level changes at locations where the convex \( m(x) \) touches the cumulative data polygon and changes slope. as.stepfun() returns a stepfun object which can be more parsimonious.

Value
isoreg() returns an object of class isoreg which is basically a list with components

- x: original (constructed) abscissa values x.
- y: corresponding y values.
- yf: fitted values corresponding to ordered x values.
- yc: cumulative y values corresponding to ordered x values.
- iKnots: integer vector giving indices where the fitted curve jumps, i.e., where the convex minorant has kinks.
- isOrd: logical indicating if original x values were ordered increasingly already.
- ord: if(!isOrd): integer permutation order(x) of original x.
- call: the call to isoreg() used.

Note
The code should be improved to accept weights additionally and solve the corresponding weighted least squares problem.
“Patches are welcome!”

References
See Also

the plotting method `plot.isoreg` with more examples; `isoMDS()` from the MASS package internally uses isotonic regression.

Examples

```r
(ir <- isoreg(c(1,0,4,3,5,4,2,0)))
plot(ir, plot.type = "row")

(ir3 <- isoreg(y3 <- c(1,0,4,3,5,4,2,3)) # last "3", not "0"
(f13 <- as.stepfun(ir3))
(ir4 <- isoreg(1:10, y4 <- c(5, 9, 1:2, 5:8, 3, 8)))
cat("R^2 =", formatC(sum(residuals(ir4)^2) / (9*var(y4)), dig=2),"\n")
```

KalmanLike

Kalman Filtering

Description

Use Kalman Filtering to find the (Gaussian) log-likelihood, or for forecasting or smoothing.

Usage

```r
KalmanLike(y, mod, nit = 0, fast=TRUE)
KalmanRun(y, mod, nit = 0, fast=TRUE)
KalmanSmooth(y, mod, nit = 0)
KalmanForecast(n.ahead = 10, mod, fast=TRUE)
makeARIMA(phi, theta, Delta, kappa = 1e6)
```

Arguments

- `y`: a univariate time series.
- `mod`: A list describing the state-space model: see Details.
- `nit`: The time at which the initialization is computed. `nit = 0` implies that the initialization is for a one-step prediction, so \(P_n\) should not be computed at the first step.
- `n.ahead`: The number of steps ahead for which prediction is required.
- `phi, theta`: numeric vectors of length \(\geq 0\) giving AR and MA parameters.
- `Delta`: vector of differencing coefficients, so an ARMA model is fitted to \(y[t] - \Delta[1]*y[t-1] - \ldots\)
- `kappa`: the prior variance (as a multiple of the innovations variance) for the past observations in a differenced model.
- `fast`: If TRUE the `mod` object may be modified.
Details

These functions work with a general univariate state-space model with state vector \( a \), transitions \( a \leftarrow T a + R e \), \( e \sim \mathcal{N}(0, \kappa Q) \) and observation equation \( y = Z' a + \text{eta}, \text{eta} \sim \mathcal{N}(0, \kappa h) \). The likelihood is a profile likelihood after estimation of \( \kappa \).

The model is specified as a list with at least components

- \( T \) the transition matrix
- \( Z \) the observation coefficients
- \( h \) the observation variance
- \( V \) \( RQR' \)
- \( a \) the current state estimate
- \( P \) the current estimate of the state uncertainty matrix
- \( Pn \) the estimate at time \( t - 1 \) of the state uncertainty matrix

\( \text{KalmanSmooth} \) is the workhorse function for \( \text{tsSmooth} \).

\( \text{makeARIMA} \) constructs the state-space model for an ARIMA model.

Value

For \( \text{KalmanLike} \), a list with components \( \text{Lik} \) (the log-likelihood less some constants) and \( s2 \), the estimate of \( \kappa \).

For \( \text{KalmanRun} \), a list with components \( \text{values} \), a vector of length 2 giving the output of \( \text{KalmanLike} \), \( \text{resid} \) (the residuals) and \( \text{states} \), the contemporaneous state estimates, a matrix with one row for each time.

For \( \text{KalmanSmooth} \), a list with two components. Component \( \text{smooth} \) is a \( n \) by \( p \) matrix of state estimates based on all the observations, with one row for each time. Component \( \text{var} \) is a \( n \) by \( p \) by \( p \) array of variance matrices.

For \( \text{KalmanForecast} \), a list with components \( \text{pred} \), the predictions, and \( \text{var} \), the unscaled variances of the prediction errors (to be multiplied by \( s2 \)).

For \( \text{makeARIMA} \), a model list including components for its arguments.

Warning

These functions are designed to be called from other functions which check the validity of the arguments passed, so very little checking is done.

In particular, \( \text{KalmanLike} \) alters the objects passed as the elements \( a, P \) and \( Pn \) of \( \text{mod} \), so these should not be shared. Use \( \text{fast=} \text{FALSE} \) to prevent this.

References

See Also

\( \text{arima}, \text{StructTS}, \text{tsSmooth} \).
**kernapply**  
*Apply Smoothing Kernel*

**Description**

kernapply computes the convolution between an input sequence and a specific kernel.

**Usage**

kernapply(x, ...)

## Default S3 method:
kernapply(x, k, circular = FALSE, ...)

## S3 method for class 'ts':
kernapply(x, k, circular = FALSE, ...)

## S3 method for class 'vector':
kernapply(x, k, circular = FALSE, ...)

## S3 method for class 'tskernel':
kernapply(x, k, ...)

**Arguments**

x  
an input vector, matrix, time series or kernel to be smoothed.

k  
smoothing "tskernel" object.

circular  
a logical indicating whether the input sequence to be smoothed is treated as circular, i.e., periodic.

...  
arguments passed to or from other methods.

**Value**

A smoothed version of the input sequence.

**Author(s)**

A. Trapletti

**See Also**

kernel, convolve, filter, spectrum

**Examples**

## see 'kernel' for examples
**Smoothing Kernel Objects**

**Description**

The "tskernel" class is designed to represent discrete symmetric normalized smoothing kernels. These kernels can be used to smooth vectors, matrices, or time series objects. There are print, plot and \( \text{methods for these kernel objects.} \)

**Usage**

```r
kernel(coef, m, r, name)

df.kernel(k)
bands.kernel(k)
is.tskernel(k)
## S3 method for class 'tskernel':
plot(x, type = "h", xlab = "k", ylab = "W[k]",
     main = attr(x,"name"), ...)
```

**Arguments**

- `coef`: the upper half of the smoothing kernel coefficients (including coefficient zero) or the name of a kernel (currently "daniell","dirichlet","fejer" or "modified.daniell").
- `m`: the kernel dimension(s). When \( m \) has length larger than one, it means the convolution of kernels of dimension \( m[j] \), for \( j \) in \( 1: \text{length}(m) \). Currently this is supported only for the named "daniell" kernels.
- `name`: the name the kernel will be called.
- `r`: the kernel order for a Fejer kernel.
- `k,x`: a "tskernel" object.
- `type, xlab, ylab, main, ...`: arguments passed to `plot.default`.

**Details**

`kernel` is used to construct a general kernel or named specific kernels. The modified Daniell kernel halves the end coefficients (as used by S-PLUS).

The \( \text{[ method allows natural indexing of kernel objects with indices in } (-m) : m \). The normalization is such that for \( k <- kernel(*) \), \( \text{sum(k[[-k\text{m} : k\text{m}ℤ]}) \) is one.

`df.kernel` returns the “equivalent degrees of freedom” of a smoothing kernel as defined in Brockwell and Davies (1991), page 362, and `bands.kernel` returns the equivalent bandwidth as defined in Bloomfield (1976), p. 201, with a continuity correction.

**Value**

`kernel()` returns an object of class "tskernel" which is basically a list with the two components `coef` and the kernel dimension `m`. An additional attribute is "name".
kmeans

K-Means Clustering

Description

Perform k-means clustering on a data matrix.

Usage

kmeans(x, centers, iter.max = 10, nstart = 1,
       algorithm = c("Hartigan-Wong", "Lloyd", "Forgy", "MacQueen"))
**kmeans**

**Arguments**

- **x**: A numeric matrix of data, or an object that can be coerced to such a matrix (such as a numeric vector or a data frame with all numeric columns).
- **centers**: Either the number of clusters or a set of initial (distinct) cluster centres. If a number, a random set of (distinct) rows in `x` is chosen as the initial centres.
- **iter.max**: The maximum number of iterations allowed.
- **nstart**: If `centers` is a number, how many random sets should be chosen?
- **algorithm**: character: may be abbreviated.

**Details**

The data given by `x` is clustered by the *k*-means method, which aims to partition the points into *k* groups such that the sum of squares from points to the assigned cluster centres is minimized. At the minimum, all cluster centres are at the mean of their Voronoi sets (the set of data points which are nearest to the cluster centre).

The algorithm of Hartigan and Wong (1979) is used by default. Note that some authors use *k*-means to refer to a specific algorithm rather than the general method: most commonly the algorithm given by MacQueen (1967) but sometimes that given by Lloyd (1957) and Forgy (1965). The Hartigan–Wong algorithm generally does a better job than either of those, but trying several random starts is often recommended.

Except for the Lloyd–Forgy method, *k* clusters will always be returned if a number is specified. If an initial matrix of centres is supplied, it is possible that no point will be closest to one or more centres, which is currently an error for the Hartigan–Wong method.

**Value**

An object of class "kmeans" which is a list with components:

- **cluster**: A vector of integers indicating the cluster to which each point is allocated.
- **centers**: A matrix of cluster centres.
- **withinss**: The within-cluster sum of squares for each cluster.
- **size**: The number of points in each cluster.

There is a print method for this class.

**References**

Examples

# a 2-dimensional example
x <- rbind(matrix(rnorm(100, sd = 0.3), ncol = 2),
           matrix(rnorm(100, mean = 1, sd = 0.3), ncol = 2))
colnames(x) <- c("x", "y")
(cl <- kmeans(x, 2))
plot(x, col = cl$cluster)
points(cl$centers, col = 1:2, pch = 8, cex=2)

## random starts do help here with too many clusters
(cl <- kmeans(x, 5, nstart = 25))
plot(x, col = cl$cluster)
points(cl$centers, col = 1:5, pch = 8)

kruskal.test

Kruskal-Wallis Rank Sum Test

Description

Performs a Kruskal-Wallis rank sum test.

Usage

kruskal.test(x, ...)

## Default S3 method:
kruskal.test(x, g, ...)

## S3 method for class 'formula':
kruskal.test(formula, data, subset, na.action, ...)

Arguments

x
  a numeric vector of data values, or a list of numeric data vectors.

g
  a vector or factor object giving the group for the corresponding elements of x. Ignored if x is a list.

formula
  a formula of the form lhs ~ rhs where lhs gives the data values and rhs the corresponding groups.

data
  an optional matrix or data frame (or similar: see model.frame) containing the variables in the formula formula. By default the variables are taken from environment(formula).

subset
  an optional vector specifying a subset of observations to be used.

na.action
  a function which indicates what should happen when the data contain NAs. Defaults to getOption("na.action").

...  
  further arguments to be passed to or from methods.
kruskal.test performs a Kruskal-Wallis rank sum test of the null that the location parameters of the distribution of \( x \) are the same in each group (sample). The alternative is that they differ in at least one.

If \( x \) is a list, its elements are taken as the samples to be compared, and hence have to be numeric data vectors. In this case, \( g \) is ignored, and one can simply use \texttt{kruskal.test(x)} to perform the test. If the samples are not yet contained in a list, use \texttt{kruskal.test(list(x, \ldots))}.

Otherwise, \( x \) must be a numeric data vector, and \( g \) must be a vector or factor object of the same length as \( x \) giving the group for the corresponding elements of \( x \).

Value

A list with class "htest" containing the following components:

- \texttt{statistic} the Kruskal-Wallis rank sum statistic.
- \texttt{parameter} the degrees of freedom of the approximate chi-squared distribution of the test statistic.
- \texttt{p.value} the p-value of the test.
- \texttt{method} the character string "Kruskal-Wallis rank sum test".
- \texttt{data.name} a character string giving the names of the data.

References

See Also

The Wilcoxon rank sum test (\texttt{wilcox.test}) as the special case for two samples; \texttt{lm} together with \texttt{anova} for performing one-way location analysis under normality assumptions; with Student’s t test (\texttt{t.test}) as the special case for two samples.

Examples

```r
## Hollander & Wolfe (1973), 116.
## Mucociliary efficiency from the rate of removal of dust in normal
## subjects, subjects with obstructive airway disease, and subjects
## with asbestosis.
x <- c(2.9, 3.0, 2.5, 2.6, 3.2) # normal subjects
y <- c(3.8, 2.7, 4.0, 2.4) # with obstructive airway disease
z <- c(2.8, 3.4, 3.7, 2.2, 2.0) # with asbestosis
kruskal.test(list(x, y, z))
## Equivalently,
x <- c(x, y, z)
g <- factor(rep(1:3, c(5, 4, 5)),
          labels = c("Normal subjects",
                      "Subjects with obstructive airway disease",
                      "Subjects with asbestosis"))
kruskal.test(x, g)

## Formula interface.
boxplot(Ozone ~ Month, data = airquality)
kruskal.test(Ozone ~ Month, data = airquality)
```
ks.test

Kolmogorov-Smirnov Tests

Description

Performs one or two sample Kolmogorov-Smirnov tests.

Usage

ks.test(x, y, ..., alternative = c("two.sided", "less", "greater"),
        exact = NULL)

Arguments

x        a numeric vector of data values.
y        either a numeric vector of data values, or a character string naming a distribution
        function.
...      parameters of the distribution specified (as a character string) by y.
alternative indicates the alternative hypothesis and must be one of "two.sided" (de-
        fault), "less", or "greater". You can specify just the initial letter of the value, but the argument name must be give in full. See Details for the meanings of the possible values.
exact    NULL or a logical indicating whether an exact p-value should be computed. See
        Details for the meaning of NULL. Not used for the one-sided two-sample case.

Details

If y is numeric, a two-sample test of the null hypothesis that x and y were drawn from the same continuous distribution is performed.

Alternatively, y can be a character string naming a continuous distribution function. In this case, a one-sample test is carried out of the null that the distribution function which generated x is distribution y with parameters specified by ... .

The presence of ties generates a warning, since continuous distributions do not generate them.

The possible values "two.sided", "less" and "greater" of alternative specify the null hypothesis that the true distribution function of x is equal to, not less than or not greater than the hypothesized distribution function (one-sample case) or the distribution function of y (two-sample case), respectively. This is a comparison of cumulative distribution functions, and the test statistic is the maximum difference in value, with the statistic in the "greater" alternative being 

\[ D^+ = \max_u[F_x(u) - F_y(u)] ] \]

Thus in the two-sample case alternative="greater" includes distributions for which x is stochastically smaller than y (the CDF of x lies above and hence to the left of that for y), in contrast to t.test or wilcox.test.

Exact p-values are not available for the one-sided two-sample case, or in the case of ties. If exact = NULL (the default), an exact p-value is computed if the sample size if less than 100 in the one-sample case, and if the product of the sample sizes is less than 10000 in the two-sample case. Otherwise, asymptotic distributions are used whose approximations may be inaccurate in small samples. In the one-sample two-sided case, exact p-values are obtained as described in Marsaglia, Tsang & Wang (2003). The formula of Birnbaum & Tingey (1951) is used for the one-sample one-sided case.
If a single-sample test is used, the parameters specified in... must be pre-specified and not estimated from the data. There is some more refined distribution theory for the KS test with estimated parameters (see Durbin, 1973), but that is not implemented in ks.test.

Value

A list with class "htest" containing the following components:

- statistic: the value of the test statistic.
- p.value: the p-value of the test.
- alternative: a character string describing the alternative hypothesis.
- method: a character string indicating what type of test was performed.
- data.name: a character string giving the name(s) of the data.

References

Durbin, J. (1973) Distribution theory for tests based on the sample distribution function. SIAM.

See Also

shapiro.test which performs the Shapiro-Wilk test for normality.

Examples

```r
x <- rnorm(50)
y <- runif(30)
# Do x and y come from the same distribution?
ks.test(x, y)
# Does x come from a shifted gamma distribution with shape 3 and rate 2?
ks.test(x+2, "pgamma", 3, 2) # two-sided, exact
ks.test(x+2, "pgamma", 3, 2, exact = FALSE)
ks.test(x+2, "pgamma", 3, 2, alternative = "gr")

# test if x is stochastically larger than x2
x2 <- rnorm(50, -1)
plot(ecdf(x), xlim=range(c(x, x2)))
plot(ecdf(x2), add=TRUE, lty="dashed")
t.test(x, x2, alternative="g")
wilcox.test(x, x2, alternative="g")
ks.test(x, x2, alternative="l")
```
ksmooth  

Kernel Regression Smoother

Description

The Nadaraya-Watson kernel regression estimate.

Usage

```r
ksmooth(x, y, kernel = c("box", "normal"), bandwidth = 0.5,
        range.x = range(x), n.points = max(100, length(x)), x.points)
```

Arguments

- `x`: input x values
- `y`: input y values
- `kernel`: the kernel to be used.
- `bandwidth`: the bandwidth. The kernels are scaled so that their quartiles (viewed as probability densities) are at ±0.25*bandwidth.
- `range.x`: the range of points to be covered in the output.
- `n.points`: the number of points at which to evaluate the fit.
- `x.points`: points at which to evaluate the smoothed fit. If missing, `n.points` are chosen uniformly to cover `range.x`.

Value

A list with components

- `x`: values at which the smoothed fit is evaluated. Guaranteed to be in increasing order.
- `y`: fitted values corresponding to `x`.

Note

This function is implemented purely for compatibility with S, although it is nowhere near as slow as the S function. Better kernel smoothers are available in other packages.

Examples

```r
with(cars, {
  plot(speed, dist)
  lines(ksmooth(speed, dist, "normal", bandwidth=2), col=2)
  lines(ksmooth(speed, dist, "normal", bandwidth=5), col=3)
})
```
**Description**

Compute a lagged version of a time series, shifting the time base back by a given number of observations.

**Usage**

```r
lag(x, ...)  
## Default S3 method:  
lag(x, k = 1, ...)  
```

**Arguments**

- `x`: A vector or matrix or univariate or multivariate time series
- `k`: The number of lags (in units of observations).
- `...`: further arguments to be passed to or from methods.

**Details**

- Vector or matrix arguments `x` are coerced to time series.
- `lag` is a generic function; this page documents its default method.

**Value**

A time series object.

**Note**

Note the sign of `k`: a series lagged by a positive `k` starts earlier.

**References**

**See Also**

`diff`, `deltat`

**Examples**

```r
lag(ldeaths, 12) # starts one year earlier
```
lag.plot

Time Series Lag Plots

Description

Plot time series against lagged versions of themselves. Helps visualizing “auto-dependence” even when auto-correlations vanish.

Usage

lag.plot(x, lags = 1, layout = NULL, set.lags = 1:lags,
main = NULL, asp = 1,
diag = TRUE, diag.col = "gray", type = "p", oma = NULL,
ask = NULL, do.lines = (n <= 150), labels = do.lines, ...)

Arguments

x time-series (univariate or multivariate)
lnags number of lag plots desired, see arg set.lags.
lnlayout the layout of multiple plots, basically the mfrow par () argument. The default
lnset.lags uses about a square layout (see n2mfrow such that all plots are on one page.
lnmain vector of positive integers allowing specification of the set of lags used; defaults
to 1:lags.
lnasp character with a main header title to be done on the top of each page.
lnpar Aspect ratio to be fixed, see plot.default.
lndiag logical indicating if the x=y diagonal should be drawn.
lndiag.col color to be used for the diagonal if(diag).
lnype plot type to be used, but see plot.ts about its restricted meaning.
lnoma outer margins, see par.
lnask logical or NULL; if true, the user is asked to confirm before a new page is started.
lnodolines logical indicating if lines should be drawn.
lnlabels logical indicating if labels should be used.
ln... Further arguments to plot.ts. Several graphical parameters are set in
this function and so cannot be changed: these include xlab, ylab, mgp, col.lab and font.lab: this also applies to the arguments xy.labels
and xy.lines.

Details

If just one plot is produced, this is a conventional plot. If more than one plot is to be produced,
par(mfrow) and several other graphics parameters will be set, so it is not (easily) possible to mix
such lag plots with other plots on the same page.

If ask = NULL, par(ask = TRUE) will be called if more than one page of plots is to be
produced and the device is interactive.
Note

It is more flexible and has different default behaviour than the S version. We use `main` instead of `head` for internal consistency.

Author(s)

Martin Maechler

See Also

`plot.ts` which is the basic work horse.

Examples

```r
lag.plot(nhtemp, 8, diag.col = "forest green")
lag.plot(nhtemp, 5, main="Average Temperatures in New Haven")
## ask defaults to TRUE when we have more than one page:
lag.plot(nhtemp, 6, layout = c(2,1), asp = NA,
    main = "New Haven Temperatures", col.main = "blue")
## Multivariate (but non-stationary! ...)
lag.plot(freeny.x, lag = 3)
## Not run:
no lines for long series :
lag.plot(sqrt(sunspots), set = c(1:4, 9:12), pch = ".", col = "gold")
## End(Not run)
```

Description

Fit a line robustly as recommended in *Exploratory Data Analysis*.

Usage

```r
line(x, y)
```

Arguments

- `x, y` the arguments can be any way of specifying x-y pairs.

Value

An object of class "tukeyline".

Methods are available for the generic functions `coef`, `residuals`, `fitted`, and `print`.

References

lm.

Examples

```
plot(cars)
(z <- line(cars))
abline(coef(z))
## Tukey-Anscombe Plot :
plot(residuals(z) ~ fitted(z), main = deparse(z$call))
```

Fitting Linear Models

Description

lm is used to fit linear models. It can be used to carry out regression, single stratum analysis of variance and analysis of covariance (although aov may provide a more convenient interface for these).

Usage

```
lm(formula, data, subset, weights, na.action, 
    method = "qr", model = TRUE, x = FALSE, y = FALSE, qr = TRUE, 
    singular.ok = TRUE, contrasts = NULL, offset, ...)
```

Arguments

- **formula**: an object of class "formula" (or one that can be coerced to that class): a symbolic description of the model to be fitted. The details of model specification are given under Details.
- **data**: an optional data frame, list or environment (or object coercible by `as.data.frame` to a data frame) containing the variables in the model. If not found in data, the variables are taken from `environment(formula)`, typically the environment from which lm is called.
- **subset**: an optional vector specifying a subset of observations to be used in the fitting process.
- **weights**: an optional vector of weights to be used in the fitting process. Should be NULL or a numeric vector. If non-NULL, weighted least squares is used with weights `weights` (that is, minimizing `sum(w*e^2)`); otherwise ordinary least squares is used.
- **na.action**: a function which indicates what should happen when the data contain NAs. The default is set by the `na.action` setting of `options`, and is `na.fail` if that is unset. The “factory-fresh” default is `na.omit`. Another possible value is `NULL`, no action. Value `na.exclude` can be useful.
- **method**: the method to be used; for fitting, currently only `method = "qr"` is supported; `method = "model.frame"` returns the model frame (the same as with `model = TRUE`, see below).
model, x, y, qr

logicals. If TRUE the corresponding components of the fit (the model frame, the model matrix, the response, the QR decomposition) are returned.

singular.ok logical. If FALSE (the default in S but not in R) a singular fit is an error.

contrasts an optional list. See the contrasts.arg of model.matrix.default.

offset this can be used to specify an a priori known component to be included in the linear predictor during fitting. This should be NULL or a numeric vector of length either one or equal to the number of cases. One or more offset terms can be included in the formula instead or as well, and if both are specified their sum is used. See model.offset.

... additional arguments to be passed to the low level regression fitting functions (see below).

Details

Models for \texttt{lm} are specified symbolically. A typical model has the form \texttt{response ~ terms} where \texttt{response} is the (numeric) response vector and \texttt{terms} is a series of terms which specifies a linear predictor for \texttt{response}. A terms specification of the form \texttt{first + second} indicates all the terms in \texttt{first} together with all the terms in \texttt{second} with duplicates removed. A specification of the form \texttt{first:second} indicates the set of terms obtained by taking the interactions of all terms in \texttt{first} with all terms in \texttt{second}. The specification \texttt{first*second} indicates the cross of \texttt{first} and \texttt{second}. This is the same as \texttt{first + second + first:second}.

If the formula includes an \texttt{offset}, this is evaluated and subtracted from the response.

If \texttt{response} is a matrix a linear model is fitted separately by least-squares to each column of the matrix.

See \texttt{model.matrix} for some further details. The terms in the formula will be re-ordered so that main effects come first, followed by the interactions, all second-order, all third-order and so on: to avoid this pass a \texttt{terms} object as the formula (see \texttt{aov} and \texttt{demo(glm.vr)} for an example).

A formula has an implied intercept term. To remove this use either \texttt{y ~ x - 1} or \texttt{y ~ 0 + x}.

See \texttt{formula} for more details of allowed formulae.

\texttt{lm} calls the lower level functions \texttt{lm.fit}, etc, see below, for the actual numerical computations. For programming only, you may consider doing likewise.

All of \texttt{weights}, \texttt{subset} and \texttt{offset} are evaluated in the same way as variables in \texttt{formula}, that is first in \texttt{data} and then in the environment of \texttt{formula}.

Value

\texttt{lm} returns an object of class "\texttt{lm}" or for multiple responses of class \texttt{c("mlm", "\texttt{lm}").}

The functions \texttt{summary} and \texttt{anova} are used to obtain and print a summary and analysis of variance table of the results. The generic accessor functions \texttt{coefficients}, \texttt{effects}, \texttt{fitted.values} and \texttt{residuals} extract various useful features of the value returned by \texttt{lm}.

An object of class "\texttt{lm}" is a list containing at least the following components:

\texttt{coefficients} a named vector of coefficients

\texttt{residuals} the residuals, that is response minus fitted values.

\texttt{fitted.values} the fitted mean values.

\texttt{rank} the numeric rank of the fitted linear model.

\texttt{weights} (only for weighted fits) the specified weights.
df.residual  the residual degrees of freedom.
call         the matched call.
terms        the terms object used.
contrasts     (only where relevant) the contrasts used.
xlevels       (only where relevant) a record of the levels of the factors used in fitting.
offset        the offset used (missing if none were used).
y            if requested, the response used.
x            if requested, the model matrix used.
model        if requested (the default), the model frame used.

In addition, non-null fits will have components assign, effects and (unless not requested) qr relating to the linear fit, for use by extractor functions such as summary and effects.

Using time series

Considerable care is needed when using lm with time series.

Unless na.action = NULL, the time series attributes are stripped from the variables before the regression is done. (This is necessary as omitting NAs would invalidate the time series attributes, and if NAs are omitted in the middle of the series the result would no longer be a regular time series.)

Even if the time series attributes are retained, they are not used to line up series, so that the time shift of a lagged or differenced regressor would be ignored. It is good practice to prepare a data argument by ts.intersect(..., dframe = TRUE), then apply a suitable na.action to that data frame and call lm with na.action = NULL so that residuals and fitted values are time series.

Note

Offsets specified by offset will not be included in predictions by predict.lm, whereas those specified by an offset term in the formula will be.

Author(s)

The design was inspired by the S function of the same name described in Chambers (1992). The implementation of model formula by Ross Ihaka was based on Wilkinson & Rogers (1973).

\textbf{\texttt{lm.fit} --- Fitter Functions for Linear Models}

\textbf{Description}

These are the basic computing engines called by \texttt{lm} used to fit linear models. These should usually not be used directly unless by experienced users.

\textbf{Usage}

\begin{verbatim}
\texttt{lm.fit} \( (x, y, \quad \text{offset = NULL, method = "qr", tol = 1e-7, singular.ok = TRUE, \ldots}) \)
\texttt{lm.wfit} (x, y, w, \quad \text{offset = NULL, method = "qr", tol = 1e-7, singular.ok = TRUE, \ldots})
\end{verbatim}

\textbf{Arguments}

\begin{itemize}
  \item \texttt{x} \quad design matrix of dimension \( n \times p \).
  \item \texttt{y} \quad vector of observations of length \( n \), or a matrix with \( n \) rows.
  \item \texttt{w} \quad vector of weights (length \( n \)) to be used in the fitting process for the \texttt{wfit} functions. Weighted least squares is used with weights \( w \), i.e., \( \sum (w * e^2) \) is minimized.
\end{itemize}
offset numeric of length n). This can be used to specify an \textit{a priori} known component to be included in the linear predictor during fitting.

method currently, only \texttt{method=qr} is supported.

tol tolerance for the \texttt{qr} decomposition. Default is 1e-7.

singular.ok logical. If FALSE, a singular model is an error. 

... currently disregarded.

**Value**

a list with components

coefficients $p$ vector

residuals $n$ vector or matrix

fitted.values

  n vector or matrix

effects (not null fits): vector of orthogonal single-df effects. The first rank of them correspond to non-aliased coefficients, and are named accordingly.

weights $n$ vector — only for the \texttt{*wfit*} functions.

ranks integer, giving the rank

df.residual degrees of freedom of residuals

qr (not null fits) the QR decomposition, see \texttt{qr}.

**See Also**

\texttt{lm} which you should use for linear least squares regression, unless you know better.

**Examples**

```r
set.seed(129)
n <- 7 ; p <- 2
X <- matrix(rnorm(n * p), n,p) # no intercept!
y <- rnorm(n)
w <- rnorm(n)^2

str(lmw <- lm.wfit(x=X, y=y, w=w))

str(lm. <- lm.fit (x=X, y=y))
```

---

**lm.influence**

**Regression Diagnostics**

**Description**

This function provides the basic quantities which are used in forming a wide variety of diagnostics for checking the quality of regression fits.
Usage

```
influence(model, ...)  # S3 method for class 'lm':
influence(model, do.coef = TRUE, ...)  # S3 method for class 'glm':
influence(model, do.coef = TRUE)
```

Arguments

- `model`: an object as returned by `lm` or `glm`.
- `do.coef`: logical indicating if the changed coefficients (see below) are desired. These need $O(n^2p)$ computing time.
- `...`: further arguments passed to or from other methods.

Details

The `influence.measures()` and other functions listed in See Also provide a more user oriented way of computing a variety of regression diagnostics. These all build on `lm.influence`. Note that for GLMs (other than the Gaussian family with identity link) these are based on one-step approximations which may be inadequate if a case has high influence.

An attempt is made to ensure that computed hat values that are probably one are treated as one, and the corresponding rows in `sigma` and `coefficients` are NaN. (Dropping such a case would normally result in a variable being dropped, so it is not possible to give simple drop-one diagnostics.)

`naresid` is applied to the results and so will fill in with NAs it the fit had `na.action = na.exclude`.

Value

A list containing the following components of the same length or number of rows $n$, which is the number of non-zero weights. Cases omitted in the fit are omitted unless a `na.action` method was used (such as `na.exclude`) which restores them.

- `hat`: a vector containing the diagonal of the “hat” matrix.
- `coefficients` (unless `do.coef` is false) a matrix whose i-th row contains the change in the estimated coefficients which results when the i-th case is dropped from the regression. Note that aliased coefficients are not included in the matrix.
- `sigma`: a vector whose i-th element contains the estimate of the residual standard deviation obtained when the i-th case is dropped from the regression. (The approximations needed for GLMs can result in this being NaN.)
- `wt.res`: a vector of weighted (or for class `glm` rather `deviance`) residuals.

Note

The `coefficients` returned by the R version of `lm.influence` differ from those computed by S. Rather than returning the coefficients which result from dropping each case, we return the changes in the coefficients. This is more directly useful in many diagnostic measures. Since these need $O(n^2p)$ computing time, they can be omitted by `do.coef = FALSE`.

Note that cases with `weights == 0` are dropped (contrary to the situation in S).
If a model has been fitted with `na.action=na.exclude` (see `na.exclude`), cases excluded in the fit are considered here.

References
See the list in the documentation for `influence.measures`.

See Also
`summary.lm` for `summary` and related methods;
`influence.measures`,
`hat` for the hat matrix diagonals,
`dfbetas, dffits, covratio, cooks.distance, lm`.

Examples
```r
## Analysis of the life-cycle savings data
## given in Belsley, Kuh and Welsch.
summary(lm.SR <- lm(sr ~ pop15 + pop75 + dpi + ddpi,
                   data = LifeCycleSavings),
       corr = TRUE)
str(lmI <- lm.influence(lm.SR))
## For more "user level" examples, use example(influence.measures)
```

---

**lm.summaries**

## Accessing Linear Model Fits

### Description

All these functions are methods for class "lm" objects.

### Usage

```r
## S3 method for class 'lm':
family(object, ...)

## S3 method for class 'lm':
formula(x, ...)

## S3 method for class 'lm':
residuals(object,
          type = c("working", "response", "deviance", "pearson",
                   "partial"),
          ...)

## S3 method for class 'lm':
labels(object, ...)

weights(object, ...)
```

Arguments

object, x  an object inheriting from class lm, usually the result of a call to lm or aov.
... further arguments passed to or from other methods.
type  the type of residuals which should be returned.

Details

The generic accessor functions coef, effects, fitted and residuals can be used to extract various useful features of the value returned by lm.

The working and response residuals are “observed - fitted”. The deviance and person residuals are weighted residuals, scaled by the square root of the weights used in fitting. The partial residuals are a matrix with each column formed by omitting a term from the model. In all these, zero weight cases are never omitted (as opposed to the standardized rstudent residuals, and the weighted.residuals).

How residuals treats cases with missing values in the original fit is determined by the na.action argument of that fit. If na.action = na.omit omitted cases will not appear in the residuals, whereas if na.action = na.exclude they will appear, with residual value NA. See also naresid.

The "lm" method for generic labels returns the term labels for estimable terms, that is the names of the terms with an least one estimable coefficient.

### loadings

**Print Loadings in Factor Analysis**

#### Description

Extract or print loadings in factor analysis (or principal components analysis).

#### Usage

```r
loadings(x)
```

#### Arguments

- `x` an object of class "factanal" or "princomp" or the `loadings` component of such an object.
- `digits` number of decimal places to use in printing uniquenesses and loadings.
- `cutoff` loadings smaller than this (in absolute value) are suppressed.
- `sort` logical. If true, the variables are sorted by their importance on each factor. Each variable with any loading larger than 0.5 (in modulus) is assigned to the factor with the largest loading, and the variables are printed in the order of the factor they are assigned to, then those unassigned.
- `...` further arguments for other methods, such as `cutoff` and `sort` for `print.factanal`.

#### See Also

`factanal`, `princomp`

---

### loess

**Local Polynomial Regression Fitting**

#### Description

Fit a polynomial surface determined by one or more numerical predictors, using local fitting.

#### Usage

```r
loess(formula, data, weights, subset, na.action, model = FALSE, span = 0.75, enp.target, degree = 2, parametric = FALSE, drop.square = FALSE, normalize = TRUE, family = c("gaussian", "symmetric"), method = c("loess", "model.frame"), control = loess.control(...), ...)
```
Arguments

formula  a *formula* specifying the numeric response and one to four numeric predictors (best specified via an interaction, but can also be specified additively). Will be coerced to a formula if necessary.

data  an optional data frame, list or environment (or object coercible by `as.data.frame` to a data frame) containing the variables in the model. If not found in data, the variables are taken from `environment(formula)`, typically the environment from which `loess` is called.

weights  optional weights for each case.

subset  an optional specification of a subset of the data to be used.

na.action  the action to be taken with missing values in the response or predictors. The default is given by `getOption("na.action")`.

model  should the model frame be returned?

span  the parameter $\alpha$ which controls the degree of smoothing.

enp.target  an alternative way to specify `span`, as the approximate equivalent number of parameters to be used.

degree  the degree of the polynomials to be used, up to 2.

parametric  should any terms be fitted globally rather than locally? Terms can be specified by name, number or as a logical vector of the same length as the number of predictors.

drop.square  for fits with more than one predictor and `degree=2`, should the quadratic term (and cross-terms) be dropped for particular predictors? Terms are specified in the same way as for `parametric`.

normalize  should the predictors be normalized to a common scale if there is more than one? The normalization used is to set the 10% trimmed standard deviation to one. Set to false for spatial coordinate predictors and others know to be a common scale.

family  if "gaussian" fitting is by least-squares, and if "symmetric" a re-descending M estimator is used with Tukey’s biweight function.

method  fit the model or just extract the model frame.

control  control parameters: see `loess.control`.

...  control parameters can also be supplied directly.

Details

Fitting is done locally. That is, for the fit at point $x$, the fit is made using points in a neighbourhood of $x$, weighted by their distance from $x$ (with differences in 'parametric' variables being ignored when computing the distance). The size of the neighbourhood is controlled by $\alpha$ (set by `span` or `enp.target`). For $\alpha < 1$, the neighbourhood includes proportion $\alpha$ of the points, and these have tricubic weighting (proportional to $(1 - (\text{dist/maxdist})^3)^3$). For $\alpha > 1$, all points are used, with the ‘maximum distance’ assumed to be $\alpha^{1/p}$ times the actual maximum distance for $p$ explanatory variables.

For the default family, fitting is by (weighted) least squares. For `family="symmetric"` a few iterations of an M-estimation procedure with Tukey’s biweight are used. Be aware that as the initial value is the least-squares fit, this need not be a very resistant fit.

It can be important to tune the control list to achieve acceptable speed. See `loess.control` for details.
loess.control

Set Parameters for Loess

Description

Set control parameters for loess fits.

Usage

loess.control(surface = c("interpolate", "direct"),
              statistics = c("approximate", "exact"),
              trace.hat = c("exact", "approximate"),
              cell = 0.2, iterations = 4, ...)
Logistic

Arguments

surface should be fitted surface be computed exactly or via interpolation from a kd tree?

statistics should the statistics be computed exactly or approximately? Exact computation can be very slow.

trace.hat should the trace of the smoother matrix be computed exactly or approximately? It is recommended to use the approximation for more than about 1000 data points.

cell if interpolation is used this controls the accuracy of the approximation via the maximum number of points in a cell in the kd tree. Cells with more than floor(n*span*cell) points are subdivided.

iterations the number of iterations used in robust fitting.

... further arguments which are ignored.

Value

A list with components

surface
statistics
trace.hat

cell
iterations

with meanings as explained under ‘Arguments’.

See Also

loess

Description

Density, distribution function, quantile function and random generation for the logistic distribution with parameters location and scale.

Usage

dlogis(x, location = 0, scale = 1, log = FALSE)
plogis(q, location = 0, scale = 1, lower.tail = TRUE, log.p = FALSE)
qlogis(p, location = 0, scale = 1, lower.tail = TRUE, log.p = FALSE)
rlogis(n, location = 0, scale = 1)
Arguments

- \(x, q\) vector of quantiles.
- \(p\) vector of probabilities.
- \(n\) number of observations. If \(\text{length}(n) > 1\), the length is taken to be the number required.
- location, scale location and scale parameters.
- log, log.p logical; if TRUE, probabilities \(p\) are given as \(\log(p)\).
- lower.tail logical; if TRUE (default), probabilities are \(P[X \leq x]\), otherwise, \(P[X > x]\).

Details

If location or scale are omitted, they assume the default values of 0 and 1 respectively.

The Logistic distribution with location = \(\mu\) and scale = \(\sigma\) has distribution function

\[
F(x) = \frac{1}{1 + e^{-(x-\mu)/\sigma}}
\]

and density

\[
f(x) = \frac{1}{\sigma} \frac{e^{(x-\mu)/\sigma}}{(1 + e^{(x-\mu)/\sigma})^2}
\]

It is a long-tailed distribution with mean \(\mu\) and variance \(\pi^2/3\sigma^2\).

Value

dlogis gives the density, plogis gives the distribution function, qlogis gives the quantile function, and rlogis generates random deviates.

Note

qlogis(p) is the same as the well known ‘logit’ function, \(\logit(p) = \log(p/(1 - p))\), and plogis(x) has consequently been called the “inverse logit”.

The distribution function is a rescaled hyperbolic tangent, \(\text{plogis}(x) = (1 + \tanh(x/2))/2\), and it is called sigmoid function in contexts such as neural networks.

Source

[dpr]logis are calculated directly from the definitions.
rlogis uses inversion.

References

Examples

\[
\text{var(rlogis(4000, 0, s = 5))} \approx \pi^2/3 \times 5^2
\]
logLik

Extract Log-Likelihood

Description

This function is generic; method functions can be written to handle specific classes of objects. Classes which already have methods for this function include: glm, lm, nls, Arima and gls, lme and others in package nlme.

Usage

logLik(object, ...)

## S3 method for class 'lm':
logLik(object, REML = FALSE, ...)

Arguments

object any object from which a log-likelihood value, or a contribution to a log-likelihood value, can be extracted.

... some methods for this generic function require additional arguments.

REML an optional logical value. If TRUE the restricted log-likelihood is returned, else, if FALSE, the log-likelihood is returned. Defaults to FALSE.

Details

For a "glm" fit the family does not have to specify how to calculate the log-likelihood, so this is based on the family’s aic() function to compute the AIC. For the gaussian, Gamma and inverse.gaussian families it assumed that the dispersion of the GLM is estimated has been counted as a parameter in the AIC value, and for all other families it is assumed that the dispersion is known.

Note that this procedure is not completely accurate for the gamma and inverse gaussian families, as the estimate of dispersion used is not the MLE.

For "lm" fits it is assumed that the scale has been estimated (by maximum likelihood or REML), and all the constants in the log-likelihood are included.

Value

Returns an object, say r, of class logLik which is a number with attributes, attr(r, "df") (degrees of freedom) giving the number of (estimated) parameters in the model. There is a simple print method for logLik objects.

The details depend on the method function used; see the appropriate documentation.

Author(s)

Jose Pinheiro and Douglas Bates
loglin

For logLik.lm:

logLik.gls, logLik.lme, in package nlme, etc.

Examples

```r
x <- 1:5
lmx <- lm(x ~ 1)
logLik(lmx) # using print.logLik() method
str(logLik(lmx))
```

```r
## lm method
(fm1 <- lm(rating ~ ., data = attitude))
logLik(fm1)
logLik(fm1, REML = TRUE)
res <- try(data(Orthodont, package="nlme"))
if(!inherits(res, "try-error")) {
  fm1 <- lm(distance ~ Sex * age, Orthodont)
  print(logLik(fm1))
  print(logLik(fm1, REML = TRUE))
}
```

---

loglin

**Fitting Log-Linear Models**

**Description**

loglin is used to fit log-linear models to multidimensional contingency tables by Iterative Proportional Fitting.

**Usage**

```r
loglin(table, margin, start = rep(1, length(table)), fit = FALSE,
       eps = 0.1, iter = 20, param = FALSE, print = TRUE)
```

**Arguments**

- **table**
  a contingency table to be fit, typically the output from table.

- **margin**
  a list of vectors with the marginal totals to be fit.

(Hierarchical) log-linear models can be specified in terms of these marginal totals which give the “maximal” factor subsets contained in the model. For example, in a three-factor model, `list(c(1, 2), c(1, 3))` specifies a model which contains parameters for the grand mean, each factor, and the 1-2 and 1-3 interactions, respectively (but no 2-3 or 1-2-3 interaction), i.e., a model where factors 2 and 3 are independent conditional on factor 1 (sometimes represented as ‘[12][13]’).
The names of factors (i.e., `names(dimnames(table))`) may be used rather than numeric indices.

`start`  
a starting estimate for the fitted table. This optional argument is important for incomplete tables with structural zeros in `table` which should be preserved in the fit. In this case, the corresponding entries in `start` should be zero and the others can be taken as one.

`fit`  
a logical indicating whether the fitted values should be returned.

`eps`  
maximum deviation allowed between observed and fitted margins.

`iter`  
maximum number of iterations.

`param`  
a logical indicating whether the parameter values should be returned.

`print`  
a logical. If `TRUE`, the number of iterations and the final deviation are printed.

Details

The Iterative Proportional Fitting algorithm as presented in Haberman (1972) is used for fitting the model. At most `iter` iterations are performed, convergence is taken to occur when the maximum deviation between observed and fitted margins is less than `eps`. All internal computations are done in double precision; there is no limit on the number of factors (the dimension of the table) in the model.

Assuming that there are no structural zeros, both the Likelihood Ratio Test and Pearson test statistics have an asymptotic chi-squared distribution with `df` degrees of freedom.

Package `MASS` contains `loglm`, a front-end to `loglin` which allows the log-linear model to be specified and fitted in a formula-based manner similar to that of other fitting functions such as `lm` or `glm`.

Value

A list with the following components.

- `lrt`  
  the Likelihood Ratio Test statistic.

- `pearson`  
  the Pearson test statistic (X-squared).

- `df`  
  the degrees of freedom for the fitted model. There is no adjustment for structural zeros.

- `margin`  
  list of the margins that were fit. Basically the same as the input `margin`, but with numbers replaced by names where possible.

- `fit`  
  An array like `table` containing the fitted values. Only returned if `fit` is `TRUE`.

- `param`  
  A list containing the estimated parameters of the model. The “standard” constraints of zero marginal sums (e.g., zero row and column sums for a two factor parameter) are employed. Only returned if `param` is `TRUE`.

Author(s)

Kurt Hornik

Lognormal

See Also

- `table`
- `loglm` in package MASS for a user-friendly wrapper.
- `glm` for another way to fit log-linear models.

Examples

```r
## Model of joint independence of sex from hair and eye color.
fm <- loglin(HairEyeColor, list(c(1, 2), c(1, 3), c(2, 3)))
fm
1 - pchisq(fm$lrt, fm$df)
## Model with no three-factor interactions fits well.
```

---

Lognormal

The Log Normal Distribution

Description

Density, distribution function, quantile function and random generation for the log normal distribution whose logarithm has mean equal to `meanlog` and standard deviation equal to `sdlog`.

Usage

```r
dlnorm(x, meanlog = 0, sdlog = 1, log = FALSE)
plnorm(q, meanlog = 0, sdlog = 1, lower.tail = TRUE, log.p = FALSE)
qlnorm(p, meanlog = 0, sdlog = 1, lower.tail = TRUE, log.p = FALSE)
rlnorm(n, meanlog = 0, sdlog = 1)
```

Arguments

- `x, q` vector of quantiles.
- `p` vector of probabilities.
- `n` number of observations. If `length(n) > 1`, the length is taken to be the number required.
- `meanlog, sdlog` mean and standard deviation of the distribution on the log scale with default values of 0 and 1 respectively.
- `log, log.p` logical; if TRUE, probabilities p are given as log(p).
- `lower.tail` logical; if TRUE (default), probabilities are \( P[X \leq x] \), otherwise, \( P[X > x] \).

Details

The log normal distribution has density

\[
f(x) = \frac{1}{\sqrt{2\pi}\sigma x} e^{-(\log(x) - \mu)^2 / 2\sigma^2}
\]

where \( \mu \) and \( \sigma \) are the mean and standard deviation of the logarithm. The mean is \( E(X) = \exp(\mu + 1/2\sigma^2) \), and the variance \( \text{Var}(X) = \exp(2\mu + \sigma^2)(\exp(\sigma^2) - 1) \) and hence the coefficient of variation is \( \sqrt{\exp(\sigma^2) - 1} \) which is approximately \( \sigma \) when that is small (e.g., \( \sigma < 1/2 \)).
Value

dlnorm gives the density, plnorm gives the distribution function, qlnorm gives the quantile function, and rlnorm generates random deviates.

Note

The cumulative hazard $H(t) = -\log(1 - F(t))$ is -plnorm(t, r, lower = FALSE, log = TRUE).

Source

dlnorm is calculated from the definition (in Details). [pqr]lnorm are based on the relationship to the normal.

References

See Also

dnorm for the normal distribution.

Examples

dlnorm(1) == dnorm(0)

---

**lowess**

**Scatter Plot Smoothing**

Description

This function performs the computations for the LOWESS smoother which uses locally-weighted polynomial regression (see the references).

Usage

lowess(x, y = NULL, f = 2/3, iter = 3, 
delta = 0.01 * diff(range(xy$x[o])))

Arguments

x, y vectors giving the coordinates of the points in the scatter plot. Alternatively a single plotting structure can be specified.

f the smoother span. This gives the proportion of points in the plot which influence the smooth at each value. Larger values give more smoothness.

iter the number of ‘robustifying’ iterations which should be performed. Using smaller values of iter will make lowess run faster.

delta See Details. Defaults to 1/100th of the range of x.
Details

`lowess` is defined by a complex algorithm, the Ratfor original of which (by W. S. Cleveland) can be found in the R sources as file `src/appl/lowess.doc`. Normally a local linear polynomial fit is used, but under some circumstances (see the file) a local constant fit can be used. ‘Local’ is defined by the distance to the floor(f*n)th nearest neighbour, and tricubic weighting is used for x which fall within the neighbourhood.

The initial fit is done using weighted least squares. If iter > 0, further weighted fits are done using the product of the weights from the proximity of the x values and case weights derived from the residuals at the previous iteration. Specifically, the case weight is Tukey’s biweight, with cutoff 6 times the MAD of the residuals. (The current R implementation differs from the original in stopping iteration if the MAD is effectively zero since the algorithm is highly unstable in that case.)

delta is used to speed up computation: instead of computing the local polynomial fit at each data point it is not computed for points within delta of the last computed point, and linear interpolation is used to fill in the fitted values for the skipped points.

Value

`lowess` returns a list containing components `x` and `y` which give the coordinates of the smooth. The smooth can be added to a plot of the original points with the function `lines`: see the examples.

References

See Also

`loess`, a newer formula based version of `lowess` (with different defaults!).

Examples

```r
plot(cars, main = "lowess(cars)")
lines(lowess(cars), col = 2)
lines(lowess(cars, f=.2), col = 3)
legend(5, 120, c(paste("f = ", c("2/3", ",.2"))), lty = 1, col = 2:3)
```

---

**ls.diag**

*Compute Diagnostics for 'lsfit' Regression Results*

Description

Computes basic statistics, including standard errors, t- and p-values for the regression coefficients.

Usage

`ls.diag(ls.out)`
Arguments

ls.out Typically the result of lsfit()

Value

A list with the following numeric components.

- **std.dev**  The standard deviation of the errors, an estimate of \( \sigma \).
- **hat**  diagonal entries \( h_{ii} \) of the hat matrix \( H \)
- **std.res**  standardized residuals
- **stud.res**  studentized residuals
- **cooks**  Cook’s distances
- **dfits**  DFITS statistics
- **correlation**  correlation matrix
- **std.err**  standard errors of the regression coefficients
- **cov.scaled**  Scaled covariance matrix of the coefficients
- **cov.unscaled**  Unscaled covariance matrix of the coefficients

References

See Also

hat for the hat matrix diagonals, ls.print, lm.influence, summary.lm, anova.

Examples

```r
##-- Using the same data as the lm(.) example:
lsD9 <- lsfit(x = as.numeric(gl(2, 10, 20)), y = weight)
dlsD9 <- ls.diag(lsD9)
str(dlsD9, give.attr=FALSE)
abs(1 - sum(dlsD9$hat) / 2) < 10*.Machine$double.eps # sum(h.ii) = p
plot(dlsD9$hat, dlsD9$stud.res, xlim=c(0,0.11))
abline(h = 0, lty = 2, col = "lightgray")
```
**Arguments**

- **ls.out**
  Typically the result of `lsfit()`

- **digits**
  The number of significant digits used for printing

- **print.it**
  A logical indicating whether the result should also be printed

**Value**

A list with the components

- **summary**
  The ANOVA table of the regression

- **coef.table**
  Matrix with regression coefficients, standard errors, t- and p-values

**Note**

Usually, you’d rather use `summary(lm(...))` and `anova(lm(...))` for obtaining similar output.

**See Also**

`ls.diag`, `lsfit`, also for examples; `lm`, `lm.influence` which usually are preferable.

---

### lsfit

#### Find the Least Squares Fit

**Description**

The least squares estimate of $\beta$ in the model

$$ Y = X\beta + \epsilon $$

is found.

**Usage**

```r
lsfit(x, y, wt = NULL, intercept = TRUE, tolerance = 1e-07, yname = NULL)
```

**Arguments**

- **x**
  A matrix whose rows correspond to cases and whose columns correspond to variables.

- **y**
  The responses, possibly a matrix if you want to fit multiple left hand sides.

- **wt**
  An optional vector of weights for performing weighted least squares.

- **intercept**
  Whether or not an intercept term should be used.

- **tolerance**
  The tolerance to be used in the matrix decomposition.

- **yname**
  Names to be used for the response variables.
Details

If weights are specified then a weighted least squares is performed with the weight given to the \( j \)th case specified by the \( j \)th entry in wt.

If any observation has a missing value in any field, that observation is removed before the analysis is carried out. This can be quite inefficient if there is a lot of missing data.

The implementation is via a modification of the LINPACK subroutines which allow for multiple left-hand sides.

Value

A list with the following named components:

- **coef**: the least squares estimates of the coefficients in the model (\( \beta \) as stated above).
- **residuals**: residuals from the fit.
- **intercept**: indicates whether an intercept was fitted.
- **qr**: the QR decomposition of the design matrix.

References

See Also

- `lm` which usually is preferable; `ls.print`, `ls.diag`.

Examples

```r
##-- Using the same data as the lm(.) example:
lsD9 <- lsfit(x = unclass(gl(2,10)), y = weight)
ls.print(lsD9)
```

mad

### Median Absolute Deviation

Description

Compute the median absolute deviation, i.e., the (lo-/hi-) median of the absolute deviations from the median, and (by default) adjust by a factor for asymptotically normal consistency.

Usage

```r
mad(x, center = median(x), constant = 1.4826, na.rm = FALSE,
    low = FALSE, high = FALSE)
```
Arguments

x     a numeric vector.
center Optionally, the centre: defaults to the median.
constant scale factor.
na.rm if TRUE then NA values are stripped from x before computation takes place.
low if TRUE, compute the “lo-median”, i.e., for even sample size, do not average the two middle values, but take the smaller one.
high if TRUE, compute the “hi-median”, i.e., take the larger of the two middle values for even sample size.

Details

The actual value calculated is constant * cMedian(abs(x - center)) with the default value of center being median(x), and cMedian being the usual, the “low” or “high” median, see the arguments description for low and high above.

The default constant = 1.4826 (approximately 1/Φ^{-1}(3/4) = 1/qnorm(3/4)) ensures consistency, i.e.,

\[ E[\text{mad}(X_1, \ldots, X_n)] = \sigma \]

for \( X_i \) distributed as \( N(\mu, \sigma^2) \) and large \( n \).

If na.rm is TRUE then NA values are stripped from \( x \) before computation takes place. If this is not done then an NA value in \( x \) will cause mad to return NA.

See Also

IQR which is simpler but less robust, median, var.

Examples

```r
mad(c(1:9))
print(mad(c(1:9), constant=1)) ==
mad(c(1:8,100), constant=1) # = 2 ; TRUE
x <- c(1,2,3, 5,7,8)
sort(abs(x - median(x)))
c(mad(x, co=1), mad(x, co=1, lo = TRUE), mad(x, co=1, hi = TRUE))
```

---

mahalanobis

Mahalanobis Distance

Description

Returns the squared Mahalanobis distance of all rows in \( x \) and the vector \( \mu = \text{center} \) with respect to \( \Sigma = \text{cov} \). This is (for vector \( x \)) defined as

\[ D^2 = (x - \mu)'\Sigma^{-1}(x - \mu) \]

Usage

```r
mahalanobis(x, center, cov, inverted=FALSE, ...)
```
make.link

Create a Link for GLM Families

Description

This function is used with the family functions in glm(). Given the name of a link, it returns a link function, an inverse link function, the derivative d\mu/d\eta and a function for domain checking.

Usage

make.link(link)

Arguments

link character or numeric; one of "logit", "probit", "cloglog", "identity", "log", "sqrt", "1/mu^2", "inverse", or (deprecated) a non-negative number, say \lambda resulting in power link = \mu^\lambda. Also (deprecated) a string like "power(0.5)" to indicate a call to power.
Value

A object of class "link-glm", a list with components

- `linkfun` Link function function(mu)
- `linkinv` Inverse link function function(eta)
- `mu.eta` Derivative function(eta) $d\mu/d\eta$
- `valideta` function(eta) TRUE if eta is in the domain of linkinv.
- `name` a name to be used for the link.

See Also

power, glm, family.

Examples

str(make.link("logit"))
See Also

model.frame, poly, scale; bs and ns in package splines, cars

Examples

```r
## using poly: this did not work in R < 1.5.0
fm <- lm(weight ~ poly(height, 2), data = women)
plot(women, xlab = "Height (in)", ylab = "Weight (lb)")
ht <- seq(57, 73, len = 200)
lines(ht, predict(fm, data.frame(height=ht)))
## see also example(cars)
## see bs and ns for spline examples.
```

manova

Multivariate Analysis of Variance

Description

A class for the multivariate analysis of variance.

Usage

```r
manova(...)  
```

Arguments

... Arguments to be passed to aov.

Details

Class "manova" differs from class "aov" in selecting a different summary method. Function manova calls aov and then add class "manova" to the result object for each stratum.

Value

See aov and the comments in Details here.

Note

manova does not support multistratum analysis of variance, so the formula should not include an Error term.

References

See Also

aov, summary.manova, the latter containing examples.
Description

Performs a Cochran-Mantel-Haenszel chi-squared test of the null that two nominal variables are conditionally independent in each stratum, assuming that there is no three-way interaction.

Usage

mantelhaen.test(x, y = NULL, z = NULL,
               alternative = c("two.sided", "less", "greater"),
               correct = TRUE, exact = FALSE, conf.level = 0.95)

Arguments

x          either a 3-dimensional contingency table in array form where each dimension is at least 2 and the last dimension corresponds to the strata, or a factor object with at least 2 levels.
y          a factor object with at least 2 levels; ignored if x is an array.
z          a factor object with at least 2 levels identifying to which stratum the corresponding elements in x and y belong; ignored if x is an array.

alternative indicates the alternative hypothesis and must be one of "two.sided", "greater" or "less". You can specify just the initial letter. Only used in the 2 by 2 by K case.
correct    a logical indicating whether to apply continuity correction when computing the test statistic. Only used in the 2 by 2 by K case.
exact      a logical indicating whether the Mantel-Haenszel test or the exact conditional test (given the strata margins) should be computed. Only used in the 2 by 2 by K case.
conf.level confidence level for the returned confidence interval. Only used in the 2 by 2 by K case.

Details

If x is an array, each dimension must be at least 2, and the entries should be nonnegative integers. NA’s are not allowed. Otherwise, x, y and z must have the same length. Triples containing NA’s are removed. All variables must take at least two different values.

Value

A list with class "htest" containing the following components:

  statistic  Only present if no exact test is performed. In the classical case of a 2 by 2 by K table (i.e., of dichotomous underlying variables), the Mantel-Haenszel chi-squared statistic; otherwise, the generalized Cochran-Mantel-Haenszel statistic.
  parameter  the degrees of freedom of the approximate chi-squared distribution of the test statistic (1 in the classical case). Only present if no exact test is performed.
  p.value    the p-value of the test.
mantelhaen.test

conf.int  a confidence interval for the common odds ratio. Only present in the 2 by 2 by $K$ case.
estimate  an estimate of the common odds ratio. If an exact test is performed, the conditional Maximum Likelihood Estimate is given; otherwise, the Mantel-Haenszel estimate. Only present in the 2 by 2 by $K$ case.
null.value  the common odds ratio under the null of independence, 1. Only present in the 2 by 2 by $K$ case.
alternative  a character string describing the alternative hypothesis. Only present in the 2 by 2 by $K$ case.
method  a character string indicating the method employed, and whether or not continuity correction was used.
data.name  a character string giving the names of the data.

Note

The asymptotic distribution is only valid if there is no three-way interaction. In the classical 2 by 2 by $K$ case, this is equivalent to the conditional odds ratios in each stratum being identical. Currently, no inference on homogeneity of the odds ratios is performed.

See also the example below.

## hours delayed penicillin in protecting rabbits against a lethal
## injection with beta-hemolytic streptococci.
Rabbits <-
array(c(0, 0, 6, 5,
       3, 0, 3, 6,
       6, 2, 0, 4,
       5, 1, 6, 0,
       2, 5, 0, 0),
    dim = c(2, 2, 5),
    dimnames = list(
      Delay = c("None", "1.5h"),
      Response = c("Cured", "Died"),
      Penicillin.Level = c("1/8", "1/4", "1/2", "1", "4")))
Rabbits
## Classical Mantel-Haenszel test
mantelhaen.test(Rabbits)
## => p = 0.047, some evidence for higher cure rate of immediate
## injection
## Exact conditional test
mantelhaen.test(Rabbits, exact = TRUE)
## => p = 0.040
## Exact conditional test for one-sided alternative of a higher
## cure rate for immediate injection
mantelhaen.test(Rabbits, exact = TRUE, alternative = "greater")
```
## => p = 0.020

### UC Berkeley Student Admissions

mantelhaen.test(UCBAdmissions)

### No evidence for association between admission and gender when adjusted for department. However,

apply(UCBAdmissions, 3, function(x) (x[1,1]*x[2,2])/(x[1,2]*x[2,1]))

### This suggests that the assumption of homogeneous (conditional) odds ratios may be violated. The traditional approach would be using the Woolf test for interaction:

woolf <- function(x) {
  n <- x + 1 / 2
  k <- dim(x)[3]
  or <- apply(x, 3, function(x) (x[1,1]*x[2,2])/(x[1,2]*x[2,1]))
  w <- apply(x, 3, function(x) 1 / sum(1 / x))
  1 - pchisq(sum(w * (log(or) - weighted.mean(log(or), w)) ^ 2), k - 1)
}

woolf(UCBAdmissions)

### => p = 0.003, indicating that there is significant heterogeneity. (And hence the Mantel-Haenszel test cannot be used.)

### Job Satisfaction example.

Satisfaction <- as.table(array(c(1, 2, 0, 0, 3, 3, 1, 2,
11, 17, 8, 4, 2, 3, 5, 2,
1, 0, 0, 1, 3, 1, 0, 1,
2, 5, 7, 9, 1, 1, 3, 6),
dim = c(4, 4, 2),
dimnames =
list(Income = c("<5000", "5000-15000", "15000-25000", ">25000"),
"Job Satisfaction" = c("V_D", "L_S", "M_S", "V_S"),
Gender = c("Female", "Male")))

### (Satisfaction categories abbreviated for convenience.)

ftable(. ~ Gender + Income, Satisfaction)

### See Table 7.8 in Agresti (2002), p. 288.

mantelhaen.test(Satisfaction)

---

### mauchly.test

**Mauchly’s Test of Sphericity**

**Description**

Tests whether a Wishart-distributed covariance matrix (or transformation thereof) is proportional to a given matrix.

**Usage**

```r
mauchly.test(object, Sigma = diag(nrow = p),
  T = Thin.row(proj(M) - proj(X)), M = diag(nrow = p), X = ~0,
  idata = data.frame(index = seq_len(p)), ...)
```
Arguments

- **object**: object of class `SSD` or `mlm`.
- **Sigma**: matrix to be proportional to.
- **T**: transformation matrix. By default computed from M and X.
- **M**: formula or matrix describing the outer projection (see below).
- **X**: formula or matrix describing the inner projection (see below).
- **idata**: data frame describing intra-block design.
- **...**: arguments to be passed to or from other methods.

Details

Mauchly’s test test for whether a covariance matrix can be assumed to be proportional to a given matrix.

It is common to transform the observations prior to testing. This typically involves transformation to intra-block differences, but more complicated within-block designs can be encountered, making more elaborate transformations necessary. A transformation matrix $T$ can be given directly or specified as the difference between two projections onto the spaces spanned by $M$ and $X$, which in turn can be given as matrices or as model formulas with respect to `idata` (the tests will be invariant to parametrization of the quotient space $M/X$).

The common use of this test is in repeated measurements designs, with $X=\sim 1$. This is almost, but not quite the same as testing for compound symmetry in the untransformed covariance matrix.

This is a generic function with methods for classes `{mlm}` and `{SSD}`.

Value

An object of class `{htest}`

Note

The p-value differs slightly from that of SAS because a second order term is included in the asymptotic approximation in $R$.

References

See Also

`SSD`, `anova.mlm`

Examples

```r
example(SSD) # Brings in the mlmfit and reacttime objects

### traditional test of intrasubj. contrasts
mauchly.test(mlmfit, X=~1)

### tests using intra-subject 3x2 design
idata <- data.frame(deg=gl(3,1,6, labels=c(0,4,8)),
                      noise=gl(2,3,6, labels=c("A","P"))),
mauchly.test(mlmfit, X = ~ deg + noise, idata = idata)
mauchly.test(mlmfit, M = ~ deg + noise, X = ~ noise, idata=idata)
```
Description

Performs McNemar's chi-squared test for symmetry of rows and columns in a two-dimensional contingency table.

Usage

mcnemar.test(x, y = NULL, correct = TRUE)

Arguments

x
  either a two-dimensional contingency table in matrix form, or a factor object.

y
  a factor object; ignored if x is a matrix.

correct
  a logical indicating whether to apply continuity correction when computing the test statistic.

Details

The null is that the probabilities of being classified into cells \([i,j]\) and \([j,i]\) are the same.

If x is a matrix, it is taken as a two-dimensional contingency table, and hence its entries should be nonnegative integers. Otherwise, both \(x\) and \(y\) must be vectors of the same length. Incomplete cases are removed, the vectors are coerced into factor objects, and the contingency table is computed from these.

Continuity correction is only used in the 2-by-2 case if correct is TRUE.

Value

A list with class "htest" containing the following components:

statistic
  the value of McNemar's statistic.

parameter
  the degrees of freedom of the approximate chi-squared distribution of the test statistic.

p.value
  the p-value of the test.

method
  a character string indicating the type of test performed, and whether continuity correction was used.

data.name
  a character string giving the name(s) of the data.

Performance
mcnemar.test(Performance)
## => significant change (in fact, drop) in approval ratings

median

### Description

Compute the sample median.

### Usage

median(x, na.rm = FALSE)

### Arguments

- **x**: an object for which a method has been defined, or a numeric vector containing
  the values whose median is to be computed.
- **na.rm**: a logical value indicating whether NA values should be stripped before the com-putation proceeds.

### Details

This is a generic function for which methods can be written. However, the default method makes
use of sort and mean, both of which are generic, and so the default method will work for most
classes (e.g. "Date") for which a median is a reasonable concept.

### References

Brooks/Cole.

### See Also

quantile for general quantiles.

### Examples

median(1:4)# = 2.5 [even number]
median(c(1:3,100,1000))# = 3 [odd, robust]
**Median Polish of a Matrix**

**Description**

Fits an additive model using Tukey’s *median polish* procedure.

**Usage**

```r
medpolish(x, eps = 0.01, maxiter = 10, trace.iter = TRUE, na.rm = FALSE)
```

**Arguments**

- `x` a numeric matrix.
- `eps` real number greater than 0. A tolerance for convergence: see `Details`.
- `maxiter` the maximum number of iterations
- `trace.iter` logical. Should progress in convergence be reported?
- `na.rm` logical. Should missing values be removed?

**Details**

The model fitted is additive (constant + rows + columns). The algorithm works by alternately removing the row and column medians, and continues until the proportional reduction in the sum of absolute residuals is less than `eps` or until there have been `maxiter` iterations. The sum of absolute residuals is printed at each iteration of the fitting process, if `trace.iter` is `TRUE`. If `na.rm` is `FALSE` the presence of any `NA` value in `x` will cause an error, otherwise `NA` values are ignored.

`medpolish` returns an object of class `medpolish` (see below). There are printing and plotting methods for this class, which are invoked via by the generics `print` and `plot`.

**Value**

An object of class `medpolish` with the following named components:

- `overall` the fitted constant term.
- `row` the fitted row effects.
- `col` the fitted column effects.
- `residuals` the residuals.
- `name` the name of the dataset.

**References**

**See Also**

`median`; `aov` for a *mean* instead of *median* decomposition.
Examples

```r
## Deaths from sport parachuting; from ABC of EDA, p.224:

deaths <-
  rbind(c(14,15,14),
        c( 7, 4, 7),
        c( 8, 2,10),
        c(15, 9,10),
        c(0, 2, 0))

dimnames(deaths) <- list(c("1-24", "25-74", "75-199", "200++", "NA"),
                          paste(1973:1975))

deads

(med.d <- medpolish(deaths))
plot(med.d)

## Check decomposition:
all(deaths == med.d$overall + outer(med.d$row,med.d$col, "+") + med.d$resid)
```

model.extract

Extract Components from a Model Frame

Description

Returns the response, offset, subset, weights or other special components of a model frame passed as optional arguments to `model.frame`.

Usage

```r
model.extract(frame, component)
model.offset(x)
model.response(data, type = "any")
model.weights(x)
```

Arguments

- `frame, x, data`
  A model frame.
- `component`
  literal character string or name. The name of a component to extract, such as "weights", "subset".
- `type`
  One of "any", "numeric", "double". Using either of latter two coerces the result to have storage mode "double".

Details

`model.extract` is provided for compatibility with S, which does not have the more specific functions. It is also useful to extract e.g. the etastart and mustart components of a `glm` fit. `model.offset` and `model.response` are equivalent to `model.extract(, "offset")` and `model.extract(, "response")` respectively. `model.offset` sums any terms specified by `offset` terms in the formula or by `offset` arguments in the call producing the model frame: it does check that the offset is numeric.

`model.weights` is slightly different from `model.frame(, "weights")` in not naming the vector it returns.
Value

The specified component of the model frame, usually a vector.

See Also

model.frame, offset

Examples

```r
a <- model.frame(cbind(ncases,ncontrols) ~ agegp+tobgp+alcgp, data=esoph)
model.extract(a, "response")
stopifnot(model.extract(a, "response") == model.response(a))

a <- model.frame(ncases/(ncases+ncontrols) ~ agegp+tobgp+alcgp,
data = esoph, weights = ncases+ncontrols)
model.response(a)
model.extract(a, "weights")

a <- model.frame(cbind(ncases,ncontrols) ~ agegp,
something = tobgp, data = esoph)
names(a)
stopifnot(model.extract(a, "something") == esoph$tobgp)
```

model.frame

Extracting the “Environment” of a Model Formula

Description

model.frame (a generic function) and its methods return a data.frame with the variables needed to use formula and any ... arguments.

Usage

```r
model.frame(formula, ...) 
```

## Default S3 method:
```r
model.frame(formula, data = NULL, 
subset = NULL, na.action = na.fail, 
drop.unused.levels = FALSE, xlev = NULL, ...)
```

## S3 method for class 'aovlist':
```r
model.frame(formula, data = NULL, ...)
```

## S3 method for class 'glm':
```r
model.frame(formula, ...)
```

## S3 method for class 'lm':
```r
model.frame(formula, ...)
```

get_all_vars(formula, data, ...)
Arguments

- **formula**: a model formula or terms object or an R object.
- **data**: a data.frame, list or environment (or object coercible by `as.data.frame`) to a data.frame, containing the variables in formula. Neither a matrix nor an array will be accepted.
- **subset**: a specification of the rows to be used: defaults to all rows. This can be any valid indexing vector (see `\[.data.frame\]`) for the rows of data or if that is not supplied, a data frame made up of the variables used in formula.
- **na.action**: how NAs are treated. The default is first, any na.action attribute of data, second a na.action setting of options, and third na.fail if that is unset. The "factory-fresh" default is `na.omit`. Another possible value is `NULL`.
- **drop.unused.levels**: should factors have unused levels dropped? Defaults to `FALSE`.
- **xlev**: a named list of character vectors giving the full set of levels to be assumed for each factor.
- **...**: further arguments such as `data`, `na.action`, `subset`. Any additional arguments such as `offset` and `weights` which reach the default method are used to create further columns in the model frame, with parenthesised names such as "(offset)".

Details

Exactly what happens depends on the class and attributes of the object `formula`. If this is an object of fitted-model class such as "lm", the method will either returned the saved model frame used when fitting the model (if any, often selected by argument `model = TRUE`) or pass the call used when fitting on to the default method. The default method itself can cope with rather standard model objects such as those of class "lqs" from package MASS if no other arguments are supplied.

The rest of this section applies only to the default method.

If either `formula` or `data` is already a model frame (a data frame with a "terms" attribute and the other is missing, the model frame is returned. Unless `formula` is a terms object, `as.formula` and then `terms` is called on it. (If you wish to use the keep.order argument of `terms.formula`, pass a terms object rather than a formula.)

Row names for the model frame are taken from the `data` argument if present, then from the names of the response in the formula (or rownames if it is a matrix), if there is one.

All the variables in `formula`, `subset` and in `...` are looked for first in `data` and then in the environment of `formula` (see the help for `formula()` for further details) and collected into a data frame. Then the `subset` expression is evaluated, and it is is used as a row index to the data frame. Then the `na.action` function is applied to the data frame (and may well add attributes). The levels of any factors in the data frame are adjusted according to the `drop.unused.levels` and `xlev` arguments.

Unless `na.action = NULL`, time-series attributes will be removed from the variables found (since they will be wrong if NAs are removed).

Note that all the variables in the formula are included in the data frame, even those preceded by -. Only variables whose type is raw, logical, integer, real, complex or character can be included in a model frame: this includes classed variables such as factors (whose underlying type is integer), but excludes lists.
get_all_vars returns a codedata.frame containing the variables used in formula plus those specified ... Unlike model.frame.default, it returns the input variables and not those resulting from function calls in formula.

Value

A data.frame containing the variables used in formula plus those specified ....

model.matrix for the “design matrix”, formula for formulas and expand.model.frame for model.frame manipulation.

Examples

data.class(model.frame(dist ~ speed, data = cars))

model.matrix

Construct Design Matrices

Description

model.matrix creates a design matrix.

Usage

model.matrix(object, ...)

## Default S3 method:
model.matrix(object, data = environment(object),
contrasts.arg = NULL, xlev = NULL, ...)

Arguments

object an object of an appropriate class. For the default method, a model formula or
terms object.

data a data frame created with model.frame. If another sort of object,
model.frame is called first.

contrasts.arg A list, whose entries are contrasts suitable for input to the contrasts replace-
ment function and whose names are the names of columns of data containing
factors.

xlev to be used as argument of model.frame if data has no "terms" attribute.

... further arguments passed to or from other methods.
model.matrix

Details

model.matrix creates a design matrix from the description given in terms(object), using
the data in data which must contain variables with the same names as would be created by a
call to model.frame(object) or, more precisely, by evaluating attr(terms(object),
"variables"). If it is a data frame, there may be other columns and the order of columns is not
important. Any character variables are coerced to factors, with a warning. After coercion, all the
variables used in RHD of the formula must be logical, integer, numeric or factor.

If contrasts.arg is specified for a factor it overrides the default factor coding for that variable
and any "contrasts" attribute set by contrasts.

In an interaction term, the variable whose levels vary fastest is the first one to appear in the formula
(and not in the term), so in ~ a + b + b:a the interaction will have a varying fastest.

By convention, if the response variable also appears on the right-hand side of the formula it is
dropped (with a warning), although interactions involving the term are retained.

Value

The design matrix for a regression model with the specified formula and data.

There is an attribute "assign", an integer vector with an entry for each column in the matrix
giving the term in the formula which gave rise to the column. Value 0 corresponds to the intercept
(if any), and positive values to terms in the order given by the terms.labels attribute of the
terms structure corresponding to object.

If there are any factors in terms in the model, there is an attribute "contrasts", a named list
with an entry for each factor. This specifies the contrasts that would be used in terms in which the
factor is coded by contrasts (in some terms dummy coding may be used), either as a character vector
naming a function or as a numeric matrix.

Examples

ff <- log(Volume) ~ log(Height) + log(Girth)
str(m <- model.frame(ff, trees))
mat <- model.matrix(ff, m)

dd <- data.frame(a = gl(3,4), b = gl(4,1,12))# balanced 2-way
options("contrasts")
model.matrix(~ a + b, dd)
model.matrix(~ a + b, dd, contrasts = list(a="contr.sum"))
model.matrix(~ a + b, dd, contrasts = list(a="contr.sum", b="contr.poly"))
m.orth <- model.matrix(~a+b, dd, contrasts = list(a="contr.helmert"))
crossprod(m.orth)# m.orth is ALMOST orthogonal
model.tables  Compute Tables of Results from an Aov Model Fit

Description
Computes summary tables for model fits, especially complex aov fits.

Usage
model.tables(x, ...)

## S3 method for class 'aov':
model.tables(x, type = "effects", se = FALSE, cterms, ...)

## S3 method for class 'aovlist':
model.tables(x, type = "effects", se = FALSE, ...)

Arguments

x  a model object, usually produced by aov

type  type of table: currently only "effects" and "means" are implemented.

se  should standard errors be computed?

cterms  A character vector giving the names of the terms for which tables should be computed. The default is all tables.

...  further arguments passed to or from other methods.

Details
For type = "effects" give tables of the coefficients for each term, optionally with standard errors.
For type = "means" give tables of the mean response for each combinations of levels of the factors in a term.
The "aov" method cannot be applied to components of a "aovlist" fit.

Value
An object of class "tables.aov", as list which may contain components
tables  A list of tables for each requested term.

n  The replication information for each term.

se  Standard error information.

Warning
The implementation is incomplete, and only the simpler cases have been tested thoroughly.
Weighted aov fits are not supported.

### Examples

```r
N <- c(0,1,0,1,1,0,0,1,1,0,1,0,1,0,1,0,0,1,0,1,1,0,0)
P <- c(1,1,0,0,0,1,0,1,1,0,0,0,0,0,1,0,1,0,0,1,1,0)
K <- c(1,0,0,1,0,1,1,0,0,1,0,1,0,1,0,0,0,1,1,0,0,0)
yield <- c(49.5,62.8,46.8,57.0,59.8,58.5,55.5,56.0,62.8,55.8,69.5, 55.0, 62.0,48.8,45.5,44.2,52.0,51.5,49.8,48.8,57.2,59.0,53.2,56.0)

npk <- data.frame(block=gl(6,4), N=factor(N), P=factor(P),
                   K=factor(K), yield=yield)
options(contrasts=c("contr.helmert", "contr.treatment"))
npk.aov <- aov(yield ~ block + N*P*K, npk)
model.tables(npk.aov, "means", se = TRUE)

## as a test, not particularly sensible statistically
npk.aovE <- aov(yield ~ N*P*K + Error(block), npk)
model.tables(npk.aovE, se=TRUE)
model.tables(npk.aovE, "means")
```

### Description

These functions plot seasonal (or other) subseries of a time series. For each season (or other category), a time series is plotted.

### Usage

```r
monthplot(x, ...)
```

---

**monthplot**

*Plot a Seasonal or other Subseries from a Time Series*

---

### Usage

```r
monthplot(x, ...)
```

---

These functions plot seasonal (or other) subseries of a time series. For each season (or other category), a time series is plotted.

### Usage

```r
monthplot(x, ...)
```
Arguments

- **x**: Time series or related object.
- **labels**: Labels to use for each “season”.
- **ylab**: y label.
- **times**: Time of each observation.
- **phase**: Indicator for each “season”.
- **base**: Function to use for reference line for subseries.
- **choice**: Which series of an stl or StructTS object?
- ...: Arguments to be passed to the default method or graphical parameters.
- **axes**: Should axes be drawn (ignored if add=TRUE)?
- **type**: Type of plot. The default is to join the points with lines, and "h" is for histogram-like vertical lines.
- **box**: Should a box be drawn (ignored if add=TRUE)?
- **add**: Should thus just add on an existing plot.

Details

These functions extract subseries from a time series and plot them all in one frame. The ts, stl, and StructTS methods use the internally recorded frequency and start and finish times to set the scale and the seasons. The default method assumes observations come in groups of 12 (though this can be changed).

If the labels are not given but the phase is given, then the labels default to the unique values of the phase. If both are given, then the phase values are assumed to be indices into the labels array, i.e., they should be in the range from 1 to length(labels).

Value

These functions are executed for their side effect of drawing a seasonal subseries plot on the current graphical window.

mood.test  

Mood Two-Sample Test of Scale

Description

Performs Mood's two-sample test for a difference in scale parameters.

Usage

```r
mood.test(x, ...)  
```

## Default S3 method:  
mood.test(x, y, alternative = c("two.sided", "less", "greater"), ...)

## S3 method for class 'formula':  
mood.test(formula, data, subset, na.action, ...)

Arguments

- `x, y` numeric vectors of data values.
- `alternative` indicates the alternative hypothesis and must be one of "two.sided" (default), "greater" or "less" all of which can be abbreviated.
- `formula` a formula of the form `lhs ~ rhs` where `lhs` is a numeric variable giving the data values and `rhs` a factor with two levels giving the corresponding groups.
- `data` an optional matrix or data frame (or similar: see `model.frame`) containing the variables in the formula `formula`. By default the variables are taken from `environment(formula)`.
- `subset` an optional vector specifying a subset of observations to be used.
- `na.action` a function which indicates what should happen when the data contain NAs. Defaults to `getOption("na.action")`.
- `...` further arguments to be passed to or from methods.
Details

The underlying model is that the two samples are drawn from \( f(x - l) \) and \( f((x - l)/s)/s \), respectively, where \( l \) is a common location parameter and \( s \) is a scale parameter.

The null hypothesis is \( s = 1 \).

There are more useful tests for this problem.

Value

A list with class "htest" containing the following components:

- statistic: the value of the test statistic.
- p.value: the p-value of the test.
- alternative: a character string describing the alternative hypothesis.
- method: the character string "Mood two-sample test of scale".
- data.name: a character string giving the names of the data.

References

- ansari.test for another rank-based two-sample test for a difference in scale parameters;
- var.test and bartlett.test for parametric tests for the homogeneity in variance.

Examples

```r
## Same data as for the Ansari-Bradley test:
## Serum iron determination using Hyland control sera
ramsay <- c(111, 107, 100, 99, 102, 106, 109, 108, 104, 99,
            101, 96, 97, 102, 107, 113, 116, 113, 110, 98)
jung.parekh <- c(107, 108, 106, 98, 105, 103, 110, 105, 104,
mood.test(ramsay, jung.parekh)
## Compare this to ansari.test(ramsay, jung.parekh)
```

---

### The Multinomial Distribution

**Description**

Generate multinomially distributed random number vectors and compute multinomial “density” probabilities.

**Usage**

```
rmultinom(n, size, prob)
dmultinom(x, size = NULL, prob, log = FALSE)
```
Multinomial

 Arguments

 x vector of length K of integers in 0:size.
n number of random vectors to draw.
size integer, say N, specifying the total number of objects that are put into K boxes in the typical multinomial experiment. For dmultinom, it defaults to sum(x).
prob numeric non-negative vector of length K, specifying the probability for the K classes; is internally normalized to sum 1.
log logical; if TRUE, log probabilities are computed.

Details

 If x is a K-component vector, dmultinom(x, prob) is the probability

 \[ P(X_1 = x_1, \ldots, X_k = x_k) = C \times \prod_{j=1}^{K} \pi_j^{x_j} \]

 where C is the “multinomial coefficient” \( C = N!/(x_1! \cdots x_K!) \) and \( N = \sum_{j=1}^{K} x_j \).

 By definition, each component \( X_j \) is binomially distributed as \( \text{Bin}(\text{size}, \text{prob}[j]) \) for \( j = 1, \ldots, K \).

 The rmultinom() algorithm draws binomials from \( \text{Bin}(n_j, P_j) \) sequentially, where \( n_1 = N \) (\( N \equiv \text{size} \)), \( P_1 = \pi_1 \) (\( \pi \) is \( \text{prob} \) scaled to sum 1), and for \( j \geq 2 \), recursively \( n_j = N - \sum_{k=1}^{j-1} n_k \) and \( P_j = \pi_j/(1 - \sum_{k=1}^{j-1} \pi_k) \).

 Value

 For rmultinom(), an integer \( K \times n \) matrix where each column is a random vector generated according to the desired multinomial law, and hence summing to size. Whereas the transposed result would seem more natural at first, the returned matrix is more efficient because of columnwise storage.

 Note

dmultinom is currently not vectorized at all and has no C interface (API); this may be amended in the future.

 See Also

rbinom which is a special case conceptually.

 Examples

 rmultinom(10, size = 12, prob=c(0.1,0.2,0.8))

 pr <- c(1,3,6,10) # normalization not necessary for generation
 rmultinom(10, 20, prob = pr)

 ## all possible outcomes of Multinom(N = 3, K = 3)
 X <- t(as.matrix(expand.grid(0:3, 0:3))); X <- X[, colSums(X) <= 3]
 X <- rbind(X, 3:3 - colSums(X)); dimnames(X) <- list(letters[1:3], NULL)
 X
 round(apply(X, 2, function(x) dmultinom(x, prob = c(1,2,5))), 3)
**na.action**

**NA Action**

**Description**

`na.action` is a generic function, and `na.action.default` its default method.

**Usage**

`na.action(object, ...)`

**Arguments**

- `object`: any object whose `NA` action is given.
- `...`: further arguments special methods could require.

**Value**

The “NA action” which should be applied to `object` whenever `NAs` are not desired.

**References**

**See Also**

`options("na.action"), na.omit, na.fail, also for na.exclude, na.pass`.

**Examples**

`na.action(c(1, NA))`

---

**na.contiguous**

**Find Longest Contiguous Stretch of non-NAs**

**Description**

Find the longest consecutive stretch of non-missing values in a time series object. (In the event of a tie, the first such stretch.)

**Usage**

`na.contiguous(object, ...)`

**Arguments**

- `object`: a univariate or multivariate time series.
- `...`: further arguments passed to or from other methods.
**na.fail**

**Value**

A time series without missing values. The class of object will be preserved.

**See Also**

`na.omit` and `na.omit.ts`; `na.fail`

**Examples**

```r
na.contiguous(presidents)
```

---

**Handle Missing Values in Objects**

**Description**

These generic functions are useful for dealing with NAs in e.g., data frames. `na.fail` returns the object if it does not contain any missing values, and signals an error otherwise. `na.omit` returns the object with incomplete cases removed. `na.pass` returns the object unchanged.

**Usage**

```r
na.fail(object, ...)
na.omit(object, ...)
nा.exclude(object, ...)
ną.pass(object, ...)
```

**Arguments**

- `object`  
an R object, typically a data frame
- `...`  
further arguments special methods could require.

**Details**

At present these will handle vectors, matrices and data frames comprising vectors and matrices (only).

If `na.omit` removes cases, the row numbers of the cases form the "na.action" attribute of the result, of class "omit".

`na.exclude` differs from `na.omit` only in the class of the "na.action" attribute of the result, which is "exclude". This gives different behaviour in functions making use of `naresid` and `napredict`: when `na.exclude` is used the residuals and predictions are padded to the correct length by inserting NAs for cases omitted by `na.exclude`.

**References**

**See Also**

`na.action`; `options` with argument `na.action` for setting “NA actions”; and `lm` and `glm` for functions using these. `na.contiguous` as alternative for time series.
**Examples**

```r
DF <- data.frame(x = c(1, 2, 3), y = c(0, 10, NA))
na.omit(DF)
m <- as.matrix(DF)
na.omit(m)
stopifnot(all(na.omit(1:3) == 1:3)) # does not affect objects with no NA's
try(na.fail(DF)) # Error: missing values in ...
options("na.action")
```

---

**naprint**  
*Adjust for Missing Values*

**Description**

Use missing value information to report the effects of an `na.action`.

**Usage**

```r
naprint(x, ...)
```

**Arguments**

- `x`  
  An object produced by an `na.action` function.

- `...`  
  Further arguments passed to or from other methods.

**Details**

This is a generic function, and the exact information differs by method. `naprint.omit` reports the number of rows omitted: `naprint.default` reports an empty string.

**Value**

A character string providing information on missing values, for example the number.

---

**naresid**  
*Adjust for Missing Values*

**Description**

Use missing value information to adjust residuals and predictions.

**Usage**

```r
naresid(omit, x, ...)
napredict(omit, x, ...)
```
Arguments

omit an object produced by an `na.action` function, typically the "na.action" attribute of the result of `na.omit` or `na.exclude`.

x a vector, data frame, or matrix to be adjusted based upon the missing value information.

... further arguments passed to or from other methods.

Details

These are utility functions used to allow `predict`, `fitted` and `residuals` methods for modelling functions to compensate for the removal of NAs in the fitting process. They are used by the default, "lm", "glm" and "nls" methods, and by further methods in packages MASS, rpart and survival. Also used for the scores returned by `factanal`, `prcomp` and `princomp`.

The default methods do nothing. The default method for the `na.exclude` action is to pad the object with NAs in the correct positions to have the same number of rows as the original data frame.

Currently `naresid` and `napredict` are identical, but future methods need not be. `naresid` is used for residuals, and `napredict` for fitted values and predictions.

Value

These return a similar object to `x`.

Note

Packages rpart and survival5 used to contain versions of these functions that had an `na.omit` action equivalent to that now used for `na.exclude`.

---

NegBinomial

The Negative Binomial Distribution

Description

Density, distribution function, quantile function and random generation for the negative binomial distribution with parameters `size` and `prob`.

Usage

```r
dnbinom(x, size, prob, mu, log = FALSE)
pnbinom(q, size, prob, mu, lower.tail = TRUE, log.p = FALSE)
qnbinom(p, size, prob, mu, lower.tail = TRUE, log.p = FALSE)
rnbinom(n, size, prob, mu)
```

Arguments

- `x` vector of (non-negative integer) quantiles.
- `q` vector of quantiles.
- `p` vector of probabilities.
- `n` number of observations. If `length(n) > 1`, the length is taken to be the number required.
NegBinomial

size  
target for number of successful trials, or dispersion parameter (the shape parameter of the gamma mixing distribution). Must be strictly positive.

prob  
probability of success in each trial. $0 < \text{prob} \leq 1$.

mu  
alternative parametrization via mean: see Details

log, log.p  
logical; if TRUE, probabilities p are given as log(p).

lower.tail  
logical; if TRUE (default), probabilities are $P[X \leq x]$, otherwise, $P[X > x]$.

Details

The negative binomial distribution with $\text{size} = n$ and $\text{prob} = p$ has density

$$p(x) = \frac{\Gamma(x + n)}{\Gamma(n)x!} p^n (1 - p)^x$$

for $x = 0, 1, 2, \ldots, n > 0$ and $0 < p \leq 1$.

This represents the number of failures which occur in a sequence of Bernoulli trials before a target number of successes is reached.

A negative binomial distribution can arise as a mixture of Poisson distributions with mean distributed as a $\Gamma$ distribution with scale parameter $(1 - \text{prob})/\text{prob}$ and shape parameter $\text{size}$. (This definition allows non-integer values of $\text{size}$.) In this model $\text{prob} = \text{scale} / (1 + \text{scale})$, and the mean is $\text{size} * (1 - \text{prob})/\text{prob}$.

The alternative parametrization (often used in ecology) is by the mean $\mu$, and $\text{size}$, the dispersion parameter, where $\text{prob} = \text{size} / (\text{size} + \mu)$. The variance is $\mu + \mu^2/\text{size}$ in this parametrization or $n(1 - p)/p^2$ in the first one.

If an element of $x$ is not integer, the result of $\text{dnbinom}$ is zero, with a warning.

The quantile is defined as the smallest value $x$ such that $F(x) \geq p$, where $F$ is the distribution function.

Value

$\text{dnbinom}$ gives the density, $\text{pnbinom}$ gives the distribution function, $\text{qnbinom}$ gives the quantile function, and $\text{rnbinom}$ generates random deviates.

Invalid $\text{size}$ or $\text{prob}$ will result in return value NaN, with a warning.

Source

$\text{dnbinom}$ computes via binomial probabilities, using code contributed by Catherine Loader (see $\text{dbinom}$).

$\text{pnbinom}$ uses $\text{pbeta}$.

$\text{qnbinom}$ uses the Cornish–Fisher Expansion to include a skewness correction to a normal approximation, followed by a search.

See Also

$\text{dbinom}$ for the binomial, $\text{dpois}$ for the Poisson and $\text{dgeom}$ for the geometric distribution, which is a special case of the negative binomial.
Examples

\begin{verbatim}
x <- 0:11
dnbinom(x, size = 1, prob = 1/2) * 2^(1 + x) # == 1
126 / dnbinom(0:8, size = 2, prob = 1/2) #= theoretically integer

## Cumulative ('p') = Sum of discrete prob.s ('d'); Relative error :
summary(1 - cumsum(dnbinom(x, size = 2, prob = 1/2)) / 
   pnbinom(x, size = 2, prob = 1/2))

x <- 0:15
size <- (1:20)/4

   beside = TRUE, col = c("red","blue","cyan"),
   names.arg = round(h1$breaks[-length(h1$breaks)]))
\end{verbatim}

Description

`nextn` returns the smallest integer, greater than or equal to `n`, which can be obtained as a product of powers of the values contained in `factors`. `nextn` is intended to be used to find a suitable length to zero-pad the argument of `fft` so that the transform is computed quickly. The default value for `factors` ensures this.

Usage

`nextn(n, factors = c(2,3,5))`

Arguments

- `n` an integer.
- `factors` a vector of positive integer factors.

See Also

`convolve`, `fft`. 
Examples

```r
nextn(1001) # 1024
table(sapply(599:630, nextn))
```

### nlm

#### Non-Linear Minimization

**Description**

This function carries out a minimization of the function $f$ using a Newton-type algorithm. See the references for details.

**Usage**

```r
nlm(f, p, hessian = FALSE, typsize=rep(1, length(p)), fscale=1,
    print.level = 0, ndigit=12, gradtol = 1e-6,
    stepmax = max(1000 * sqrt(sum((p/typsize)^2)), 100),
    steptol = 1e-6, iterlim = 100, check.analyicals = TRUE, ...)
```

**Arguments**

- **f**: the function to be minimized. If the function value has an attribute called `gradient` or both `gradient` and `hessian` attributes, these will be used in the calculation of updated parameter values. Otherwise, numerical derivatives are used. `deriv` returns a function with suitable `gradient` attribute. This should be a function of a vector of the length of `p` followed by any other arguments specified by the `...` argument.

- **p**: starting parameter values for the minimization.

- **hessian**: if `TRUE`, the hessian of $f$ at the minimum is returned.

- **typsize**: an estimate of the size of each parameter at the minimum.

- **fscale**: an estimate of the size of $f$ at the minimum.

- **print.level**: this argument determines the level of printing which is done during the minimization process. The default value of 0 means that no printing occurs, a value of 1 means that initial and final details are printed and a value of 2 means that full tracing information is printed.

- **ndigit**: the number of significant digits in the function $f$.

- **gradtol**: a positive scalar giving the tolerance at which the scaled gradient is considered close enough to zero to terminate the algorithm. The scaled gradient is a measure of the relative change in $f$ in each direction $p[i]$ divided by the relative change in $p[i]$.

- **stepmax**: a positive scalar which gives the maximum allowable scaled step length. `stepmax` is used to prevent steps which would cause the optimization function to overflow, to prevent the algorithm from leaving the area of interest in parameter space, or to detect divergence in the algorithm. `stepmax` would be chosen small enough to prevent the first two of these occurrences, but should be larger than any anticipated reasonable step.

- **steptol**: A positive scalar providing the minimum allowable relative step length.
iterlim a positive integer specifying the maximum number of iterations to be performed before the program is terminated.

check.analyticals a logical scalar specifying whether the analytic gradients and Hessians, if they are supplied, should be checked against numerical derivatives at the initial parameter values. This can help detect incorrectly formulated gradients or Hessians.

... additional arguments to $f$.

Details

If a gradient or hessian is supplied but evaluates to the wrong mode or length, it will be ignored if check.analyticals = TRUE (the default) with a warning. The hessian is not even checked unless the gradient is present and passes the sanity checks.

From the three methods available in the original source, we always use method “1” which is line search.

The functions supplied must always return finite (including not NA and not NaN) values.

Value

A list containing the following components:

minimum the value of the estimated minimum of $f$.
estimate the point at which the minimum value of $f$ is obtained.
gradients the gradient at the estimated minimum of $f$.
hessians the hessians at the estimated minimum of $f$ (if requested).
code an integer indicating why the optimization process terminated.

1: relative gradient is close to zero, current iterate is probably solution.
2: successive iterates within tolerance, current iterate is probably solution.
3: last global step failed to locate a point lower than estimate. Either estimate is an approximate local minimum of the function or steptol is too small.
4: iteration limit exceeded.
5: maximum step size stepmax exceeded five consecutive times. Either the function is unbounded below, becomes asymptotic to a finite value from above in some direction or stepmax is too small.

iterations the number of iterations performed.

**nlminb**

*Optimization using PORT routines*

**Description**

Unconstrained and constrained optimization using PORT routines.

**Usage**

```r
nlminb(start, objective, gradient = NULL, hessian = NULL, scale = 1, control = list(), lower = -Inf, upper = Inf, ...)
```

**Arguments**

- **start**: numeric vector, initial values for the parameters to be optimized.
- **objective**: Function to be minimized. Must return a scalar value (possibly NA/Inf). The first argument to `objective` is the vector of parameters to be optimized, whose initial values are supplied through `start`. Further arguments (fixed during the course of the optimization) to `objective` may be specified as well (see `...`).
- **gradient**: Optional function that takes the same arguments as `objective` and evaluates the gradient of `objective` at its first argument. Must return a vector as long as `start`.
- **hessian**: Optional function that takes the same arguments as `objective` and evaluates the hessian of `objective` at its first argument. Must return a square matrix of order `length(start)`. Only the lower triangle is used.
- **scale**: See PORT documentation (or leave alone).
- **control**: A list of control parameters. See below for details.
- **lower, upper**: vectors of lower and upper bounds, replicated to be as long as `start`. If unspecified, all parameters are assumed to be unconstrained.
- **...**: Further arguments to be supplied to `objective`. 
Details

Value

A list with components:

- **par**  The best set of parameters found.
- **objective**  The value of objective corresponding to par.
- **convergence**  An integer code. 0 indicates successful convergence.
- **message**  A character string giving any additional information returned by the optimizer, or NULL. For details, see PORT documentation.
- **iterations**  Number of iterations performed.
- **evaluations**  Number of objective function and gradient function evaluations

Control parameters

Possible names in the control list and their default values are:

- **eval.max**  Maximum number of evaluations of the objective function allowed. Defaults to 200.
- **iter.max**  Maximum number of iterations allowed. Defaults to 150.
- **trace**  The value of the objective function and the parameters is printed every trace’th iteration. Defaults to 0 which indicates no trace information is to be printed.
- **abs.tol**  Absolute tolerance. Defaults to 1e-20.
- **rel.tol**  Relative tolerance. Defaults to 1e-10.
- **x.tol**  X tolerance. Defaults to 1.5e-8.
- **step.min**  Minimum step size. Defaults to 2.2e-14.

```
nls

Nonlinear Least Squares

Description

Determine the nonlinear (weighted) least-squares estimates of the parameters of a nonlinear model.

Usage

nls(formula, data, start, control, algorithm, trace, subset, weights, na.action, model, lower, upper, ...)
Arguments

**formula**
a nonlinear model formula including variables and parameters. Will be coerced to a formula if necessary.

**data**
an optional data frame in which to evaluate the variables in formula. Can also be a list or an environment, but not a matrix.

**start**
a named list or named numeric vector of starting estimates. Since R 2.4.0, when start is missing, a very cheap guess for start is tried (if algorithm != "plinear").

**control**
an optional list of control settings. See nls.control for the names of the settable control values and their effect.

**algorithm**
character string specifying the algorithm to use. The default algorithm is a Gauss-Newton algorithm. Other possible values are "plinear" for the Golub-Pereyra algorithm for partially linear least-squares models and "port" for the 'nl2sol' algorithm from the Port package.

**trace**
logical value indicating if a trace of the iteration progress should be printed. Default is FALSE. If TRUE the residual (weighted) sum-of-squares and the parameter values are printed at the conclusion of each iteration. When the "plinear" algorithm is used, the conditional estimates of the linear parameters are printed after the nonlinear parameters. When the "port" algorithm is used the objective function value printed is half the residual (weighted) sum-of-squares.

**subset**
an optional vector specifying a subset of observations to be used in the fitting process.

**weights**
an optional numeric vector of (fixed) weights. When present, the objective function is weighted least squares.

**na.action**
a function which indicates what should happen when the data contain NAs. The default is set by the na.action setting of options, and is na.fail if that is unset. The "factory-fresh" default is na.omit. Value na.exclude can be useful.

**model**
logical. If true, the model frame is returned as part of the object. Default is FALSE.

**lower, upper**
vectors of lower and upper bounds, replicated to be as long as start. If unspecified, all parameters are assumed to be unconstrained. Bounds can only be used with the "port" algorithm. They are ignored, with a warning, if given for other algorithms.

... Additional optional arguments. None are used at present.

Details

An nls object is a type of fitted model object. It has methods for the generic functions anova, coef, confint, deviance, df.residual, fitted, formula, logLik, predict, print, profile, residuals, summary, vcov and weights.

Variables in formula are looked for first in data, then the environment of formula and finally along the search path. Functions in formula are searched for first in the environment of formula and then along the search path.

Value

A list of
an nlsModel object incorporating the model.

the expression that was passed to nls as the data argument. The actual data values are present in the environment of the m component.

the matched call with several components, notably algorithm.

the "na.action" attribute (if any) of the model frame.

the "dataClasses" attribute (if any) of the "terms" attribute of the model frame.

if model = TRUE, the model frame.

if weights is supplied, the weights.

when algorithm is not "port", a list with convergence information.

the control list used, see the control argument.

for an algorithm = "port" fit only, a convergence code (0 for convergence) and message.

Note that setting warnOnly = TRUE in the control argument (see nls.control) returns a non-converged object (since R version 2.5.0) which might be useful for further convergence analysis, but not for inference.

Warning

Do not use nls on artificial "zero-residual" data.

The nls function uses a relative-offset convergence criterion that compares the numerical imprecision at the current parameter estimates to the residual sum-of-squares. This performs well on data of the form

\[ y = f(x, \theta) + \epsilon \]

(with var(\epsilon) > 0). It fails to indicate convergence on data of the form

\[ y = f(x, \theta) \]

because the criterion amounts to comparing two components of the round-off error. If you wish to test nls on artificial data please add a noise component, as shown in the example below.

The algorithm = "port" code appears unfinished, and does not even check that the starting value is within the bounds. Use with caution, especially where bounds are supplied.

nls.control

Control the Iterations in nls

Description

Allow the user to set some characteristics of the nls nonlinear least squares algorithm.

Usage

nls.control(maxiter = 50, tol = 1e-05, minFactor = 1/1024,
            printEval = FALSE, warnOnly = FALSE)

Arguments

maxiter  A positive integer specifying the maximum number of iterations allowed.
tol  A positive numeric value specifying the tolerance level for the relative offset convergence criterion.
minFactor  A positive numeric value specifying the minimum step-size factor allowed on any step in the iteration. The increment is calculated with a Gauss-Newton algorithm and successively halved until the residual sum of squares has been decreased or until the step-size factor has been reduced below this limit.
printEval  a logical specifying whether the number of evaluations (steps in the gradient direction taken each iteration) is printed.
warnOnly  a logical specifying whether nls() should return instead of signalling an error in the case of termination before convergence. Termination before convergence happens upon completion of maxiter iterations, in the case of a singular gradient, and in the case that the step-size factor is reduced below minFactor.
**NLSstAsymptotic**

**Value**

A list with exactly five components:

- maxiter
- tol
- minFactor
- printEval
- warnOnly

with meanings as explained under ‘Arguments’.

---

**NLSstAsymptotic**  
*Fit the Asymptotic Regression Model*

**Description**

Fits the asymptotic regression model, in the form \( b0 + b1 \times (1 - \exp(-\exp(lrc) \times x)) \) to the \( xy \) data. This can be used as a building block in determining starting estimates for more complicated models.

**Usage**

NLSstAsymptotic(xy)

**Arguments**

- \( xy \)  
  
  a sortedXyData object

**Value**

A numeric value of length 3 with components labelled \( b0, b1, \) and \( lrc \). \( b0 \) is the estimated intercept on the y-axis, \( b1 \) is the estimated difference between the asymptote and the y-intercept, and \( lrc \) is the estimated logarithm of the rate constant.

NLSstAsymptotic(sortedXyData(expression(age), expression(height), Lob.329))

NLSstClosestX <- function(xy, yval) {
  # Inverse linear interpolation to approximate the x value at which
  # the function represented by xy is equal to yval.
  y <- xy$y
  x <- xy$x
  diff <- yval - y
  ind <- which.min(abs(diff))
  # Linear interpolation between the two closest points
  x <- x[ind] + diff[ind] * (x[ind+1] - x[ind]) / (y[ind+1] - y[ind])
  return(x)
}

# Example
DNase.2 <- DNase[ DNase$Run == "2", ]
DN.srt <- sortedXyData(expression(log(conc)), expression(density), DNase.2)
NLSstClosestX(DN.srt, 1.0)
NLSstLfAsymptote  *Horizontal Asymptote on the Left Side*

**Description**

Provide an initial guess at the horizontal asymptote on the left side (i.e., small values of x) of the graph of y versus x from the xy object. Primarily used within initial functions for self-starting nonlinear regression models.

**Usage**

\[ \text{NLSstLfAsymptote}(xy) \]

**Arguments**

- `xy` a `sortedXyData` object

**Value**

A single numeric value estimating the horizontal asymptote for small x.

**Author(s)**

Jose Pinheiro and Douglas Bates

**See Also**

`sortedXyData`, `NLSstClosestX`, `NLSstRtAsymptote`, `selfStart`

**Examples**

```r
DNase.2 <- DNase[ DNase$Run == "2", ]
DN.srt <- sortedXyData( expression(log(conc)), expression(density), DNase.2 )
NLSstLfAsymptote( DN.srt )
```

NLSstRtAsymptote  *Horizontal Asymptote on the Right Side*

**Description**

Provide an initial guess at the horizontal asymptote on the right side (i.e., large values of x) of the graph of y versus x from the xy object. Primarily used within initial functions for self-starting nonlinear regression models.

**Usage**

\[ \text{NLSstRtAsymptote}(xy) \]

**Arguments**

- `xy` a `sortedXyData` object
Normal

Value

A single numeric value estimating the horizontal asymptote for large \( x \).

Author(s)

Jose Pinheiro and Douglas Bates

See Also

`sortedXyData`, `NLSstClosestX`, `NLSstRtAsymptote`, `selfStart`

Examples

```r
DNase.2 <- DNase[ DNase$Run == "2", ]
DN.srt <- sortedXyData( expression(log(conc)), expression(density), DNase.2 )
NLSstRtAsymptote( DN.srt )
```

---

Normal

The Normal Distribution

Description

Density, distribution function, quantile function and random generation for the normal distribution with mean equal to `mean` and standard deviation equal to `sd`.

Usage

```r
dnorm(x, mean=0, sd=1, log = FALSE)
pnorm(q, mean=0, sd=1, lower.tail = TRUE, log.p = FALSE)
qnorm(p, mean=0, sd=1, lower.tail = TRUE, log.p = FALSE)
rnorm(n, mean=0, sd=1)
```

Arguments

- `x,q` vector of quantiles.
- `p` vector of probabilities.
- `n` number of observations. If `length(n) > 1`, the length is taken to be the number required.
- `mean` vector of means.
- `sd` vector of standard deviations.
- `log, log.p` logical; if TRUE, probabilities `p` are given as `log(p)`.
- `lower.tail` logical; if TRUE (default), probabilities are `P[X ≤ x]`, otherwise, `P[X > x]`. 
Details

If mean or sd are not specified they assume the default values of 0 and 1, respectively.

The normal distribution has density

\[ f(x) = \frac{1}{\sqrt{2\pi \sigma}} e^{-(x-\mu)^2/2\sigma^2} \]

where \( \mu \) is the mean of the distribution and \( \sigma \) the standard deviation.

qnorm is based on Wichura’s algorithm AS 241 which provides precise results up to about 16 digits.

Value

dnorm gives the density, pnorm gives the distribution function, qnorm gives the quantile function, and rnorm generates random deviates.

Source

For pnorm, based on

For qnorm, the code is a C translation of

For rnorm, see RNG for how to select the algorithm and for references to the supplied methods.

References

See Also

runif and .Random.seed about random number generation, and dlnorm for the Lognormal distribution.

Examples

dnorm(0) == 1/ sqrt(2*pi)
dnorm(1) == exp(-1/2)/ sqrt(2*pi)
dnorm(1) == 1/ sqrt(2*pi*exp(1))

## Using "log = TRUE" for an extended range :
par(mfrow=c(2,1))
plot(function(x) dnorm(x, log=TRUE), -60, 50, 
     main = "log { Normal density }")
curve(log(dnorm(x)), add=TRUE, col="red",lwd=2)
mtext("dnorm(x, log=TRUE)", adj=0)
mtext("log(dnorm(x))", col="red", adj=-1)

numericDeriv

Evaluate derivatives numerically

Description
	numericDeriv numerically evaluates the gradient of an expression.

Usage

numericDeriv(expr, theta, rho = parent.frame(), dir = 1)

Arguments

expr The expression to be differentiated. The value of this expression should be a numeric vector.
theta A character vector of names of numeric variables used in expr.
rho An environment containing all the variables needed to evaluate expr.
dir A numeric vector of directions to use for the finite differences.

Details

This is a front end to the C function numeric_deriv, which is described in Writing R Extensions. The numeric variables must be of type real and not integer.

Value

The value of eval(expr, envir = rho) plus a matrix attribute called gradient. The columns of this matrix are the derivatives of the value with respect to the variables listed in theta.

Author(s)

Saikat DebRoy (saikat@stat.wisc.edu)

Examples

myenv <- new.env()
assign("mean", 0., env = myenv)
assign("sd", 1., env = myenv)
assign("x", seq(-3., 3., len = 31), env = myenv)
numericDeriv(quote(pnorm(x, mean, sd)), c("mean", "sd"), myenv)
offset

Include an Offset in a Model Formula

Description

An offset is a term to be added to a linear predictor, such as in a generalised linear model, with known coefficient 1 rather than an estimated coefficient.

Usage

offset(object)

Arguments

object An offset to be included in a model frame

Details

There can be more than one offset in a model formula, but – is not supported for offset terms (and is equivalent to +).

Value

The input value.

See Also

model.offset, model.frame.

For examples see glm and Insurance in package MASS.

oneway.test Test for Equal Means in a One-Way Layout

Description

Test whether two or more samples from normal distributions have the same means. The variances are not necessarily assumed to be equal.

Usage

oneway.test(formula, data, subset, na.action, var.equal = FALSE)
Arguments

formula  
a formula of the form \( \text{lhs} \sim \text{rhs} \) where \( \text{lhs} \) gives the sample values and \( \text{rhs} \) the corresponding groups.

data  
an optional matrix or data frame (or similar: see \texttt{model.frame}) containing the variables in the formula \texttt{formula}. By default the variables are taken from \texttt{environment(formula)}.

subset  
an optional vector specifying a subset of observations to be used.

na.action  
a function which indicates what should happen when the data contain NAs. Defaults to \texttt{getOption("na.action")}.

var.equal  
a logical variable indicating whether to treat the variances in the samples as equal. If \texttt{TRUE}, then a simple F test for the equality of means in a one-way analysis of variance is performed. If \texttt{FALSE}, an approximate method of Welch (1951) is used, which generalizes the commonly known 2-sample Welch test to the case of arbitrarily many samples.

Value

A list with class "\texttt{htest}") containing the following components:

statistic  
the value of the test statistic.

parameter  
the degrees of freedom of the exact or approximate F distribution of the test statistic.

p.value  
the p-value of the test.

method  
a character string indicating the test performed.

data.name  
a character string giving the names of the data.

References

See Also

The standard t test (\texttt{t.test}) as the special case for two samples; the Kruskal-Wallis test \texttt{kruskal.test} for a nonparametric test for equal location parameters in a one-way layout.

Examples

```r
## Not assuming equal variances
oneway.test(extra ~ group, data = sleep)
## Assuming equal variances
oneway.test(extra ~ group, data = sleep, var.equal = TRUE)
## which gives the same result as
anova(lm(extra ~ group, data = sleep))
```
General-purpose Optimization

Description

General-purpose optimization based on Nelder–Mead, quasi-Newton and conjugate-gradient algorithms. It includes an option for box-constrained optimization and simulated annealing.

Usage

```r
optim(par, fn, gr = NULL,
     method = c("Nelder-Mead", "BFGS", "CG", "L-BFGS-B", "SANN"),
     lower = -Inf, upper = Inf,
     control = list(), hessian = FALSE, ...)
```

Arguments

- `par`: Initial values for the parameters to be optimized over.
- `fn`: A function to be minimized (or maximized), with first argument the vector of parameters over which minimization is to take place. It should return a scalar result.
- `gr`: A function to return the gradient for the "BFGS", "CG" and "L-BFGS-B" methods. If it is `NULL`, a finite-difference approximation will be used. For the "SANN" method it specifies a function to generate a new candidate point. If it is `NULL` a default Gaussian Markov kernel is used.
- `method`: The method to be used. See Details.
- `lower`, `upper`: Bounds on the variables for the "L-BFGS-B" method.
- `control`: A list of control parameters. See Details.
- `hessian`: Logical. Should a numerically differentiated Hessian matrix be returned?
- `...`: Further arguments to be passed to `fn` and `gr`. Beware of partial matching to earlier arguments.

Details

By default this function performs minimization, but it will maximize if `control`$fnscale is negative.

The default method is an implementation of that of Nelder and Mead (1965), that uses only function values and is robust but relatively slow. It will work reasonably well for non-differentiable functions.

Method "BFGS" is a quasi-Newton method (also known as a variable metric algorithm), specifically that published simultaneously in 1970 by Broyden, Fletcher, Goldfarb and Shanno. This uses function values and gradients to build up a picture of the surface to be optimized.

Method "CG" is a conjugate gradients method based on that by Fletcher and Reeves (1964) (but with the option of Polak–Ribiere or Beale–Sorenson updates). Conjugate gradient methods will generally be more fragile than the BFGS method, but as they do not store a matrix they may be successful in much larger optimization problems.

Method "L-BFGS-B" is that of Byrd et al. (1995) which allows box constraints, that is each variable can be given a lower and/or upper bound. The initial value must satisfy the constraints.
This uses a limited-memory modification of the BFGS quasi-Newton method. If non-trivial bounds are supplied, this method will be selected, with a warning.

Nocedal and Wright (1999) is a comprehensive reference for the previous three methods.

Method "SANN" is by default a variant of simulated annealing given in Belisle (1992). Simulated-annealing belongs to the class of stochastic global optimization methods. It uses only function values but is relatively slow. It will also work for non-differentiable functions. This implementation uses the Metropolis function for the acceptance probability. By default the next candidate point is generated from a Gaussian Markov kernel with scale proportional to the actual temperature. If a function to generate a new candidate point is given, method "SANN" can also be used to solve combinatorial optimization problems. Temperatures are decreased according to the logarithmic cooling schedule as given in Belisle (1992, p. 890); specifically, the temperature is set to \( \text{temp} / \log(((t-1) \% \% \text{tmax})*\text{tmax} + \exp(1)) \), where \( t \) is the current iteration step and \( \text{temp} \) and \( \text{tmax} \) are specifiable via \texttt{control}, see below. Note that the "SANN" method depends critically on the settings of the control parameters. It is not a general-purpose method but can be very useful in getting to a good value on a very rough surface.

Function \( \text{fn} \) can return \texttt{NA} or \texttt{Inf} if the function cannot be evaluated at the supplied value, but the initial value must have a computable finite value of \( \text{fn} \). (Except for method "L-BFGS-B" where the values should always be finite.) \texttt{optim} can be used recursively, and for a single parameter as well as many.

The \texttt{control} argument is a list that can supply any of the following components:

\begin{itemize}
  \item \texttt{trace} Non-negative integer. If positive, tracing information on the progress of the optimization is produced. Higher values may produce more tracing information: for method "L-BFGS-B" there are six levels of tracing. (To understand exactly what these do see the source code: higher levels give more detail.)
  \item \texttt{fnscale} An overall scaling to be applied to the value of \( \text{fn} \) and \( \text{gr} \) during optimization. If negative, turns the problem into a maximization problem. Optimization is performed on \( \text{fn}(\text{par})/\text{fnscale} \).
  \item \texttt{parscale} A vector of scaling values for the parameters. Optimization is performed on \( \text{par}/\text{parscale} \) and these should be comparable in the sense that a unit change in any element produces about a unit change in the scaled value.
  \item \texttt{ndeps} A vector of step sizes for the finite-difference approximation to the gradient, on \( \text{par}/\text{parscale} \) scale. Defaults to \( 1e-3 \).
  \item \texttt{maxit} The maximum number of iterations. Defaults to 100 for the derivative-based methods, and 500 for "Nelder-Mead". For "SANN" \texttt{maxit} gives the total number of function evaluations. There is no other stopping criterion. Defaults to 10000.
  \item \texttt{abstol} The absolute convergence tolerance. Only useful for non-negative functions, as a tolerance for reaching zero.
  \item \texttt{reltol} Relative convergence tolerance. The algorithm stops if it is unable to reduce the value by a factor of \( \text{reltol} * (\text{abs(val)} + \text{reltol}) \) at a step. Defaults to \( \sqrt{.\text{Machine}\_\text{double} \_\text{eps}} \), typically about \( 1e-8 \).
  \item \texttt{alpha, beta, gamma} Scaling parameters for the "Nelder-Mead" method. \texttt{alpha} is the reflection factor (default 1.0), \texttt{beta} the contraction factor (0.5) and \texttt{gamma} the expansion factor (2.0).
  \item \texttt{REPORT} The frequency of reports for the "BFGS" and "L-BFGS-B" methods if \texttt{control\_\text{trace}} is positive. Defaults to every 10 iterations.
  \item \texttt{type} for the conjugate-gradients method. Takes value 1 for the Fletcher–Reeves update, 2 for Polak–Ribiere and 3 for Beale–Sorenson.
**optim** is an integer giving the number of BFGS updates retained in the "L-BFGS-B" method. It defaults to 5.

**factr** controls the convergence of the "L-BFGS-B" method. Convergence occurs when the reduction in the objective is within this factor of the machine tolerance. Default is $1e7$, that is a tolerance of about $1e-8$.

**pgtol** helps control the convergence of the "L-BFGS-B" method. It is a tolerance on the projected gradient in the current search direction. This defaults to zero, when the check is suppressed.

**temp** controls the "SANN" method. It is the starting temperature for the cooling schedule. Defaults to 10.

**tmax** is the number of function evaluations at each temperature for the "SANN" method. Defaults to 10.

Any names given to par will be copied to the vectors passed to fn and gr.

### Value

A list with components:

- **par** The best set of parameters found.
- **value** The value of fn corresponding to par.
- **counts** A two-element integer vector giving the number of calls to fn and gr respectively. This excludes those calls needed to compute the Hessian, if requested, and any calls to fn to compute a finite-difference approximation to the gradient.
- **convergence** An integer code. 0 indicates successful convergence. Error codes are
  - 1 indicates that the iteration limit maxit had been reached.
  - 10 indicates degeneracy of the Nelder–Mead simplex.
  - 51 indicates a warning from the "L-BFGS-B" method; see component message for further details.
  - 52 indicates an error from the "L-BFGS-B" method; see component message for further details.
- **message** A character string giving any additional information returned by the optimizer, or NULL.
- **hessian** Only if argument hessian is true. A symmetric matrix giving an estimate of the Hessian at the solution found. Note that this is the Hessian of the unconstrained problem even if the box constraints are active.

### Note

optim will work with one-dimensional pars, but the default method does not work well (and will warn). Use optimize instead.

### Source

The code for methods "Nelder-Mead", "BFGS" and "CG" was based originally on Pascal code in Nash (1990) that was translated by p2c and then hand-optimized. Dr Nash has agreed that the code can be made freely available.

The code for method "L-BFGS-B" is based on Fortran code by Zhu, Byrd, Lu-Chen and Nocedal obtained from Netlib (file ‘opt/lbfgs bcm.shar’: another version is in ‘toms/778’).

The code for method "SANN" was contributed by A. Trapletti.

**optimize**

### One Dimensional Optimization

**Description**

The function optimize searches the interval from lower to upper for a minimum or maximum of the function f with respect to its first argument.
optimize is an alias for optimise.

### Usage

```r
optimize(f = , interval = , lower = min(interval),
         upper = max(interval), maximum = FALSE,
         tol = .Machine$double.eps^0.25, ...)
```

```r
optimise(f = , interval = , lower = min(interval),
         upper = max(interval), maximum = FALSE,
         tol = .Machine$double.eps^0.25, ...)```

### Arguments

- **f**: the function to be optimized. The function is either minimized or maximized over its first argument depending on the value of `maximum`.
- **interval**: a vector containing the end-points of the interval to be searched for the minimum.
- **lower**: the lower end point of the interval to be searched.
- **upper**: the upper end point of the interval to be searched.
- **maximum**: logical. Should we maximize or minimize (the default)?
- **tol**: the desired accuracy.
- **...**: additional named or unnamed arguments to be passed to `f` (but beware of partial matching to other arguments).

### Details

The method used is a combination of golden section search and successive parabolic interpolation. Convergence is never much slower than that for a Fibonacci search. If `f` has a continuous second derivative which is positive at the minimum (which is not at `lower` or `upper`), then convergence is superlinear, and usually of the order of about 1.324.

The function `f` is never evaluated at two points closer together than \( \epsilon|x_0| + (tol/3) \), where \( \epsilon \) is approximately \( \text{sqrt}(\text{.Machine}\$\text{double}\$.eps) \) and \( x_0 \) is the final abscissa `optimize()`$\text{minimum}`.

If `f` is a unimodal function and the computed values of `f` are always unimodal when separated by at least \( \epsilon|x| + (tol/3) \), then \( x_0 \) approximates the abscissa of the global minimum of `f` on the interval lower, upper with an error less than \( \epsilon|x_0| + tol \).

If `f` is not unimodal, then `optimize()` may approximate a local, but perhaps non-global, minimum to the same accuracy.

The first evaluation of `f` is always at \( x_1 = a + (1-\phi)(b-a) \) where \( (a,b) = (\text{lower}, \text{upper}) \) and \( \phi = (\sqrt{5} - 1)/2 = 0.61803.. \) is the golden section ratio. Almost always, the second evaluation is at \( x_2 = a + \phi(b-a) \). Note that a local minimum inside \( [x_1, x_2] \) will be found as solution, even when `f` is constant in there, see the last example.

`f` will be called as `f(x, ...)` for a numeric value of `x`.

### Value
